BOARD MEETING DATE: December 4, 2015 AGENDA NO. 30

PROPOSAL: Proposed Amendments to NOx RECLAIM Program (Regulation XX)

SYNOPSIS: The proposed amended Regulation XX will implement Control Measure CMB-01 of the 2012 Air Quality Management Plan and make further reductions of NOx from RECLAIM facilities. The proposed amendments implement NOx Best Available Retrofit Control (BARCT) for various equipment by establishing RECLAIM Trading Credit (RTC) reduction targets and RTC adjustment factors for year 2016 and beyond. The proposed amendments include a Regional New Source Review Holding Account for electricity generating facilities, a delay in relative accuracy testing audit due dates for specified situations, both a quarterly maximum (quicker response) and changed and new minimum price triggers for RECLAIM program review, and other administrative changes. In addition, an off-ramp for electricity generating facilities at BACT or BARCT is proposed as well as provisions that would remove RTCs from the RECLAIM Program for equipment and facilities that have shutdown. At full implementation the proposed amendments will reduce NOx RTCs by 14 tons per day by December 2022.

COMMITTEE: Stationary Source Committee, March 21, 2014, July 24, 2015, October 16, 2015, November 20, 2015, and Special Stationary Source Committee, September 23, 2015, Reviewed.

RECOMMENDED ACTION:
Adopt the attached resolution:

1. Certifying the Final Program Environmental Assessment (PEA) for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM); and

2. Amending Proposed Rules 2001 – Applicability; 2002 – Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx); Rule 2005 – New Source Review forRECLAIM; 2011 – Attachment C – Quality Assurance and Quality Control Procedures & Attachment E – Definitions; and 2012 – Attachment C – Quality Assurance and Quality Control Procedures & Attachment F – Definitions.

Barry R. Wallerstein, D.Env.
Executive Officer

PMF:JW:JC:GQ:MHP/KO

Introduction

The AQMD Board adopted the Regional Clean Air Incentives Market (RECLAIM) program in October 1993. The purpose of the RECLAIM program is to reduce NOx and SOx emissions through a market-based program. The program replaced a series of existing and future command-and-control rules and was designed to provide facilities with the flexibility to seek the most cost-effective solution to reduce their emissions. AQMD staff is proposing amendments to Regulation XX – RECLAIM to achieve additional NOx reductions pursuant to the 2012 AQMP Control Measure CMB-01 and state law. Specifically, the proposed amendments address requirements for Best Available Retrofit Control Technology (BARCT) in accordance with California Health and Safety (H&S) Code §40440. Reductions in NOx will help the Basin attain the federal 24-hour PM2.5 standard by 2019, and the federal ozone ambient air quality standards by 2023 and 2031. Other proposed rule amendments include clarifications and changes to the protocols.

Public Process

The rulemaking process for PAR XX – NOx RECLAIM began in the 4th quarter of 2012. In 2013, a RECLAIM Working Group was formed to discuss potential amendments to the NOx RECLAIM program.

To gather pertinent information for rule development, staff sent out Survey Questionnaires to 38 facilities, including the top 37 emitting facilities in 2011 and a cement facility which was the highest NOx stationary emission source in 2008. Since January 2013, fourteen Working Group Meetings were held to discuss potential BARCT levels for major NOx sources, the emissions inventory, potential for emission reductions, and proposals for RTC reductions. In September 2014, SCAQMD staff contracted with two consultants (Environmental Technology Services, Inc. (ETS) and Norton Engineering Consultants Inc. (NEC)) to conduct independent BARCT analyses. The consultants completed their analyses in December 2014, and staff held the 8th Working Group Meeting in January 7, 2015 to report on the consultants' findings to the stakeholders. A CEQA and Socioeconomic scoping session was held on January 8, 2015.

From January to March 2015, staff reviewed the consultants' analyses and addressed comments received in response to the CEQA and Socioeconomic scoping session. Staff also extended the contract for NEC to allow time to produce confidential proprietary information reports for each refinery, and this task was completed in April 2015.

In addition to the thirteen Working Group Meetings, there were over 50 meetings held with various stakeholders individually or in groups to discuss the BARCT analysis and the proposed allocation reduction distribution (shave) methodology. Staff also met with a number of air pollution control manufacturers to discuss control technologies, and invited the manufacturers to write manuscripts and give presentations at the 2014 Air & Waste Management Association annual conference in Long Beach. Several refinery representatives participated in the discussions at the conference.

A Public Workshop was conducted on July 22, 2015, a Public Consultation Meeting was conducted on September 29, 2015, the draft Program Environmental Assessment was released on August 14, 2015 for 53 days of public comment, and the draft socioeconomic analysis was released on September 9, 2015. Five Stationary Source Committee meetings were held: March 21, 2014; July 24, 2014; October 14, 2015; a special session on September 23, 2015 requested by industry devoted to RECLAIM; and November 20, 2015. The staff presentations for the three most recent Stationary Source Committee meetings are shown in Attachments K (September 23, 2015), L (October 14, 2015), and M (November 20, 2015). The industry and environmental group coalition presentations from the September 23, 2015 Stationary Source Committee are in Attachments N and O.

NOx RECLAIM Facilities

There were 276 facilities in RECLAIM as of June, 2011. These facilities either elected to enter the program or had NOx emissions greater than or equal to four tons per year in 1990 or any subsequent year. The distribution of the 2011 audited emissions and RTC allocations by industry type are shown in Figures 1 and 2, respectively.

FIGURE 1
Distribution of 20 tpd NOx Emissions (End of Compliance Year 2011)

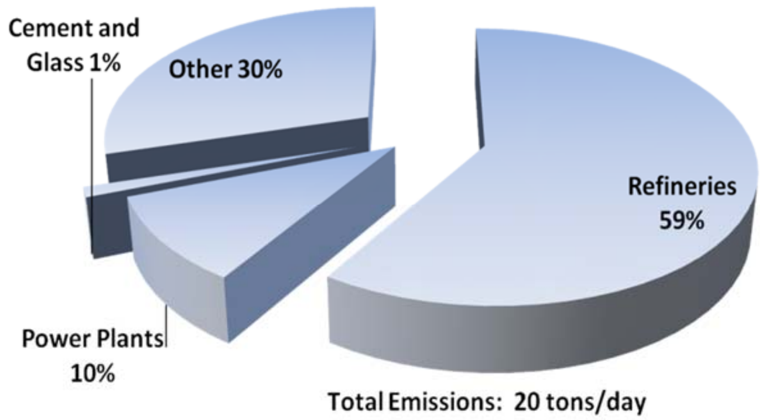

FIGURE 2
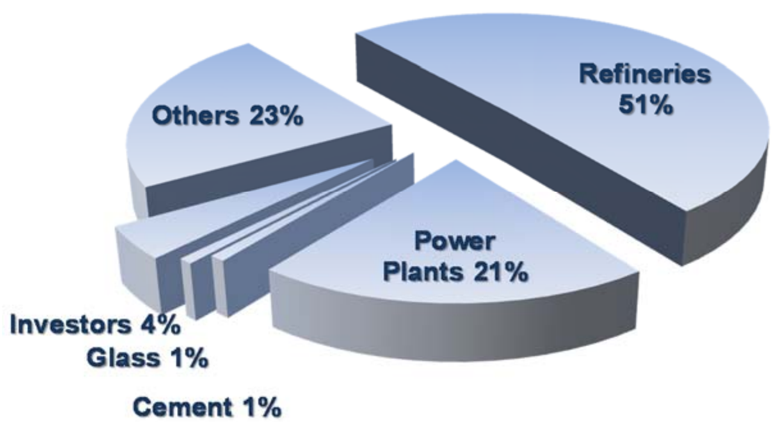
Distribution of 26.5 tpd RTC Holdings (End of Compliance Year 2020)



The top 37 facilities emitted 17.10 tpd NOx in 2011, more than 85% of emissions. The NOx emissions from RECLAIM facilities are generated from a wide range of equipment, and the top NOx emitting sources at the 37 facilities are refinery coke calciners, refinery fluidized catalytic cracking units, refinery and non-refinery gas turbines, refinery boilers and heaters, glass melting furnaces, sodium silicate furnaces, metal heat treating furnaces, internal combustion engines, and refinery sulfur recovery and tail gas incinerators. Cement kilns were the highest emitting stationary NOx source in 2008. The 2011 inventory did not include the cement kilns in the inventory since they were non-operational and subsequently shut down in 2012. However, staff did identify a new BARCT level for this operation and included the equivalent amount in the projected remaining BARCT-level NOx emissions in 2023.

Staff Proposal
The descriptions of the staff proposal below includes staff's rationale for the proposed rule amendments. The descriptions also include key changes made to the proposal as a result of comments and feedback on key issues received throughput the rulemaking process.

BARCT Levels
When the NOx RECLAIM program was first adopted, the NOx RECLAIM facilities were issued NOx annual allocations (also known as facility caps), which declined annually from 1993 until 2003 and remained constant after 2003. The annual allocations issued to the NOx RECLAIM facilities reflected the levels of Best Available Retrofit Control Technology (BARCT) envisioned to be in place at the RECLAIM facilities, and were the result of a BARCT analysis conducted in 1993. As previously mentioned, BARCT reassessment is required by California Health & Safety Code (H&SC) §40440 to assess the advancement in control technology, to ensure that RECLAIM facilities achieve the same emission reductions that would have occurred under a command-and-control approach, and that emission reductions from the program fully contribute to the efforts in the Basin to achieve the federal National Ambient Air Quality Standards (NAAQS). There was a BARCT reassessment for NOx in 2005 and another for SOx in 2010, and the RECLAIM rules were subsequently amended to reduce the facility annual allocations. The 2012 AQMP Control Measure CMB-01 identified a new group of RECLAIM NOx emitting equipment that needed to be subject to a BARCT analysis. This new BARCT analysis began in October 2012.

Over the next few years the BARCT analysis resulted in the BARCT levels, incremental emission reductions by 2023, costs, and cost effectiveness shown in Table 1. For the refinery sector, new BARCT levels are proposed for fluid catalytic cracking units, boilers/heaters >40 mmbtu/hr, gas turbines, coke calciners, and sulfur recovery and tail gas incinerators. For the non-refinery sector, a new BARCT level is proposed for container glass melting furnaces, cement kilns, sodium silicate furnaces, metal melting furnaces >150 mmbtu/hr, gas turbines and ICEs not located on the outer continental shelf (OCS). No new BARCT is proposed for electricity generating facilities (EGF) given that the vast majority of equipment in this sector is already permitted at BARCT or BACT.

TABLE 1
Summary of Proposed new BARCT Since 2005 NOx RECLAIM Amendments

	2015 BARCT	Incremental Emission Reductions from 2000/2005 BARCT (tpd)	Number of Affected Facilities	Estimated No of Control Devices	Incremental Cost Effectiveness (thousand dollars/ton)
Refinery Sector					
FCCUs	2 ppmv	0.43	5	5 SCRs (or 2 SCRs + 3 LoTOx/WGS)	3 - 13
Boilers and Heaters	2 ppmv	0.94	8	73 SCRs	28
Refinery Gas Turbines	2 ppm	4.14	5	7 SCRs and adding catalysts to 4 SCRs	1 - 3
Coke Calciner	10 ppmv	0.17	1	1 UltraCat (or 1 LoTOx/WGS)	22 - 35
SRU/TG Incinerators	2 ppmv	0.32	4	6 SCRs (or 1 SCRs + 5 LoTOx/WGS)	28 – 40
Refinery Total		**6.00**		**91 SCRs + 1 UltraCat (or 83 SCRs and 9 LoTOx/WGS) and adding catalysts to SCRs**	**10 - 17**
Non-Refinery Sector					
Glass Melting Furnaces	80% reduction	0.24	1	2 SCRs (or 1 UltraCat)	3 – 7
Sodium Silicate Furnace	80% reduction	0.09	1	1 SCR (or 1 UltraCat)	4 – 8
Metal Heat Treating	9 ppmv	0.56	1	1 SCR	3 – 4
Gas Turbines (non-OCS)	2 ppmv	1.04	3	14 SCRs	5 – 36
ICEs (non-OCS)	11 ppmv	0.84	7	16 SCRs	5 – 8
Non-Refinery Total (w/o Cement Kilns)		**2.77**		**34 SCRs (or 31 SCRs and 2 UltraCat)**	**6 - 7**
Overall		**8.77**		**125 SCRs + 1 UltraCat (or 114 SCRs + 9 LoTOx/WGS + 2 ultracat)**	**9 – 14***

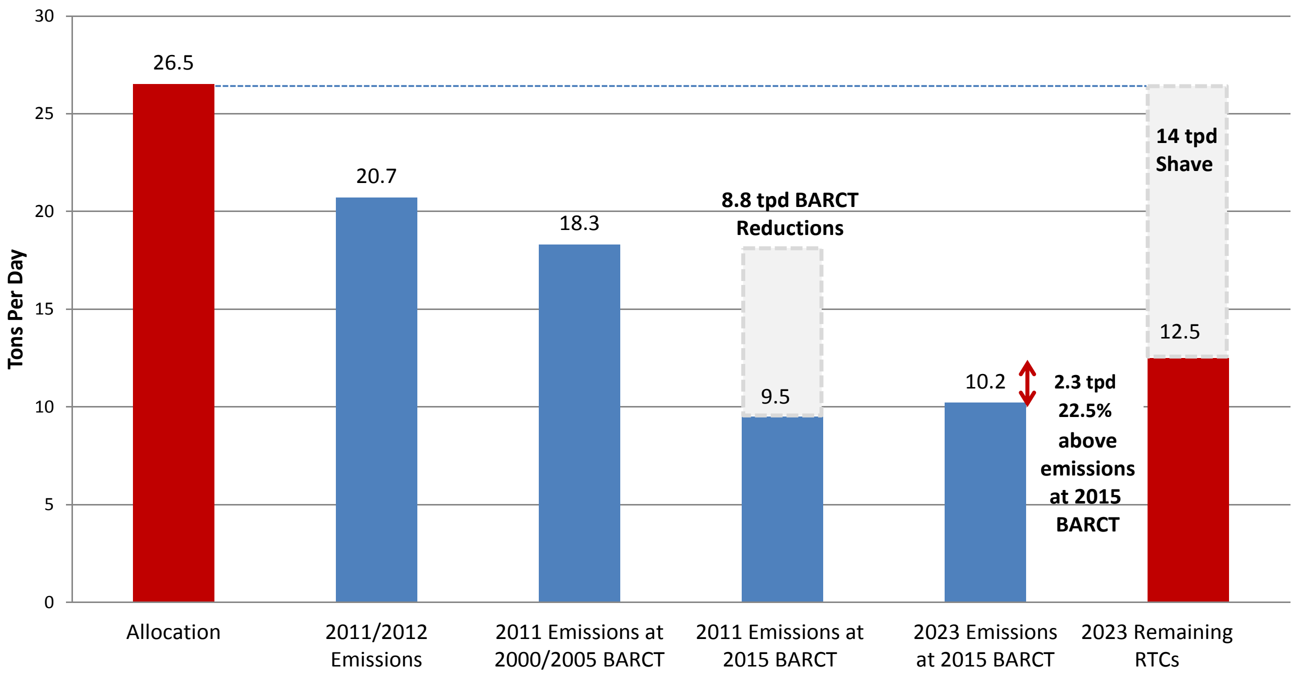
***overall average cost effectiveness**

The total cost of the proposed amendments ranges from $728 million to $1.1 billion, and the overall average cost effectiveness of the emission reductions range from $9 K to $14 K per ton NOx reduced.

RTC Reductions

As shown in Table 1, the total BARCT-equivalent emission reductions are 8.77 tpd (6.00 tpd for the refinery sector and 2.77 tpd for the non-refinery sector.) Due to projected growth, the remaining emissions in 2023 at these proposed 2015 BARCT levels would be 10.23 tpd (2.76 tpd for the refinery sector and 7.47 tpd for the non-refinery sector.) A 10% compliance margin has been added to the 2023 remaining emissions. In addition, the remaining emissions from shutdown glass and cement facilities have been added at BARCT levels, as well as the emissions for new facilities entering RECLAIM program since 2005, thereby adding to the total remaining emissions. Furthermore, an adjustment has been included to account for uncertainties that arose in the BARCT analysis and for additional 2011 activity level adjustments. This results in total proposed NOx RTC reductions of 14 tpd from the current RTC holdings of 26.5 tpd in 2023. The remaining RTCs for the NOx RECLAIM universe would be 12.5 tpd (26.5 tpd – 14 tpd = 12.5 tpd), which is 2.3 tpd or 22.5% above the projected remaining emissions from RECLAIM NOx sources in 2023. See Figure 3. It should be noted that the 2.3 tpd includes the compliance margin as well as activity and uncertainty adjustments.

FIGURE 3
Audited Emissions and RTC Holdings



Staff is proposing to distribute the 14 tpd NOx RTC reductions to 56 facilities and investors that hold 90% of the 26.5 tpd RTCs. Investors are grouped with the refineries and treated as a facility for shave purposes. The remaining 219 facilities that hold 10% of the 26.5 tpd RTC are not proposed to be shaved because there was limited or no new BARCT for the types of equipment and operations at these facilities. The current proposal is to weight the amount of shave considering the technology available to different facility types and is summarized below:

66% shave for 9 refineries and 15 investors;

49% shave for 21 electricity generating facilities;

49% shave for 26 other major facilities; and

0% shave for 219 remaining facilities.

The 2023 remaining emissions after installing BARCT, the RTC holdings after the shave, and the surplus or deficit RTCs after the shave for each industry sector are presented in Table 2. After the shave, the 9 refinery facilities, the investors, and the 21 electricity generating facilities would have surplus RTCs. Note that even though no new BARCT is proposed for the electricity generating facilities, Table 2 shows that their post-shave holdings are still projected to exceed their NOx emissions. Some facilities in the 26 non-electricity generating facilities and the 219 remaining facilities would not be subject to any shave; however their emissions would grow above their current RTC holdings and they would have to purchase RTCs from other industry sectors to reconcile their projected emissions. Overall, there is a projected net 2.3 tpd of surplus RTCs for the entire RECLAIM universe.

TABLE 2
Summary of 2023 RTC Holdings and 2023 Emissions After BARCT

	9 RefineryF acilities	**15 Investors**	**21 Electricity Generating Facilities**	**26 Non-Electricity Generating Facilities**	**219 Other Facilities**	**Net Total**
Current RTC Holdings (tpd) (note)	14.15	0.42	5.63	3.45	2.86	26.5
% Shave	66%	66%	49%	49%	0%	
RTC Holdings After Shave (tpd)	4.81	0.14	2.87	1.76	2.86	12.5
2023 Emissions After BARCT (tpd)	2.76	0	2.04	1.93	3.5	10.2
Surplus or Deficit RTCs (tpd)	2.05	0.14	0.83	(0.17)	(0.64)	2.3

Note: RTC Holdings as of September 22, 2015

The 14 tpd RTC reduction is proposed to be implemented over a 7-year period from 2016 to 2022 to help the Basin meet the PM2.5 standard deadlines as well as the ozone standards in 2023 and 2031. The implementation schedule for NOx RTC reductions would be:

2016 – 4 tons per day
2018 – 2 tons per day
2019 – 2 tons per day
2020 – 2 tons per day
2021 – 2 tons per day
2022 – 2 tons per day

Over the past five years from 2009-2013, the unused RTCs in the NOx RECLAIM program ranged from 5 tpd to 8 tpd, and thus staff is proposing a 4 tpd RTC reduction in

2016. Additional BARCT implementation will take about 2 – 4 years for planning, permitting, and construction, so the proposal assesses the remaining shave of 10 tpd over five years from 2018 to 2022.

Price Triggers

Safeguards for the integrity of the RECLAIM program have been in place for the last several years in the form of a price trigger. The current price trigger is $15,000 per ton based on a 12-month rolling average. If the trigger is exceeded then the Executive Officer reports to the Governing Board with recommendations to stabilize the market.

During this rulemaking process the following points have been made:

- The current price trigger has never been adjusted for inflation.
- Depending on the impacts, the current program safeguard may not respond quickly enough to adequately protect the RECLAIM program.
- There is not a minimum price trigger that could be used to encourage additional NOx reductions.

To address the abovementioned points, the current 12-month rolling average trigger has been proposed to change from $15,000 to $22,500 per ton (discrete credits). For a quicker response a trigger level of $35,000 per ton, also for discrete credits, has been added for a 3-month rolling average. If RTC prices exceed either of these levels, a report to the Board and a program review are required. Also included in the proposal is a new 12-month rolling average for Infinite Year Block (IYB) RTCs of $200,000 per ton. If credit prices are lower than this amount, then a report to the Board is also required.

The abovementioned report would include a commitment and schedule to conduct a more rigorous cost-effectiveness, market analysis, and socioeconomic impact assessment of the RECLAIM program.

Regional NSR Holding Account

Rule 2005 sets forth requirements for new or modified equipment or processes at RECLAIM facilities. The purpose of the rule is to ensure that the RECLAIM program is equivalent to the federal and state New Source Review (NSR) program requirements. One of the requirements is to ensure that the facility must hold sufficient RTCs to offset emission increases for one year prior to commencement of operation and at the beginning of every compliance year thereafter. For a RECLAIM facility existing prior to the adoption of the RECLAIM program, the amendments made in June 3, 2011 required the RECLAIM facility to hold adequate RTCs for the first year of operation prior to commencement of operation of a new or modified source, but did not require the facility to hold RTCs at the commencement of subsequent compliance years, provided that the facility emission level remains below its starting Allocation plus non-tradable credits.

However, a new RECLAIM facility will have to continue to hold adequate RTCs equal to the amount of emission increases at the beginning of each compliance year. Any unused RTCs cannot be sold until the end of the compliance year, or the applicable quarters if the facility has permit conditions to cap its emissions during each quarter, thus allowing sale of unused RTCs at the end of the quarter. To remedy this burdensome RTC holding requirement for new electricity generating facilities (EGF) that cannot change their allowable NOx emissions in their Facility Permit, staff is proposing a Regional NSR Holding Account. Proposed changes in Rule 2005 would assure that the RTCs in the Account would only be used the for the purpose of complying with the NSR requirements

State of Emergency Related to Electricity Generating Facilities

There is a distinct possibility that EGFs' ability to comply with their NOx RECLAIM requirements would be compromised in a State of Emergency declared by the Governor. To alleviate this potential problem from occurring it is proposed that impacted EGFs would have access to various sources of RTCs. For example, rule provisions have been added to convert Non-tradable/Non-usable RTCS to Non-tradable/usable RTCs during a State of Emergency declared by the Governor related to electricity demand or power grid stability within the SCAQMD jurisdictional boundaries. Thus during a State of Emergency, the current compliance year Non-tradable/Non-usable NOx RTCs held by any electricity generating facilities that generate and distribute electricity to the grid system affected by the State of Emergency may be used to offset emissions after completely exhausting their own Tradable/Usable NOx RTCs.

If such a facility has completely exhausted their Non-tradable/Non-usable NOx RTCs, the EGF owner or operator may apply for the use of the NOx RTCs in the Regional NSR Holding Account. The use of such RTCs in this Account would be based on availability at the end of each quarter. The owner or operator of each electricity generating facility requesting NOx RTCs from the Regional NSR Holding Account would be required to submit a written request to the Executive Officer specifying the amount of RTCs needed and the basis for requesting the required amount.

Electricity Generating Facilities Opting-Out of RECLAIM

EGF owners and operators have provided compelling reasons that, given the extent of the proposed shave and the unique conditions facing the electricity generation sector, EGFs should be given the option to exit NOx RECLAIM. SCAQMD staff agree that it appropriate to provide this option.

These provisions would allow the owner or operator of an EGF to opt out of the NOx RECLAIM program. To achieve this exit from NOx RECLAIM, a plan submitted by the EGF would need to demonstrate that at least 99 percent of the EGF's NOx emissions for the most recent three compliance years are at current BARCT or BACT. The proposed rule provisions specify how the New Source Review requirements would be met, how RTCs will be handled, and that Facility Permit amendments would be required to ensure that BARCT or BACT levels would be maintained. The EGF operator would need to comply with any source specific rule limits as quickly as possible, but no later than three years after approval of their opt-out plan. The owner or operator of multiple EGFs under common control would have one opportunity to apportion the NOx limits among its facilities. Monitoring, reporting, and recordkeeping requirements of Rule 2012 and its associated protocols would continue to apply unless the Executive Officer approves an alternative plan that is sufficient to determine compliance with all applicable rules.

RTC Reduction Exemption

The RECLAIM program currently includes an exemption for facilities that meet certain very stringent requirements. Given that no facilities in the RECLAIM program applied for the exemption, the staff proposal removes this provision.

Facility and Equipment Shutdowns

Currently, RTCs resulting from permanently shut down facilities have been sold and reintroduced back into the RECLAIM program. This source of RTCs does not provide an adequate incentive for the remaining facilities to reduce their NOx emissions and may incentivize owners to shut down their facilities. On this basis, staff is proposing to have the RTCs retired from the larger NOx emitting facilities that have shut down. This change is needed to achieve equivalency to command and control rules.

Specifically, the proposal will have the RTCs retired from complete facility closure or equipment shutdowns that represent twenty-five percent or more of a facility's emissions for any quarter within the previous 2 compliance years. This would apply to any facility listed in proposed Tables 7 or 8 of Rule 2002 (i.e., the larger NOx emitting facilities). Permits associated with the equipment being shut down would be surrendered, and the RTCs for future years would be retired from the RECLAIM program.

Future Electricity Demands

Board Resolution language has been introduced to direct staff to follow-up on the extent and impact that future power demands may have on EGFs. This language would direct staff to monitor trends in NOx emissions from EGFs that could be attributable to increasing reliance on renewable sources of energy or increasing market penetration of electric vehicles. On or before April 30, 2017, and on an annual basis thereafter, staff will meet with a working group that includes representatives from the electricity generating industry to discuss and quantify any potential increases in NOx emissions resulting from these trends. On or before June 30, 2017, and on an annual basis thereafter, staff will report to the Stationary Source Committee regarding any NOx emission increases from these facilities attributable to increased renewable energy or electric vehicle utilization, relative to the basin-wide NOx and greenhouse gas reduction benefits from these technologies.

If staff finds that increased power supply intermittency and/or power demand are leading to increased NOx emissions from EGFs, but that these NOx emission increases are outweighed by the NOx and GHG reduction benefits of renewable energy and electrified mobile sources, then no later than 60 days after making that determination staff will make recommendations to the Stationary Source Committee on proposed program amendments designed to assist the affected EGFs with complying with their NOx RECLAIM obligations

Other Proposed Administrative Amendments

Miscellaneous other minor changes to the RECLAIM program are also included in the staff proposal:

- 5-Year Limitation on Amending Annual Emission Reports
- New procedures and criteria for postponing the due date of semi-annual or annual assessments
- Various clarifications and minor edits

Other Key Issues/Comments from the Public

There are a number of key issues regarding the proposed amendments that have been raised and discussed during the rulemaking process. These issues include:

- Emission reduction target, including the amount and timing of NOx RTC reductions
- Equipment life assumptions
- Gap between allocations and actual emissions
- Future electricity demand
- EGF opt-out of RECLAIM;
- Retirement of RTCs from facility and equipment shutdowns
- Potential dismantling of cap and trade underpinnings of RECLAIM

Staff's responses to these issues are described below.

Emission Reductions

SCAQMD staff have significant concerns that proposals with less than 14 tons per day (TPD) of RTC reductions would not meet state law requirements for BARCT and command and control equivalency. The regulated community proposes that 8.77 tpd is the BARCT adjustment and that the additional 5.23 tpd of reductions proposed by staff goes beyond BARCT. On the other hand, environmental groups feel that all NOx reductions are needed to attain the ambient air quality standards. Therefore, the total reductions should be 14.8 tpd, including the 0.8 tpd that covers the potential uncertainties in the BARCT analysis.

With regard the regulated community's proposal, staff believes that in order to demonstrate equivalency with command and control regulations, there must be 10.23 tpd remaining emissions in 2023. After adding allowances for uncertainty, growth, and compliance margin, this equates to a shave of 14 tpd which is the amount needed to achieve BARCT. It does not go beyond BARCT.

In considering NOx emission reductions while maintaining the stability of a functioning market, staff feels that a 0.8 tpd adjustment to account for uncertainty in the BARCT analysis is appropriate. Specifically, this 0.8 tpd is intended to cover the differences in engineering assumptions between staff and the consultant that reviewed staff's analysis, and other uncertainties that arose during the BARCT analysis.

Timing of the RTC reductions

According to the regulated industry the initial RTC reduction of 4 tpd in 2016 is excessive. They feel that the timing of the RTC reductions should be delayed and back-loaded in the later years.

Staff believes that the 4 tpd RTC reductions proposed for 2016 could be achieved merely by removing excess, unused RTCs from the market without the need to install control equipment. Actual NOx reductions by control equipment would not be needed until 2018. A uniform reduction from that point on will help to avoid concurrent demand for materials, contractors and other resources at the end shave.

Equipment Life

The regulated community have raised concerns that the use of the discounted cash flow (DCF) method and that a 25-year useful life overstates the cost effectiveness of controls. They feel that ten years is more appropriate.

Staff provides both DCF and levelized cash flow (LCF) cost effectiveness estimates. Refineries have acknowledged that the equipment in question frequently lasts 25 years. This lifespan is consistent with assessments by U.S. EPA and other agencies. A 10-year life, as proposed by the regulated community, assumes that a rule significantly affecting this equipment is adopted in 10 years AND that all equipment investments made become obsolete at that time. This is not a reasonable assumption.

Staff is using the same cost effectiveness threshold of $50,000/ton that was approved for SOx RECLAIM. Moreover, the current NOx cost-effectiveness value has not been adjusted for inflation over the last 7 years.

The average incremental cost effective for this proposed amendment is:

- Refinery Sector: $10,000/ton - $17,000/ton
- Non-Refinery Sector: $9,000/ton - $14,000/ton

The Gap between Allocations and Actual Emissions
The regulated industry have commented that the gap between allocations and actual emissions should be much larger than what is being proposed. They feel that this gap is important for the market to function, including a compliance margin, growth, investor holdings, and RTCs for new facilities and structural buyers.

The staff proposal includes a 10% compliance margin, adjustments, and growth projections for existing and new businesses. The resulting 22.5% gap is sufficient and consistent with past gaps in a well-functioning market.

Future Electricity Demands
EGFs have commented that there will be a significant adverse impact on achieving compliance with NOx RECLAIM due to future increases in electrical demand. In response to this concern, Board Resolution language has been introduced to require staff to follow-up on the extent and impact that future power demands may be have on the EGFs relative to RECLAIM. This language directs staff to monitor trends in NOx emissions from EGFs that could be attributable to increasing reliance on intermittent renewable sources of energy or increasing market penetration of electric vehicles. On or before April 30, 2017, and on an annual basis thereafter, staff will meet with a working group that includes representatives from the electricity generating industry to discuss and quantify any potential increases in NOx emissions resulting from these market trends. On or before June 30, 2017, and on an annual basis thereafter, staff will report to the Stationary Source Committee regarding any NOx emission increases from these facilities attributable to increased renewable energy or electric vehicle utilization, relative to the basin-wide NOx and greenhouse gas reduction benefits from these technologies.

If staff finds that increased power supply intermittency and/or power demand are leading to increased NOx emissions from EGFs, but that these NOx emission increases are outweighed by the NOx and GHG reduction benefits of renewable energy and electrified mobile sources, then no later than 60 days after making that determination staff will make recommendations to the Stationary Source Committee on proposed program amendments designed to assist the affected EGFs with complying with their NOx RECLAIM obligations. Note that the proposal to provide an option for EGFs to opt out of RECLAIM could help to address this issue.

EGF Opt-out of RECLAIM
Industry representatives other than the EGFs have questioned why EGFs would be the only industrial sector allowed to opt-out of RECLAIM.

For the following reasons staff feels that due to the unique situation of EGFs, they should be the only sector allowed to exit RECLAIM at this time:

- The electrical grid system has changed over time such that EGF's must respond when asked to provide grid stability
- EGFs are highly regulated and thus have or will modernize (i.e. Once-Through Cooling Regulation)
- Most units already at BARCT or BACT
- EGFs provide an essential public service - other essential public services exempt from RECLAIM
- EGFs need to hold extra RTCs to meet NSR and/or resource adequacy requirements

Retirement of RTCs from facility and equipment shutdowns
The regulated community has questioned why RTCs should be retired from facilities that have permanently shut down their equipment. They feel that these RTCs should remain in the RECLAIM program in order to maintain market stability.

Staff's response is that under command and control shutdown credits are significantly discounted to BACT and are based on the last 2 years of operation. Currently under RECLAIM if a facility shutdowns, there is no such discount of credits. In addition, these credits, if not removed from the program, reduce the incentive to implement cost-effective controls that would be required under command and control.

Potential dismantling of cap and trade underpinnings of RECLAIM
The Los Angeles County Business Federation (BizFed) has commented (on November 18, 2015) that the November 4, 2015 proposed rule language (1) allowing EGFs to opt-out RECLAIM, and (2) requiring the retirement of RTCs from permanent facility and equipment shutdowns would constitute a significant step towards the dismantling the cap and trade structure of RECLAIM. As such they requested additional Working Group meetings to discuss the impacts of the proposed rule language and its impact on RECLAIM.

Staff has responded by conducting two Working Group meetings (November 24 and 30, 2015) focused on the recent proposed rule language amendments. Staff does not believe the amendments in any way dismantle the market-based structure of the RECLAIM program. If all identified cost-effective controls are implemented, there will still be sufficient surplus RTCs to allow the market to function as it has in the past. Allowing the EGFs to opt-out, as stated above, is in recognition of their unique circumstances and their limited ability to implement additional controls. The retirement of RTCs upon permanent facility or equipment shutdown is necessary to maintain equivalency with command and control regulations.

California Environmental Quality Act (CEQA) Analysis
Pursuant to California Environmental Quality Act (CEQA) Guidelines §15252 and §15168 and SCAQMD Rule 110, the SCAQMD has prepared a Program Environmental

Assessment (PEA) for proposed amended Regulation XX. Only the topics of air quality and GHGs, hydrology (water demand), and hazards and hazardous materials (due to ammonia transportation) were identified in the Draft PEA as exceeding the SCAQMD's significance thresholds. The Draft PEA was circulated for a 53-day public review and comment period from August 14, 2015 to October 6, 2015. Eight comment letters were received from the public relative to the Draft PEA and responses to the comments have been prepared and are included in the Final PEA.

Subsequent to release of the Draft PEA for public review and comment, modifications were made to the proposed project and some of the revisions were made in response to verbal and written comments received. These modifications are reflected in the Final PEA as underlined/ ~~strikethrough~~ text. Staff has reviewed the modifications to the proposed project and concluded that none of the modifications constitute: 1) significant new information which discloses that a significant new environmental impact would result from the project or that there would be a substantial increase in the severity of an environmental impact; or 2) provide new information of substantial importance relative to the Draft PEA. As a result, the modifications do not require recirculation of the document pursuant to CEQA Guidelines §15073.5 and §15088.5. Therefore, the document is a now a Final PEA and is included as an attachment to this Governing Board package.

Socioeconomic Analysis

A socioeconomic assessment has been conducted as part of this rulemaking process. The report can be found in Attachment J of this Board package. Key findings from the assessment are reported below.

The proposed amendments would reduce (or "shave") 14 tons per day (tpd) of NOx RECLAIM Trading Credits (RTCs) by the year 2023. The proposed shave would affect the current RTC holdings for 56 out of 275 RECLAIM facilities and investors. The 56 affected facilities would include 9 major refinery facilities, 21 electrical generating facilities, and 26 other top emitting non-refinery facilities which represent manufacturing, mining, oil and gas exploration, utilities, amusement and recreation industries, and a military facility. The remaining 219 facilities could be potentially affected if the proposed shave would induce changes in NOx RTC prices. These facilities represent a range of industries, but are largely comprised of manufacturing, mining, oil and gas exploration, and utilities industries.

Cost Impacts

The proposed amendments are assumed to induce full BARCT installation by 2023 at the 9 refineries and 11 non-refinery facilities where the 2015 BARCT analysis identified cost-effective controls for their major NOx emission sources. This assumption is made to arrive at the most conservative (i.e., maximum) compliance cost estimates. In reality, the RECLAIM program affords facilities with compliance flexibility so that the actual costs may be lower if a facility identifies any other more cost-effective alternatives to remain in compliance, such as RTC purchases and operational changes. Total compliance cost associated with control equipment installation by 9 refineries and 11 non-refinery facilities would range from $728 million to $1.1 billion in present worth values. However, these estimates do not consider the possibility that these 20 facilities could potentially sell surplus NOx RTCs gained after control installation, which would then offset control installation costs.

The proposed shave could potentially affect facilities with no identified cost-effective controls in two ways. First, 36 of these facilities would be subject to the proposed shave, and some of them would need to buy additional NOx RTCs to reconcile actual emissions. Second, all facilities could potentially pay a higher price for NOx RTCs that they purchase each year for compliance. Additionally, higher NOx RTC prices could be potentially induced by the opt-out of any electricity generating facilities or the shut-down of any RECLAIM facilities that regularly sell their surplus credits. Furthermore, under the proposed amendments, the 12-month rolling average price trigger would be raised to $22,500 per ton (discrete credits), thus potentially allowing NOx RTC prices to increase further before non-tradable/non-usable NOx RTCs are converted to tradable/usable NOx RTCs; however, the proposed addition of a 3-month rolling average price trigger of $35,000 per ton (discrete credits) would ensure short-term price stability during the period of proposed phase-in shave. Total incremental compliance cost associated with RTC purchases over the course of 25 years is estimated to range from $19 million—if discrete NOx RTC prices remain the same—to $500 million—if the average annual discrete NOx RTC prices increase to $22,499/ton for a total of 25 years and none of the affected facilities pursue any other more cost-effective compliance options. (Cost estimates are expressed in 2014 dollars.)

Job Impacts

Assuming that the proposed amendments would induce full BARCT installation by 2023 and the 9 refineries and 11 non-refinery facilities would incur the high-end estimated costs, it is projected that about 20 jobs on the net would be created on an annual average between 2018 and 2035, and about 140 net jobs would be foregone when the analysis horizon is extended to 2043. (Note that jobs foregone may include either losses of existing jobs or projected additional jobs not created.) The difference is because the majority of jobs, mostly in the construction sector, would be created at the beginning of the analysis period (2018-2022) when control installation is assumed to take place. Despite having a large share of the total compliance cost, the refinery industry is projected to have fewer jobs forgone relative to other industries with similar magnitude of cost impact due to the fact that the industry is the most capital-intensive. As such, less labor would be required to produce the same amount of products or services. Note that the projected job impact would be more positive if the 9 refineries and 11 non-refinery facilities would sell their surplus NOx RTCs to offset control installation costs.

Regarding the incremental compliance cost that could be potentially incurred by the rest of NOx RECLAIM facilities, the associated job impacts have been estimated under various scenarios of discrete NOx RTC prices. If prices remain the same, little job impact is expected due to the proposed amendments. If the average annual discrete NOx RTC prices increase to $24,999/ton and none of the affected facilities pursue any other more cost-effective compliance options, then about 40 jobs on the net would be foregone annually between 2023 and 2035. However, this latter price scenario is unlikely to occur, particularly if the 9 refineries and 11 non-refinery facilities would sell surplus NOx RTCs after control installation and thus increase the market supply of NOx RTCs.

Costs of Command-and-Control Compared to RECLAIM

RECLAIM allows facilities to use the least costly option to remain in compliance. Unlike command-and-control regulations where every source has to be controlled to the same emission standard, RECLAIM facilities can pursue operational changes or purchase RTCs from investors and other facilities with surplus credits in lieu of upgrading existing control equipment or installing new control equipment. Therefore, by design, total costs to install controls under the RECLAIM program since its adoption have been less than they would have been under command and control. The stream of cost-savings for any RECLAIM facility would only be reduced when, at a point in time, it becomes more economical for the facility to install the control equipment that would have been required under command-and-control. However, the future cost-savings may not be completely eliminated by control installation as long as the facility is able to sell surplus RTCs to offset control installation costs. Therefore, the costs of RECLAIM in the aggregate, following implementation of staff's proposal, would not exceed the costs of command and control regulations.

Implementation and Resources

It is expected that there will be a workload increase due to applications submitted for installing new control equipment or retrofitting/modifying existing processes and there might be an increase in RTC trading activities. However, current AQMD resources are adequate to implement the proposed amended rules.

ATTACHMENT A
SUMMARY OF PROPOSAL

Electricity Generating Facilities Opt-out of NOx RECLAIM (Rule 2001 - paragraphs (g)(1) to (g)(4) and subparagraphs (i)(1)(K) and (i)(2)(O))

These provisions would allow the owner or operator of an electricity generating facility (EGF) to opt out of the NOx RECLAIM program. An opt-out plan would need to demonstrate that at least 99 percent of the EGF's NOx emissions for the most recent 3 compliance years are at current BARCT or BACT. These proposed provisions specify how New Source Review requirements would be met, how RTCs will be handled, and that Facility Permit amendments would be required to ensure that BARCT or BACT levels would be maintained. The EGF operator would need to comply with any source specific rule limits as quickly as possible, but no later than 3 years after approval of their opt-out plan. The owner or operator at multiple EGFs under common control would have one opportunity to apportion the NOx limits among its facilities. Monitoring, reporting, and recordkeeping requirements of Rule 2012 and its associated protocols would continue to apply unless the Executive Office approves an alternative plan that is sufficient to determine compliance with all applicable rules.

New Proposed BARCT Levels (Rule 2002 - Table 6 and subparagraph (f)(1)(L))

- 2 ppmv for FCCUs, Refinery and Non-Refinery Gas Turbines, Refinery Boilers and Heaters greater than 40 mmbtu/hr, SRU/TGs, cement kilns and coal fired boiler
- 9 ppmv for Metal Heat Treating
- 10 ppmv for petroleum coke calciner
- 80% reduction for glass melting furnaces and Sodium Silicate Furnace, and
- 11 ppmv for internal combustion engines

Proposed RTC Reductions and Use of Non-tradable/Non-usable NOx RTCs (Rule 2002 - subparagraphs (f)(1)(B), (f)(1)(C), (f)(1)(D), Table 7, and Table 8)

These provisions distribute the 14 tpd NOx RTC reductions to 56 facilities and investors that hold 90% of the RTCs. Investors are grouped with the refineries and treated as a facility for shave purposes. The remaining 219 facilities that hold 10% of the RTCs are not proposed to be shaved because there was limited or no new BARCT for the types of equipment and operation at these facilities.

The overall NOx RTC reductions of 14 tpd are expected to be achieved incrementally from 2016 to 2022, according to the following implementation schedule:

- 2016 – 4 tons per day
- 2018 – 2 tons per day
- 2019 – 2 tons per day
- 2020 – 2 tons per day
- 2021 – 2 tons per day
- 2022 – 2 tons per day

Proposed Price Triggers (Rule 2002 - subparagraphs (f)(1)(E), (f)(1)(H), (f)(1)(I), and (f)(1)(J))
The 12-month rolling average trigger is proposed to be updated from $15,000 to $22,500 per ton for discrete credits. A trigger level of $35,000 per ton, also for discrete credits, has been added for a 3-month rolling average. If RTC prices exceed either of these levels, a report to the Board and a program review are required. Also included is a 12-month rolling average for Infinite Year Block (IYB) RTCs of $200,000 per ton. If credit prices are lower than this amount, then a report to the Board is also required.

The abovementioned report would include a commitment and schedule to conduct a more rigorous cost-effectiveness, market analysis, and socioeconomic impact assessment of the RECLAIM program.

Regional NSR Holding Account (Rule 2002 - subparagraphs (f)(1)(F), (f)(1)(G), (f)(1)(K) and Table 9; Rule 2005 - subparagraph (b)(2)(A) and paragraphs (f)(2) and (f)(3))
A Regional NSR Holding Account, held by the SCAQMD, would be used for the purpose of helping newer electricity generating facilities comply with the NSR requirements specified in Rule 2005 – New Source Review Requirements for RECLAIM.

State of Emergency Related to Electricity Generating Facilities (Rule 2002 - paragraphs (f)(4) and (f)(5))
These provisions address the activation of Non-tradable/Non-usable RTCs and the Regional NSR Holding Account during a State of Emergency declared by the Governor related to electricity demand or power grid stability within the SCAQMD jurisdictional boundaries. Also in these rule provisions are the procedures to determine the amount and distribution of the RTCs to the requesting EGFs.

RTC Reduction Exemption (Rule 2002 - subdivision (i))
Given that no facilities have applied for an exemption pursuant to subdivision (i) staff is proposing to remove the subdivision in its entirety.

Facility and Equipment Shutdowns (Rule 2002 - subdivision (i))
The proposed rule amendment includes a provision to address the retirement of RTCs from complete facility closure or equipment shutdowns that represent twenty-five percent or more of a facility's emissions for any quarter within the previous 2 compliance years. This would apply to any facility listed in Table 7 or 8 of Rule 2002. Permits associated with the equipment being shut down would be surrendered, and the RTCs for future years would be retired from the RECLAIM program.

Other Proposed Administrative Amendments

- 5-Year Limitation on Amending Annual Emission Reports (Rule 2002(b)(5))
- New procedures and criteria for postponing the due date of semi-annual or annual assessments (Appendix A to Rules 2011 and 2012)
- Various clarifications and minor edits

ATTACHMENT B

KEY ISSUES

Issue	Industry Comment	Staff Response
Amount of RTC Reductions	The 14 tpd emissions reduction as proposed by staff goes beyond the BARCT analysis. The 8.77 tpd is the BARCT adjustment. The additional 5.23 tpd goes beyond BARCT.	SCAQMD staff have significant concerns that proposals with less than 14 tons per day (TPD) would not meet the state law requirements for BARCT and command and control equivalency. The regulated community propose that the 8.77 tpd is the BARCT adjustment and that the additional 5.23 tpd goes beyond BARCT. On the other hand, the environmental community feel that all NOx reductions are needed to attain the ambient air quality standards. Therefore, the total reductions should be 14.8 tpd, including the 0.8 tpd that covers the potential uncertainties in the BARCT analysis. With regards the regulated community's proposal, staffs response has been that in order to achieve command and control equivalency there must be 10.21 tpd remaining emissions in 2023. This equates to a shave of 14 tpd which is the amount needed to achieve BARCT. It does not go beyond BARCT.
Timing of the RTC reductions	The initial RTC reduction of 4 tpd in 2016 is excessive. The timing of the RTC reductions should be back loaded in the later years.	Staff's response to this comment is that there are enough excess RTCs in the RECLAIM program to reduce the 4 tpd by 2016 without installing control equipment. Actual NOx reductions by control equipment would not be needed until 2018.

Issue	Industry Comment	Staff Response
		A uniform reduction from that point on will help avoid the concentration of materials, contractors and other resources at the end shave.
Equipment Life	The regulated community have raised concerns that the use of the discounted cash flow (DCF) method and 25-year useful life overstates cost effectiveness of controls. They feel that ten years is more appropriate	Staff provides both DCF and levelized cash flow (LCF) cost effectiveness estimates. Refineries have acknowledged that equipment lasts 25 years. The lifespan is consistent with other agencies and EPA assessments. A 10 year life assumes only if a rule is amended in 10 years that and investments are stranded assets. This is not a reasonable assumption. Staff is using the same cost effective threshold of \$50,000/ton that was approved for SOx RECLAIM. Moreover, the current NOx cost-effectiveness value has not been adjusted for inflation over the last 7 years. The average incremental cost effective for this proposed amendment is: • Refinery Sector: \$10,000/ton - \$17,000/ton • Non-Refinery Sector: \$9,000/ton - \$14,000/ton
The Gap Between Allocations and Actual Emissions	The regulated industry have commented that the gap between allocations and actual emissions should be much larger than what is being proposed. They feel that	The staff proposal includes a 10% compliance margin, adjustments, and growth projections for existing and new businesses. The resulting 23%

Issue	Industry Comment	Staff Response
	this gap is important for market function, including compliance margin, growth, investor holdings, and RTCs for new facilities and structural buyers.	gap is sufficient and consistent with past gaps in a functioning market.
Future Electricity Demands	The electricity generating facilities (EGF) have commented that there will be a significant adverse impact on achieving compliance with the NOx emissions due to future increased in electrical demand.	In response to this concern a Board Resolution language has been introduced to require staff to follow-up on the extent and impact that future power demands may be have on the EGFs. This language directs staff to monitor trends in NOx emissions from EGFs that could be attributable to increasing reliance on renewable sources of energy or increasing market penetration of electric vehicles. On or before April 30, 2017, and on an annual basis thereafter, staff will meet with a working group that includes representatives from the electricity generating industry to discuss and quantify any potential increases in NOx emissions resulting from these market trends. On or before June 30, 2017, and on an annual basis thereafter, staff will report to the Stationary Source Committee regarding any NOx emission increases from these facilities attributable to increased renewable energy or electric vehicle utilization, relative to the basin-wide NOx and greenhouse gas reduction benefits from technologies.

Issue	Industry Comment	Staff Response
		If staff finds that increased power supply intermittency and/or power demand are leading to increased NOx emissions from EGFs, but that these NOx emission increases are outweighed by the NOx and GHG reduction benefits of renewable energy and electrified mobile sources, then no later than 60 days after making that determination staff will make recommendations to the Stationary Source Committee on proposed program amendments designed to assist the affected EGFs with complying with their NOx RECLAIM obligations
EGF Opt-out of RECLAIM	Industry representatives outside of the EGFs have questioned why EGFs would be the industrial sector allowed to opt-out of RECLAIM.	For the following reasons staff feels EGFs should be the industrial sector to be allowed to opt-out of RECLAIM: • Electrical grid system has changed over time • EGFs are unique • Once-Through Cooling Regulation – older units repowered with cleaner, more efficient units • EGFs highly regulated • Most units already at BARCT or BACT • Provide essential public service • Other essential public services exempt from RECLAIM • Need to hold extra RTCs for NSR and/or to meet resource adequacy

Issue	Industry Comment	Staff Response
Retirement of RTCs from facility and equipment shutdowns	The regulated community have questioned why RTCs should be retired from facilities that have permanently shut down their equipment. They feel that these RTCs should remain in the RECLAIM program in order to maintain market stability.	Staff's response is that under command and control shutdown credits are discounted to BACT and based on last 2 years of operation. Currently, under a RECLAIM facility shutdown there is no discount of credits. In addition, these credits, if not removed from the program, reduce the incentive to implement cost-effective controls that would be required under command and control.
Potential dismantling of cap and trade underpinnings of RECLAIM	The Los Angeles County Business Federation (BizFed) has commented (on November 18, 2015) that the November 4, 2015 proposed rule language of (1) allowing EGFs to opt-out RECLAIM, and (2) requiring the retirement of RTCs from the facility and equipment permanently shut down would constitute a significant step towards dismantling the cap and trade structure of RECLAIM. As such they requested additional Working Group meetings to discuss the impacts of the proposed rule language and its impact on the face of RECLAIM.	Staff has responded by conducting two Working Group meetings (November 24 and 30, 2015) focused on the recent proposed rule language amendments. Staff does not believe the amendments in any way dismantle the market-based structure of the RECLAIM program. If all identified cost-effective controls are implemented, there will still be sufficient surplus RTCs to allow the market to function as it has in the past. Allowing the EGFs to opt-out, as stated above, is in recognition of their unique circumstances and their limited ability to implement additional controls. The retirement of RTCs upon permanent facility or equipment shutdown is necessary to maintain equivalency with command and control regulations.

Issue	Environmental Community Comment	Staff Response
Amount of RTC Reductions	The environmental groups feel that all NOx reductions are needed to attain the ambient air quality standards. Therefore, the total reductions should be 14.8 tpd, including the 0.8 tpd that covers the potential uncertainties in the BARCT analysis.	In considering NOx emission reductions while maintaining the stability of a functioning market, staff feels that a 0.8 tpd adjustment to account for uncertainty in the BARCT analysis is appropriate. Specifically, this 0.8 tpd is intended to cover the differences in engineering assumptions between staff and the consultant that reviewed staff's analysis, and other uncertainties that arose during the BARCT analysis

RESOLUTION NO. 2015-____

A Resolution of the Governing Board of the South Coast Air Quality Management District (SCAQMD) certifying the Final Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM).

A Resolution of the SCAQMD Governing Board amending Regulation XX – Regional Clean Air Incentives Market (RECLAIM).

WHEREAS, the 2012 AQMP was adopted by the SCAQMD Governing Board on December 7, 2012 and subsequently approved by the California Air Resources Board and submitted to the U.S. Environmental Protection Agency for inclusion into the State Implementation Plan; and

WHEREAS, the 2012 AQMP contained a control measure, CMB-01, that proposed to decrease NOx RECLAIM allocations and to reflect Best Available Retrofit Control Technology (BARCT) as required by state law; and

WHEREAS, the SCAQMD Governing Board has determined with certainty that the Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), is considered a "project" pursuant to the California Environmental Quality Act (CEQA); and

WHEREAS, the SCAQMD has had its regulatory program certified pursuant to Public Resources Code §21080.5 and has conducted a CEQA review pursuant to such program (SCAQMD Rule 110); and

WHEREAS, SCAQMD staff has prepared a Draft Program Environmental Assessment (PEA) pursuant to its certified regulatory program and CEQA Guidelines §15252 and §15168, setting forth the potential environmental consequences of Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM); and

WHEREAS, the Draft PEA was circulated for a 53-day public review period from August 14, 2015 to October 6, 2015; and

WHEREAS, the Draft PEA has been revised to include the comments received on the Draft PEA and the responses, such that it is now a Final PEA; and,

WHEREAS, it is necessary that the adequacy of the Final PEA, including responses to comments, be determined by the SCAQMD Governing Board prior to its certification; and

WHEREAS, the SCAQMD Governing Board finds and determines, taking into consideration the factors in Section (d)(4)(D) of the Governing Board Procedures, that the modifications which have been made to Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), since notice of public hearing was published do not significantly change the meaning of the proposed amended regulation within the meaning of the Health and Safety Code §40726 and would not constitute significant new information requiring recirculation of the Draft PEA pursuant to CEQA Guidelines §15073.5 and §15088.5; and,

WHEREAS, it is necessary that the SCAQMD prepare Findings and a Statement of Overriding Considerations pursuant to CEQA Guidelines §15091 and §15093, respectively, regarding potentially significant adverse environmental impacts that cannot be mitigated to insignificance; and a Mitigation Monitoring Plan pursuant to Public Resources Code §21081.6, regarding the mitigation included in the Final PEA; and

WHEREAS, the SCAQMD Governing Board has determined that the Socioeconomic Report for Regulation XX (RECLAIM), as proposed to be amended, is consistent with the March 17, 1989 and October 14, 1994 Board Socioeconomic Resolution for rule adoption; and

WHEREAS, the SCAQMD Governing Board has determined that the Socioeconomic Report for Regulation XX complies with Health and Safety Code §40440.8 (a) and (b), §40440.5, and §40728.5; and

WHEREAS, the SCAQMD Governing Board has determined that Proposed Amended Regulation XX may result in increased costs to industry, yet is considered to be appropriate, with total annualized costs as specified in the Final Socioeconomic Impact Assessment; and

WHEREAS, the SCAQMD Governing Board has actively considered the Socioeconomic Impact Assessment and has made a good faith effort to minimize such impacts; and

WHEREAS, the SCAQMD Governing Board obtains its authority to adopt, amend or repeal rules and regulations from §§ 39002, 39650 et. seq., 40000, 40001, 40440, 40441, 40702, 40725 through 40728, 41508, 41700, and 44390 through 44394 of the Health and Safety Code; and

WHEREAS, Health and Safety Code §40727 requires that prior to adopting, amending or repealing a rule or regulation, the SCAQMD Governing Board shall make findings of necessity, authority, clarity, consistency, non-duplication, and

WHEREAS, the SCAQMD Governing Board has determined that a need exists to amend Regulation XX to implement the 2012 AQMP and BARCT as required by state law; and

WHEREAS, the SCAQMD Governing Board has determined that Proposed Amended Regulation XX is written or displayed so that the meaning can be easily understood by the persons directly affected by it; and

WHEREAS, the SCAQMD Governing Board has determined that Proposed Amended Regulation XX is in harmony with and not in conflict with or contradictory to, existing statutes, court decisions or state or federal regulations; and

WHEREAS, the SCAQMD Governing Board has determined that Proposed Amended Regulation XX will not impose the same requirements as any existing state or federal regulations. The amendments are necessary and proper to execute the powers and duties granted to, and imposed upon, AQMD; and

WHEREAS, the SCAQMD Governing Board has determined that by adopting Proposed Amended Regulation XX, the SCAQMD Governing Board will be implementing, interpreting and making specific the provisions of the Health and Safety Code §§ 39002, 40000, 40001, 40440 (a), 40440.1, 40702, and 40725 through 40728.5; and Title 42 U.S.C. §§ 7410 and 7511a; and

WHEREAS, the SCAQMD Governing Board has determined that there is a problem, that the proposed amendments to Regulation XX will alleviate (Health and Safety Code § 40001(c)). Specifically, RECLAIM facility NOx emissions do not currently reflect BARCT levels, as required by section 40440, and these proposed amendments will reduce NOx credits in the RECLAIM market so as to reflect BARCT; and

WHEREAS, the Governing Board finds that Health and Safety Code section 39616 does not apply to the proposed amendments to RECLAIM. The Governing Board further finds that in the absence of the 39616 findings being made, the Board could and would nonetheless adopt these proposed amendments. Nonetheless, the SCAQMD Governing Board makes the following findings when considering the NOx RECLAIM program on an aggregate basis, that:

> pursuant to Health and Safety Code §39616(c)(l), the proposed amendments to RECLAIM achieve the emissions levels projected to result from implementation of the rules and control measures subsumed by RECLAIM and current BARCT at equal or less cost, as set forth and explained in the Socioeconomic Report; and
>
> pursuant to Health and Safety Code §39616(c)(2), the proposed amendments to RECLAIM do not change the previous findings that RECLAIM provides a level of

enforcement and monitoring comparable to or more stringent than command and control air quality measures by requiring more frequent and more accurate monitoring, more frequent and more complete emissions reports, electronic emissions reporting, maintenance of on-site records of emissions reports and underlying data for three years, annual or more frequent facility inspections, and annual emissions audits; and

pursuant to Health and Safety Code §39616(c)(4), the proposed amendment to RECLAIM will not result in a greater loss of jobs or more significant shifts from higher to lower skilled jobs, on an overall District-wide basis, than would exist under command and control air quality measures, as set forth and explained in the Socioeconomic Report; and

pursuant to Health and Safety Code §39616(c)(5), the proposed amendments to RECLAIM do not affect the findings previously made by the Governing Board with respect to this subdivision; and

pursuant to Health and Safety Code §39616(c)(6), the proposed amendments to RECLAIM will not in any manner delay, postpone, or otherwise hinder District compliance with District plans to attain state Ambient Air Quality Standards because the amendments implement BARCT as required by Health and Safety Code §40919(a)(3) ; and

pursuant to Health and Safety Code §39616(c)(7), the proposed amendment to RECLAIM will not result in disproportionate impacts, measured on an aggregate basis, on those stationary sources included in the program compared to other permitted stationary sources in the SCAQMD's plan for attainment because the sources included in the amendments are subject to BARCT requirements ; and

WHEREAS, the SCAQMD specifies the Director of Regulation XX as the custodian of the documents or other materials which constitute the record of proceedings upon which the adoption of these proposed amendments is based, which are located at the South Coast Air Quality Management District, 21865 Copley Drive, Diamond Bar, California; and

WHEREAS, the SCAQMD Governing Board has determined that proposed amendments to Regulation XX should be adopted for the reasons contained in the staff report, including compliance with BARCT; and

WHEREAS, the SCAQMD Governing Board finds that pursuant to Health and Safety Code section 40920.6(a)(5) the reason that it is adopting the proposed amendments to RECLAIM is because the amendments will achieve BARCT level emissions from NOx RECLAIM sources in an equitable manner.

WHEREAS, a public hearing has been properly noticed in accordance with the provisions of Health and Safety Code § 40725; and

WHEREAS, the SCAQMD Governing Board has held a public hearing in accordance with all provisions of law; and

WHEREAS, the SCAQMD Governing Board prior to voting on Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), has reviewed, considered, and approved the Final PEA, including responses to comments, prior to its certification.

NOW, THEREFORE, BE IT RESOLVED, that the SCAQMD Governing Board does hereby certify the Final PEA for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM) was completed in compliance with CEQA and SCAQMD Rule 110 provisions; and finds that the Final PEA was presented to the Governing Board, whose members reviewed, considered and approved the information therein prior to acting on Proposed Amended Regulation XX; and

BE IT FURTHER RESOLVED, that the Governing Board adopts Findings and a Statement of Overriding Considerations pursuant to CEQA Guidelines §15091 and §15093, respectively, and a Mitigation Monitoring Plan pursuant to Public Resources Code §21081.6 regarding potentially significant adverse environmental impacts that cannot be mitigated to insignificance, as required by CEQA, and which are included as Attachment 1 and incorporated herein by reference; and

BE IT FURTHER RESOLVED, that the SCAQMD Governing Board does hereby approve the Socioeconomic Report; and

BE IT FURTHER RESOLVED, that the SCAQMD Governing Board does hereby amend, pursuant to the authority granted by law, Regulation XX, as set forth in the attached, and incorporated herein by reference; and

BE IT FURTHER RESOLVED, that the SCAQMD Governing Board does hereby direct staff to submit into the State Implementation Plan a commitment of 14 tons per day by the year 2022, less the total amount in the Regional NSR Holding Account, to further ensure that the reduction commitments comply with state law; and

BE IT FURTHER RESOLVED, that the Governing Board hereby directs the Executive Officer to submit the NOx emission reductions associated with the Non-tradable/Non-usable RTCs for a compliance year minus the amount listed in Table 9 for the same compliance year at the conclusion of that compliance year provided that NOx RTC process have not exceeded the $22,500 price threshold and provided that the Governor has not declared a State of Emergency related to electricity demand of power grid stability within the SCAQMD jurisdictional boundaries, consistent with Rule 2002(f)(1)(K); and

BE IT FURTHER RESOLVED, that the SCAQMD Governing Board does hereby direct staff to re-evaluate programmatic BARCT and command and control equivalency as part of future AQMP revisions, and propose AQMP control measures to further reduce emissions as necessary in accordance with such evaluation; and

BE IT FURTHER RESOLVED, that the SCAQMD Governing Board hereby directs the Executive Officer to submit Regulation XX, as currently amended, with the exception of the RECLAIM Trading Credits in the Regional New Source Review Holding Account as listed in Table of Rule 2002, for inclusion into the California State Implementation Plan.

BE IT FURTHER RESOLVED, that the Governing Board does hereby direct staff to monitor trends in NOx emissions from electricity generating facilities that could be attributable to increasing reliance on renewable sources of energy or increasing market penetration of electric vehicles. The Governing Board further directs that on or before April 30, 2017, and on an annual basis thereafter, staff shall meet with a working group that includes representatives from the electricity generating industry to discuss and quantify any potential increases in NOx emissions resulting from these trends. On or before June 30, 2017, and on an annual basis thereafter, staff shall report to the Stationary Source Committee regarding any NOx emission increases from these facilities attributable to increased renewable energy or electric vehicle utilization, relative to the basin-wide NOx and GHG reduction benefits. The Governing Board further directs that if staff finds that increased power supply intermittency and/or power demand are leading to increased NOx emissions from electricity generating facilities, but that these NOx emission increases are outweighed by the NOx and GHG reduction benefits of renewable energy and electrified mobile sources, then no later than 60 days after making that determination staff will make recommendations to the Stationary Source Committee on proposed program amendments designed to assist the affected electrical generating facilities with complying with their NOx RECLAIM obligations.

INTRODUCTION

The proposed amendments to Regulation XX - Regional Clean Air Incentives Market (RECLAIM) are considered a "project" as defined by the California Environmental Quality Act (CEQA) (California Public Resources Code §§21000 et seq.). The SCAQMD as Lead Agency for the proposed project, prepared a Notice of Preparation/Initial Study (NOP/IS) which identified environmental topics to be analyzed in a Draft Program Environmental Assessment (PEA). The NOP/IS provided information about the proposed project to other public agencies and interested parties prior to the intended release of the Draft PEA. The NOP/IS was distributed to responsible agencies and interested parties for a 57-day public review and comment period from December 5, 2014 to January 30, 2015. The initial evaluation in the NOP/IS identified the topics of aesthetics; air quality and greenhouse gas emissions; energy; hydrology and water quality; hazards and hazardous materials; solid and hazardous waste; and, transportation and traffic, as potentially being significantly adversely affected by the project. Since the proposed project may have statewide, regional or areawide significance, a CEQA scoping meeting is required and was held for the proposed project pursuant to Public Resources Code §21083.9 (a)(2) on January 8, 2015. Eight comment letters were received from the public regarding the preliminary analysis in the NOP/IS. None of these comment letters identified other potentially significant adverse impacts from the proposed project that should be analyzed in the PEA.

The Draft PEA was released for a 53-day public review and comment period from August 14, 2015 to October 6, 2015 and further analyzed whether or not the potential adverse impacts to the environmental topic areas identified in the NOP/IS are significant. The Draft PEA concluded that only the topics of air quality and greenhouse gases (GHGs), hydrology (water demand), and, hazards and hazardous materials (due to ammonia transportation) would have significant adverse impacts. The Draft PEA included the NOP/IS (in Appendix F), the comment letters received relative to the NOP/IS and responses to individual comments (in Appendix G), and a summary of comments made at the CEQA scoping meeting and responses to individual comments (in Appendix H).

Eight comment letters were received during the public comment period on the analysis presented in the Draft PEA. Responses to these comment letters have been prepared and are included in Appendix I of the Final PEA The Final PEA, prepared pursuant to CEQA Guidelines §15132, identifies air quality and GHGs, hydrology (water demand), and, hazards and hazardous materials (due to ammonia transportation) as areas that may be adversely affected by the proposed project.

In addition to incorporating the comment letters and the responses to comments, some modifications have been made to the Draft PEA to make it a Final PEA. SCAQMD staff evaluated these modifications and concluded that none of the modifications alter any conclusions reached in the Draft PEA, nor do they constitute significant new information[1] and, therefore, do not require recirculation of the document pursuant to CEQA Guidelines §§15073.5 and 15088.5. The Final PEA will be presented to the Governing Board prior to its December 4, 2015 public hearing.

SUMMARY OF THE PROPOSED PROJECT

To comply with the requirements in Health and Safety Code §40440 by conducting a Best Available Retrofit Control Technology (BARCT) assessment, SCAQMD staff is proposing amendments to the following rules which are part of Regulation XX – Regional Clean Air Incentives Market (RECLAIM): Rule 2001 – Applicability; Rule 2002 – Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx); Rule 2005 – New Source Review For RECLAIM; Attachment C from Rule 2011 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping Oxides of Sulfur (SOx) Emissions; and, Attachment C from Rule 2012 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping Oxides of Nitrogen (NOx) Emissions. The proposed amendments to Regulation XX would reduce emissions from equipment and processes operated at NOx RECLAIM facilities located throughout the entire SCAQMD jurisdiction. In particular, the environment could be impacted from the proposed project due to facilities installing new, or modifying existing control equipment for the following types of equipment/source categories in the NOx RECLAIM program: 1) fluid catalytic cracking units; 2) refinery boilers and heaters; 3) refinery gas turbines; 4) sulfur recovery units – tail gas treatment units; 5) non-refinery/non-power plant gas turbines; 6) non-refinery sodium silicate furnaces; 7) non-refinery/non-power plant internal combustion engines; 8) container glass melting furnaces; 9) coke calcining; and, 10) metal heat treating furnaces. For clarity and consistency throughout the regulation, other minor revisions are also proposed.

The proposed project is expected to result in a total of 14 tons per day (tpd) of reduction of NOx RECLAIM Trading Credits (RTCs) from the current 2015 RTC holdings of 26.5 tpd over a seven-year period from 2016 to 2022. The 14 tpd of NOx RTC reductions will be reduced from the allocations of 56 facilities plus the investors that, together, hold 90 percent of the NOx RTC holdings. Investors are included in the refinery sector and treated as one facility. For the remaining 219 facilities that hold 10 percent of the 26.5 tpd of the NOx RTCs, no NOx RTC

[1] Pursuant to CEQA Guidelines §§ 15073.5 and 15088.5, circumstances that would require recirculation include, for example, any of the following:

(1) A new, avoidable significant effect would result from the project or from a new mitigation measure proposed to be implemented, or new mitigation measures or project revisions must be added in order to reduce the effect to insignificance.
(2) The proposed mitigation measures or project revisions will not reduce the effects to less than significance and new measures or revisions are required.
(3) A substantial increase in the severity of an environmental impact would result unless mitigation measures are adopted that reduce the impact to a level of insignificance.
(4) A feasible project alternative or mitigation measure considerably different from others previously analyzed would clearly lessen the environmental impacts of the project, but the project's proponents decline to adopt it.
(5) The draft CEQA document was so fundamentally and basically inadequate and conclusory in nature that meaningful public review and comment were precluded.

shave is proposed because either no new BARCT (not cost effective and/or infeasible) was identified, or gains in emission reductions would be negligible, for the types of equipment and source categories at these facilities. By following this approach, the shave is distributed as follows:

- 66% shave for 9 refineries and investors (treated as one facility)
- 49% shave for 21 electricity generating facilities (EGFs)
- 49% shave for 26 non-major facilities
- 0% shave for 219 remaining facilities

In addition, the overall NOx RTC reductions of 14 tpd are expected to be achieved incrementally from 2016 to 2022, according to the following implementation schedule:

- 2016 – 4 tons per day
- 2018 – 2 tons per day
- 2019 – 2 tons per day
- 2020 – 2 tons per day
- 2021 – 2 tons per day
- 2022 – 2 tons per day

POTENTIAL SIGNIFICANT ADVERSE IMPACTS THAT CANNOT BE REDUCED BELOW A SIGNIFICANT LEVEL

The Final PEA identified the topics of air quality (during construction) and GHGs (from combined construction and operation activities), hydrology (due to water demand), and, hazards and hazardous materials (due to ammonia transportation) as the only areas that may be significantly adversely affected by the proposed project. Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one fluid catalytic cracking unit (FCCU) in 2017. Thus, the projected installation of wet gas scrubber (WGS) technology is expected to only occur at one of the two FCCUs. Further, since the release of the Draft PEA for public review and comment, the number of selective catalytic reduction (SCR) units that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74. Thus, the analysis in this PEA for the refinery sector is conservative as it overestimates the potentially significant adverse impacts that cannot be reduced below a significant level for the following environmental topics.

Air Quality Impacts During Construction

Relative to construction emissions, the "worst-case" scenario is when construction activities overlap due to concurrent construction activities occurring at a single facility and at multiple facilities. Specifically, the scenario analyzed in the Final PEA is the simultaneous activities of demolishing existing equipment, site preparation, and constructing new or modifying existing air pollution control equipment, which could occur at a single facility or at more than one facility. The analysis further assumes that the "worst-case" day is that in which each construction project is operating construction equipment that generates the greatest emissions.

Based on these assumptions for overlapping construction activities, the "worst-case" emissions were calculated to be: 429 pounds per day of volatile organic compounds (VOC); 1,656 pounds per day of NOx; 2,745 pounds per day of carbon monoxide (CO); 3 pounds per day of oxides of sulfur (SOx); 1,758 pounds per day before mitigation and 853 pounds per day after mitigation of particulate matter with an aerodynamic diameter less than 10 microns (PM10), respectively; and, 883 pounds per day before mitigation and 430 pounds per day after mitigation of particulate matter with an aerodynamic diameter less than 2.5 microns (PM2.5), respectively. The significance thresholds for construction-related emissions are: 75 pounds per day of VOC; 100 pounds per day of NOx; 550 pounds per day of CO; 150 pounds per day of SOx; 150 pounds per day of PM10; and 55 pounds per day of PM2.5. (Estimated construction emissions did not exceed the significance threshold for SOx.) Because the construction emissions for all of the pollutants except SOx exceed the applicable significance thresholds for construction, mitigation measures are required.

While the air quality mitigation measures for construction that are identified in the Mitigation Monitoring Plan section of this document may reduce construction emissions to the maximum extent feasible, none are mitigation measures that will avoid the significant impacts or reduce the construction air quality impacts to less than significant. Also, no other feasible mitigation measures have been identified to reduce construction air quality emissions to a level of insignificance. Therefore, the proposed project is considered to have significant adverse unavoidable project-specific and cumulative air quality impacts during construction.

Greenhouse Gas Impacts

With regard to GHG emissions, the proposed project involves combustion processes during both construction and operation, which could generate GHG emissions such as carbon dioxide (CO2), methane (CH4), and nitrous oxide (N2O). However, the proposed project does not affect equipment or operations that have the potential to emit non-combustion GHGs such as sulfur hexafluoride (SF6), hydrofluorocarbons (HFCs) or perfluorocarbons (PFCs).

Installation of new or modification of existing NOx control equipment as part of implementing the proposed project is expected to generate construction-related CO2 emissions. In addition, based on the type and size of equipment affected by the proposed project, CO2 emissions from the operation of the NOx control equipment are likely to increase from current levels due to electricity, fuel and water use. The proposed project will also result in an increase of GHG operational emissions produced from additional truck hauling and deliveries necessary to accommodate the additional solid waste generation and increased use of supplies and chemicals such as catalyst and caustic.

For the purposes of addressing the GHG impacts of the proposed project, the overall impacts of CO2 equivalent (CO2e) emissions from the project were estimated and evaluated from the earliest possible initial implementation of the proposed project with construction beginning in 2016. Once the proposed project is fully implemented, the potential NOx emission reductions would continue through the end of the useful life of the equipment. The analysis estimated CO2e emissions from all sources subject to the proposed project (construction and operation) from the beginning of the proposed project (2016) to the end of construction (2022). The beginning of the proposed project was assumed to be no sooner than 2016, since installing NOx control equipment requires planning and engineering in advance. Full implementation of the proposed project is expected to occur by the end of 2022 when the entire 14 tons per day of the NOx RTC shave is completed such that any installed or modified NOx controls could be constructed and operational by this final date. Thus, once construction is complete and the equipment is operational, CO2e emissions will continue to be generated but they will remain constant.

Implementing the proposed project is expected to increase GHG emissions that exceed the SCAQMD's GHG significance threshold for all 11 of the non-refinery facilities and nine refinery facilities, should these facility operators choose to install NOx control technology in response to the proposed project. This potentially significant adverse impact cannot be mitigated below significance. The SCAQMD's GHG significance threshold for industrial sources is 10,000 metric tons of CO2e emissions per year (MTCO2e/yr). While none of the affected facilities individually exceed the GHG industrial significance threshold of 10,000 MTCO2e/yr, the "worst-case" GHG emissions from the proposed project as a whole were calculated to be 41,785 MTCO2e/yr which exceeds the SCAQMD's GHG significance threshold. Thus, the overall GHG emissions exceed the GHG significance threshold and therefore, the proposed project is considered to have significant adverse GHG impacts.

Recycled water projects and the utilization of recycled water are among the most direct ways to reduce GHG from combustion activities associated with conveying water to the affected facilities if water-intensive scrubbers are installed as a result of the proposed project. Specifically, the energy it would take to treat and convey reclaimed water to a facility (e.g., 1,200 kilowatt-hours per million gallons (kWh/MMgallons)[2]) is approximately 10 times less than the amount of energy it would take for potable water (e.g., 12,700 kWh/MMgallons[3]) to be supplied, conveyed and distributed. Thus, for each facility that has access to recycled water and chooses to use recycled water to satisfy the water demands for the proposed project and in turn, mitigate CO2e emissions, less GHG emissions would be generated for the operational water use/conveyance and operational wastewater generation portions of the proposed project. After mitigation, the GHG emissions from the proposed project as a whole were calculated to be 41,100 MTCO2e/yr which still exceeds the SCAQMD's GHG significance threshold.

While the GHG mitigation measures identified in the Mitigation Monitoring Plan section of this document may reduce GHG emissions associated with water conveyance to the maximum extent feasible, none are mitigation measures that will avoid the significant impact or reduce the GHG impact to less than significant. Also, no other feasible mitigation measures have been identified to reduce GHG emissions to a level of insignificance. Therefore, the proposed project is considered to have significant adverse unavoidable cumulative GHG impacts.

---

[3] California's Water – Energy Relationship, Table 1-3, Page 11, California Energy Commission, Final Staff Report, CEC-700-2005-011-SF, November 2005. http://www.energy.ca.gov/2005publications/CEC-700-2005-011/CEC-700-2005-011-SF.PDF

Water Demand Impacts

Post-Construction/Pre-Operation Activities: Implementation of the proposed project may cause potentially significant adverse water demand impacts associated with hydrotesting equipment post-construction/pre-operation. Specifically, once construction of control equipment and support equipment is completed, but prior to operation of the control equipment, additional water is expected to be used to hydrostatically (pressure) test all storage tanks and pipelines to ensure each structure's integrity. Pressure testing or hydrotesting is typically a one-time event, unless a leak is found.

The analysis in the Final PEA shows that the potential increase in water use for all 20 facilities conducting hydrotesting activities in one day is approximately 353,724 gallons per day which is greater than the SCAQMD's significance threshold of 262,820 gallons per day of potable water. Thus, the amount of potable water that may be used on a daily basis for hydrotesting activities post-construction but prior to operation is potentially significant. However, water used for pressure testing does not have to be of potable quality, but can be recycled water. Alternately, facility operators may substitute the use of purchased recycled water with non-potable water such as treated process water (e.g., cooling tower blowdown water, etc.) that is temporarily re-routed or diverted from elsewhere within the facility. In addition, water used during hydrotesting can be sent somewhere else within a facility for future re-use. Nonetheless, without being able to predict what type of water each facility will use for hydrotesting purposes, the "worst-case" analysis in the Final PEA assumes that 100 percent of potable water could be utilized for hydrotesting purposes and concludes that hydrotesting could cause significant adverse water demand impacts post-construction but prior to operation.

While the use of recycled water may reduce potable water demand during hydrotesting to the maximum extent feasible, the use of recycled water will not avoid the significant impact or reduce the potable water demand impact post-construction but prior to operation to less than significant. Therefore, the proposed project may cause significant potable water demand impacts during hydrotesting post-construction but prior to operation.

Thus, while the mitigation measures that are identified in the Mitigation Monitoring Plan section of this document may reduce potable water demand associated with hydrotesting activities to the maximum extent feasible, the overall effectiveness of the mitigation measures is dependent upon whether each facility has access to either recycled water or other sources of non-potable water. While feasible mitigation measures have been identified to reduce the potable water demand, the potable water demand may not necessarily be reduced to a level of insignificance because of limitations with access to recycled water or other sources of non-potable water. Thus, the proposed mitigation measures may not fully avoid the significant impact or reduce the potable water demand impact to less than significant. Also, no other feasible mitigation measures have been identified to reduce the potable water demand during hydrotesting to a level of insignificance. Therefore, the proposed project is considered to have significant adverse unavoidable cumulative water demand impacts during hydrotesting.

Operation Activities: Implementation of the proposed project may cause potentially significant adverse water demand impacts associated with operating NOx control equipment. Specifically, of the technologies proposed as BARCT for NOx control, only WGSs utilize water. For this reason, only WGS technology was identified as having the potential to generate potentially significant adverse water demand impacts during operation and WGS technology would be BARCT for equipment at seven of the 20 facilities, and all seven of these facilities belong to the refinery sector (e.g., Refineries 1, 2, 4, 5, 6, 8 and 9).

The analysis in the Draft PEA shows that the potential increase in water use for seven facilities that may operate WGSs is approximately 602,814 gallons per day which is greater than the SCAQMD's significance threshold of 262,820 gallons per day of potable water. However, operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the installation of WGS technology along with the corresponding increased water demand and wastewater generation projections that were originally contemplated for one of the two FCCUs (e.g., Refineries 4 and 9) are no longer expected to occur. Thus, the potential increase in operational water demand is expected to be less than what was originally analyzed in the Draft PEA. To protect the identity of the refinery in this document, the revised potential increase in operational water demand has been presented as a range in the Final PEA, from 553,499 to 558,978 gallons per day, instead of 602,814 gallons per day.

Of the seven affected refineries, three (e.g., Refineries 1, 5, and 6) currently access recycled water from the Harbor Refineries Recycled Water Pipeline (HRRWP) which is maintained by the Los Angeles Department of Water and Power (LADWP), in conjunction with the West Basin Municipal Water District (WBMWD). The LADWP/WBMWD currently provides 35 million gallons per day (MMgal/day) of recycled water to its customers, which include Refineries 1, 5, and 6. The WBMWD is also in the process of expanding its Hyperion Pump Station to accommodate a throughput of 70 MMgal/day of source water which would result in about 55 to 60 MMgal/day of saleable recycled water if, and when needed to accommodate any increased need by their customers. Thus, should operators of these three refineries commit to utilizing recycled water in lieu of potable water to satisfy the water demand for the NOx control equipment, then the LADWP/WBMWD would be able to supply the additional water (e.g., 398,767 gallons per day or approximately 71 percent of the projected water demand). If these facilities do not utilize recycled water for the proposed project, SCAQMD staff conducted an analysis of potable water supply and concluded that potable water would be available to supply the projected increased water demand at Refineries 1, 5 and 6 (see Final PEA, Chapter 4, Subchapter 4.5 – Hydrology and Water Quality, pp. 4.5-15 to 4.5-20).

Refineries 4, 8, and 9 are not currently connected to the HRRWP to access recycled water. However, Refinery 4 is in the process of finalizing an agreement with WBMWD to acquire 2,240 acre-feet/year (AF/yr)[4] of recycled water (equivalent to two MMgal/day) to replace its current potable water use with recycled water by 2018. In addition, Refineries 4, 8, and 9 are currently in talks with the LADWP and WBMWD to negotiate options for replacing as much as 11,100 AF/yr (equivalent to approximately 9.9 MMgal/day) of current potable water use with

[4] 1 acre-foot = 325,851 gallons

recycled water instead via the HRRWP[5]. Thus, if Refineries 4, 8 and 9 need additional recycled water in response to this proposed project, the LADWP/WBMWD has the capacity to provide additional recycled water as necessary. Again, if these facilities do not obtain access to recycled water for the proposed project, SCAQMD staff conducted an analysis of potable water supply and concluded that potable water would be available to supply the projected increased water demand at Refineries 4, 8 and 9 (see Final PEA, Chapter 4, Subchapter 4.5 – Hydrology and Water Quality, pp. 4.5-15 to 4.5-20).

Refinery 2 is not located near the HRRWP nor any other recycled water pipeline so it is unlikely that Refinery 2 would be able to obtain recycled water should facility operators choose to install a WGS and instead, would need to satisfy the water demand with potable water. According to the LBWD's 2010 UWMP that was prepared in accordance with the California Water Code §10608.20, the potable water delivery projections to their industrial and commercial customers show a long-term projected increase in potable water supply with a slight tapering occurring in years 2030 and 2035 to reflect offsetting by increased deliveries of recycled water to other customers currently being supplied by LBWD with potable water. Based on LBWD's short- and long-term projections for potable water supplies, SCAQMD staff believes that the potential increased water demand of 40,896 gallons per day for Refinery 2 can be accommodated with potable water (see Final PEA, Chapter 4, Subchapter 4.5 – Hydrology and Water Quality, p. 4.5-20).

In addition, it is important to keep in mind that operators of Refinery 2 have two different types of control equipment options available for consideration. As summarized in the PEA (see Tables 1-2 and 1-3 for the petroleum coke calciner source category), the BARCT NOx levels of 10 ppmv corrected for 3% oxygen can be achieved with either a WGS which uses water, or a DGS, which does not. While the analysis in this subchapter considers the technology with the worst-case impacts to water demand and water quality, for Refinery 2, installing WGS technology is not their only option. Should operators choose to install a DGS, instead of a WGS, then no water would be needed.

Thus, while the amount of water demand that would be needed to operate NOx control equipment would be 398,767 gallons per day at Refineries 1, 5 and 6 and the amount of water demand at Refineries 2, 4, 8, and 9 would be in the range of 113,836 gallons per day to 160,211 gallons per day, which collectively is greater than the significance threshold of 262,820 gallons per day of potable water but less than the significance threshold of five million gallons per day of total water (e.g., potable, recycled, and groundwater), in consideration that Refineries 1, 5 and 6 have a high potential to use recycled water because of their current access and in light of the negotiations for recycled water at Refineries 4, 8, and 9, potable water only may be needed for a future project occurring at Refinery 2, or not at all if operators of Refinery 2 choose to install a DGS instead of a WGS. In any case, the previous analysis shows that water purveyor would be able to supply potable water to Refinery 2 and to Refineries 1, 4, 5, 6, 8 and 9, if needed. Thus,

[5] City of Los Angeles, Inter-Departmental Correspondence to City Council From Los Angeles Department of Water and Power and Los Angeles Department of Public Works Bureau of Sanitation, Council File No. 15-0018 Harbor Refineries Pipeline Project/Advanced Water Purification Facility/Water Supply Efforts, April 10, 2015. https://cityclerk.lacity.org/lacityclerkconnect/index.cfm?fa=ccfi.viewrecord&cfnumber=15-0018

using an abundance of caution, because the peak daily water demand for the proposed project exceeds the potable water threshold of 262,820 gallons per day and because recycled water is not currently available at Refineries 4, 8 and 9, and no contractual commitments to increase recycled water demand above the existing recycled water baseline for the three refineries that already have access to recycled water (e.g., Refineries 1, 5 and 6) have been finalized, the analysis conservatively assumes that significant adverse impacts associated with water demand are expected from the proposed project during operation.

Thus, while the mitigation measures that are identified in the Mitigation Monitoring Plan section of this document may reduce potable water demand associated with operation activities to the maximum extent feasible, the overall effectiveness of the mitigation measures is dependent upon whether each facility has access to recycled water. While feasible mitigation measures have been identified to reduce the potable water demand, the potable water demand may not necessarily be reduced to a level of insignificance because of limitations with access to recycled water. Thus, the proposed mitigation measures may not fully avoid the significant impact or reduce the potable water demand impact to less than significant. Also, no other feasible mitigation measures have been identified to reduce the operational potable water demand to a level of insignificance. Therefore, the proposed project is considered to have significant adverse unavoidable cumulative water demand impacts during operation.

Hazards and Hazardous Materials Impacts From Delivering Ammonia

The Final PEA assumes that some facilities may opt to reduce NOx emissions by installing NOx control equipment such as SCRs and DGSs which requires the use of ammonia, a chronic and acutely hazardous material. Further, an increase in the use of ammonia in response to the proposed project may increase the current existing risk setting associated with deliveries (i.e., truck and road accidents). In particular, the analysis assumes that as many as 117 SCRs could be installed at 20 facilities and one Ultracat DGS could be installed at one facility. The analysis estimates that approximately 39.5 tons per day (equivalent to approximately 10,284 gallons per day) of aqueous ammonia (at 19 percent concentration) would be needed to operate the equipment. It is expected that the affected facilities will receive ammonia from a local ammonia supplier located in the greater Los Angeles area. Deliveries of aqueous ammonia would be made by tanker truck via public roads.

The accidental release of ammonia from a delivery is a localized event (i.e., the release of ammonia would only affect the receptors that are within the zone of the toxic endpoint). The accidental release from a delivery would also be temporally limited in the fact that deliveries are not likely to be made at the same time in the same area. Based on these limitations, the analysis in the Final PEA assumed that an accidental release would be limited to a single delivery or single facility at a time. In the ammonia transportation release scenario, the distance to the toxic endpoint from a worst-case delivery truck release was estimated to be 0.4 miles or 2,112 feet. Since sensitive receptors are expected to be found within 0.4 miles from roadways, the hazards and hazardous materials impacts due to a delivery truck accident were concluded to be potentially significant. Therefore, the proposed project was concluded to have significant adverse hazards and hazardous materials impacts due to ammonia deliveries and mitigation measures are required. However, no feasible mitigation measures have been identified, over and above the extensive safety regulations that currently apply to delivery trucks that haul ammonia.

FINDINGS

Public Resources Code §21081 and CEQA Guidelines §15091 (a) state that no public agency shall approve or carry out a project for which a CEQA document has been completed which identifies one or more significant adverse environmental effects of the project unless the public agency makes one or more written findings for each of those significant effects, accompanied by a brief explanation of the rationale for each finding. Additionally, the findings must be supported by substantial evidence in the record (CEQA Guidelines §15091 (b)). As identified in the Final PEA and summarized above, the proposed project has the potential to create significant adverse impacts for the topics of air quality during construction, water demand, and hazardous materials due to deliveries of ammonia. The SCAQMD Governing Board, therefore, makes the following findings regarding the proposed project. The findings are supported by substantial evidence in the record as explained in each finding. The findings will be included in the record of project approval and will also be noted in the Notice of Decision. The findings made by the SCAQMD Governing Board are based on the following significant adverse impacts identified in the Final PEA.

1. **Potential project-specific and cumulative VOC, CO, NOx, PM10, and PM2.5 emissions during construction exceed the SCAQMD's applicable significance air quality thresholds and cannot be mitigated to insignificance.**

   Finding and Explanation:
   The implementation of the proposed project is anticipated to trigger construction activities associated with the installation of new or the modification of existing NOx air pollution control equipment. Construction activities associated with the proposed project would result in emissions of VOC, CO NOx, SOx, PM10, and PM2.5, but only the estimated emissions for SOx are expected to remain below the SCAQMD's applicable significance air quality thresholds for construction. As a result, the proposed project is expected to have significant adverse construction air quality impacts. However, the temporary construction emissions would cease upon completion of the installation of new or modification of existing air pollution control equipment, as applicable. Once all the modified or new equipment are in place, the proposed project is expected to result in a reduction of NOx emissions of 14 tons per day by 2023.

   The Governing Board finds that mitigation measures have been identified, but they would not reduce to insignificance the significant adverse project-specific or cumulative impacts to air quality associated with construction. No other feasible mitigation measures have been identified. CEQA Guidelines §15364 defines "feasible" as "capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, social, and technological factors."

   The Governing Board further finds that the Final PEA considered alternatives pursuant to CEQA Guidelines §15126.6, but there is no alternative to the project, other than the No Project Alternative (Alternative 4), that would reduce to insignificant levels the significant project-specific or cumulative construction air quality impacts that were identified for the proposed project. However, the No Project Alternative (Alternative 4) was rejected due to infeasibility. Specifically Alternative 4 was determined to not be a legally viable alternative because it violates a state law requirement in Health and Safety Code §40440 that regulations mandate the use of BARCT for existing sources.

2. **Potential GHG emissions exceed the SCAQMD's applicable significance GHG threshold and cannot be mitigated to insignificance.**

Finding and Explanation:
While none of the affected facilities individually exceed the SCAQMD's industrial GHG significance threshold of 10,000 MTCO2e/yr, if the proposed project is implemented, the analysis indicates that there would be a significant increase in GHG emissions for the project as a whole. Because there are significant adverse GHG impacts from the proposed project, the PEA must describe feasible measures that could minimize significant adverse impacts.

The Governing Board finds that mitigation measures have been identified, but they would not reduce to insignificance the significant adverse GHG emission impacts. No other feasible mitigation measures have been identified. CEQA Guidelines §15364 defines "feasible" as "capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, social, and technological factors."

The Governing Board further finds that the Final PEA considered alternatives pursuant to CEQA Guidelines §15126.6, but there is no alternative to the project, other than the No Project Alternative (Alternative 4), that would reduce to insignificant levels the significant GHG impacts that were identified for the proposed project. However, the No Project Alternative (Alternative 4) was rejected due to infeasibility. Specifically Alternative 4 was determined to not be a legally viable alternative because it violates a state law requirement in Health and Safety Code §40440 that regulations mandate the use of BARCT for existing sources.

3. **Potential potable water demand would use a substantial amount of potable water and cannot be mitigated to insignificance.**

Finding and Explanation:
The Final PEA concluded that the proposed project may cause significant adverse potable water demand impacts during hydrotesting post-construction but prior to operation and during operation of NOx control equipment. Because there are significant adverse potable water demand impacts from the proposed project, the Final PEA must describe feasible measures that could minimize significant adverse impacts. Mitigation measures have been identified that may be effective in reducing the amount of potable water needed, however, they may not completely avoid or reduce the adverse potable water demand impact to a less than significant level.

The Governing Board finds that mitigation measures have been identified, but they would not reduce to insignificance the significant adverse water demand impacts. No other feasible mitigation measures have been identified. CEQA Guidelines §15364 defines "feasible" as "capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, social, and technological factors."

The Governing Board further finds that the Final PEA considered alternatives pursuant to CEQA Guidelines §15126.6, but there is no alternative to the project, other than the No Project Alternative (Alternative 4), that would reduce to insignificant levels the significant water demand impacts that were identified for the proposed project. However, the No Project Alternative (Alternative 4) was rejected due to infeasibility. Specifically Alternative 4 was determined to not be a legally viable alternative because it violates a state law requirement in Health and Safety Code §40440 that regulations mandate the use of BARCT for existing sources.

4. **Potential hazards and hazardous materials impacts due to deliveries of ammonia may significantly increase the current existing risk setting associated with truck and road accidents and cannot be mitigated to insignificance.**

<u>Finding and Explanation</u>:
The Final PEA concluded that the proposed project may cause significant adverse hazards and hazardous materials impacts during deliveries of ammonia to facilities that may install NOx emissions control equipment that require the use of ammonia. Because there are significant adverse hazards and hazardous materials impacts from the proposed project, the Final PEA must describe feasible measures that could minimize significant adverse impacts. However, no feasible mitigation measures have been identified, over and above the extensive safety regulations that currently apply to delivery trucks that haul ammonia, that could minimize or reduce the significant hazards and hazardous materials impacts due to deliveries of ammonia.

The Governing Board finds that no feasible mitigation measures have been identified that would reduce to insignificance the significant adverse hazards and hazardous materials impacts due to deliveries of ammonia. CEQA Guidelines §15364 defines "feasible" as "capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, social, and technological factors."

The Governing Board further finds that the Final PEA considered alternatives pursuant to CEQA Guidelines §15126.6, but there is no alternative to the project, other than the No Project Alternative (Alternative 4), that would reduce to insignificant levels the significant hazards and hazardous materials impacts due to deliveries of ammonia that were identified for the proposed project. However, the No Project Alternative (Alternative 4) was rejected due to infeasibility. Specifically Alternative 4 was determined to not be a legally viable alternative because it violates a state law requirement in Health and Safety Code §40440 that regulations mandate the use of BARCT for existing sources.

Conclusion of Findings

The Governing Board finds that feasible mitigation measures have been identified to help minimize the potentially significant adverse impacts to the following topics: air quality during construction, GHG emissions, and water demand. The Governing Board also finds that no feasible mitigation measures have been identified to help minimize the potentially significant adverse impacts to hazards and hazardous materials due to deliveries of ammonia. CEQA defines "feasible" as "capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, social, and technological factors" (Public Resources Code §21061.1).

The Governing Board further finds that the Final PEA considered alternatives pursuant to CEQA Guidelines §15126.6, but there is no alternative to the project, other than the No Project Alternative (Alternative 4), that would reduce to insignificant levels the significant impacts to the topics of air quality during construction, GHG emissions, water demand, and hazards and hazardous materials due to deliveries of ammonia that were identified for the proposed project. However, the No Project Alternative (Alternative 4) was rejected due to infeasibility. Specifically Alternative 4 was determined to not be a legally viable alternative because it violates a state law requirement in Health and Safety Code §40440 that regulations mandate the use of BARCT for existing sources.

The Governing Board further finds that a Mitigation Monitoring Plan (pursuant to Public Resources Code §21081.6) needs to be prepared since feasible mitigation measures were identified for the topics of air quality during construction, GHG emissions, and water demand.

The Governing Board further finds that the findings required by CEQA Guidelines §15091 (a) are supported by substantial evidence in the record. Further, to comply with CEQA Guidelines §15091 (e), the SCAQMD specifies the director of Regulation XX as the custodian of the documents or other materials which constitute the record of proceedings upon which the adoption of these proposed amendments and the approval of this project is based, and which are located at the SCAQMD headquarters, 21865 Copley Drive, Diamond Bar, California 91765.

STATEMENT OF OVERRIDING CONSIDERATIONS

If significant adverse impacts of a proposed project remain after incorporating mitigation measures, or no measures or alternatives to mitigate the adverse impacts are identified, the lead agency must make a determination that the benefits of the project outweigh the unavoidable adverse environmental effects if it is to approve the project. CEQA requires the decision-making agency to balance, as applicable, the economic, legal, social, technological, or other benefits of a proposed project against its unavoidable environmental risks when determining whether to approve the project [CEQA Guidelines §15093 (a)]. If the specific economic, legal, social, technological, or other benefits of a proposed project outweigh the unavoidable adverse environmental effects, the adverse environmental effects may be considered “acceptable” [CEQA Guidelines §15093 (a)]. Accordingly, a Statement of Overriding Considerations regarding potentially significant adverse impacts to air quality during construction, GHGs, water demand, and hazardous materials due to deliveries of ammonia that may result from the proposed project has been prepared. This Statement of Overriding Considerations is included as part of the record of the project approval for the proposed project. Pursuant to CEQA Guidelines

§15093 (c), the Statement of Overriding Considerations will also be noted in the Notice of Decision for the proposed project.

Despite the inability to incorporate changes into the proposed project that will mitigate potentially significant adverse impacts to a level of insignificance for the topics of air quality during construction, GHG emissions, water demand, and, hazards and hazardous materials due to deliveries of ammonia, the SCAQMD's Governing Board finds that the following benefits and considerations outweigh the significant unavoidable adverse environmental impacts:

1. The analysis of potential adverse environmental impacts incorporates a “worst-case” approach. This entails the premise that whenever the analysis requires that assumptions be made, those assumptions that result in the greatest adverse impacts are typically chosen. This method likely overestimates the actual environmental impacts from the proposed project.

2. Each of the alternatives was crafted to show the various possibilities or permutations of how operators of NOx RECLAIM facilities could achieve actual NOx reductions, but ultimately, there is no way to predict what each facility operator will do. Further, because of the compliance flexibility inherent in the RECLAIM program, affected operators may choose to reduce NOx emissions using compliance options that minimize or eliminate significant environmental impacts at their facilities.

3. The 2012 AQMP identifies ambient air pollutant levels relative to federal and state ambient air quality standards (AAQS), establishes baseline and future emissions, and develops control measures to ensure attainment of the AAQS. Construction is a continuous activity in the district and is accounted for in the AQMP. Thus, any changes in air quality as a result of construction emissions from the proposed project are accounted for in the AQMP and would not be expected to interfere with the attainment demonstrations.

4. The proposed project implements 2012 AQMP Control Measure #CMB-01: Further NOx Reductions from RECLAIM (e.g., at least three to five tons per day by 2023). The proposed project will remove NOx RTCs by 14 tons per day by 2023. In addition, the proposed project is designed to implement both the Phase I and Phase II reduction commitments described in #CMB-01.

5. Although the proposed project also has the largest amount of adverse environmental impacts overall when compared to the alternatives, it achieves the maximum level of NOx reductions and corresponding health benefits.

6. Considering the need for expeditious improvement in air quality, the proposed project is preferred over the other alternatives considered because it provides the best balance between reducing NOx emissions relative to the adverse impacts.

7. Implementing the control measures in the 2012 AQMP will result in an overall net reduction in criteria pollutant emissions. Therefore, cumulative air quality impacts from the proposed project and all other AQMP control measures when considered together, are not expected to

be significant because implementation of all AQMP control measures is expected to result in net emission reductions and overall air quality improvement.

The SCAQMD's Governing Board finds that the above-described considerations outweigh the unavoidable significant effects to the environment as a result of the proposed project.

MITIGATION MONITORING PLAN

When making findings as required by Public Resources Code §21081 and CEQA Guidelines §15091, the lead agency must adopt a reporting or monitoring program for the changes to the project which it has adopted or made a condition of project approval in order to mitigate or avoid significant effects on the environment. [Public Resources Code §21081.6 and CEQA Guidelines §15097 (a)]. To fulfill the requirements of Public Resources Code §21081.6 and CEQA Guidelines §15097, the SCAQMD has developed this mitigation monitoring plan for anticipated impacts resulting from implementing the proposed project. Each operator of any facility required to comply with a mitigation monitoring plan shall keep records onsite of applicable compliance activities to demonstrate the steps taken to assure compliance with all of the mitigation measures, as applicable.

1. **Air Quality Impacts During Construction**

Impacts Summary: Project-specific and cumulative construction-related emissions of VOC, NOx, CO, PM10, and PM2.5 emissions, based on a "worst-case" analysis, would exceed the SCAQMD's regional mass daily significance thresholds for these pollutants. Emission sources include worker vehicles and heavy construction equipment. The following mitigation measures are intended to minimize the emissions associated with these sources during construction activities. No feasible mitigation measures have been identified to reduce emissions to a level of insignificance.

Mitigation Measures: The following construction mitigation measures are required for each of the affected facilities whose operators choose to install NOx control equipment. SCAQMD staff will conduct a CEQA evaluation of each facility-specific project proposed in response to the proposed project and determine if the project is covered by the analysis in this PEA. In addition, these mitigation measures will be included in a mitigation monitoring plan as part of issuing SCAQMD permits to construct for the facility-specific project. The mitigation measures will be enforceable by SCAQMD personnel.

On-Road Mobile Sources

AQ-1 Develop a Construction Emission Management Plan for each affected facility to minimize emissions from vehicles including, but not limited to: consolidating truck deliveries; scheduling deliveries to avoid peak hour traffic conditions; describing truck routing; describing deliveries including logging delivery times; describing entry/exit points; identifying locations of parking; identifying construction schedule; and prohibiting truck idling in excess of five consecutive minutes or another time-frame as allowed by the California Code of Regulations, Title 13 §2485 - CARB's Airborne Toxic Control Measure to Limit Diesel-Fueled Commercial Motor Vehicle Idling. The Construction Emission Management Plan shall be submitted to SCAQMD CEQA for approval prior to the start of construction. At a minimum the Construction Emission Management Plan would include the following types of mitigation measures.

<u>Off-Road Mobile Sources:</u>

AQ-2 Maintain construction equipment tuned to manufacturer's recommended specifications that optimize emissions without nullifying engine warranties.

AQ-3 The project proponent shall survey and document the proposed project's construction areas and identify all construction areas that are served by electricity. This documentation shall be provided as part of the Construction Emissions Management Plan.

AQ-4 For all construction areas that are demonstrated to be served by electricity, use electricity for on-site mobile equipment instead of diesel equipment to the extent feasible. For example, electric welders should be used in lieu of diesel or gasoline-fueled welders and onsite electricity should be used in lieu of temporary power generators. If electricity is not available, use alternative fuels where feasible.

AQ-5 All off-road diesel-powered construction equipment greater than 50 hp shall meet Tier-4 off-road emission standards at a minimum. In addition, if not already supplied with a factory-equipped diesel particulate filter, all construction equipment shall be outfitted with Best Available Control Technology (BACT) devices certified by CARB. Any emissions control device used by the contractor shall achieve emissions reductions that are no less than what could be achieved by a Level 3 diesel emissions control strategy for a similarly sized engine as defined by CARB regulations. Construction equipment shall incorporate, where feasible, emissions-reducing technology such as hybrid drives and specific fuel economy standards. In the event that any equipment required under this mitigation measure is not available, the project proponent shall provide documentation in the Construction Emissions Management Plan or associated subsequent status reports as information becomes available.

AQ-6 Suspend use of all construction activities that generate air pollutant emissions during first stage smog alerts as defined in SCAQMD Rule 701.

If, at the time when each facility-specific project is proposed in response to the proposed project, that improved emission reduction technologies become available for on- and off-road construction equipment, as part of the CEQA evaluation for the facility-specific project, the construction mitigation measures will be updated accordingly.

Implementing Parties: The SCAQMD's Governing Board finds that implementing the mitigation measures AQ-1 through AQ-6 is the responsibility of the owner, operator, or agent of each affected facility who submits a permit application to comply with the proposed project.

Monitoring Agency: The SCAQMD's Governing Board finds that through its discretionary authority to issue and enforce permits for this project, the SCAQMD will ensure compliance with mitigation measures AQ-1 through AQ-6. Mitigation monitoring and reporting (MMR) will be accomplished as follows:

MMRAQ-1: Construction Emission Management Plan
Each facility operator shall develop and submit a Construction Emission Management Plan to the SCAQMD for approval prior to starting construction activities. Upon approval, each facility operator shall train all personnel subject to the requirements set forth in the Construction Emission Management Plan on how to comply with the requirements in the plan, and document that training. The SCAQMD may conduct routine inspections of the site to verify compliance. The Construction Emission Management Plan shall include, at a minimum, the following information:

- A construction schedule of activities for each construction phase that indicates the number of construction workers needed, and the type, fuel source, and number of construction equipment needed for each construction phase;
- A description of truck routing with a priority given to consolidating truck deliveries and scheduling deliveries to avoid peak hour traffic conditions;
- A format or system for logging delivery dates, times, and type of deliveries;
- A description of entry/exit points to the construction site;
- An identification of parking locations at the construction site; and,
- A description of how the prohibition of truck idling in excess of five consecutive minutes or another time-frame as allowed by the CCR Title 13 §2485, will be conveyed to truck drivers.

<u>Traffic Control</u>
Traffic requiring entrance onto each facility's property will be directed toward the entry gate or gates, if there are multiple entrances, so that congestion, as well as associated air pollution, will be minimized.

Points of entry will be selected to maximize facility security and reduce traffic-associated emissions. Each facility operator will direct their Receiving Department to consider delivery items, time of delivery, in-plant congested areas, surrounding area traffic, and gate security issues when assigning a gate entry location.

On-site parking will be used to the maximum extent available. In the event that off-site parking is required, construction workers may be requested to park at a designated off-site property. Buses or some other type of shuttle may transfer multiple workers at one time to and from the project site. No on-street parking (i.e., off of each facility's site) will be allowed.

Each facility operator will limit the number of personal and company vehicles allowed to enter each facility beyond the parking lots. This restriction helps minimize onsite emissions and promotes the use of ride sharing and alternate fueled transportation such as bicycles and electric golf carts.

<u>Construction Schedule</u>
In an effort to reduce traffic by construction workers, operators of the each facility may request its contractors to follow a compressed workweek. An example of a compressed workweek would be a four-day work week and a 10-hour work day with most work scheduled to begin by 7:00 a.m. and end after 5:30 p.m., Monday through Friday, to further minimize traffic congestion and related emissions. In addition, some work may need to be scheduled during the night shift, which will begin after 6:00 p.m. and end around 4:30 a.m. Critical path work may require a deviation from the aforementioned workweek and start- and stop-times; however, deviations will be minimized.

During process unit shutdowns, extended work shifts and night shifts, scheduled six to seven days per week, may be necessary. Each facility operator will establish in their Construction Emission Management Plan the details of the construction schedule, including operating hours, days, and number of shifts per day. This construction work schedule will need to be designed to minimize the travel time during peak travel periods.

<u>Trip Reduction Plan</u>
No feasible mitigation has been identified for the emissions from on-road vehicle trips. CEQA Guidelines §15364 defines feasible as "...capable of being accomplished in a successful manner." No feasible mitigation measures for offsite motor vehicles have been identified. Health and Safety Code §40929

prohibits the air districts and other public agencies from requiring an employee trip reduction program making such mitigation infeasible.

Delivery of Equipment and Materials
Each facility operator will coordinate the delivery of equipment and materials to avoid peak hour traffic, whenever possible. That is, delivery of construction materials to the site will be scheduled to occur during off-peak periods which are typically from 8:30 a.m. until 4:00 p.m. Monday through Friday. Each facility operator will request that equipment and material deliveries be minimized between the hours of 7:00 a.m. to 8:00 a.m. and 4:30 p.m. to 5:30 p.m. to reduce traffic in and out of each facility during high traffic peak times. Exceptions will be made for trucks carrying time-critical materials, e.g., concrete delivery and soil hauling (which eliminates the double handling or on-site stock-piling of soil, preventing it from being moved from place-to-place due to lack of adequate staging area, and subsequent removal at a later time via trucks). Delivery routes and schedules will be developed pursuant to the California Department of Transportation regulations.

It may be necessary to handle a limited amount of equipment as wide or special loads. These deliveries are subject to California Department of Transportation regulations and will be coordinated with local police departments. These trips will be scheduled to avoid peak hour traffic.

Prohibit Trucks From Idling Longer Than Five Minutes
Each facility operator will notify all vendors that during deliveries, truck idling time will be limited to no longer than five minutes or another time-frame as allowed by the California Code of Regulations, Title 13 §2485 - CARB's Airborne Toxic Control Measure to Limit Diesel-Fueled Commercial Motor Vehicle Idling. For any delivery that is expected to take longer than five minutes, each facility operator will require the truck's operator to shut off the engine. Each facility operator will notify the vendors of these delivery requirements at the time that the purchase order is issued and again when trucks enter the gates of the facility. To further ensure that drivers understand the truck idling requirement, signs will be posted at each facility entry gates stating idling longer than five minutes is not permitted.

MMRAQ-2: Maintain Construction Equipment, Tuned Up to Manufacturer's Recommended Specifications That Optimize Emissions Without Nullifying Engine Warranties

Each facility operator, in cooperation with the construction contractors, will maintain vehicle and equipment maintenance records for the construction portion of the proposed project. All construction vehicles must be maintained in compliance with the manufacturer's recommended maintenance schedule. Each facility operator will maintain their construction equipment and the construction contractor will be responsible for maintaining their equipment and maintenance records. All maintenance records for each facility and their construction contractor(s) will remain on-site for a period of at least two years from completion of construction.

MMRAQ-3: Survey of Construction Areas Where Electricity is Available for Operating Electric On-Site Mobile Equipment

Each facility operator and/or their construction contractor(s) will conduct a survey of the proposed project construction area(s) to assess whether the existing infrastructure can provide access to electricity, as available, within the facility or construction site, in order to operate electric on-site mobile equipment. For example, each facility operator and/or their construction contractor(s) will assess the number of electrical welding receptacles available.

Construction areas within the facility or construction site where electricity is and is not available must be clearly identified on a site plan as part of the Construction Emission Management Plan. The use of non-electric onsite mobile equipment shall be prohibited in areas of the facility that are shown to have access to electricity. The use of electric on-site mobile equipment within these identified areas of the facility or construction site will be allowed.

Each facility operator shall include in all construction contracts the requirement that the use of non-electric on-site mobile equipment is prohibited in certain portions of the facility as identified on the site plan. Each facility operator shall maintain records that indicate the location within the facility or construction site where all electric and non-electric on-site mobile equipment are operated, if at all, for a period of at least two years from completion of construction.

MMRAQ-4: Use Electricity or Alternate Fuels for On-Site Mobile Equipment Instead of Diesel Equipment to the Extent Feasible

Each facility operator and/or their construction contractor(s) shall evaluate the use of electricity and alternate fuels for on-site mobile construction equipment prior to the commencement of construction activities, provided that suitable equipment is available for the activity. Equipment vendors will be contacted to determine the commercial availability of electric or alternate-fueled construction equipment. Priority should be given to the use of electric on-site mobile construction equipment. If electricity is not available, then use alternative fuels to power on-site mobile construction equipment where feasible. Equipment that will use electricity or alternate fuels will be included in the Construction Emission Management Plan.

The potential equipment that may be considered includes, but is not limited to:

- Electric welders
- Electric scissor lifts
- Electric golf carts
- Bicycles
- Electric or bi-powered boom lifts

MMRAQ-5: All Off-Road Diesel-Powered Construction Equipment Greater Than 50 hp Shall Meet Tier 4 Off-Road Emission Standards and Shall Be Equipped With CARB-Certified Best Available Control Technology (BACT) Emissions Control Devices

Each facility operator shall include in all construction contracts the requirement that all off-road diesel-powered construction equipment greater than 50 hp shall meet Tier-4 off-road emission standards at a minimum. In addition, if not already supplied with a factory-equipped diesel particulate filter, all construction equipment shall be outfitted with Best Available Control Technology (BACT) devices certified by CARB. Any emissions control device used by the contractor shall achieve emissions reductions that are no less than what could be achieved by a Level 3 diesel emissions control strategy for a similarly sized engine as defined by CARB regulations. In addition, construction equipment shall incorporate, where feasible, emissions savings technology such as hybrid drives and specific fuel economy standards. In the event that any equipment required under this mitigation measure is not available, the project proponent shall provide documentation in the Construction Emissions Management Plan or associated subsequent status reports as information becomes available.

MMRAQ-6: Suspend All Construction Activities That Generate Air Emissions During First Stage Smog Alerts

If and when any first stage smog alert or greater occurs, each facility operator will record the date and time of each alert, will suspend all construction activities that generate emissions, and will record the date and time when the use of construction equipment and construction activities are suspended. This log shall be maintained on-site for a period of at least two years from completion of construction.

2. <u>GHG Impacts</u>

Impact Summary: Based on a "worst-case" analysis, none of the affected facilities individually exceed the industrial GHG significance threshold. However, if the proposed project gets implemented, the analysis indicates that there will be a significant increase in GHG emissions for the project as a whole. Because there are significant adverse GHG impacts from the proposed project, the PEA must describe feasible measures which could minimize the significant adverse impacts. The following mitigation measures are intended to minimize the GHG emissions associated with water conveyance. No feasible mitigation measures have been identified to reduce GHG emissions to a level of insignificance.

Mitigation Measures: The following mitigation measures will apply to any facility whose operator chooses to install NOx control equipment that utilizes water for its operation. SCAQMD staff will conduct a CEQA evaluation of each facility-specific project proposed in response to the proposed project and determine if the project is covered by the analysis in this PEA. In addition, these mitigation measures will be included in a mitigation monitoring plan as part of issuing SCAQMD permits to construct for the facility-specific project. The mitigation measures will be enforceable by SCAQMD personnel.

GHG-1: When NOx control equipment is installed and water is required for its operation, the facility operator is required to use recycled water, if available, to satisfy the water demand for the NOx control equipment.

GHG-2: In the event that recycled water cannot be delivered to the affected facility, the facility operator is required to submit a written declaration with the application for a Permit to Construct for the NOx control equipment, to be signed by an official of the water purveyor indicating the reason(s) why recycled water cannot be supplied to the project.

Implementing Parties: The SCAQMD's Governing Board finds that implementing mitigation measures GHG-1 through GHG-2 is the responsibility of the owner, operator, or agent of each affected facility who submits a permit application to comply with the proposed project.

Monitoring Agency: The SCAQMD's Governing Board finds that through its discretionary authority to issue and enforce permits for this project, the SCAQMD will ensure compliance with mitigation measures GHG-1 through GHG-2. Mitigation monitoring and reporting (MMR) will be accomplished as follows:

MMRGHG-1: Use Recycled Water, If Available, for NOx Control Equipment That Requires Water for Its Operation
At the time of submitting an application for a Permit to Construct for NOx control equipment and water is required for its operation, each facility operator shall submit a copy of a Memorandum of Understanding agreement reached between the facility operator and the recycled water supplier or purveyor that indicates recycled water will be used to supply water to the NOx control equipment. Once the NOx control equipment becomes operational, on a monthly basis, each facility operator will record the amount of recycled water delivered to the NOx control equipment from the recycled water bill. This log shall be maintained on-site for a period of at least two years from initiating operation.

MMRGHG-2: Submit Written Declaration if Recycled Water is Not Available
The facility operator is required to submit a written declaration with the application for a Permit to Construct for the NOx control equipment, to be signed by an official of the water purveyor indicating the reason(s) why recycled water cannot be delivered to the project.

3. <u>Water Demand Impacts</u>

Impacts Summary - Hydrotesting: Some NOx control equipment may also require the installation of support equipment such as storage tanks, for example, which need to undergo hydrotesting in order to verify the structural integrity prior to operation. Because hydrotesting can utilize a substantial amount of water, significant adverse impacts associated with water demand during hydrotesting are expected from the proposed project post-construction but prior to operation. For example, for any facility that installs NOx control equipment that also requires the installation of support equipment, such as a storage tank or other equipment, to be installed and hydrotested as part of the proposed project, the use of non-potable water such as recycled water or diverted process water can help substantially reduce the water demand impacts to a less than significant level if facility operators that have access to recycled water or diverted non-potable process water are required to use recycled water or diverted non-potable process water.

The water demand analysis during hydrotesting shows that the potential increase in potable water use cannot be fully supplied entirely with recycled water because recycled water is not currently delivered to all of the affected facilities. While there are ongoing negotiations to connect some of the affected facilities to recycled water at a future date, there are currently no contractual commitments in place to bring recycled water to these facilities. Further, for the facilities that currently have access to recycled water, there are currently no contractual commitments in place with the recycled water purveyors to provide an increased amount of recycled water deliveries above the existing baseline, even though there is plenty of recycled water supply available, to accommodate the increased demand for hydrotesting water that may result from the proposed project. Also, the potential increase in potable water use for hydrotesting cannot be fully supplied entirely by other non-potable water such as diverted process water because not all of the facilities have on-site sources of process water that can be diverted for hydrotesting purposes. Thus, some potable water may still be required to conduct hydrotesting.

In conclusion, because potable water may still be needed in the event that recycled water or other non-potable process water may not be available to all of the affected facilities, the analysis conservatively assumes that the water demand impacts during hydrotesting could remain significant after mitigation.

Because there are significant adverse water demand impacts from the proposed project post-construction but prior to operation during hydrotesting of support equipment, the PEA must describe feasible measures which could minimize the significant adverse impacts for hydrotesting activities. The following mitigation measures are intended to minimize the amount of potable water used for hydrotesting by requiring either recycled water or other non-potable water as a substitute, but the overall effectiveness of the mitigation measures is dependent upon whether each facility has access to these alternate water sources. While the following feasible mitigation measures have been identified to reduce the potable water demand, the potable water demand may not necessarily be reduced to a level of insignificance because of the aforementioned limitations with access to either recycled water or other non-potable water.

Mitigation Measures for Hydrotesting: The following water demand mitigation measures are required during hydrotesting for any facility that installs NOx control equipment with support equipment that requires hydrotesting prior to its operation as part of the proposed project. SCAQMD staff will conduct a CEQA evaluation of each facility-specific project proposed in response to the proposed project and determine if the project is covered by the analysis in this PEA. In addition, these mitigation measures will be included in a mitigation monitoring plan as part of issuing SCAQMD permits to construct for the facility-specific project. The mitigation measures will be enforceable by SCAQMD personnel.

HWQ-1 When support equipment such as a storage tank is installed to support operations of installed NOx control equipment and hydrotesting is required prior to operation, the facility operator is required to use, in lieu of potable water, recycled water or other non-potable process water temporarily diverted from elsewhere within the facility, if available, to satisfy the water demand for hydrotesting.

HWQ-2 For hydrotesting purposes, in the event that recycled water cannot be delivered to the affected facility and diverted non-potable process water is not used, the facility operator is required to submit two written declarations with the application for a Permit to Construct for the NOx control equipment and any support equipment such as a storage tank or other equipment that requires hydrotesting, one to be signed by an official of the water purveyor indicating the reason(s) why recycled water cannot be delivered to the project and one from a high-ranking officer at the facility indicating the reason(s) and the supporting evidence that explains why the non-potable process water cannot be diverted to the project from elsewhere within the facility.

Impacts Summary – Operation of Air Pollution Control Equipment: Of the technologies proposed as BARCT for NOx control, only wet gas scrubber (WGS) technology utilizes water as part of their day-to-day operations and the amount of water needed on a daily basis is substantial and exceeds the significance threshold for potable water. Thus, significant adverse impacts associated with water demand during operation of WGSs are also expected from the proposed project. However, for any facility that installs NOx control equipment that also requires water for its operation, the use of recycled water can help substantially reduce the water demand impacts to a less than significant level if facility operators that have access to recycled water are required to use recycled water instead of potable water. SCAQMD staff has verified that the water supply projections made by the water purveyors that provide water to the affected sources will be able to supply either potable water or recycled water, as applicable, to satisfy the potential water demand needs of the proposed project. However, the water demand analysis during operation shows that the potential increase in potable water use cannot be fully replaced with all recycled water because recycled water is not currently delivered to all of the affected facilities. While there are ongoing negotiations to connect some of the affected facilities to recycled water at a future date, there are currently no contractual commitments in place to bring recycled water to these facilities. Further, for the facilities that currently have access to recycled water, there are currently no contractual commitments in place with the recycled water purveyors to provide an increased amount of recycled water deliveries above the existing baseline. Thus, some potable water may still be required to operate air pollution control equipment.

In conclusion, because potable water may still be needed in the event that recycled water may not be available to all of the affected facilities, the analysis conservatively assumes that the water demand impacts during operation could remain significant after mitigation.

Because there are significant adverse water demand impacts from the proposed project during operation, the PEA must describe feasible measures which could minimize the significant adverse water demand impacts during operation. The following mitigation measures are intended to minimize the amount of potable water used for operating air pollution control equipment by requiring recycled water, but the overall effectiveness of the mitigation measures is dependent upon whether each facility has access to recycled water, even if plenty of recycled water is available. While the following feasible mitigation measures have been identified to reduce the potable water demand, the potable water demand may not necessarily be reduced to a level of insignificance because of the aforementioned limitations with access to recycled water.

Mitigation Measures for Operations of NOx Control Equipment That Utilizes Water: The following water demand mitigation measures are required during operation of any WGS or any other type of NOx control equipment that utilizes water for its operation that is installed as part of the proposed project.

HWQ-3 When NOx control equipment is installed and water is required for its operation, the facility operator is required to use recycled water, if available, to satisfy the water demand for the NOx control equipment.

HWQ-4 In the event that recycled water cannot be delivered to the affected facility, the facility operator is required to submit a written declaration with the application for a Permit to Construct for the NOx control equipment, to be signed by an official of the water purveyor indicating the reason(s) why recycled water cannot be delivered to the project.

Implementing Parties: The SCAQMD's Governing Board finds that implementing the mitigation measures HWQ-1 through HWQ-4 is the responsibility of the owner, operator, or agent of each affected facility who submits a permit application to comply with the proposed project.

Monitoring Agency: The SCAQMD's Governing Board finds that through its discretionary authority to issue and enforce permits for this project, the SCAQMD will ensure compliance with mitigation measures HWQ-1 through HWQ-4. Mitigation monitoring and reporting (MMR) will be accomplished as follows:

MMRHWQ-1: USE RECYCLED WATER OR OTHER NON-POTABLE PROCESS WATER, IF AVAILABLE, FOR HYDROTESTING

At the time of submitting an application for a Permit to Construct for NOx control equipment and any support equipment such as storage tank or other equipment that requires hydrotesting, each facility operator shall submit one of the following: 1) a copy of a Memorandum of Understanding agreement reached between the facility operator and the recycled water supplier or purveyor that indicates recycled water will be used to supply water to conduct hydrotesting; or, 2) a supplement to the application(s) that describes how other non-potable process water will be diverted for hydrotesting. Once hydrotesting is complete, each facility operator will record one of the following: 1) the amount of recycled water delivered for hydrotesting from the recycled water bill; or 2) the amount of diverted process water used for hydrotesting. This log shall be maintained on-site for a period of at least two years from conducting hydrotesting.

MMRHWQ-2: SUBMIT WRITTEN DECLARATION IF RECYCLED WATER AND OTHER NON-POTABLE PROCESS WATER IS NOT USED FOR HYDROTESTING

The facility operator is required to submit two written declarations with the application for a Permit to Construct for the NOx control equipment and any support equipment such as a storage tank or other equipment that requires hydrotesting, one to be signed by an official of the water purveyor indicating the reason(s) why recycled water cannot be delivered to the project and one from a high-ranking officer at the facility indicating the reason(s) and the supporting evidence that explains why the non-potable process water cannot be diverted to the project from elsewhere within the facility.

MMRHWQ-3: USE RECYCLED WATER, IF AVAILABLE, FOR NOX CONTROL EQUIPMENT THAT REQUIRES WATER FOR ITS OPERATION

At the time of submitting an application for a Permit to Construct for NOx control equipment that requires water for its operation, each facility operator shall submit a copy of a Memorandum of Understanding agreement reached between the facility operator and the recycled water supplier or purveyor that indicates recycled water will be used to supply water to the NOx control equipment. Once the NOx control equipment becomes operational, on a monthly basis, each facility operator will record the amount of recycled water delivered to the NOx control equipment from the recycled water bill. This log shall be maintained on-site for a period of at least two years from initiating operation.

MMRHWQ-4: SUBMIT WRITTEN DECLARATION IF RECYCLED WATER IS NOT AVAILABLE FOR NOX CONTROL EQUIPMENT THAT REQUIRES WATER FOR ITS OPERATION

The facility operator is required to submit a written declaration with the application for a Permit to Construct for the NOx control equipment, to be signed by an official of the water purveyor indicating the reason(s) why recycled water cannot be delivered to the project.

CONCLUSION

Based on a “worst-case” analysis, the potential adverse construction air quality impacts, GHG impacts, water demand impacts, and hazards and hazardous materials impacts due to deliveries of ammonia from the adoption and implementation of the proposed project are considered significant and unavoidable. Feasible mitigation measures have been identified for construction air quality impacts, GHG impacts, and water demand impacts that would reduce these impacts associated with the proposed project; however, the mitigation measures are not sufficient to reduce the impacts to insignificance. No feasible mitigation measures have been identified to help minimize the potentially significant adverse impacts to hazards and hazardous materials due to deliveries of ammonia.

Further, none of the alternatives analyzed would reduce the construction air quality impacts, GHG impacts, water demand impacts, and hazards and hazardous materials impacts due to deliveries of ammonia to less than significant. As a result, no other feasible mitigation measures or project alternatives have been identified that would further reduce these impacts while still achieving the overall objectives of the proposed project.

(Adopted October 15, 1993)(Amended December 7, 1995)
(Amended February 14, 1997)(Amended May 11, 2001)(Amended January 7, 2005)
(Amended May 6, 2005)(Amended December 4, 2015)

RULE 2001. APPLICABILITY

(a) Purpose

This rule specifies criteria for inclusion in RECLAIM for new and existing facilities. It also specifies requirements for sources electing to enter RECLAIM and identifies provisions in District rules and regulations that do not apply to RECLAIM sources.

(b) Criteria for Inclusion in RECLAIM

The Executive Officer will maintain a listing of facilities which are subject to RECLAIM. The Executive Officer will include facilities, unless otherwise exempted pursuant to subdivision (i), if emissions fee data for 1990 or any subsequent year filed pursuant to Rule 301 - Permit Fees, shows four or more tons per year of NO_X or SO_X emissions where:

(1) NO_X emissions do not include emissions from:

(A) any NO_X source which was exempt from permit pursuant to Rule -219 Equipment Not Requiring A Written Permit Pursuant to Regulation II;

(B) any NO_X process unit which was rental equipment with a valid District Permit to Operate issued to a party other than the facility;

(C) on-site, off-road mobile sources; or

(D) ships as specified in Rule 2000(c)(62)(C) and (D).

(2) SO_X emissions do not include emissions from:

(A) any SO_X source which was exempt from permit pursuant to Rule -219 Equipment Not Requiring A Written Permit Pursuant to Regulation II; or

(B) any SO_X source that burned natural gas exclusively, unless the emissions are at a facility that elected to enter the program pursuant to subparagraph (i)(2)(A); or

(C) any SO_X process unit which was rental equipment with a valid District Permit to Operate issued to a party other than the facility;

(D) on-site, off-road mobile sources; or

(E) ships as specified in Rule 2000(c)(62)(C) and (D).

The Executive Officer will not include a facility in RECLAIM if a permit holder requests exclusion no later than January 1, 1996 and demonstrates prior to October 15, 1993 through the addition of control equipment, the possession of a valid Permit to Construct for such control equipment, or a Permit to Operate condition that the emissions fee data received pursuant to Rule 301, which shows emissions equal to or greater than four tons per year of a RECLAIM pollutant, is not representative of future emissions.

(c) Amendments to RECLAIM Facility Listing

(1) The Executive Officer will amend the RECLAIM facility listing to add, delete, change designation of any facility or make any other necessary corrections upon any of the following actions:

(A) Approval by the Executive Officer pursuant to Rule 2007 - Trading Requirements, of the permanent transfer or relinquishment of all RTCs applicable to a facility.

(B) Approval by the Executive Officer of a change of Facility Permit holder or change of facility name.

(C) Approval by the Executive Officer of a Facility Permit for a new facility if such new facility would, under RECLAIM, have a starting Allocation equal to or greater than four tons per year of a RECLAIM pollutant NO_X or SO_X, unless the facility would be exempt pursuant to subdivision (i).

(D) Approval by the Executive Officer of a Facility Permit for an existing non-RECLAIM facility, which reports NO_X or SO_X emissions pursuant to Rule 301 - Permit Fees, for any year which are equal to or greater than four tons, as specified in subdivision (b), unless the facility would be exempt pursuant to subdivision (i).

(E) Approval by the Executive Officer of the election of a facility to enter the RECLAIM program pursuant to subdivision (f).

(F) Upon delegation of authority from EPA to the District for Outer Continental Shelf (OCS) sources and inclusion of RECLAIM in 40 CFR Part 55 pursuant to the consistency update process, such OCS sources shall be RECLAIM facilities. The OCS sources' starting Allocation for the year of entry and Allocations for the years 2000 and 2003 and interim years, shall be determined pursuant to Rule 2002 - Allocations for Oxides of Nitrogen (NO_X) and Oxides of Sulfur (SO_X), except that fuel usage and emissions data reported to the Minerals Management Service of the Department of the Interior be utilized where emissions data reported pursuant to Rule 301 is not available, provided that the permit holder substantiates the accuracy of such fuel usage and emissions data. The starting Allocation shall be adjusted to reflect the rate of reduction which would have been applicable to the facility if it had been in the RECLAIM program as of October 15, 1993.

(2) The actions specified in this subdivision shall be effective only upon amendment of the Facility Listing.

(d) Cycles

(1) The Executive Officer will assign RECLAIM facilities to one of two compliance cycles by computer-generated random assignment which, to the extent possible, ensures an even distribution of RTCs. The Facility Listing will distinguish between Cycle 1 facilities, which will have a compliance year of January 1 to December 31 of each year, and Cycle 2 facilities, with a compliance year of July 1 to June 30 of each year.

(2) The issue and expiration dates of the RTCs allocated to a facility shall coincide with the beginning and ending dates of the facility's compliance year.

(3) Within 30 days of October 15, 1993, facilities assigned to Cycle 2 may petition the Executive Office or the Hearing Board to change their cycle designation. Facilities assigned to Cycle 1 may not petition the Executive Officer or Hearing Board to change their cycle designation. Facilities entering the RECLAIM program after October 15, 1993 will be assigned to the cycle with the greatest amount of time remaining in the compliance year.

(e) High Employment/Low Emissions (HILO) Facility Designation

A new facility may, after January 1, 1997 apply to the District for classification as a HILO Facility. The Executive Officer will approve the HILO designation upon the determination that the emission rate for NO_X, SO_X, ROC, and PM_{10} is less than or equal to one-half (1/2) of any target specified in the AQMP for emissions per full-time manufacturing employee by industry class in the year 2010.

(f) Entry Election

(1) A non-RECLAIM facility may elect to permanently enter the RECLAIM program, provided that:

(A) the owner or operator files an Application for Entry;

(B) the facility is not listed as exempt under paragraph (i)(1);

(C) the facility is not operating under an Order for Abatement or in violation of any District rule; and

(D) the facility is not subject to a compliance date in an existing rule within six months of the date of Application for Entry.

(2) Upon approval of an Application for Entry, the Executive Officer will issue a Facility Permit. The facility's starting Allocation for the year of entry and Allocations for the years 2000 and 2003 and interim years, shall be determined pursuant to Rule 2002 - Allocations for Oxides of Nitrogen (NO_X) and Oxides of Sulfur (SO_X). If necessary, the Allocation shall be adjusted to equal the Allocations which would have been applicable to the facility if it had been subject to the RECLAIM program as of October 15, 1993.

(3) Entry into the RECLAIM program will be effective upon issuance of a Facility Permit pursuant to Rule 2006 - Permits, and publication of the addition of the facility to the Facility Listing.

(g) Exit from RECLAIM

(1) The owner or operator of an electricity generating facility (EGF) may submit a plan application (i.e., opt-out plan) subject to plan fees specified in Rule 306 to request to opt-out of the NOx RECLAIM program provided that the following requirements are met as demonstrated in an opt-out plan submitted to the Executive Officer:

(A) At least 99 percent of the EGF's NOx emissions for the most recent three full compliance years are from equipment that meets current Best Available Control Technology (BACT) or Best Available Retrofit Control Technology (BARCT), for NOx.

(B) The EGF is subject to NOx RECLAIM as of [*date of amendment*] or has been subject to NOx RECLAIM for at least 10 years as of the plan submittal date.

For the purpose~~s~~ of this rule an electricity generating facility (EGF) is a NOx RECLAIM facility that generates electricity for distribution in the state or local grid system, excluding cogeneration facilities.

(2) If the Executive Officer approves an opt-out plan, based on the criteria specified in paragraph (g)(1), then the EGF Facility Permit holder shall submit applications to include in its permit and accept permit conditions that ensure all of the following apply:

(A) NOx RTCs held by the EGF shall be treated as follows:

(i) For an EGF~~*s for which all permits were issued on or after January 1, 1994*~~ that does not meet the definition of an existing facility, as defined in Rule 2000(c)(35), the quantity of NOx RTCs for all compliance years after the date of approval of the opt-out plan required to be held by the EGF pursuant to Rule 2005 – New Source Review for RECLAIM shall be surrendered by the facility, retired from the market, and used to satisfy any NOx requirements for continuing obligations under Regulation XIII – New Source Review. If needed to equal this amount, any Non-tradable/Non-usable RTCs and any RTCs corresponding to the EGF's contribution to the Regional NSR Holding Account may be used for this purpose and, if RTCs from the Regional NSR Holding Account are used, these RTCs shall be removed from the Regional NSR Holding Account.

(ii) For existing EGFs, that meet the definition of an existing facility, as defined in Rule 2000(c)(35), an amount of NOx RTCs equivalent to the EGF's NOx holdings as of September 22, 2015 ~~*as*~~ adjusted pursuant to Rule 2002(f)(1) for all compliance years after the date of approval of the opt-out plan shall be surrendered by the EGF and retired from the market.

(iii) Any NOx RTCs held by an EGF beyond those referred to in clauses (i) and (ii) above may be sold, traded, or transferred by the facility.

(B) The EGF operator shall ensure that all equipment identified in the opt-out plan as meeting BACT or BARCT shall not exceed the respective BACT or BARCT levels of emissions or any existing permit condition limiting NOx emissions that is lower than BACT or BARCT as of the date of the opt-out plan submittal.

(C) Limits on EGF Emissions ~~*For existing EGFs, total facility emissions shall be limited to the amount of Compliance Year 2015 RTCs held as of September 22, 2015. The facility NOx emission limit shall be apportioned to each NOx source in the same proportion as its share of the EGF's emissions during the three complete compliance years prior to the date of opt-out plan submittal.*~~

(i) For an EGF that meets the definition of an existing facility in Rule 2000(c)(35), total facility emissions shall be limited to the amount of Compliance Year 2015 RTCs held as of September 22, 2015.

(ii) For an EGF that does not meet the definition of an existing facility in Rule 2000(c)(35), emissions from each NOx source shall be limited to the amount of RTCs required to be held for that source pursuant to Rule 2005 as of the date of opt-out plan approval.

(D) The owner or operator of multiple EGFs under common control shall have one opportunity to apportion the NOx emission limits among its facilities under common control for the purpose of meeting the requirements of clause (C)(i) or (C)(ii) as part of its opt-out plan as specified in paragraph (g)(1), provided all of the facilities opt out concurrently. The apportionment shall be described in the opt-out plan that shall be submitted to the Executive Officer. Each facility shall not have a limit that exceeds the amount of emissions that can be generated by all equipment located at the facility. ~~*For EGFs for which all permits were issued on or after January 1, 1994, emissions from each NOx source shall be limited to the amount of RTCs required to be held for that source pursuant to Rule 2005 as of the date of the opt-out plan submittal.*~~

(E) Subdivision (j) shall not be applicable to the EGF for any equipment installed or modified after the date of approval of the opt-out plan, and for ~~existing~~ other equipment at the earliest practicable date but no later than three years after the date of approval of the opt-out plan except Regulation XIII – New Source Review shall apply upon permit issuance.

(F) Notwithstanding the requirements specified in subparagraph (g)(2)(E), ~~*T*~~the EGF operator shall continue to comply with the requirements of Rule 2012 and its associated protocols unless the Executive Officer has approved an alternative monitoring and recordkeeping plan which is sufficient to determine compliance with all applicable rules.

(G) Notwithstanding the requirements specified in subparagraph (g)(2)(E), ~~*F*~~for EGFs not subject to Regulation XXX, the EGF's permit shall be re-designated as an "opt-out facility permit" and shall remain in effect, subject to annual renewal, unless expired, revoked, or modified pursuant to applicable rules. The EGF operator shall continue to pay RECLAIM permit fees pursuant to Rule 301(l).

(3) The Executive Officer shall approve or deny the opt-out plan within 180 days of receipt of a complete plan, unless the EGF and the Executive Officer have mutually agreed upon a longer time period. The Executive Officer shall not approve the opt-out plan unless it has been determined that the requirements of subparagraphs (g)(1)(A) and (g)(1)(B) are met, and the EGF accepts appropriate permit conditions to ensure compliance with the requirements of subparagraphs (g)(2)(B) through (~~G~~H). If, within 180 days or within the mutually agreed upon time period of receiving a complete opt-out plan, the Executive Officer does not take action on ~~it~~the plan, the EGF may consider ~~it~~the plan denied. Executive Officer denial of an opt-out plan can be appealed to the Hearing Board. The Executive Officer shall not re-issue the facility permit removing the EGF from RECLAIM unless the EGF surrender~~ed~~s the required amount of RTCs pursuant to subparagraph (g)(2)(A). Removal from RECLAIM of an EGF with an approved opt-out plan is effective upon issuance of a facility permit incorporating the conditions specified in paragraph (g)(2).

(4) No facility, on the initial Facility Listing or subsequently admitted to RECLAIM, may opt out of the program, unless approved by the Executive Officer pursuant to paragraph (g)(3).

(h) Non-RECLAIM Facility Generation of RTCs

Non-RECLAIM facilities may not obtain RTCs due to a shutdown or curtailment of operations which occurs after October 15, 1993. ERCs generated by non-RECLAIM facilities may not be converted to RTCs if the ERCs are based on a shutdown or curtailment of operations after October 15, 1993.

(i) Exemptions

(1) The following sources, including those that are part of or located on a Department of Defense facility, shall not be included in RECLAIM and are prohibited from electing to enter RECLAIM:

(A) dry cleaners;

(B) fire fighting facilities;

(C) construction and operation of landfill gas control, processing or landfill gas energy recovery facilities;

(D) facilities which have converted all sources to operate on electric power prior to October 15, 1993;

(E) police facilities;

(F) public transit;

(G) restaurants;

(H) potable water delivery operations;

(I) facilities located in the Riverside County portions of the Salton Sea and Mojave Desert Air Basins, except for a facility that has elected to enter the RECLAIM program pursuant to subparagraph (i)(2)(M); and

(J) facilities that have permanently ceased operations of all sources before January 1, 1994.

(K) The facility was removed from RECLAIM pursuant to paragraph (g)(3).

(2) The following sources, including those that are part of or located on a Department of Defense facility, shall not be initially included in RECLAIM but may enter the program pursuant to subdivision (f):

(A) electric utilities (exemption only for the SO_X program);

(B) equipment rental facilities;

(C) facilities possessing solely "various location" permits;

(D) hospitals;

(E) prisons;

(F) publicly owned municipal waste-to-energy facilities;

(G) portions of facilities conducting research operations;

(H) schools or universities;

(I) sewage treatment facilities which are publicly owned and operated consistent with an approved regional growth plan;

(J) electric power generating systems owned and operated by the City of Burbank, City of Glendale or City of Pasadena or any of their successors;

(K) ski resorts;

(L) facilities located on San Clemente Island;

(M) any electric generating facility that has submitted complete permit applications for all equipment requiring permits at the facility on or after January 1, 2001 may elect to enter the NOx RECLAIM program if the facility is located in the Riverside County portions of the Salton Sea or Mojave Desert Air Basins; and

(N) facilities that are an agricultural source as defined in California Health and Safety Code § 39011.5~~.~~; and

(O) any EGF as defined in paragraph (g)(1), except for an EGF that has been removed from NOx RECLAIM, pursuant to paragraph (g)(3).

(j) Rule Applicability

Facilities operating under the provisions of the RECLAIM program shall be required to comply concurrently with all provisions of District rules and regulations, except those provisions applicable to NOx emissions under the rules listed in Table 1, shall not apply to NO_X emissions from NOx RECLAIM facilities, and those provisions applicable to SOx emissions of the rules listed in Table 2 shall not apply to SOx emissions from SOx RECLAIM facilities after the later of the following:

(1) December 31, 1994 for Cycle 1 facilities and June 30, 1995 for Cycle 2 facilities; or

(2) the date the facility has demonstrated compliance with all monitoring and reporting requirements of Rules 2011 or 2012, as applicable.

Notwithstanding the above, NOx and SOx RECLAIM facilities shall not be required to comply with those provisions applicable respectively to NOx and SOx emissions of the listed District rules in Tables 1 and 2 which have initial implementation dates in 1994. The Facility Permit holder shall comply with all other provisions of the rules listed in Table 1 and 2 relating to any other pollutant.

PROPOSED AMENDED RULE 2002. ALLOCATIONS FOR OXIDES OF NITROGEN (NO_X) AND OXIDES OF SULFUR (SOx)

(a) Purpose

The purpose of this rule is to establish the methodology for calculating facility Allocations and adjustments to RTC holdings for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx).

(b) RECLAIM Allocations

(1) RECLAIM Allocations will begin in 1994.

(2) An annual Allocation will be assigned to each facility for each compliance year starting from 1994.

(3) Allocations and RTC holdings for each year after 2011 are equal to the 2011 Allocation and RTC holdings, as determined pursuant to subdivision (f) unless, as part of the AQMP process, and pursuant to Rule 2015 (b)(1), (b)(3), (b)(4), or (c), the District Governing Board determines that additional reductions are necessary to meet air quality standards, taking into consideration the current and projected state of technology available and cost-effectiveness to achieve further emission reductions.

(4) The Facility Permit or relevant sections thereof shall be re-issued at the beginning of each compliance year to include allocations determined pursuant to subdivisions (c), (d), (e), and (f) and any RECLAIM Trading Credits (RTC) obtained pursuant to Rule 2007 - Trading Requirements for the next fifteen years thereafter and any other modifications approved or required by the Executive Officer.

(5) Annual emission reports submitted pursuant to Rule 301 more than five years after the original due date shall not be considered by the Executive Officer in determining facility Allocations.

(c) Establishment of Starting Allocations

(1) The starting Allocation for RECLAIM NO_X and SO_X facilities initially permitted by the District prior to October 15, 1993, shall be determined by the Executive Officer utilizing the following methodology:

Starting Allocation=Σ[A X B_1]+ERCs+External Offsets

where

A = the throughput for each NO_X and SO_X source or process unit in the facility for the maximum throughput year from 1989 to 1992 inclusive; and

B_1 = the applicable starting emission factor for the subject source or process unit as specified in Table 1 or Table 2

(2) (A) Use of 1992 data is subject to verification and revision by the Executive Officer or designee to assure validity and accuracy.

(B) The maximum throughput year will be determined by the Executive Officer or designee from throughput data reported through annual emissions reports submitted pursuant to Rule 301 - Permit Fees, or may be designated by the permit holder prior to issuance of the Facility Permit.

(C) To determine the applicable starting emission factor in Table 1 or Table 2, the Executive Officer or designee will categorize the equipment at each facility based on information relative to hours of operation, equipment size, heating capacity, and permit information submitted pursuant to Rule 201 - Permit to Construct, and other relevant parameters as determined by the Executive Officer or designee. No information used for purposes of this subparagraph may be inconsistent with any information or statement previously submitted on behalf of the facility to the District, including but not limited to information and statements previously submitted pursuant to Rule 301 - Permit Fees, unless the facility can demonstrate, by clear and convincing documentation, that such information or statement was inaccurate.

(D) Throughput associated with each piece of equipment or NOx or SOx source will be multiplied by the starting emission factors specified in Table 1 or Table 2. If a lower emission factor was utilized for a given piece of equipment or NOx or SOx source pursuant to Rule 301 - Permit Fees, than the factor in Table 1 or Table 2, the lower factor will be used for determining that portion of the Allocation.

(E) Fuel heating values may be used to convert throughput records into the appropriate units for determining Allocations based on the emission factors in Table 1 or Table 2. If a different unit basis than set forth in Tables 1 and 2 is needed for emissions calculations, the Executive Officer shall use a default heating value to determine source emissions, unless the Facility Permit holder can demonstrate with substantial evidence to the Executive Officer that a different value should be used to determine emissions from that source.

(3) All NO_X and SO_X ERCs generated at the facility and held by a RECLAIM Facility Permit holder shall be reissued as RTCs. RECLAIM facilities will have these RTCs added to their starting Allocations. RTCs generated from the conversion of ERCs shall have a zero rate of reduction for the year 1994 through the year 2000. Such RTCs shall have a cumulative rate of reduction for the years 2001, 2002, and 2003, equal to the percentage inventory adjustment factor applied to 2003 Allocations pursuant to paragraph (e)(1) of this rule and shall have a rate of reduction for compliance year 2004 and subsequent years determined pursuant to paragraph (f)(1) of this rule.

(4) Non-RECLAIM facilities may elect to have their ERCs converted to RTCs and listed on the RTC Listing maintained by the Executive Officer or designee pursuant to Rule 2007 - Trading Requirements, so long as the written request is filed before July 1, 1994. Such RTCs will be assigned to the trading zone in which the generating facility is located. RTCs generated from the conversion of ERCs shall have a zero rate of reduction for the year 1994 through the year 2000. Such RTCs shall have a cumulative rate of reduction for the years, 2001, 2002, and 2003, equal to the percentage inventory adjustment factor applied to 2003 Allocations pursuant to paragraph (e)(1) of this rule.

(5) External offsets provided pursuant to Regulation XIII - New Source Review, not including any offsets in excess of a 1 to 1 ratio, will be added to the starting Allocation pursuant to paragraph (c)(1) provided:

(A) The offsets were not received from either the Community Bank or the Priority Reserve.

(B) External offsets will only be added to the starting Allocation to the extent that the Facility Permit holder demonstrates that they have not already been included in the starting Allocation or as an ERC. RTCs issued for external offsets shall not include any offsets in excess of a 1 to 1 ratio required under Regulation XIII - New Source Review.

(C) RTCs generated from the conversion of external offsets shall have a zero rate of reduction for the year 1994 through the year 2000. These RTCs shall have a cumulative rate of reduction for the years 2001, 2002, and 2003, equal to the percentage inventory adjustment factor applied to 2003 Allocations pursuant to paragraph (e)(1) of this rule, and for compliance year 2004 and subsequent years allocations shall be determined pursuant to paragraph (f)(1) of this rule. The rate of reduction for the year 2001 through year 2003 shall not be applied to new facilities initially totally permitted on or after January 7, 2005.

(D) Existing facilities with units that have Permits to Construct issued pursuant to Regulation II - Permits, dated on or after January 1, 1992, or existing facilities which have, between January 1, 1992 and October 15, 1993, installed air pollution control equipment that was exempt from offset requirements pursuant to Rule 1304 (a)(5), shall have their starting Allocations increased by the total external offsets provided, or the amount that would have been offset if the exemption had not applied.

(E) Existing facilities with units whose reported emissions are below capacity due to phased construction, and/or where the Permit to Operate issued pursuant to Regulation II - Permits, was issued after January 1, 1992, shall have their starting Allocations increased by the total external offsets provided.

(6) If a Facility Permit holder can demonstrate that its 1994 Allocation is less than the 1992 emissions reported pursuant to Rule 301 - Permit Fees, and that the facility was, in 1992, operating in compliance with all applicable District rules in effect as of December 31, 1993, the facility's starting Allocation will be equal to the 1992 reported emissions.

(7) For new facilities initially totally permitted on or after January 1, 1993 but prior to October 15, 1993, the starting Allocation shall be equal to the external offsets provided by the facility to offset emission increases at the

facility pursuant to Regulation XIII - New Source Review, not including any offsets in excess of a 1 to 1 ratio.

(8) The Allocation for new facilities initially totally permitted on and after October 15, 1993, shall be equal to the total RTCs provided by the facility to offset emission increases at the facility pursuant to Rule 2005- New Source Review for RECLAIM.

(9) The starting Allocation for existing facilities which enter the RECLAIM program pursuant to Rule 2001 - Applicability, shall be determined by the methodology in paragraph (c)(1) of this rule. The most recent two years reported emission fee data filed pursuant to Rule 301 - Permit Fees, may be used if 1989 through 1992 emission fee data is not available. For facilities lacking reported emission fee data, the Allocation shall be equal to the external offsets provided pursuant to Regulation XIII - New Source Review, not including any offsets in excess of a 1 to 1 ratio. The Allocation shall not include any emission offsets received from either the Community Bank or the Priority Reserve.

(10) A facility may not receive more than one set of Allocations.

(11) A facility that is no longer holding a valid District permit on January 1, 1994 will not receive an Allocation, but may, if authorized by Regulation XIII, apply for ERCs.

(12) Clean Fuel Adjustment to Starting Allocation

Any refiner who is required to make modifications to comply with CARB Phase II reformulated gasoline production (California Code of Regulations, Title 13, Sections 2250, 2251.5, 2252, 2260, 2261, 2262, 2262.2, 2262.3, 2262.4, 2262.5, 2262.6, 2262.7, 2263, 2264, 2266, 2267, 2268, 2269, 2270, and 2271) or federal requirements (Federal Clean Air Act, Title II, Part A, Section 211; 42 U.S.C. Section 7545) may receive (an) increase(s) in his Allocations except to the extent that there is an increase in maximum rating of the new or modified equipment. Each facility requesting an increase to Allocations shall submit an application for permit amendment specifying the necessary modifications and tentative schedule for completion. The Facility Permit holder shall establish the amount of emission increases resulting from the reformulated gasoline modifications for each year in which the increase in Allocations is requested. The increase to its Allocations will be issued contemporaneously with the modification according to a schedule approved by the Executive Officer or designee (i.e., 1994 through 1997 depending on the refinery). Each increase to the Allocations shall be equal to the increased emissions resulting from the modifications solely to comply with the state or federal reformulated gasoline requirements at the refinery or facility producing hydrogen for reformulated gasoline production, and shall be established according to present and future compliance limits in current District rules or permits. Allocation increases for each refiner pursuant to this paragraph, shall not exceed 5 percent of the refiner's total starting Allocation, unless any refiner emits less than 0.0135 tons of NO_X per thousand barrels of crude processed, in which case the Allocation increases for such refiner shall not exceed 20 percent of that refiner's starting Allocation. The emissions per amount of crude processed will be determined on the basis of information reported to the District pursuant to Rule 301 - Permit Fees, for the same calendar year as the facility's peak activity year for their NO_X starting Allocation.

(d) Establishment of Year 2000 Allocations

(1) (A) The year 2000 Allocations for RECLAIM NO_X and SO_X facilities will be determined by the Executive Officer or designee utilizing the following methodology:

Year 2000 Allocation = Σ [A X B_2] + RTCs created from ERCs + External Offsets,

where

A = the throughput for each NO_X or SO_X source or process unit in the facility for the maximum throughput year from 1987 to 1992, inclusive, as reported pursuant to Rule 301 - Permit Fees; and

B_2 = the applicable Tier I year Allocation emission factor for the subject source or process unit, as specified in Table 1 or Table 2.

(B) The maximum throughput year will be determined by the Executive Officer or designee from throughput data reported through annual emissions reports pursuant to Rule 301 - Permit Fees, or may be designated by the permit holder prior to issuance of the Facility Permit.

(C) To determine the applicable emission factor in Table 1 or Table 2, the Executive Officer or designee will categorize the equipment at each facility based on information on hours of operation, equipment size, heating capacity, and permit information submitted pursuant to Rule 201 - Permit to

Construct, and other parameters as determined by the Executive Officer or designee. No information used for purposes of this subparagraph may be inconsistent with any information or statement previously submitted on behalf of the facility to the District including but not limited to information and statements previously submitted pursuant to Rule 301 - Permit Fees, unless the facility can demonstrate, by clear and convincing documentation, that such information or statement was inaccurate.

(D) Throughput associated with each piece of equipment or NO_X or SO_X source will be multiplied by the Tier I emission factor specified in Table 1 or Table 2. If a factor lower than the factor in Table 1 or Table 2 was utilized for a given piece of equipment or NO_X or SO_X source pursuant to Rule 301, the lower factor will be used for determining that portion of the Allocation.

(E) The fuel heating value may be considered in determining Allocations and will be set to 1.0 unless the Facility Permit holder demonstrates that it should receive a different value.

(F) The year 2000 Allocation is the sum of the resulting products for each piece of equipment or NO_X or SO_X source multiplied by any inventory adjustment pursuant to paragraph (d)(4) of this rule.

(2) For facilities existing prior to October 15, 1993 which enter RECLAIM after October 15, 1993, the year 2000 Allocation will be determined according to paragraph (d)(1). The most recent two years reported emission fee data filed pursuant to Rule 301 - Permit Fees, may be used if 1989 through 1992 emission fee data is not available. For facilities lacking reported emission fee data, the Allocation shall be equal to their external offsets provided pursuant to Regulation XIII - New Source Review, not including any offsets in excess of a 1 to 1 ratio.

(3) No facility shall have a year 2000 Allocation [calculated pursuant to subdivision (d)] greater than the starting Allocation [calculated pursuant to subdivision (c)].

(4) If the sum of all RECLAIM facilities' year 2000 Allocations differs from the year 2000 projected inventory for these sources under the 1991 AQMP, the Executive Officer or designee will establish a percentage inventory adjustment factor that will be applied to adjust each facility's year 2000

Allocation. The inventory adjustment will not apply to RTCs generated from ERCs or external offsets.

(e) Allocations for the Year 2003

(1) The 2003 Allocations will be determined by the Executive Officer or designee applying a percentage inventory adjustment to reduce each facility's unadjusted year 2000 Allocation so that the sum of all RECLAIM facilities' 2003 Allocations will equal the 1991 AQMP projected inventory for RECLAIM sources for the year 2003, corrected based on actual facility data reviewed for purposes of issuing Facility Permits and to reflect the highest year of actual Basin-wide economic activity for RECLAIM sources considered as a whole during the years 1987 through 1992.

(2) No facility shall have a 2003 Allocation (calculated pursuant this subdivision) greater than the year 2000 Allocation [calculated pursuant to subdivision (d)].

(f) Annual Allocations for NO_X and SOx and Adjustments to RTC Holdings

(1) Allocations for the years between 1994 and 2000, for RECLAIM NO_X and SO_X facilities shall be determined by a straight line rate of reduction between the starting Allocation and the year 2000 Allocation. For the years 2001 and 2002, the Allocations shall be determined by a straight line rate of reduction between the year 2000 and year 2003 Allocations. NOx Allocations for 2004, 2005, and 2006 and SOx Allocations for 2004 through 2012 are equal to the facility's 2003 Allocation, as determined pursuant to subdivision (e). NOx RTC Allocations and holdings subsequent to the year 2006 and SOx Allocations and holdings subsequent to the year 2012 shall be adjusted to the nearest pound as follows:

(A) The Executive Officer will adjust NOx RTC holdings, as of January 7, 2005 for compliance years 2007 and thereafter by multiplying the amount of RTC holdings by the following adjustment factors for the relevant compliance year, to obtain tradable/usable and non-tradable/non-usable holdings:

Compliance <u>Year</u>	Tradable/Usable NOx RTC Adjustment <u>Factor</u>	~~Non-tradable/ Non-usable NOx RTC Adjustment Factor~~
2007	0.883	~~0~~
2008	0.856	~~0.027~~
2009	0.829	~~0.054~~

2010	0.802	~~0.081~~
2011 and after~~and after through 2015~~	0.775	~~0.108~~

~~RTCs designated as non-tradable/non-usable pursuant to this subparagraph shall be held, but shall not be used or traded. The adjustment factors in this subparagraph are subject to change pursuant to paragraph (i)(5).~~

(B) The Executive Officer shall adjust NOx RTCs held as of September 22, 2015 by the RTC holders identified in Table 7 and their successors using the following adjustment factors to obtain Tradable/Usable and Non-Tradable/Non-Usable RTC Holdings:

Compliance Year	Tradable/Usable NOx RTC Adjustment Factor	Non-tradable/ Non-usable NOx RTC Adjustment Factor
2015	1.0	0
2016	0.812	0.188
2017	0.812	0
2018	0.718	0.094
2019	0.625	0.093
2020	0.531	0.094
2021	0.437	0.094
2022	0.343	0.094
2023 and after	0.343	0

RTC holdings traded from RTC holders in Table 7 on and after~~since~~ September 22, 2015 and held by other RTC holders not listed in Table 7 shall be subjected to the above adjustment factors. ~~*For purposes of assigning the appropriate*~~ The adjustment factor(s) for any RTC sold by an RTC holder that both purchased and sold RTCs between September 22, 2015 and *[date of amendment]*~~,~~ shall be based on a last in/first out basis ~~*at the time each transaction was registered*~~.

(C) The Executive Officer shall adjust NOx RTCs held as of September 22, 2015 by the RTC holders identified in Table 8 and their successors using the following adjustment factors to obtain Tradable/Usable and Non-Tradable/Non-Usable RTC holdings:

Compliance	Tradable/Usable NOx RTC	Non-tradable/ Non-usable NOx RTC

Year	Adjustment Factor	Adjustment Factor
2015	1.0	0
2016	0.861	0.139
2017	0.861	0
2018	0.792	0.069
2019	0.722	0.07
2020	0.653	0.069
2021	0.583	0.07
2022	0.514	0.069
2023 and after	0.514	0

RTC holdings traded from RTC holders in Table 8 on and after September 22, 2015 and held by other RTC holders not listed in Table 8 shall be subjected to the above adjustment factors. ~~*For purposes of assigning the appropriate*~~ The adjustment factor(s) for any RTC sold by an RTC holder that both purchased and sold RTCs between September 22, 2015 and *[date of adoption]*~~,~~ shall be based on a last in/first out basis ~~*at the time each transaction was registered*~~.

(D) RTCs designated as non-tradable/non-usable pursuant to subparagraphs (f)(1)(B) and (f)(1)(C) shall be held, but shall not be traded or used for reconciling ~~for~~ emissions pursuant to Rule 2004. ~~The adjustment factors in this subparagraphs (f)(1)(B) and (f)(1)(C) are subject to change pursuant to paragraph (i)(5).~~

(~~B~~E) Commencing on January 1, 2008 with NOx RTC prices averaged from January 1, 2007 through December 31, 2007, the Executive Officer will calculate the 12-month rolling average RTC price for all trades for the current compliance year. Commencing on May 1, 2016 with NOx RTC prices averaged from January 1, 2016 through March 31, 2016, the Executive Officer will calculate the 3-month rolling average NOx RTC price for all trades for the current compliance year NOx RTCs and the 12-month rolling average NOx RTC price for all trades for infinite year block NOx RTC as defined in subparagraph (f)(1)(~~J~~I). The Executive Officer will update the 3-month and 12-month rolling average once per month. The computation of the rolling average prices will not include RTC transactions reported at no price or RTC swap transactions.

~~*(F)*~~ ~~*At the conclusion of any of the compliance years 2016 through 2022 if the NOx RTC prices have not exceeded the $22,500 per*~~

~~*ton threshold as specified in subparagraph (f)(1)(I) and a State of Emergency related to electricity demand orf power grid stability within the SCAQMD jurisdictional boundaries as specified in paragraph (f)(4) has not been declared by the Governor, then the Non-tradable/Non-usable NOx RTCs for that compliance year, except for those RTCs specified in subparagraph (f)(1)(G), shall be submitted as part of the State Implementation Plan commitment.*~~

(~~G~~F) The Executive Officer shall transfer to a Regional NSR Holding account the amount of NOx RTCs holdings listed in Table 9 of this Rule from the corresponding facilities identified in the same table.

(~~H~~G) For purposes of meeting the NSR holding requirement as specified in subdivision (f) of Rule 2005, the facilities identified in Table 9 may use a combination of their Tradable/Usable and Non-tradable/Non-usable RTCs specified in subparagraph (f)(1)(C) and the amount listed for each facility in Table 9, which represents the RTCs in the Regional NSR Holding account.

(~~C~~IH) ~~Notwithstanding the requirements of non-tradable/non-usable credits specified in subparagraphs (f)(1)(A), i~~In the event that the NOx RTC prices exceed ~~$15,000~~$22,500 per ton (~~*discrete*~~ current compliance year credits) based on the 12-month rolling average, or exceed $35,000 per ton (~~*discrete*~~ current compliance year credits) based on the 3-month rolling average calculated pursuant to subparagraph (f)(1)(~~B~~E), the Executive Officer will report the determination to the Governing Board. If the Governing Board finds that the 12-month rolling average RTC price exceeds ~~$15,000~~$22,500 per ton or the 3-month rolling average RTC price exceeds $35,000 per ton, then the ~~incremental~~ Non-tradable/Non-usable NOx ~~reductions~~ RTCs, as specified in subparagraphs (f)(1)(~~D~~B) and (f)(1)(C) valid for the period in which the RTC price is found to have exceeded the applicable threshold,~~*compliance year in which Cycle 1 facilities are currently operating*~~ shall be -converted to Tradable/Usable NOx RTCs upon Governing Board concurrence.

(~~J~~I) In the event that the infinite year block NOx RTC prices fall below $200,000 per ton based on the 12-month rolling average, calculated pursuant to subparagraph (f)(1)(E) beginning in 2019 for the compliance year in which Cycle 1 facilities are operating, the Executive Officer will report the determination to the Governing Board.

For the purpose of this rule, infinite year block refers to trades involving blocks of RTCs with a specified start year and continuing into the future for ten or more years.

(~~K~~J) Pursuant to subparagraphs (f)(1)(~~I~~H) and (f)(1)(~~J~~I) ~~The~~ the Executive Officer's report to the Board will also include a commitment and schedule to conduct a more rigorous control technology implementation, emission reduction, cost-effectiveness, market analysis, and socioeconomic impact assessment of the RECLAIM program. The Executive Officer's report to the Board will be made at a public hearing at the earliest possible regularly scheduled Board Meeting, but no more than ~~60~~ 90 days from Executive Officer determination.

~~(D) The incremental NOx RTCS restored shall be the difference between the Non-tradable/Non-usable Adjustment Factors, as specified in subparagraph (f)(1)(A), of the current compliance year and the most recent prior year the adjustment factor was implemented.~~

~~(E) RTC conversion pursuant to subparagraph (f)(1)(C) shall only occur in the compliance year in which Cycle 1 facilities are operating.~~

~~(F) Notwithstanding the adjustment factors required pursuant to subparagraph (f)(1)(A), beginning with the following December and each year thereafter that the Governing Board finds the $15,000 per ton NOx RTC price is exceeded pursuant to subparagraph (f)(1)(C), the Executive Officer will publish the applicable adjustment factors for the next compliance year beginning January 1. The adjustment factors will be published at a public hearing during a regularly scheduled Board Meeting. The adjustment factors will be determined as follows:~~

~~(i) If the 12-month rolling average falls below $15,000 per ton for at least 6 consecutive months, then the emission adjustment factors for the following compliance year shall equal the next more stringent adjustment factors listed in subparagraph (f)(1)(A) than the factors currently in effect; otherwise;~~

~~(ii) The next compliance year adjustment factors shall equal the compliance year adjustment factors currently in place.~~

~~The Executive Officer need no longer comply with the annual public hearing requirement once the adjustment factors for the 2010 compliance year have been implemented for a 12-month period.~~

(~~G~~~~L~~K) The NOx *emission reductions associated with the* RTC adjustment factors for compliance years 20~~08~~16, and 2018 through 20~~10~~22 shall not be submitted for inclusion into the State Implementation Plan until the adjustments have been in effect for one full compliance year. However, the amount of NOx RTCs adjustments specified in sub-paragraph (f)(1)(~~G~~F) shall not be submitted for inclusion in the State Implementation Plan. ~~The 2011 NOx RTC adjustment factors shall not be submitted for inclusion into the State Implementation Plan until 12-months after the adjustments have been in effect for one full compliance year.~~

(~~H~~~~M~~L) NOx Allocations for existing facilities that enter RECLAIM after (*date of adoption*) for Compliance Year 2016 and all subsequent years shall be the amount determined pursuant to subparagraph (d)(1)(A) except the variable B2 shall be the lowest of:

(i) The applicable 2000 (Tier I) Ending Emission Factor for the subject source(s) or process unit(s), as specified in Table 1 multiplied by the percentage inventory adjustment pursuant to subdivision (e) (0.72~~8~~);

(ii) The BARCT Emission factor for the subject source as specified in Table 3; and

(iii) The BARCT Emission factor for the subject ~~as~~ source, as specified in Table 6.

~~NOx Allocations for facilities that enter RECLAIM after January 7, 2005 for compliance years 2007 and after shall be determined by applying the Tradable/Usable and Non-tradable/Non-usable NOx RTC Adjustment Factors under subparagraph (f)(1)(A) to the facility's Compliance Year 2006 Allocation.~~

(~~I~~NM) SOx RTC Holdings as of November 5, 2010, for compliance years 2013 and after shall be adjusted to achieve an overall reduction in the following amounts:

Compliance Year	Minimum emission reductions (lbs.)
2013	2,190,000
2014	2,920,000
2015	2,920,000
2016	2,920,000
2017	3,650,000
2018	3,650,000
2019 and after	4,161,000

(~~J~~ON) The Executive Officer shall determine Tradable/usable SOx RTC Adjustment Factor~~s~~ for each compliance year~~s~~ after 2012 as follows:

$$F_{\text{compliance year i}} = 1 - [Xi / (Ai + Bi + Ci)]$$

Where:

$F_{\text{compliance year i}}$ = Tradable/usable SOx RTC Adjustment Factor for compliance year i starting with 2013

Ai = Total SOx RTCs for compliance year i held as of November ~~11~~5, 2010, by all RTC holders, except those listed in Table 5

Bi = Total SOx RTCs for compliance year i credited to any facilities listed in Table 5 between August 29, 2009 and ~~(rule adoption date)~~November 5, 2010, and not included~~s~~ in Ci

Ci = Total SOx RTCs held as of ~~(rule adoption date)~~November 5, 2010 by facilities listed in Table 5 for compliance year i in excess of allocations as determined pursuant to subdivision (e).

Xi = Amount to be reduced for compliance year i starting with 2013 as listed in subparagraph (f)(1)(~~I~~NM).

(~~KP~~O) The Executive Officer shall determine Non-tradable/Non-usable SOx RTC Adjustment Factors for compliance years 2017 through 2019 as follows:

$$N_{\text{compliance year j}} = F_{\text{compliance year 2016}} - F_{\text{compliance year j}}$$

Where:

$N_{\text{compliance year j}}$ = Non-tradable/Non-usable SOx RTC Adjustment Factor for compliance year j

$F_{\text{compliance year j}}$ = Tradable/Usable SOx RTC Adjustment Factor for compliance year j as determined pursuant to subparagraph (f)(1)(~~J~~O~~N~~)

j = 2017 through 2019

$F_{\text{compliance year 2016}}$ = Tradable/usable SOx RTC Adjustment Factor for compliance year 2016 as determined pursuant to subparagraph (f)(1)(~~J~~O~~N~~)

Non-tradable/Non-usable SOx RTC Adjustment Factors for compliance years 2013, 2014, 2020, and all years after 2020 shall be 0.0.

(~~L~~QP) The Executive Officer shall adjust the SOx RTC holdings as of November 5, 2010, for compliance years 2013 and after as follows:

(i) Apply the Tradable/Usable SOx RTC Adjustment Factor ($F_{\text{compliance year i}}$) and Non-tradable/Non-usable SOx RTC Adjustment Factor ($N_{\text{compliance year j}}$) for the corresponding compliance year as published under subparagraph (f)(1)(~~M~~RQ) to SOx RTC holdings held by any RTC holder except those listed in Table 5;

(ii) Apply no adjustment to SOx RTC holdings that are held as of August 29, 2009 by a facility listed in Table 5, and that are less than or equal to the facility's allocations as determined pursuant to subdivision (e), and that were not credited between August 29, 2009 and November 5, 2010;

(iii) Apply the Tradable/Usable SOx RTC Adjustment Factor ($F_{compliance\ year\ i}$) and Non-tradable/Non-usable SOx RTC Adjustment Factor ($N_{compliance\ year\ j}$) for the corresponding compliance year as published under subparagraph (f)(1)(~~M~~~~R~~Q) to any SOx RTC holding as of ~~(~~November 5, 2010~~)~~, that is held by a facility that is listed in Table 5, and that is over the facility's allocations as determined pursuant to subdivision (e); and

(iv) Apply the Tradable/Usable SOx RTC Adjustment Factor ($F_{compliance\ year\ i}$) and Non-tradable/non-usable SOx RTC Adjustment Factor ($N_{compliance\ year\ j}$) for the corresponding compliance year as published under subparagraph (f)(1)(~~M~~~~R~~Q) to any SOx RTC holding that was acquired between August 29, 2009 and November 5, 2010, by a facility that is listed in Table 5.

No SOx RTC holding shall be subject to the SOx RTC adjustments as published under subparagraph (f)(1)(~~M~~~~R~~Q) more than once.

(~~M~~~~R~~Q) The Executive Officer shall publish the SOx RTC Adjustment Factors determined according to subparagraphs (f)(1)(~~J~~~~O~~N) and (f)(1)(~~K~~~~P~~O) within 30 days after November 5, 2010.

(~~N~~~~S~~R) Commencing on January 1, 2017 and ending on February 1, 2020, the Executive Officer will calculate the 12-month rolling average SOx RTC price for all trades during the preceding 12 months for the current compliance year. The Executive Officer will update the 12-month rolling average once per month. The computation of the rolling average prices will not include RTC transactions reported at no price or RTC swap transactions.

(~~O~~~~T~~S) In the event that the SOx RTC prices exceed $50,000 per ton based on the 12-month rolling average calculated pursuant to subparagraph (f)(1)(~~N~~~~S~~R), the Executive Officer will report to the Governing Board at a duly noticed public hearing to be held no more than 60 days from Executive Officer determination. The Executive Officer will announce that determination on the SCAQMD website. At the public hearing, the Governing Board will decide whether or not to convert any portion of the Non-tradable/Non-usable RTCs, as determined pursuant to subparagraphs (f)(1)(~~K~~~~P~~<u>O</u>) and (f)(1)(~~L~~~~Q~~<u>P</u>), and how much to convert if any, to Tradable/Usable RTCs. The portion of Non-tradable/Non-usable RTCs available for conversion to Tradable/Usable RTCs shall not include any portion of Non-tradable/Non-usable RTCs that are designated for previous compliance years and has not already been converted by the Governing Board, or that has been otherwise included in the State Implementation Plan pursuant to subparagraph (f)(1)(~~P~~~~U~~<u>T</u>).

(~~P~~~~U~~<u>T</u>) The Executive Officer will not submit the emission reductions obtained through subparagraph (f)(1)(~~I~~~~N~~<u>M</u>) for compliance years 2017 through 2019 for inclusion into the State Implementation Plan until the adjustments for the RTC Holdings have been in effect for one full compliance year.

(~~Q~~~~V~~<u>U</u>) SOx Allocations for compliance years 2013 and after, for facilities that enter RECLAIM after November 5, 2010, and for basic equipment listed in Table 4 shall be determined according to the BARCT level listed in Table 4 or the permitted emission limits, whichever is lower.

(<u>V</u>) <u>By no later than July 1, 2012, SOx emissions at the exhaust of a Fluidized Catalytic Cracking Unit, as measured at the final stack venting gases originating from the facility's FCC Regenerator, including after the CO Boiler or any additional controls in the system following the regenerator (the final stack shall constitute the only exhaust gas compliance point within the FCCU facility), shall not exceed a concentration of 25 ppm dry @ 0% oxygen on a 365-day rolling average. The numeric concentration-based limit does not apply during time periods in which SOx data are determined to be incorrect due to analyzer calibration or malfunction. For the purpose of demonstrating compliance with this limit, the operator of a FCCU shall commence the use of SOx reducing additives in the FCCU no later than July 1, 2011, unless the operator has an existing wet gas scrubber in operation at BARCT levels prior to November 5, 2010 or can demonstrate to the Executive Officer that the FCCU will achieve this limit by using other control methods.</u>

(2) New facilities initially totally permitted, on and after October 15, 1993, but prior to January 7, 2005, and entering the RECLAIM program after January 7, 2005 shall not have a rate of reduction until 2001. Reductions from 2001 to 2003, inclusive, shall be implemented pursuant to subdivision (e). New facilities initially totally permitted on or after January 7, 2005 using external offsets shall have a rate of reduction for such offsets pursuant to subparagraph (c)(5)(C). New facilities initially totally permitted on or after January 7, 2005 using RTCs shall have no rate of reduction for such RTCs, provided that RTCs obtained have been adjusted according to paragraph (f)(1), as applicable. The Facility Permit for such facilities will require the Facility Permit holder to, at the commencement of each compliance year, hold RTCs equal to the amount of RTCs provided as offsets pursuant to Rule 2005.

(3) Increases to Allocations for permits issued for Clean Fuel adjustments pursuant to paragraph (c)(12), shall be added to each year's Allocation.

(4) During a State of Emergency declared by the Governor related to electricity demand or power grid stability within the SCAQMD jurisdictional boundaries, the current compliance year Non-tradable/Non-usable NOx RTCs held by electricity generating facilities as defined in Rule 2001(g)(1) that generate and distribute electricity to the grid system(s) affected by the State of Emergency may be used to offset their emissions after completely exhausting their own Tradable/Usable NOx RTCs.

If such a facility has completely exhausted their Non-tradable/Non-usable NOx RTCs, the owner or operator of the facility may apply for the use of the NOx RTCs in the Regional NSR Holding Account. The use of such RTCs in this Account shall be based on availability at the end of each quarter. The owner or operator of each ~~electrical~~electricity generating facility requesting NOx RTCs from the Regional NSR Holding Account shall submit a written request to the Executive Officer specifying the amount of RTCs needed and the basis for requesting the required amount.

The Executive Officer will determine the amount and distribution of the NOx RTCs from the Regional NSR Holding Account based on the requesting facility meeting the following criteria:

(i) The State of Emergency related to electricity demand or power grid stability within the SCAQMD jurisdictional boundaries, as declared by the Governor, was the direct cause of the excess emissions~~.~~;

(ii) The facility has been ordered to generate electricity in an increased amount and/or frequency due to the State of Emergency~~.~~;

(iii) The facility has adequately demonstrated their need for the specific amount of RTCs from the Regional NSR Holding Account~~.~~; and

(iv) The facility owner or operator has not sold any part of their RTC holdings for the subject compliance year.

If the total RTCs requested exceed the supply of RTCs in this Account, the RTCs will be distributed proportionately according to the offset needs of the facilities on a quarterly basis. These RTCs will be non-tradable, but usable to offset emissions.

(5) The Executive Officer will report to the Governing Board within 60 days of the end of the quarter in which a State of Emergency was declared by the Governor related to electricity demand or power grid stability within the SCAQMD jurisdictional boundaries~~in the Basin~~. Included in this report will be, as applicable:

(i) the quantity of RTCs from the Regional NSR Holding Account that were distributed for compliance with the requirement to reconcile quarterly and annual emissions;

(ii) any adverse impacts that the State of Emergency is having on the RECLAIM program; and

(iii) any potential changes to the RECLAIM program that will be needed to help correct these impacts.

(g) High Employment/Low Emissions (HILO) Facility

The Executive Officer or designee will establish a HILO bank funded with the following maximum total annual emission Allocations:

(1) 91 tons per year of NO_X

(2) 91 tons per year of ~~So_X~~SO_X

(3) After January 1, 1997, new facilities may apply to the HILO bank in order to obtain non-tradable RTCs. Requests will be processed on a first-come, first-served basis, pending qualification.

(4) When credits are available, annual Allocations will be granted for the year of application and all subsequent years.

(5) HILO facilities receiving such Allocations from the HILO bank must verify their HILO status on an annual basis through their APEP report.

(6) Failure to qualify will result in all subsequent years' credits being returned to the HILO bank.

(7) Facilities failing to qualify for the HILO bank Allocations may reapply at any time during the next or subsequent compliance year when credits are available.

(h) Non-Tradable Allocation Credits

(1) Any existing RECLAIM facility with reported emissions pursuant to Rule 301 - Permit Fees, in either 1987, 1988, or 1993, greater than its starting Allocation, shall be assigned non-tradable credits for the first three years of the program which shall be determined according to the following methodology:

Non-tradable credit for NO_X and SO_X:

Year 1 = $(\Sigma [A \times B_1])$ - 1994 Allocation;

Where:

A	=	the throughput for each NO_X or SO_X source or process unit in the facility from the single maximum throughput year from 1987, 1988, or 1993; and
B_1	=	the applicable starting emission factor, as specified in Table 1 or Table 2.
Year 2	=	Year 1 non-tradable credits X 0.667
Year 3	=	Year 1 non-tradable credits X 0.333
Year 4 and subsequent years	=	Zero non-tradable credit.

(2) The use of non-tradable credits shall be subject to the following requirements:

(A) Non-tradable credits may only be used for an increase in throughput over that used to determine the facility's starting Allocation. Non-tradable credits may not be used for emissions increases associated with equipment modifications, change in feedstock or raw materials, or any other changes except increases in throughput. The Executive Officer or designee may impose Facility Permit conditions necessary to ensure compliance with this subparagraph.

(B) The use of activated non-tradable credits shall be subject to a non-tradable RTC mitigation fee, as specified in Rule 301 subdivision (n).

(C) In order to utilize non-tradable credits, the Facility Permit holder shall submit a request to the Executive Officer or designee in writing, including a demonstration that the use of the non-tradable credits complies with all requirements of this paragraph, pay any fees required pursuant to Rule 301 - Fees, and have received written approval from the Executive Officer or designee for their use. The Executive Officer or designee shall deny the request unless the Facility Permit holder demonstrates compliance with all requirements of this paragraph. The Executive Officer or designee shall, in writing, approve or deny the request within three business days of submittal of a complete request and notify the Facility Permit holder of the decision. If the request is denied, the Executive Officer or designee will refund the mitigation fee.

(D) In the event that a facility transfers any RTCs for the year in which non-tradable credits have been issued, the non-tradable credit Allocation shall be invalid, and is no longer available to the facility.

~~(i) RTC Reduction Exemption~~

~~(1) A facility may file an application for Executive Officer approval to be exempted from all or a portion of the requirements pursuant to subparagraphs (f)(1)(A) with the exception of RTC holdings as of January 7, 2005 and thereafter in excess of the initial allocation. For the purposes of this rule, initial allocation refers to the RTCs issued by the District to a facility upon entering the RECLAIM program. The application shall~~

~~contain sufficient data to demonstrate to the satisfaction of the Executive Officer that the facility meets the following criteria:~~

~~(A)~~ ~~the facility has been in the program since the start of RECLAIM, or existed prior to 1994, but subsequently entered RECLAIM pursuant to Rule 2001 because facility emissions exceeded 4 tons per year;~~

~~(B)~~ ~~at least 99 percent of the facility's emissions reported for compliance year is from equipment not listed in Table 3 and the achieved emission rates for each and every piece of equipment at the facility is less than or equal to the 2000 (Tier I) Ending Emission Factor listed in Table 1 or the emission factor listed in Table 3, whichever is lower, for the corresponding equipment type;~~

~~(C)~~ ~~RTCs that were part of the total initial allocation for the facility have never been transferred or sold by the facility for year2007 or later; and~~

~~(D)~~ ~~the cumulative NOx compliance costs incurred by the facility up to the submittal date of the application as specified in paragraph (i)(3) to comply with the RECLAIM Allocation as required under Rule 2004(b) and (d)(1) exceed the compliance costs that otherwise would have occurred to meet and maintain emission limits specified in Table 1, for each and every piece of equipment at the facility. The compliance costs shall be based on the following parameters:~~

~~(i)~~ ~~cost of controlling emissions using the parameters and procedures for determining total direct and indirect capital investment and total annual costs as specified in the most recent edition of the Control Cost Manual published by the U.S. EPA Office of Air Quality and Planning Standards, excluding control costs for any equipment listed in Table 3, if any;~~

~~(ii)~~ ~~realized and anticipated revenues and expenditures of the Facility Permit holder resulting from buying and selling any RTCs that are or were held by the facility where the contract of sale or purchase was executed prior to the date of application for exemption pursuant to paragraph (i)(1);~~

~~(iii) costs associated with compliance with the New Source Review provisions of Rule 2005, Rule 2012(c), or other applicable state or federal requirements shall not be included;~~

~~(iv) costs that result only in improving process efficiency or product quality, costs of projects that were initiated before the date the facility was subject to RECLAIM requirements, or legal costs or any other costs that do not directly reduce NOx emissions shall not be included; and~~

~~(v) any cost savings that resulted in implementing any NOx emissions strategy, such as fuel savings, increased production or sale; or~~

~~(2) A facility may file an application for Executive Officer approval to be exempted from all or a portion of the requirements pursuant to subparagraph (f)(1)(A) for the initial allocations portion of a facility's RTC holdings provided that the facility meets all of the following:~~

~~(A) The facility's starting and year 2000 Allocations were calculated using the same emission factors that are equal to or lower than the 2000 (Tier 1) emission factors listed in Table 1;~~

~~(B) Emission rate achieved for each source at the facility is less than or equal to the emission factors listed in Table 3 for the corresponding equipment type; and~~

~~(C) RTCs for 2007 or later compliance years for the facility have never been transferred or sold.~~

~~(3) A facility shall submit the applications specified pursuant to paragraphs (i)(1) or (i)(2) no later than July 7, 2005, pay the appropriate evaluation fee pursuant to Rule 306, and accept enforceable permit conditions to ensure compliance with the provisions of this subdivision, in order for the Executive Officer to approve the exemption. If approved, the facility's initial RTC allocation shall be designated as non-tradable and additional RTCs purchased above the initial allocation shall be subject to the RTC adjustments specified in subparagraph (f)(1)(A), as appropriate. The Executive Officer shall deny an application that is not filed within the time periods specified in this paragraph, lacks any information specified under paragraph (i)(7), or fails to demonstrate that it meets the requirements in paragraphs (i)(1) or (i)(2).~~

~~(4) Upon approval the exemption shall:~~

~~(A) be limited to the adjustment factors specified in subparagraph (f)(1)(A);~~

~~(B) begin the next compliance year following the exemption approval; and~~

~~(C) not apply to reductions resulting from future periodic BARCT review.~~

~~(5) RTC adjustments exempted pursuant to this subdivision shall be distributed proportionally among the remainder of the RTC holders and implemented two years from the compliance year of the applicable exemption and are subject to applicable paragraph (f)(1) provisions. Public notification of the distributed reductions shall occur at least one year prior to implementation.~~

~~(6) A Facility Permit holder has the right to appeal the denial of the exemption application to the Hearing Board in the same manner as a permit denial as specified in Health and Safety Code Section 42302.~~

~~(7) An application submitted to request an exemption from the RTCs reduction pursuant to paragraphs (i)(1) or (i)(2) shall include the following information.~~

~~(A) Detailed description of each project and itemized listing of how it relates to meeting the RECLAIM reduction requirements;~~

~~(B) Date of start and completion of each project listed in (A);~~

~~(C) Detailed calculations or emissions data demonstrating NOx emission reductions resulting from each project or combination of projects directly resulting in reductions. The emission levels achieved shall be based on actual CEMS data or source tests results;~~

~~(D) Itemized revenue and expenditures for each RTC trading activity since participation in the RECLAIM program;~~

~~(E) Itemized costs for each project and corresponding receipts or other equivalent documentation as approved by the Executive Officer for such expenditures; and~~

~~(F) Cost savings resulting from each project(s) (e.g. fuel savings, improved productivity, increased sales, etc.) and documentation of the values of such savings.~~

~~(8) A facility qualifying for exemption shall report as part of its Annual Permit Emission Program (APEP) report, submitted pursuant to Rule 2004(b)(4), whether or not emissions from equipment listed in Tables 3, if any, remain~~

~~less than or equal to 1 percent of the total facility emissions on an annual basis for the duration of the exemption. If the emissions exceed 1 percent, the facility shall be in violation of the rule for each and every day of the compliance year and the Executive Officer shall reduce the facility's initial allocation for the next compliance year to the emissions level specified for that year pursuant to subparagraph (f)(1)(A).~~

~~(9) A facility applying for exemption shall have 1 percent of its initial allocations subject to the requirements pursuant to subparagraph (f)(1)(A).~~

~~(10) Non-tradable RTC allocations designated pursuant to paragraph (i)(3) shall become tradable in the event the facility permanently ceases to operate.~~

(i) Facility and Equipment Shutdowns

(1) Starting (*date of amendment*) the highest ranking official of any facility listed in Table 7 or 8 selling any infinite year block (IYB) RTCs shall provide the Executive Officer a written statement that there is no current intent~~*ion*~~ to shut down the facility within the next five years. For the purpose of this rule, IYB refer to trades involving blocks of RTCs with a specified start year and continuing into the future for ten or more years.

(2) On or after [*2 years after date of amendment*], ~~*A*~~any Facility Permit Holder of a facility listed in Table 7 or 8 permanently shutting down ~~*some or all*~~one or more pieces of equipment with emissions greater than or equal to 25 percent of the facility's total NOx emissions for any quarter within the previous 2 compliance years shall surrender:

(A) NOx RTCs as determined under paragraph (i)(3) to the District for retirement from the RECLAIM Program; and

(B) the permit(s) for the equipment that is shutdown.

Equipment shall be deemed permanently shut down and subject to the RTC and permit surrender requirements of this paragraph if it is non-operational for a period of two consecutive years or longer, unless the Executive Officer determines, based on evidence provided by the operator, that the subject equipment is used in a cyclical operation with a cyclic period of two or more years, or that the equipment's period of non-operation extends beyond two years due to circumstances that are beyond the control of the operator and otherwise the equipment would have been fully operational.

(3) The NOx RTCs to be surrendered as specified in paragraph (i)(2) shall include those valid for all compliance years starting from the compliance year after the shutdown occurs and be equal to the NOx Allocations issued by the District to the facility multiplied by the maximum quarterly ratio in the previous 2 years. For the purposes of this rule, each quarterly ratio shall be calculated as follows:

$$Quarterly\ Ratio = \frac{Quarterly\ NOx\ emissions\ from\ the\ shutdown\ equipment}{Total\ facility\ \cancel{certified}\ quarterly\ NOx\ emissions\ for\ the\ same\ quarter}$$

(4) The requirements specified in paragraphs (i)(2) and (i)(3) shall not apply to shutdown equipment for which the equipment's operational capacity is replaced by new or existing equipment serving the same functional needs at the same facility or another facility under common control.

(5) Notwithstanding the requirements of Rule 204, the Executive Officer shall notify the Facility Permit Holder 60 days prior to re-issuing the Facility Permit to reflect removal of the shutdown equipment from the Facility Permit.

Table 1

RECLAIM NO_X Emission Factors

Nitrogen Oxides Basic Equipment	Fuel	"Throughput" Units	Starting Ems Factor *	2000 (Tier I) Ending Ems Factor *

PROPOSED AMENDED RULE 2005. NEW SOURCE REVIEW FOR RECLAIM

(a) Purpose

This rule sets forth pre-construction review requirements for new facilities subject to the requirements of the RECLAIM program, for modifications to RECLAIM facilities, and for facilities which increase their allocation to a level greater than their starting Allocation plus non-tradable credits. The purpose of this rule is to ensure that the operation of such facilities does not interfere with progress in attainment of the National Ambient Air Quality Standards, and that future economic growth in the South Coast Air Basin is not unnecessarily restricted.

(b) Requirements for New or Relocated RECLAIM Facilities

(1) The Executive Officer shall not approve the application for a Facility Permit to authorize construction or installation of a new or relocated facility unless the applicant demonstrates that:

(A) Best Available Control Technology will be applied to every emission source located at the facility; and

(B) the operation of any emission source located at the new or relocated facility will not cause a violation nor make significantly worse an existing violation of the state or national ambient air quality standard at any receptor location in the District for NO2 as specified in Appendix A. The applicant shall use the modeling procedures specified in Appendix A.

(2) The Executive Officer shall not approve the application for a Facility Permit authorizing operation of a new or relocated facility, unless the applicant demonstrates that:

(A) the facility holds sufficient RTCs, including any RTCs from Table 9 in Rule 2002, to offset the total facility emissions for the first year of operation, at a 1-to-1 ratio; and

(B) the RTCs procured to comply with the requirements of subparagraph (b)(2)(A) were obtained pursuant to the requirements of subdivision (e), and

(C) the total facility emissions determined to comply with the requirements of subparagraph (b)(2)(A) shall also include ship emissions directly associated with activities at stationary sources subject to this rule as follows:

(i) all emissions from ships during the loading and unloading of cargo and while at berth where the cargo is loaded or unloaded; and

(ii) non-propulsion ship emissions within coastal waters under District jurisdiction.

(c) Requirements for Existing RECLAIM Facilities, Modification to New RECLAIM Facilities, Facilities which Undergo a Change of Operator, or Facilities which Increase an Annual Allocation to a Level Greater Than the Facility's Starting Allocation Plus Non-tradable Credits.

(1) The Executive Officer shall not approve an application for a Facility Permit Amendment to authorize the installation of a new source or modification of an existing source which results in an emission increase as defined in subdivision (d), unless the applicant demonstrates that:

(A) Best Available Control Technology will be applied to the source; and

(B) the operation of the source will not result in a significant increase in the air quality concentration for NO2 as specified in Appendix A. The applicant shall use the modeling procedures specified in Appendix A.

(2) The Executive Officer shall not approve an application for a Facility Permit Amendment to authorize operation of the new or modified source which results in an emission increase as defined in subdivision (d), unless the applicant demonstrates that the facility holds sufficient RTCs to offset the annual emission increase for the first year of operation at a 1-to-1 ratio.

(3) The Executive Officer shall not approve an application for Change of Operator for a Facility Permit unless the applicant demonstrates that the facility holds sufficient RTCs for the compliance year in which the change of operator permit is issued. Credits must be held in an amount equal to:

(A) The annual Allocation initially issued to the original Facility Permit holder for existing facility as defined in Rule 2000 for the same compliance year, in which the change of operator permit is issued, multiplied, where applicable, by the Tradable/Usable RTC Adjustment Factor for the same compliance year as listed in Rule 2002(f)(1)(A); or

(B) The sum of annual RECLAIM pollutants from all the sources located at the facility. The amount of annual RECLAIM pollutants for each source shall be calculated by the maximum hourly potential to emit, over an operating schedule of 24 hours per day and 365 days per year, or shall be based on a permit condition limiting the source's emission.

(4) The Executive Officer shall not approve an application to increase an annual Allocation to a level greater than the facility's starting Allocation plus non-tradable credits, unless the applicant demonstrates that:

(A) each source which creates an emission increase as defined in subdivision (d) will:

(i) apply Best Available Control Technology;

(ii) not result in a significant increase in the air quality concentration for NO2 as specified in Appendix A; and

(B) the facility holds sufficient RTCs acquired pursuant to subdivision (e) to offset the annual increase in the facility's starting Allocation plus non-tradable credits at a 1-to-1 ratio for a minimum of one year.

(d) Emission Increase

An increase in emissions occurs if a source's maximum hourly potential to emit immediately prior to the proposed modification is less than the source's post-modification maximum hourly potential to emit. The amount of emission increase will be determined by comparing pre-modification and post-modification emissions on an annual basis by using: (1) an operating schedule of 24 hours per day, 365 days per year; or (2) a permit condition limiting mass emissions.

(e) Trading Zones Restrictions

Any increase in an annual Allocation to a level greater than the facility's starting plus non-tradable Allocations, and all emissions from a new or relocated facility must be fully offset by obtaining RTCs originated in one of the two trading zones as illustrated in the RECLAIM Trading Zones Map. A facility in Zone 1 may only obtain RTCs from Zone 1. A facility in Zone 2 may obtain RTCs from either Zone 1 or 2, or both.

(f) Offsets

The Facility Permit for a new or modified facility shall require compliance with this subdivision, if applicable.

(1) Any facility which was required to provide offsets pursuant to paragraphs (b)(2), or subparagraph (c)(4)(B) or any new facility required to provide offsets pursuant to paragraph (c)(2) shall, at the commencement of each compliance year, hold RTCs, including any RTCs from Table 9 in Rule 2002, in an amount equal to the amount of such required offsets. The Facility Permit holder may reduce the amount of offsets required pursuant to this subdivision by accepting a permit condition limiting emissions which shall serve in lieu of the starting Allocation plus non-tradable credits for purposes of paragraph (c)(4).

(2) Except for the RTCs referenced in Table 9 of Rule 2002, ~~Unused~~ unused RTCs acquired to comply with this subdivision or with paragraphs (b)(2), (c)(2), or subparagraph (c)(4)(B) may be sold only during the reconciliation period for the fourth quarter of the applicable compliance year.

(3) In lieu of compliance with paragraph (f)(2), the Facility Permit holder may accept a permit condition limiting quarterly emissions from the facility. A facility with quarterly emission limits may sell, at any time after the end of that quarter and prior to the end of the reconciliation period for that compliance year, unused RTCs acquired pursuant to this subdivision, excluding the RTCs referenced in Table 9 of Rule 2002, at the amount not to exceed the difference between the permitted emission limit for that quarter and the emissions during that quarter as reported to the District in the Quarterly Emission Certification. Any facility with quarterly certified emissions exceeding the quarterly emission limit for any quarter may sell RTCs, excluding the RTCs referenced in Table 9 of Rule 2002, only during the reconciliation period for the fourth quarter of the applicable compliance year. If there are a total of three exceedances in any five consecutive compliance years, the facility shall permanently comply with paragraph (f)(2) in lieu of (f)(3).

(g) Additional Federal Requirements for Major Stationary Sources

The Executive Officer shall not approve the application for a Facility Permit or an Amendment to a Facility Permit for a new, relocated or modified major stationary source, as defined in the Clean Air Act, 42 U.S.C. Section 7511a(e), unless the applicant:

(1) certifies that all other major stationary sources in the state which are controlled by the applicant are in compliance or on a schedule for compliance with all applicable federal emission limitations or standards (42 U.S.C. Section 7503(a)(3)); and

(2) submits an analysis of alternative sites, sizes, production processes and environmental control techniques for the proposed source which demonstrates that the benefits of the proposed source significantly outweigh the environmental and social cost imposed as a result of its location, construction, or modification (42 U.S.C. Section 7503(a)(5));

(3) Compliance Through California Environmental Quality Act

The requirements of paragraph (g)(2) may be met through compliance with the California Environmental Quality Act in the following manner.

(A) if the proposed project is exempt from California Environmental Quality Act analysis pursuant to a statutory or categorical exemption pursuant to Title 14, California Code of Regulations, Sections 15260 to 15329, paragraph (g)(2) shall not apply to that project;

(B) if the proposed project qualifies for a negative declaration pursuant to Title 14 California Code of Regulations, Section 15070, or a mitigated negative declaration as defined in Public Resources Code Section 21064.5, paragraph (g)(2) shall not apply to that project; or

(C) if the proposed project has been analyzed by an environmental impact report pursuant to Public Resources Code Section 21002.1 and Title 14 California Code of Regulations, Section 15080 et seq., paragraph (g)(2) shall be deemed satisfied.

(4) Protection of Visibility

(A) Conduct a modeling analysis for plume visibility in accordance with the procedures specified in Appendix B if the net emission increase from the new or modified source exceeds 40 tons/year of NO_X; and the location of the source, relative to the closest boundary of a specified_Federal Class I area, is within the distance specified in Table 4-1.

Table 4-1

Federal Class I Area	*Distance (km)*
Agua Tibia	28
Cucamonga	28
Joshua Tree	29
San Gabriel	29
San Gorgonio	32
San Jacinto	28

(B) In relation to a permit application subject to the modeling analysis required by subparagraph (g)(4)(A), the Executive Officer shall:

(i) deem a permit application complete only when the applicant has complied with the requisite modeling analysis for plume visibility pursuant to subparagraph (g)(4)(A);

(ii) notify and provide a copy of the complete permit application file to the applicable Federal Land Manager(s) within 30 calendar days after the application has been deemed complete and at least 60 days prior to final action on the permit application;

(iii) consider written comments, relative to visibility impacts from the new or modified source, from the responsible Federal Land Manager(s), including any regional haze modeling performed by the Federal Land Manager(s), received within 30 days of the date of notification when determining the terms and conditions of the permit;

(iv) consider the Federal Land Manager(s) findings with respect to the geographic extent, intensity, duration, frequency and time of any identified visibility impairment of an affected Federal Class I area, including how these factors correlate with times of visitor use of the Federal Class I area, and the frequency and timing of natural conditions that reduce visibility; and,

(v) explain its decision or give notice as to where to obtain this explanation if the Executive Officer finds that the Federal Land Manager(s) analysis does not demonstrate that a new or modified source may have an adverse impact on visibility in an affected Federal Class I area.

(C) If a project has an adverse impact on visibility in an affected Federal Class I area, the Executive Officer may consider the cost of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, the useful life of the source, and all other relevant factors in determining whether to issue or deny the Permit to Construct or Permit to Operate.

(h) Public Notice

The applicant shall provide public notice, if required, pursuant to Rule 212 - Standards for Approving Permits.

(i) Rule 1401

All new or modified sources shall comply with the requirements of Rule 1401 - New Source Review of Carcinogenic Air Contaminants, if applicable.

(j) Compliance with State and Federal New Source Review Requirements

The Executive Officer will report to the District Governing Board regarding the effectiveness of Rule 2005 in meeting the state and federal New Source Review requirements for the preceding year. The Executive Officer may impose permit conditions to monitor and ensure compliance with such requirements. This report shall be incorporated in the Annual Program Audit Report prepared pursuant to Rule 2015(b)(1).

(k) Exemptions

(1) Functionally identical source replacements are exempt from the requirements of subparagraph (c)(1)(B) of this rule.

(2) Physical modifications that consist of the installation of equipment where the modification will not increase the emissions rate of any RECLAIM pollutant, and will not cause an increase in emissions above the facility's current year Allocation, shall be exempt from the requirements of paragraph (c)(2).

(3) Increases in hours of operation or throughput for equipment or processes permitted prior to October 15, 1993 that the applicant demonstrates would not violate any permit conditions in effect on October 15, 1993 which were imposed in order to limit emissions to implement New Source Review offset requirements, shall be exempt from the requirements of this rule.

(4) Increase to RECLAIM emission concentration limits or emission rates not associated with Best Available Control Technology permit conditions provided that the increase is not a result of any modification to equipment shall be exempt from the requirements of this rule.

(5) The requirements under subparagraphs (b)(1)(B) and (c)(1)(B), and clause (c)(4)(A)(ii) shall not apply to equipment used exclusively on a standby basis for non-utility electrical power generation or any other equipment used on a standby basis in case of emergency, provided the source does not operate more than 200 hours per year as evidenced by an engine-hour meter or equivalent method and is listed as emergency equipment in the Facility Permit.

APPENDIX A

The following sets forth the procedure for complying with the air quality modeling requirements. An applicant must either (1) provide an analysis approved by the Executive Officer or designee, or (2) show by using the Screening Analysis below, that a significant change (increase) in air quality concentration will not occur at any receptor location for which the state or national ambient air quality standard for NO_2 is exceeded.

Table A-1 of the screening analysis is subject to change by the Executive Officer, based on improved modeling data.

SCREENING ANALYSIS

Compare the emissions from the equipment you are applying for to those in Table A-1. If the emissions are less than the allowable emissions, no further analysis is required. If the emissions are greater than the allowable emissions, a more detailed air quality modeling analysis is required.

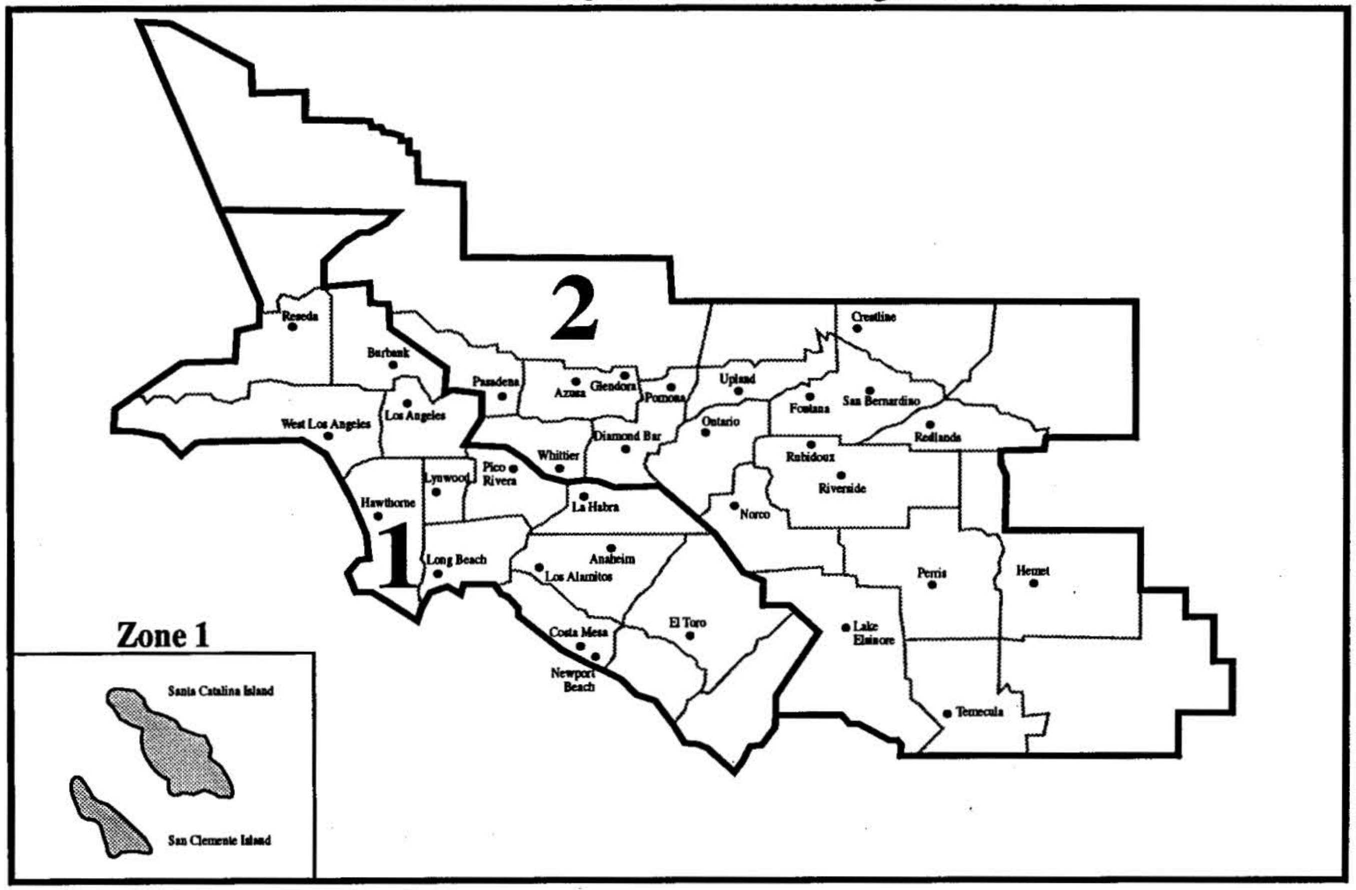
Table A-1
Allowable Emissions
for Noncombustion Sources and for
Combustion Sources less than 40 Million BTUs per hour

Heat Input Capacity (million BTUs/hr)	NOx (lbs/hr)
Noncombustion Source	0.068
2	0.20
5	0.31
10	0.47
20	0.86
30	1.26
40	1.31

Table A-2
Most Stringent Ambient Air Quality Standard and
Allowable Change in Concentration
For Each Air Contaminant/Averaging Time Combination

Air Contaminant	Averaging Time	Most Stringent Air Quality Standard		Significant Change in Air Quality Concentration	
Nitrogen Dioxide	1-hour	25 pphm	500 ug/m^3	1 pphm	20 ug/m^3
	Annual	5.3 pphm	100 ug/m^3	0.05 pphm	1 ug/m^3

RECLAIM Trading Zones
South Coast AQMD Air Monitoring Stations



APPENDIX B

MODELING ANALYSIS FOR VISIBILITY

(a) The modeling analysis performed by the applicant shall consider:

(1) the net emission increase from the new or modified source; and

(2) the location of the source and its distance to the closest boundary of specified Federal Class I area(s).

(b) Level 1 and 2 screening analysis for adverse plume impact pursuant to paragraph (g)(4) of this rule for modeling analysis of plume visibility shall consider the following applicable screening background visual ranges:

Federal Class I Area	Screening Background Visual Range (km)
Agua Tibia	171
Cucamonga	171
Joshua Tree	180
San Gabriel	175
San Gorgonio	192
San Jacinto	171

For level 1 and 2 screening analysis, no adverse plume impact on visibility results when the total color contrast value (Delta-E) is 2.0 or less and the plume contrast value (C) is 0.05 or less. If these values are exceeded, the Executive Officer shall require additional modeling. For level 3 analysis the appropriate background visual range, in consultation with the Executive Officer, shall be used. The Executive Officer may determine that there is no adverse visibility impact based on substantial evidence provided by the project applicant.

(c) When more detailed modeling is required to determine the project's visibility impact or when an air quality model specified in the Guidelines below is deemed inappropriate by the Executive Officer for a specific source-receptor application, the model may be modified or another model substituted with prior written approval by the Executive Officer, in consultation with the federal Environmental Protection Agency and the Federal Land Managers.

(d) The modeling analysis for plume visibility required pursuant to paragraph (g)(4) of this rule shall comply with the most recent version of:

(1) "Guideline on Air Quality Model (Revised)" (1986), supplement A (1987), supplement B (1993) and supplement C (1994), EPA-450/2-78-027R, US EPA, Office of Air Quality Planning and Standards Research Triangle Park, NC 27711; and

(2) "Workbook for Plume Visual Impact Screening and Analysis (Revised)," EPA-454-/R-92-023, US EPA, Office of Air Quality Planning and Standards, Research Triangle Park, NC 27711;

(3) "User's Manual for the Plume Visibility Model (PLUVUE II) (Revised)," EPA-454/B-92-008, US EPA, Office of Air Quality Planning and Standards, Research Triangle Park, NC 27711 (for Level-3 Visibility Analysis)

PROPOSED AMENDED RULE 2011 PROTOCOL- CHAPTER 3

PROCESS UNITS - PERIODIC REPORTING AND RULE 219 EQUIPMENT

TABLE OF CONTENTS

CHAPTER 3 - PROCESS UNITS - PERIODIC REPORTING

A. General Requirements 2011A-3-1
B. Emission Calculations for Reported Data 2011A-3-2
C. Total Quarterly Emissions Calculation for all SOx Process Units at the Facility 2011A-3-6
D. Reporting Procedures 2011A-3-7
E. Fuel Meter Sharing 2011A-3-7
F. Rule 219 Equipment 2011A-3-7
G. Substitute Data Procedures 2011A-3-9

Process units may share fuel meters if each equipment has the same emission factor. This chapter also includes the equations describing the methods used to calculate SO_x process unit emissions and the reporting procedures. The interim reporting period does not apply to process units since existing fuel metering equipment or timers shall be used- starting January 1, 1994 for Cycle 1 facilities and July 1, 1994 for Cycle 2 facilities.

A. GENERAL REQUIREMENTS

1. The equipment-specific or category-specific starting emission factor found in Table 2 of Rule 2002 - Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx) shall be used for quantifying quarterly mass emissions for a SOx process unit.

2. Instead of using the equipment-specific or category-specific starting emission factor found in Table 2 of Rule 2002, the Facility Permit holder of a process unit may apply to the Executive Officer to use a representative emission factor or alternative emission factor for purposes of calculating SO_x emissions. The alternative emission factor shall be established by the requirements provided in Chapter 6, Subdivision E.

3. The Facility Permit holder of a process unit shall use an emission factor or alternative emission factor to calculate the mass emission according to the methodology specified in Chapter 3, Subdivision B, Paragraph 2. (fuel totalizing meters) or Chapter 3, Subdivision B, Paragraph 3, Subparagraph a (timers).

4. The Facility Permit holder of each SO_x process unit shall use a totalizing fuel meter or timer as applicable and specified in the Facility Permit for each affected equipment to measure and report the variables listed in Tables 3-A and 3-B, respectively, for each equipment.

5. The Facility Permit holder of each SO_x process unit shall monitor, report and maintain the following records on a quarterly basis:

    a. Type and quantity of fuel burned in units of million standard cubic feet per quarter (mmscf per quarter) for gaseous fuels or thousand gallons per quarter (mgal per quarter) for liquid fuels, expressed with three significant figures minimum; or

    b. Total hours of operation.

6. The Facility Permit holder of each SO_x process unit shall also provide any other data necessary for calculating the emission rates of oxides of sulfur as determined by the Executive Officer.

7. Fuel meters and/or timers must be non-resettable and tamper-proof. They shall have seals installed by the meter/timer manufacturer to prove the integrity of the measuring device.

    Meters which are unsealed for maintenance or repairs shall be resealed by an authorized manufacturers representative.

B. EMISSION CALCULATIONS FOR REPORTED DATA

1. Quarterly Mass Emissions for Interim Periods (January 1, 1994 thru December 31, 1994 for Cycle 1 facilities; and July 1, 1994 thru June 30, 1995 for Cycle 2 facilities)

a. Pursuant to Rules 2011(d)(3) and 2011(f)(2), starting January 1, 1994 for Cycle 1 facilities, and starting July 1, 1994 for Cycle 2 facilities, the quarterly emission of each process unit shall be calculated and recorded according to:

$$E_{ip} = \sum_{j=1}^{r} d_j \times EF_{sj} \qquad \text{(Eq.15)}$$

where:

E_{ip} = The quarterly mass emission of sulfur oxides for interim period (lb/quarter).

d_j = The quarterly fuel usage for each type of fuel recorded as mmscf/quarter or mgal/quarter.

EF_{sj} = The starting emission factor used to calculate unit emissions in the initial allocation, as specified in Table 2 of Rule 2002 - Allocations for Oxides of Nitrogen (NO_x) and Oxides of Sulfur (SO_x) (lb/mmscf or lb/mgal,).

r = The number of different types of fuel.

Example calculation: IC engine burning natural gas

Starting Emission factor = 0.60 lb/mmscf
Quarterly fuel usage = 2 mmscf/quarter

E_{ip} = (0.60) x (2.0)
= 1.2 lb/quarter

2. Totalizing Fuel Meter Based Calculations

The Facility Permit holder of each equipment in a SO_x process unit when equipped with a totalizing fuel meter shall use emission factor listed in Table 2 of Rule 2002 or alternative emission factors established according to the methodology provided in Chapter 4 to obtain the quarterly mass emissions according to:

$$E_{EF} = \sum_{k=1}^{n} d_k \times EF_k \qquad \text{Eq.15)}$$

where:

E_{EF} = The quarterly emissions of SO_x obtained using emission factor (lb/quarter.)

d_k = The quarterly fuel usage for each type of fuel (mmscf/quarter or mgal/quarter.)

EF_k = The emission factor as specified in Table 2 of Rule 2002 - Allocations for Oxides of Nitrogen (NO_x) and Oxides of Sulfur (SO_x) (lb/mmscf, lb/mgal or lb/mbbl) or an alternative emission factor proposed by the Facility Permit holder as established from the source test requirement provided in Chapter 4

k = Each type of gaseous or liquid fuel consumed by each process unit throughout the quarter.

n = The total number of different types of fuel consumed by each process unit throughout the quarter

3. Timer-Based Emission Calculations

If the SOx process unit is equipped with a timer~~.~~, the Facility Permit holder shall quantify~~*estimate*~~ the quarterly fuel usage for each affected equipment according to Eq. 17 - Eq. 20 and calculate~~*estimate*~~ the quarterly mass emissions according to Eq. 16 - Eq. 20.

a. Quarterly Fuel Usage for Each Affected SO_x Process Unit

If the SO_x process unit does not measure ~~a~~ fuel usage with a fuel meter, the quarterly fuel usage for each affected equipment in a process unit shall be ~~*estimated*~~ quantified according to:

$$d = d_{pu} \times (H/H_{pu}) \qquad \text{(Eq.17)}$$

Where:

d = ——The ~~estimated~~ quarterly fuel usage of an affected SO_x process unit without a dedicated fuel meter (mmscf/quarter or mgal/quarter).

d_{pu} = The quarterly fuel usage of all SO_x process units at the facility (mmscf/quarter or mgal/quarter).

H = The quarterly heat input of an affected SO_x process unit without a dedicated fuel meter (mmBtu/quarter).

H_{pu} = ——The quarterly heat input of all SO_x process units at the facility (mmBtu/quarter).

Example Calculation:

d_{pu} = 1,587 mmscf/quarter

H = 5,400 mmBtu/quarter

H_{pu} = 27,000 mmBtu/quarter

d = d_{pu} x (H/H_{pu})

d = 1,587 mmscf/quarter x (5,400 mmBtu/quarter – 27,000 mmBtu/quarter

d = 317.4 mmscf/quarter

The quarterly fuel usage for all SO_x process units at the facility (d_{pu}) shall be calculated according to the following equation:

$$d_{pu} = d_{fac} - d_{major} \quad \text{(Eq.18)}$$

where:

d_{fac} = The quarterly fuel usage of all major sources and SO_x process units at the facility (mmscf/quarter or mgal/quarter).

d_{major} = The quarterly fuel usage of all major SO_x sources at the facility (mmscf/quarter or mgal/quarter).

Example Calculation:

d_{fac} = 58 mmscf/quarter
d_{major} = 42 mmscf/quarter
d_{pu} = F_{fac} - F_{major}
d_{pu} = 58 - 42
d_{pu} = 16 mmscf/quarter

The quarterly heat input of all SO_x process units at the facility (H_{pu}) shall be calculated according to:

$$H_{pu} = \sum_{i=1}^{n}(R_i \times T_i) \qquad \text{(Eq.19)}$$

where:

R_i = The maximum rated heat input capacity of a SO_x process unit (mmBtu/hr).

T_i = The quarterly accumulated operation hours for a SO_x process unit (hr/quarter).

i = Each process unit

n = The total number of SO_x process units at the facility.

Example Calculation:

R_1 = 3.5 mmBtu/hr
R_2 = 2.7 mmBtu/hr
T_1 = 480 hr/quarter
T_2 = 120 hr/quarter

$$H_{pu} = \sum_{i=1}^{2} (R_i \times T_i)$$

H_{pu} = (3.5 x 480) + (2.7 x 120)
H_{pu} = 2004 mmBtu/quarter

The maximum rated heat input capacity of all SO_x process units shall be in units of mmBtu/hr. Since internal combustion engines are usually rated in units of brake horse power, the maximum rated heat input capacity of an engine shall be computed as follows.

$$R = 0.002545 \times bhp / eff \qquad \text{(Eq.20)}$$

where:

R	=	The maximum rated heat input capacity
eff	=	The manufacturer's rated efficiency @LHV x (LHV/HHV)
	=	0.25, if not provided by the operator
bhp	=	The manufacturer's rated shaft output in brake horse power

Example Calculation:

eff	=	0.25
bhp	=	75 bhp
R	=	0.002545 x bhp / eff
R	=	0.002545 x 75/.25
R	=	0.7635 mmBtu/hr

If gas turbines are rated in kilowatts, the rating shall be converted to mmBtu/hr by applying the manufacturer's heat rate (in mmBtu/kw-hr). If the manufacturer's heat rate is not available, a default value of 15,000 Btu/kw-hr shall be used.

Example Calculation:

Quarterly fuel usage for an ICE with maximum rated bhp of 90 bhp, 0.25 eff and a boiler rated at 4 mmBtu/hr being served by one fuel totalizer reading 10.5 mmscf. The boiler and ICE burn landfill gas.

I.C.E.= 90 bhp Boiler= 4 mmBtu/hr C_g = 80 ppmv for landfill gas
Fuel meter reading = F_{pu} = 10.5 mmscf

I.C.E.

R = 0.002545 x 90/.25 = 0.916 mmBtu/hr
t = 3 hr/day x 7 days/wk. x 4 wk./mo. x 3 mo/qtr = 252 hr/qtr
H_{ice} = R x t = 0.916 x 252 = 230.8 mmBtu/qtr

Boiler

H_{boiler} = 4 mmBtu/hr x 24 hr./day x 7 day/wk. x 4 wk./mo. x 3 mo/qtr
H_{boiler} = 8064 mmBtu/qtr.
H_{pu} = 230.8 + 8064 = 8294.8 mmBtu/qtr.

$d_{ice} = d_{pu} \times (H_{ice}/H_{pu})$
= 10.5 mmscf/qtr. x (230.8/8294.8)
= .292 mmscf/qtr.

$d_{boiler} = d_{pu} \times (H_{boiler}/H_{pu})$
= 10.5 mmscf/qtr. x (8064/8294.8)
= 10.2 mmscf/qtr.

$E_{ice} = d_{ice} \times C_g \times 0.166$
E_{ice} = .292 mmscf/qtr x 80 ppmv x 0.166
E_{ice} = 3.88 lb/qtr.

$E_{boiler} = d_{boiler} \times C_g \times 0.166$
E_{boiler} = 10.2 mmscf/qtr x 80 ppmv x 0.166
E_{boiler} = 135 lb/qtr.

$E = E_{ice} + E_{boiler}$ = 3.88 + 135 = 138.88 lb/qtr.

C. TOTAL QUARTERLY EMISSIONS CALCULATION FOR ALL SO_X PROCESS UNITS AT THE FACILITY

Quarterly SO_x emissions of all SO_x process units at the facility shall be quantified~~estimated~~ according to:

$$E = \sum_{i=1}^{m} E_{EF} \qquad \text{(Eq.21)}$$

where:

E = The quarterly total emissions of SO_x for all SO_x process units (lb/quarter).

E_{EF} = The quarterly emissions of SO_X obtained using emission factor (lb/quarter).

i = Each process unit

m = The number of process units at the facility.

D. REPORTING PROCEDURES

1. The Facility Permit holder of any SO_x process unit that opts to monitor at the major source monitoring level shall meet the requirements set forth in Chapter 2 - "Major Sources - Continuous Emission Monitoring System."

2. The total recorded quarterly fuel usage data and SO_x emissions in pounds per quarter for all SO_x process units in any facility without RTU shall be recorded in a format approved by the Executive Officer and shall be submitted to the District as part of the Quarterly Certification of Emissions required by Rule 2004.

3. The Facility Permit holder of each SO_x process unit shall maintain daily records of hours of operation or quarterly usage for each SO_x process unit.

4. Any changes made in type of fuel used shall be recorded by the Facility Permit holder.

E. FUEL METER SHARING

1. A single totaling fuel meter shall be allowed to measure and record the fuel usage of more than one equipment in a process unit, provided that each piece of equipment elects for the same emission factor or alternative emission factor as specified in the Facility Permit.

2. Fuel meter sharing for the interim period shall be for those equipment in a process unit with the same emission factor.

F. RULE 219 EQUIPMENT

1. Emission Determination and Reporting Requirements

a. The Facility Permit holder shall determine the emissions for one or more equipment exempt under Rule 219 and report the emissions on a quarterly basis as part of the Quarterly Certified Emissions report required by Rule 2004. The Facility Permit holder shall be allowed to use the existing fuel totalizer, the monthly fuel billing statement, or any other equivalent methodology to quantify~~estimate~~ their fuel usage for a quarterly period.

b. Quarterly reporting period shall start on January 1, 1994 for Cycle 1 facilities and July 1, 1994 for Cycle 2 facilities.

c. The Facility Permit holder of each equipment shall maintain the quarterly fuel usage data for all equipment exempt under Rule 219 for three years. Such data shall be made available to District staff upon request.

d. The fuel usage for equipment exempt under Rule 219 may be used in conjunction with process units provided that they have the same emission factor.

2. Emission Calculations

The Facility Permit holder shall determine SO_x emissions for equipment exempt under Rule 219 as follows:

$$E_{EF} = \sum_{k=1}^{n} d_k \times EF_k \qquad \text{(Eq.22)}$$

where:

E_{EF} = The quarterly emissions of SO_x obtained using emission factor (lb /quarter).

d_k = The quarterly fuel usage for each type of fuel (mmscf/quarter or mgal/quarter).

EF_k = The emission factor as specified in Table 2 of Rule 2002 - Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx) (lb/mmscf, or lb/mgal or lb/mbbl or an alternative emission factor proposed by the Facility Permit holder as established from the source test requirement provided in chapter 4.

k = Each type of gaseous or liquid fuel consumed by each process unit throughout the quarter.

n = The total number of different types of fuel consumed by each process unit throughout the quarter.

3. Missing Data Periods

The Facility Permit holder shall determine SOx emissions for equipment exempt under Rule 219 using the substitute data procedures specified in Subdivision G of this Chapter for any quarter for which the Facility Permit holder did not obtain and record valid fuel consumption data as required by Subdivision F Paragraphs 1 and 2 of this Chapter.

G. SUBSTITUTE DATA PROCEDURES

1. For each process unit or process units using a common fuel meter, elapsed time meter, or equivalent monitoring device, the Facility Permit holder shall provide substitute data as described below whenever a valid quarter of usage data has not been obtained and recorded. Alternative data, based on a back-up fuel meter, elapsed time meter, or equivalent monitoring device, is acceptable for substitution if the Facility Permit holder can demonstrate to the Executive Officer that the alternative system is fully operational during meter down time and within + or - 2% accuracy. The substitute data procedures are retroactively applicable from the adoption date of the RECLAIM program.

2. Whenever data from the process monitor is not available or not recorded for the affected equipment or when the equipment is not operated within the parameter range specified in the Facility Permit, the Facility Permit holder shall calculate substitute data for each quarter, when valid data has not been obtained, according to the following procedures.

   a. For a missing data period less than or equal to one quarter, substitute data shall be calculated using the process unit(s) average quarterly fuel usage for the previous four quarters. If four quarters of data are not available, substitute data shall be calculated as if the facility has no records.

   b. For a missing data period greater than one quarter, substitute data shall be calculated using the process unit(s) highest quarterly fuel usage data for the previous four quarters. If four quarters of data are not available, substitute data shall be calculated as if the facility has no records.

   c. If the facility has no records, substitute data shall be calculated using 100% uptime during the substitution period and the process unit(s) maximum rated capacity and uncontrolled emission factor for each quarter of missing data.

PROPOSED AMENDED RULE 2011 PROTOCOL - ATTACHMENT C

QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES

TABLE OF CONTENTS

ATTACHMENT C - QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES

A. Quality Control Program..C-1
B. Frequency of Testing...C-2

ATTACHMENT C

QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES

A. QUALITY CONTROL PROGRAM

Develop and implement a quality control program for the continuous emission monitoring systems and their components. As a minimum, include in each quality control program a written plan that describes in detail complete, step-by-step procedures and operations for each of the following activities:

1. Calibration Error Test Procedures

Identify calibration error test procedures specific to the CEMS that may require variance from the procedures used during certification (for example, how the gases are to be injected, adjustments of flow rates and pressures, introduction of reference values, length of time for injection of calibration gases, steps for obtaining calibration error, determination of interferences, and when calibration adjustments should be made).

2. Calibration and Linearity Adjustments

Explain how each component of the CEMS shall be adjusted to provide correct responses to calibration gases, reference values, and/or indications of interference both initially and after repairs or corrective action. Identify equations, conversion factors, assumed moisture content, and other factors affecting calibration of each CEMS.

3. Preventative Maintenance

Keep a written record of procedures, necessary to maintain the CEMS in proper operating condition and a schedule for those procedures.

4. Audit Procedures

Keep copies of written reports received from testing firms/laboratories of procedures and details specific to the installed CEMS that were to be used by the testing firms/laboratories for relative accuracy test audits, such as sampling and analysis methods. The testing firms/laboratories shall have received approval from the District by going through the District's laboratory approval program.

5. Record Keeping Procedures

Keep a written record describing procedures that shall be used to implement the record keeping and reporting requirements.

Specific provisions of Section A-3 and A-5 above of the quality control programs shall constitute specific guidelines for facility personnel. However, facilities shall be required to take reasonable steps to monitor and assure implementation of such specific guidelines. Such reasonable steps may include periodic audits, issuance of periodic reminders, implementing training classes, discipline of employees as necessary, and other appropriate measures. Steps that a facility commits to take to monitor and assure implementation of the specific guidelines shall be set forth in the written plan and shall be the only elements of Section A-3 and A-5 that constitute enforceable requirements under the written plan, unless other program provisions are independently enforceable pursuant to other requirements of the SOx protocols or District or federal rules or regulations.

B. FREQUENCY OF TESTING

There are three situations which will result in an out-of-control period. These include failure of a calibration error test, failure of a relative accuracy test audit, and failure of a BIAS test, and are detailed in this subdivision. Data collected by a CEMS during an out-of-control period shall not be considered valid.

The frequency at which each quality assurance test must be given is as follows:

1. Periodic Assessments

For each monitor or CEMS, perform the following assessments during each day in which the unit combusts any fuel or processes any material (hereafter referred to as a "unit operating day"), or for a monitor or a CEMS on a bypass stack/duct, during each day that emissions pass through the bypass stack or duct. These requirements are effective as of the date when the monitor or CEMS completes certification testing.

a. Calibration Error Testing Requirements for Pollutant Concentration Monitors, Fuel Gas Sulfur Content Monitors, and O_2 Monitors

Test, record, and compute the calibration error of each SO_2 pollutant concentration monitor, fuel gas sulfur content monitor, if applicable, and O_2 monitor at least once on each unit operating day, or for monitors or monitoring systems on bypass stacks/ducts on each day that emissions pass through the bypass stack or duct. Conduct calibration error checks, to the extent practicable, approximately 24 hours apart. Perform the daily calibration error test according to the procedure in– Chapter 2, Subdivision B, Paragraph 1, Subparagraph a, Clause ii of this Attachment.

For units with more than one span range, perform the daily calibration error test on each scale that has been used since the last calibration error test. For example, if the emissions concentration or the fuel gas sulfur content has not exceeded the low-scale span range since the previous calendar day, the calibration error test may be performed on the low-scale only. If, however, the emissions concentration or the fuel gas sulfur content has exceeded the low-scale span range since the previous calibration error test, perform the calibration error test on both the low- and high-scales.

i. Design Requirements for Calibration Error Testing of SO_x Concentration Monitors, the Fuel Gas Sulfur Content Monitors, and O_2 Monitors

Design and equip each SO_x concentration monitor, fuel gas sulfur content monitor, and O_2 monitor with a calibration gas injection port that allows a check of the entire measurement system when calibration gases are introduced. For extractive and dilution type monitors, all monitoring components exposed to the sample gas, (for example, sample lines, filters, scrubbers, conditioners, and as much of the probe as practical) are included in the measurement system. For in situ type monitors, the calibration must check against the injected gas for the performance of all electronic and optical components (for example, transmitter, receiver, analyzer).

Design and equip each pollutant concentration monitor, fuel gas sulfur content and O_2 monitor to allow daily determinations of calibration error (positive or negative) at the zero-level (0 to 20 percent of each span range) and high-level (80 to 100 percent of each span range) concentrations.

ii. Calibration Error Test for SO_x Concentration Monitors, Fuel Gas Sulfur Content Monitors, and O_2 Monitors

Measure the calibration error of each SO_2 concentration analyzer, fuel gas sulfur analyzer, and O_2 monitor once each day according to the following procedures:

If any manual or automatic adjustments to the monitor settings are made, conduct the calibration error test in a way that the magnitude of the adjustments can be determined and recorded.

Perform calibration error tests at two concentrations: (1) zero-level and (2) high level. Zero level is 0 to 20 percent of each span range, and high level is 80 to 100 percent of each span range. All calibration gases used during certification tests and quality assurance and quality control activities shall be NIST/EPA approved standard reference materials (SRM), certified reference materials (CRM), or shall be certified according to "EPA Traceability Protocol for Assay and Certification of Gaseous Calibration Standards," September 1997, EPA 600/R-97/121 or any subsequent version published by EPA.

Introduce the calibration gas at the gas injection port as specified above. Operate each monitor in its normal sampling mode. For extractive and dilution type monitors, pass the audit gas through all filters, scrubbers, conditioners, and other monitor components used during normal sampling and through as much of the sampling probe as practical. For in situ type monitors, perform calibration checking on all active electronic and optical components, including the transmitter, receiver, and analyzer. Challenge the SO_x concentration monitors, the fuel gas sulfur content monitors, and the O_2 monitors once with each gas. Record the monitor response from the data acquisition and handling system. Use the following equation to determine the calibration error at each concentration once each day:

$$CE = \frac{|R - A|}{S} \times 100 \qquad \text{(Eq. C-1)}$$

Where:

CE = Percentage calibration error based on the span range

R = Reference value of zero- or high-level calibration gas introduced into the monitoring system.

A = Actual monitoring system response to the calibration gas.

S = Span range of the instrument

b. Calibration Error Testing Requirements for Stack Flow Monitors

Test, compute, and record the calibration error of each stack flow monitor at least once within every 14 calendar day period during which at anytime emissions flow through the stack; or for monitors or monitoring systems on bypass stacks or ducts, at least once within every 14 calendar day period during which at anytime emissions flow through the bypass stack or duct. Introduce a zero reference value to the transducer or transmitter. Record flow monitor output from the data acquisition and handling systems before and after any adjustments. Calculate the calibration error using the following equation :

$$CE = \frac{|R - A|}{S} \times 100 \qquad \text{(Eq. C-2)}$$

Where:

CE = Percentage calibration error based on the span range

R = Zero reference value introduced into the transducer or transmitter.

A = Actual monitoring system response.

S = Span range of the flow monitor.

c. Interference Check for Stack Flow Monitors

Perform the daily flow monitor interference checks specified in Chapter 2, Subdivision B, Paragraph 1, Subparagraph c of this Attachment at least once per operating day (when the unit(s) operate for any part of the day).

Design Requirements for Flow Monitor Interference Checks

Design and equip each flow monitor with a means to ensure that the moisture expected to occur at the monitoring location does not interfere with the proper functioning of the flow monitoring system. Design and equip each flow monitor with a means to detect, on at least a daily basis, pluggage of each sample line and sensing port, and malfunction of each resistance temperature detector (RTD), transceiver, or equivalent.

Design and equip each differential pressure flow monitor to provide (1) an automatic, periodic backpurging (simultaneously on both sides of the probe) or equivalent method of sufficient force and frequency to keep the probe and lines sufficiently free of obstructions on at least a daily basis to prevent sensing interference, and (2) a means to detecting leaks in the system at least on a quarterly basis (a manual check is acceptable).

Design and equip each thermal flow monitor with a means to ensure on at least a daily basis that the probe remains sufficiently clean to prevent velocity sensing interference.

Design and equip each ultrasonic flow monitor with a means to ensure on at least a daily basis that the transceivers remain sufficiently clean (for example, backpurging the system) to prevent velocity sensing interference.

d. Recalibration

Adjust the calibration, at a minimum, whenever the calibration error exceeds the limits of the applicable performance specification for the SOx monitor, O_2 monitor or stack flow monitor to meet such specifications. Repeat the calibration error test procedure following the adjustment or repair to demonstrate that the corrective actions were effective. Document the adjustments made.

e. Out-of-Control Period – Calibration Test

An out-of-control period occurs when the calibration error of an SO_2 concentration monitor or a fuel gas sulfur content monitor exceeds 5.0 percent based upon the span range value, when the calibration error of an O_2 monitor exceeds 1.0 percent O_2, or when the calibration error of a flow monitor exceeds 6.0 percent based upon the span range value, which is twice the applicable specification. The out-of-control period begins with the hour of completion of the failed calibration error test and ends with the hour of completion of following an effective recalibration. Whenever the failed calibration, corrective action, and effective recalibration occur within the same hour, the hour is not out-of-control if 2 or more valid readings are obtained during that hour as required by Chapter 2, Subdivision B, Paragraph 5, Subparagraph a.

An out-of-control period also occurs whenever interference of a flow monitor is identified. The out-of-control period begins with the hour of the failed interference check and ends with the hour of completion of an interference check that is passed.

f. Data Recording

Record and tabulate all calibration error test data according to the month, day, clock-hour, and magnitude in ppm, dscfh, and percent volume. Program monitors that automatically adjust data -to the calibrated corrected calibration values (for example, microprocessor control) to record either: (1) the unadjusted concentration or flow rate measured in the calibration error test prior to resetting the calibration, or (2) the magnitude of any adjustment. Record the following applicable flow monitor interference check data: (1) sample line/sensing port pluggage, and (2) malfunction of each RTD, transceiver, or equivalent.

2. Semi-annual Assessments

a. For each CEMS, perform the following assessments once semi-annually thereafter, as specified below for the type of test. These semi-annual assessments shall be completed within six months of the end of the calendar quarter in which the CEMS was last tested for certification purposes (initial and recertification) or within three months of the end of the calendar quarter in which the District sent notice of a provisional approval for a CEMS, whichever is later. Thereafter, the semi-annual tests shall be completed within six months of the end of the calendar quarter in which the CEMS was last tested. For CEMS on bypass stacks/ducts, the assessments shall be performed once every two successive operating quarters in which the bypass stacks/ducts were operated. These tests shall be performed after the calendar quarter in which the CEMS was last tested as part of the CEMS certification, as specified below for the type of test.

Relative accuracy tests may be performed on an annual basis rather than on a semi-annual basis if the relative accuracies during the previous audit for the SO_X pollutant concentration monitor, flow monitoring system, and SOx emission rate measurement system are~~is~~ 7.5 percent or less.

b. For CEMS on any stack or duct through which no emissions have passed in two or more successive quarters, the semi-annual assessments must be performed within 14 unit operating days after emissions pass through the stack/duct.

c. The due date for a semi-annual or annual assessment of a major source may be postponed to within 14 unit operating days from the first re-firing of the major source if the major source is physically incapable of being operated and all of the following are met:

i. All fuel feed lines to the major source are either disconnected or opened and either flanges or equivalent sealing devices are placed at both ends of the disconnected or opened lines, and

ii. The fuel meter(s) for the disconnected fuel or opened feed lines are maintained and operated and associated fuel records showing no fuel flow are maintained on site.

This paragraph applies separately for each unrelated, independent event. For any hour that fuel flow records are not available to verify no fuel flow, SOx emissions shall be calculated using the maximum valid hourly emissions from the last 30 days of operation.

Prior to re-starting operation of the major source, the Facility Permit Holder shall: (1) provide written notification to the District no later than 72 hours prior to starting up the source, (2) start the CEMS no later than 24 hours prior to the start-up of the major source, and (3) conduct and pass a Cylinder Gas Analysis (CGA) prior to the start-up of the major source. The emissions data from the CEMS after the re-start of operations is considered valid only if the Facility Permit Holder passes the CGA test. Otherwise, for a non-passing CGA, the CEMS data is considered invalid until the semi-annual or annual assessment is performed and passed. As such, SOx emissions shall be calculated using the maximum valid hourly emissions from the last 30 days of operation commencing with the hour of start up and continuing through the hour prior to performing and passing the semi-annual or annual assessment.

d. An electrical generating facility that either only operates under a California Independent System Operator (Cal ISO) contract or is owned and operated by a municipality may postpone the due date for a semi-annual or annual assessment of a major source to the next calendar quarter provided that the facility shows:

i. The semi-annual or annual assessment was scheduled to be performed during the first 45 days of the calendar quarter in which the assessment was due;

ii. The assessment was not completed due to lack of adequate operational time; and

iii. A CGA was conducted and passed within the calendar quarter when the assessment was due.

e~~a~~. Relative Accuracy Test Audit

Perform relative accuracy test audits and bias tests semi-annually and no less than 3 months apart for each $S0_2$ pollutant concentration monitor, fuel gas sulfur content monitor, stack gas volumetric flow rate measurement systems, and the $S0_2$ mass emission rate measurement system in accordance with Chapter 2, Subdivision B, Paragraphs 10, 11, ~~and~~ 12, and 13 and Attachment B of the Protocol for ~~Proposed~~ Rule 2011. The relative accuracy of the pollutant concentration monitor and the mass emission rate measurement system shall be less than or equal to 20.0 percent, and the relative accuracy of the stack gas volumetric flow rate measurement system shall be less than or equal to 15.0 percent. For monitors on bypass stacks/ducts, perform relative accuracy test audits once every two successive bypass operating quarters in accordance with Chapter 2, Subdivision B, Paragraphs 10, 11, ~~and~~ 12, and 13 and Attachment B (bias test) of the ~~Draft~~ Protocol for ~~Proposed~~ Rule 2011.

f~~b~~. Out-of-Control Period – Relative Accuracy Test Audit

An out-of-control period occurs under any of the following conditions: (1) The relative accuracy of an SO_2 pollutant concentration monitor, a fuel gas sulfur content monitor, or the $S0_2$ emission rate measurement system exceeds 20.0 percent; (2) the relative accuracy of the flow rate monitor exceeds 15.0 percent; or (3) failure to conduct a relative accuracy test audit by the due date for a semi-annual assessment. The out-of-control period begins with the hour of completion of the failed relative accuracy test audit and ends with the hour of completion of a satisfactory relative accuracy test audit.

g~~c~~. Out-of-Control Period – BIAS Test

An out-of-control period occurs if all the following conditions are met:

i. Failure of a bias test as specified in Attachment B of this Appendix;

ii. The CEMS is biased low relative to the reference method (i.e. Bias Adjustment Factor (BAF), as determined in Attachment B of this Appendix, is greater than 1); and

iii. The Facility Permit holder does not apply the BAF to the CEMS data.

The out-of-control period begins with the hour of completion of the failed bias test audit and ends with the hour of completion of a satisfactory bias test.

h~~d~~. Alternative Relative Accuracy Test Audit

i. The Facility Permit holder of a major source, that has received written approval from the Executive Officer as an intermittently operated source, may postpone the due date for a semi-annual assessment to the end of the next calendar quarter if the Facility Permit holder:

I. operated the source no more than 240 cumulative operating hours and no more than 72 consecutive hours during the calendar quarter when a semi-annual assessment is due; and

II. conducted a relative accuracy test audit on the CEMS serving the source during the previous four calendar quarters and meeting the accuracy criteria as set forth under Subparagraph B.2.e~~a~~.; and

III. conducted an alterative relative accuracy test audit on the CEMS serving the source during the calendar quarter when a semi-annual assessment is due and meeting the criteria specified under Clause B.2.h~~d~~.iii.

If any of the requirements under Subclauses B.2.h~~d~~.i.I, II and III is not met and the source did not have passing RATA during the calendar quarter when the semi-annual assessment is due, emissions from the source shall be determined pursuant to the Missing Data Procedures as specified under Rule 2011, Appendix A, Chapter 2, Subdivision E after the semi-annual assessment due date until the hour of completion of a satisfactory relative accuracy test audit.

ii. The Facility Permit holder may submit a written request to designate a major source as an intermittently operated source provided the Facility Permit holder demonstrates that:

I. During any calendar quarter within the previous two compliance years, the source was operated no more than 240 cumulative operating hours and no more than 72 consecutive hours ; or

II. During any calendar quarter within the next two compliance years, the source will be operated no more than 240 cumulative operating hours and no more than 72 consecutive hours.

iii. An alternative relative accuracy shall consist of a Cylinder Gas Analysis (CGA) method as defined under 40 CFR, Part 60, Appendix F, combined with a flow accuracy verification. For sources equipped with stack flow monitors, the flow accuracy shall be verified by calibrating the transducers and transmitters installed on the stack flow monitors using procedures under Paragraph B.3 of this attachment. For sources equipped with fuel flow meters and no stack flow monitors, the flow accuracy shall be verified by calibrating the fuel flow meters either in-line or offline in accordance with the procedures outlined in 40CFR Part 75, Appendix D. Passing flow accuracy verification results that were obtained within the past 4 quarters may be used in lieu of performing a flow accuracy verification during the calendar quarter when a semi-annual assessment is due. The calculated accuracy for the analyzer responses for NO_x and O_2 concentration shall be within 15 percent or 1 ppm, whichever is greater, as determined by the CGA method as defined under 40 CFR, Part 60, Appendix F. Successive alternative relative accuracy test audits shall be performed no less than 45 days apart.

3. Calibration of Transducers and Transmitters on Stack Flow Monitors

All transducers and transmitters installed on stack flow monitors must be calibrated every two operating calendar quarters, in which an operating calendar quarter is any calendar quarter during which at anytime emissions flow through the stack. Calibration must be done in accordance with Executive Officer approved calibration procedures that employ materials and equipment that are NIST traceable.

When a calibration produces for a transducer and transmitter a percentage accuracy of greater than ± 1%, the Facility Permit holder shall calibrate the transducer and transmitter every calendar operating quarter until a subsequent calibration which shows a percentage accuracy of less than ± 1% is achieved. An out-of-control period occurs when the percentage accuracy exceeds ±2%. If an out-of-control period occurs, the Facility Permit holder shall take corrective measures to obtain a percentage accuracy of less than ±2% prior to performing the next RATA. The out-of-control period begins with the hour of completion of the failed calibration error test and ends with the hour of completion of following an effective recalibration. Whenever the failed calibration, corrective action, and effective recalibration occur within the same hour, the hour is not out-of-control if two or more valid data readings are obtained during that hour as required by Chapter 2, Subdivision B, Paragraph 5, Subparagraph a.

PROCESS UNITS - PERIODIC REPORTING AND RULE 219 EQUIPMENT

TABLE OF CONTENTS

CHAPTER 4 - PROCESS UNITS PERIODIC REPORTING AND RULE 219 EQUIPMENT

A. Monitoring, Reporting, and Recordkeeping Requirements 2012A-4-1
B. Emission Calculations for Reporting Data 2012A-4-2
C. Total Quarterly Emissions Calculation for all NO_X Process Units at the Facility 2012A-4-11
D. Reporting Procedures 2012A-4-12
E. Fuel Meter Sharing 2012A-4-13
F. Rule 219 Equipment 2012A-4-13
G. Substitute Data Procedures 2012A-4-14

Process units are one or more pieces of equipment which are listed in Table 1-C. The process units emissions are reported quarterly as shown in Table 4-A and based primarily on fuel consumption or operating time in conjunction with an emission factor. The requirements and procedures for an emission factor and election conditions for an alternative emission factor or concentration limit shall apply to process units. For equipment designated as exempt from permit in Rule 219 emissions shall be determined according to the methodology specified in this Chapter 4, subdivision F.

Process units and equipment exempt from permit as designated in Rule 219 may share fuel meters if each equipment has the same emission factor. This chapter also includes the equations describing the methods used to calculate NO_X process unit emissions and the reporting procedures. The interim reporting period does not apply to process units since existing fuel metering equipment or timers- shall be used starting January 1, 1994 for Cycle 1 facilities and July 1, 1994 for Cycle 2 facilities.

A. MONITORING, REPORTING, AND RECORDKEEPING REQUIREMENTS

1. The category-specific starting emission factor found in Table 1 of Rule 2002 - Allocations for Oxides of Nitrogen (NO_x) and Sulfur (SO_x) shall be used for quantifying quarterly mass emissions for a NO_x process unit.

2. The Facility Permit holder of a process unit may request a category-specific emission rate that is reliable, accurate, and representative for purposes of calculating NO_x emissions. The emission rate shall be determined based on the source testing protocol specified in Chapter 5. The Facility Permit holder of a process unit may apply for a concentration limit for purposes of calculating NO_x emissions.

3. The Facility Permit holder of a process unit– shall calculate the mass emissions according to the methodology specified in Paragraph 4.B.2. (totalizing fuel meters) or 4.B.3.a. (timers).

4. The Facility Permit holder of each NO_x Process Unit shall use a totalizing fuel meter or timer as applicable, as specified in the Facility Permit for each NO_X process unit to measure and report the variables listed in Tables 4-A and 4-B, respectively, for each NO_X process unit.

5. Fuel flow measuring devices used for obtaining stack flow in conjunction with F-factors shall be tested, when required, as installed for relative accuracy using reference methods to determine stack flow.

   a. The relative accuracy of the fuel flow meter must be determined using District reference Methods 1-4 and a three-run relative accuracy audit (RAA) at normal operating load. The accuracy of the fuel flow measuring system must be determined using the following equation:

$$A = (C_m - C_a)/C_a \times 100\% \qquad \text{(Eq. 15a)}$$

where:

A = accuracy of the fuel flow meter (%)

C_m = average flow rate response (scfh)

C_a = average reference method flow rate (scfh)

The value of fuel flow meter accuracy, as defined in Eq. 15a, shall be less than or equal to 15%.

b. Other acceptable alternatives to the above procedures used to determine the relative accuracy of the facility fuel flow meter or stack flow meter are listed under Chapter 3, Subdivision H.

6. Fuel meters and/or timers have to be non-resettable and tamper-proof. They have to have seals installed by the meter/timer manufacturer to prove the integrity of the measuring device.

Meters which are unsealed for maintenance or repairs shall be resealed by an authorized manufacturers representative.

7. The Facility Permit holder of each NO_x process unit shall monitor, report, and maintain the following records on a quarterly basis:

a. Type and quantity of fuel burned, in units of millions of standard cubic feet per quarter (mmscf per quarter) for gaseous fuels or thousand gallons per quarter (mgal per quarter) for liquid fuels, expressed to at least three significant figures; or

b. Total hours of operation; and

c. Production/Processing/Feed rate.

8. The Facility Permit holder of each NO_x process unit shall also provide any other data necessary for calculating the emission rates of nitrogen oxides as determined by the Executive Officer.

B. EMISSION CALCULATION FOR REPORTING DATA

1. Quarterly Mass Emissions for Interim Periods

Pursuant to Rule 2012 (f) (1), between January 1, 1994 and December 31, 1994 for Cycle 1 facilities, and between July 1, 1994 and June 30, 1995 for Cycle 2 facilities, the monthly emission of each process unit shall be calculated and recorded according to:

$$E_{ip} = \sum_{j=1}^{r} d_j \quad x \quad EF_{sj} \qquad \text{(Eq.22)}$$

where:

E_{ip} = The quarterly mass emission of nitrogen oxides for interim period (lb/quarter).

d_j = The quarterly fuel usage for each type of fuel recorded as mmscf/quarter or mgal/quarter).

EF_{sj} = The starting emission factor used to calculate unit emissions in the initial allocation, as specified in Table 1 of Rule 2002 - Allocations for Oxides of Nitrogen (NO_X) and Sulfur (SO_X) (lb/mmscf, lb/mgal).

r = The number of different types of fuel consumed per quarter.

j = Each type of fuel.0

Example calculation: Boiler burning natural gas, rated 6 mmBtu/hr, in compliance with Rule 1146
starting year 1994
Emission factor = 49.18 lb/mmscf
Quarterly fuel usage = 1.1 mmscf per quarter

E_{ip} = (49.18) x (1.1)
= 54.1 lb/quarter

Applicable emission factor is also found in Volume II - Supporting Documentation, Appendix II-F - Methodology for NO_x and SO_x Starting and Ending Allocation Factors, Table 2-4 - Startpoint 1994 Emission Factors for Nitrogen Oxides.

2. Totalizing Fuel Meter-Based Emission Calculation

The Facility permit holder shall use an emission factor shown in Table 1 of Rule 2002 or in Table 3-D or an approved equipment-specific or category-specific emission rate for each affected NO_x Process Unit to calculate the quarterly emissions according to:

$$E_k = \sum_{j=1}^{r} d_j \times EF_j \qquad \text{(Eq.23)}$$

or

$$E_k = \sum_{j=1}^{r} d_j \times V_j \times ER_j \qquad \text{(Eq.24)}$$

where:

E_k = The quarterly emissions of nitrogen oxides (lb/quarter).

d_j = The quarterly fuel usage for each type of fuel recorded by the fuel totalizer (mmscf/quarter or mgal/quarter)

EF_j = The emission factor specified in Table 1 of Rule 2002 - Allocations for Oxides of Nitrogen (NO_X) and Sulfur (SO_X) or specified in Table 3-D (lb/mmscf, lb/mgal). The emission factor found in Table 1 of Rule 2002 may or may not include the appropriate control efficiency.

V_j = The higher heating value of each type of fuel (mmBtu/mmscf or mmBtu/mgal) determined by the Facility Permit holder or assigned from Table 3-D.

ER_j = The equipment-specific or category-specific emission rate; fuel-specific emission rate requested by the Facility Permit holder (lb/mmBtu).

r = The number of different types of fuel consumed per month.

3. Timer-Based Emission Calculations

a. If the NO_x process unit is equipped with a timer, the quarterly fuel usage shall be quantified ~~estimated~~ according to Eq. 25, 26 27, and 28 and the quarterly emissions for each affected NO_x process unit shall be calculated according to Eq. 23 and 24.

If the NO_x process unit does not measure fuel with a totalizing fuel meter, the quarterly fuel consumption for each affected equipment shall be quantified ~~estimated~~ according to:

$$d = d_{pu} \times (H/H_{pu}) \quad \text{(Eq.25)}$$

where:

d = The ~~estimated~~ quarterly fuel consumption of an affected NO_x process unit without a dedicated fuel meter (mmscf/quarter or mgal/quarter).

d_{pu} = The quarterly fuel consumption of all NO_x process units at the facility (mmscf/quarter or mgal/quarter).

H = The quarterly heat input of an affected equipment without a dedicated fuel meter (mmBtu/quarter).

H_{pu} = The quarterly heat input of all NO_x process units at the facility (mmBtu/quarter).

Example Calculation:		
d_{pu}	=	1,587 mmscf/quarter
H	=	5,400 mmBtu/quarter
H_{pu}	=	27,000 mmBtu/quarter
d	=	d_{pu} x (H/H_{pu})
d	=	1,587 mmscf/qtr x (5,400 mmBtu/qtr ÷27,000 mmBtu/qtr)
d	=	317.4 mmscf/qtr

The quarterly fuel usage for all the NO_x process units at the facility (d_{pu}) shall be calculated according to:

$$d_{pu} = d_{fac} - (d_{large} + d_{major}) \quad \text{(Eq.26)}$$

where:

d_{fac} = The quarterly fuel usage of all major and large sources and NO_x process units at the facility (mmscf/quarter or mgal/quarter).

d_{major} = The quarterly fuel usage of all major NO_x sources at the facility (mmscf/quarter or mgal/quarter).

d_{large} = The quarterly fuel usage of all large NO_x sources at the facility (mmscf/quarter or mgal/quarter).

Example Calculation:		
d_{fac}	=	174 mmscf/quarter
d_{major}	=	126 mmscf/quarter
d_{large}	=	30 mmscf/quarter
d_{pu}	=	d_{fac} - (d_{large} + d_{major})
d_{pu}	=	174 - (126 + 30)
d_{pu}	=	18 mmscf/quarter

The quarterly heat input of all the NO_x process units at the facility (H_{pu}) shall be calculated according to:

$$H_{pu} = \sum_{i=1}^{n} (R_i \times T_i) \quad \text{(Eq.27)}$$

where:

R_i = The maximum rated fuel capacity of a NO_x process unit (mmBtu/hr).

T_i = The quarterly accumulated operation hours for a NO_x process unit (hrs/quarter).

n = The total number of NO_x process units at the facility.

Example Calculation:		
R_1	=	3.5 mmBtu/hr
R_2	=	2.7 mmBtu/hr
T_1	=	480 hr/quarter
T_2	=	120 hr/quarter
H_{pu}	=	$\sum_{i=1}^{2} (R_i \times T_i)$
H_{pu}	=	(3.5 x 480) + (2.7 x 120)
H_{pu}	=	2004 mmBtu/quarter

The maximum rated heat input capacity of all NO_x process units shall be in units of mmBtu/hr. Since internal combustion engines are usually rated in units of brake horse power, the maximum rated heat input capacity of an engine shall be computed as follows:

$$R = 0.002545 \times bhp / eff \qquad \text{(Eq.28)}$$

where:

R = The maximum rated heat input capacity

eff = The manufacturer's rated efficiency @LHV x (LHV/HHV)

= 0.25, if not provided by the operator

bhp = The manufacturer's rated shaft output in brake horse power

Example Calculation:		
eff	=	0.25
bhp	=	75 bhp
R	=	0.002545 x bhp / eff
R	=	0.002545 x 75/.25
R	=	0.7635 mmBtu/hr

If gas turbines are rated in kilowatts, the rating shall be converted to mmBtu/hr by applying the manufacturer's heat rate (in mmBtu/kw-hr). If the manufacturer's heat rate is not available, a default value of 15,000 Btu/kw-hr shall be used.

Example Calculation:

Quarterly natural gas fuel usage for an ICE with maximum rated bhp of 90 bhp, 0.25 eff and a boiler rated at 4 mmBtu/hr is being served by one fuel meter reading 10.5 mmscf. The compliance emission rate of both ICE and boiler is 0.3 lb/mmBtu.

ICE = 90 bhp Boiler= 4 mmBtu/hr
Fuel meter reading = d_{pu} = 10.5 mmscf

I.C.E.
R = 0.002545 x 90/.25 = 0.916 mmBtu/hr
t = 3 hr/day x 7 days/wk. x 4 wk./mo. x 3 mo/qtr = 252 hr/qtr
H_{ice} = R x t = 0.916 x 252 = 230.8 mmBtu/ quarter

Boiler
H_{boiler} = 4 mmBtu/hr x 24 hr./day x 7 day/wk. x 4 wk./mo. x 3 mo/qtr
H_{boiler} = 8064 mmBtu/quarter
H_{pu} = 230.8 + 8064 = 8294.8 mmBtu/qtr

$d_{ice} = d_{pu} \times (H_{ice}/H_{pu})$
= 10.5 mmscf/qtr x (230.8/8294.8)
= .298 mmscf/qtr

$d_{boiler} = d_{pu} \times (H_{boiler}/H_{pu})$
= 10.5 mmscf/qtr x (8064/8294.8)
= 10.2 mmscf/qtr

$E_{ice} = d_{ice} \times V \times ER_c$
= 1050 mmBtu/mmscf x 0.30 lb/mmBtu x .298 mmscf/qtr
= 93.87 lb/qtr
$E_{boiler} = d_{boiler} \times V \times ER_c$
= 10.2 mmscf/qtr x 1050 mmBtu/mmscf x 0.3 lb/mmBtu
= 3213 lb/qtr

$E = E_{ice} + E_{boiler}$ = 93.87 + 3213 lb/qtr = 3307 lb/qtr

4. Concentration Limit based Emissions Calculations

When the Facility Permit holder elects to use the concentration limit, the quarterly mass emission shall be calculated and recorded according to one of the following equations:

a. Use the F-factor approach for oxygen except in cases where enriched oxygen is used, non-fuel sources of carbon dioxide are present (e.g., lime kilns and calciners), or the oxygen content of the stack gas is 19 percent or greater. Process units that are permitted to demonstrate compliance using the procedures in Rule 2012, Appendix A, Chapter 5, Subdivision H shall use the following equation to calculate and record nitrogen oxides mass emission rate even if the oxygen stack gas is 19 percent or greater. The following equation shall be used to calculate and record nitrogen oxides mass emission rate:

$$E_k = PPMV_{O2} \quad [20.9/(20.9 - b)] \times 1.195 \times 10^{-7} \times \sum_{j=1}^{r} (F_{dj} \times d_j \times V_j) \qquad \text{(Eq.28a)}$$

where:

E_k	=	The quarterly mass emission of nitrogen oxides (lb/quarter).
$PPMV_{O2}$	=	The RECLAIM concentration limit as listed in the Facility Permit. (ppmv) and based on standardized oxygen concentration in the exhaust stream.
b	=	The standard concentrations of oxygen as listed in the Facility Permit or as found in Table 3-F. (%).
r	=	The number of different types of fuel.
j	=	Each type of fuel.
$F_{d\,j}$	=	The oxygen-based dry F factor for oxygen for each type of fuel, the ratio of the dry gas volume of the products of combustion to the heat content of the fuel (dscf/mmBtu) specified in 40 CFR Part 60, Appendix A, Method 19.
d_j	=	The quarterly– fuel usage for each type of fuel recorded by the fuel totalizer (mmscf per quarter or mgal per quarter).
V_j	=	The higher heating value of the fuel for each type of fuel found in Table 3-D (mmBtu/mmscf or mmBtu/mgal) or determined by a continuous analyzer.

The product ($d_j \times V_j$) shall have units of mmBtu per quarter (mmBtu/quarter).

For non-standard fuels that are not listed in 40 CFR Part 60, Appendix A, Method 19, a constant F-factor and heating value may be used if the Facility Permit holder demonstrates to the Executive Officer that the natural gas, fuel oil, or other fuels have stable F-factors and gross heating values. A stable F-factor or gross heating value is defined as not varying by more than + or - 2.5% from the proposed constant value. For the fuels listed in 40 CFR 60, Appendix A, Method 19, Table 19-1, the F-factors are assumed to be stable at the value cited in Table 19-1. Any F-factor cited in Regulation XX shall supersede the F-factor in Table 19-1. For fuels not listed in the citations above, but which the Facility Permit holder demonstrates that the source-specific F-factor meets the same stability criteria, periodic reporting of F-factor may be accepted and the adequacy of the frequency of analyses shall be demonstrated by the Facility Permit operator such that the probability that any given analysis will differ from the previous analysis by more than 5% (relative to the previous analysis) or less than 5%. Analysis records shall be maintained, including all charts and laboratory notes.

For non-standard fuels that are not listed in 40 CFR Part 60, Appendix A, Method 19 and do not satisfy the criteria for constant F-factor and heating value, the fuels must be analyzed on a continuous basis using gas chromatographs or other continuous technique that is approved by the Executive Officer. The continuous technique employed shall be capable of providing at a minimum a reading every fifteen-minute period.

b. If the F-factor approach for oxygen can-not be used, use the F-factor approach for carbon dioxide as specified in 40 CFR Part 60, Appendix A, Method 19, except in cases where the carbon dioxide concentration is less than one volume percent dry, non-fuel sources of carbon dioxide are present (e.g., lime kilns and calciners), or non-metered sources of fuel are present (e.g., afterburners). The following equation shall be used to calculate and record nitrogen oxides mass emission rate:

$$E_k = PPMV_{CO2} \times (100/\%CO_2) \times 1.195 \times 10^{-7} \times \sum_{j=1}^{r} (F_{cj} \times d_i \times V_i) \quad \text{(Eq.28b)}$$

Where:

E_k	=	The quarterly mass emission of nitrogen oxides (lb/quarter).
$PPMV_{CO2}$	=	The RECLAIM concentration limit as listed in the Facility Permit (ppmv) and based on standardized carbon dioxide concentration in the exhaust stream.
$\%CO_2$	=	The standard concentrations of stack gas carbon dioxide as listed in the Facility Permit.
r	=	The number of different types of fuel.
j	=	Each type of fuel.
F_{cj}	=	The carbon dioxide-based dry F factor for carbon dioxide for each type of fuel, the ratio of the dry gas volume of the products of combustion to the

heat content of the fuel (dscf/mmBtu) specified in 40 CFR Part 60, Appendix A, Method 19.

d_j = The quarterly~~–~~ fuel usage for each type of fuel recorded by the fuel totalizer (mmscf per quarter or mgal per quarter).

V_j = The higher heating value of the fuel for each type of fuel found in Table 3-D (mmBtu/mmscf or mmBtu/mgal) or determined by a continuous analyzer.

For non-standard fuels that are not listed in 40 CFR Part 60, Appendix A, Method 19, a constant F-factor and heating value may be used if the Facility Permit holder demonstrates to the Executive Officer that the natural gas, fuel oil, or other fuels have stable F-factors and gross heating values. A stable F-factor or gross heating value is defined as not varying by more than + or - 2.5% from the proposed constant value. For the fuels listed in 40 CFR 60, Appendix A, Method 19, Table 19-1, the F-factors are assumed to be stable at the value cited in Table 19-1. Any F-factor cited in Regulation XX shall supersede the F-factor in Table 19-1. For fuels not listed in the citations above, but which the Facility Permit holder demonstrates that the source-specific F-factor meets the same stability criteria, periodic reporting of F-factor may be accepted and the adequacy of the frequency of analyses shall be demonstrated by the Facility Permit operator such that the probability that any given analysis will differ from the previous analysis by more than 5% (relative to the previous analysis) or less than 5%. Analysis records shall be maintained, including all charts and laboratory notes.

For non-standard fuels that are not listed in 40 CFR Part 60, Appendix A, Method 19 and do not satisfy the criteria for constant F-factor and heating value, the fuels must be analyzed on a continuous basis using gas chromatographs or other continuous technique that is approved by the Executive Officer. The continuous technique employed shall be capable of providing at a minimum a reading every fifteen-minute period.

c. If the F-factor approach for carbon dioxide can~~–~~not be used, the nitrogen oxides mass emission rate shall be determined based on actual monthly stack flow rate from a continuous stack flow monitor and concentration limit at stack conditions as listed in the Facility Permit. The mass emission rate shall be determined by the following equation:

$$E_k = PPMV_{ST} \times 1.195 \times 10^{-7} \times \sum_{j=1}^{N} F_j \qquad \text{(Eq. 28c)}$$

where:

E_k = The quarterly mass emission of nitrogen oxides (lb/quarter).

$PPMV_{ST}$ = The concentration limit at stack condition as listed in the Facility Permit (ppmv).

F_j = Total quarterly stack flow rate (scf/quarter) of stack j.

N = Number of exhaust stacks.

For systems that record hourly exhaust flow rate data, the total quarterly stack flow rate shall be determined by the following equation:

$$F_j = \sum_{i=1}^{M} H_{ij} \qquad \text{(Eq. 28d)}$$

F_j = Total quarterly stack flow rate (scf/quarter) of stack j.

H_{ij} = Hourly stack flow rate (scf/hour) of stack j.

M = Total number of hours for the quarter.

Whenever valid stack flow rate data is not obtained for an hour, the Facility Permit holder shall calculate substitute data using the missing data procedures applicable to flow as set forth in Appendix A, Chapter 3, Subdivision K, Paragraph 2.

C. TOTAL QUARTERLY EMISSIONS CALCULATION FOR ALL NO_X PROCESS UNITS AT THE FACILITY

The quarterly NO_X emissions of all NO_X process units at the facility shall be quantified~~*estimated*~~ according to:

$$E = \sum_{i=1}^{n} E_i \qquad \text{(Eq.29)}$$

$$E_i = \sum_{j=1}^{m} E_j \qquad \text{(Eq. 30)}$$

where:

E = The total quarterly emissions for all NO_X process units

E_i = The quarterly emission of each NO_X process unit (lb/quarter)

E_j = The quarterly emission of each NO_X process unit per type of fuel (lb/quarter)

i = Each type of affected NO_x process unit

j = Each type of fuel

m = The total number of fuels consumed for each affected NO_x process unit per quarter

n = The total number of NO_x process units at the facility.

Example Calculation:

E_1 = 163.8 lb/quarter
E_2 = 78 lb/quarter
E_3 = 120 lb/quarter

$$E = \sum_{i=1}^{n} E_i = 163.8 + 78 + 120$$

$$E = 361.8 \text{ lb/quarter}$$

D. REPORTING PROCEDURES

1. The emissions data in any facility with an RTU shall be reported to Central Station Computer at the end of any quarter and the data shall be computed to determine the quarterly total emissions for each source using Equations 22 through 28 as appropriate.

2. The total fuel usage data for all NO_x process units in any facility without an RTU shall be recorded in a format approved by the Executive Officer and submitted to the District as part of the Quarterly Certified Report required by Rule 2004.

3. The Facility Permit holder of NO_x process units shall maintain daily records of operation hours or quarterly usage rate for each NO_x process unit.

4. Any changes made in type of fuel used and rated capacity for each source shall be recorded by the Facility Permit holder.

5. The Facility Permit holder of any NO_x process unit that opts to monitor at the large source monitoring level shall meet the requirements set forth in "Chapter 3 Large Sources - Continuous Process Monitoring System (CPMS)".

E. FUEL METER SHARING

1. A single totalizing fuel meter shall be allowed to measure the cumulative fuel usage for more than one equipment provided that each equipment elects for the same emission rate or emission factor as specified in the Facility Permit and that any equipment in a process unit does not use the annual heat input in order to be categorized from a large source to a process unit.

2. One or more equipment in a process NO_x unit shall be allowed to share the fuel totalizing meter with the equipment in a process NO_x unit provided that each equipment elects for the same emission rate or emission factor as specified in the Facility Permit.

3. Fuel meter sharing for the interim period shall be allowed for those equipment in a process unit with the same emission rate or emission factor.

F. RULE 219 EQUIPMENT

1. Emission Determination And Reporting Requirements

a. The Facility Permit holder shall determine the emissions for one or more equipment exempt under Rule 219 and report the emissions on a quarterly basis as part of the Quarterly Certified Emissions Report Certification of Emissions required by Rule 2004. The Facility Permit holder shall be allowed to use the existing fuel totalizer, the monthly fuel billing statement, or any other equivalent methodology to quantify~~*estimate*~~ their fuel usage for a quarterly period.

b. Quarterly reporting periods shall start on January 1, 1994 for Cycle 1 Facilities and July 1, 1994 for Cycle 2 facilities.

c. The Facility Permit holder of each equipment shall maintain the quarterly fuel usage data for all equipment exempt under Rule 219 for three years. Such data shall be made available to District staff upon request.

d. The fuel usage for equipment exempt under Rule 219 may be used in conjunction with fuel usage for process units provided that they have the same emission factor.

2. Emission Calculations

The Facility Permit holder shall determine NO_x emissions for equipment exempt under Rule 219 as follows-:

$$E_{219} = \sum_{i=1}^{n} EFR_i \times d_i \qquad \text{(Eq. 31)}$$

where:

E_{219} = The total emissions for equipment exempt under Rule 219 quantified~~estimated~~ over a quarterly period (lb/~~per~~ quarter).

EFR_i = The equipment-specific or category-specific emission factor for each equipment exempt under Rule 219 equipment. The emission factor can be found in Table 3-D (lb/mmscf or lb/mgal). Alternatively, for an equipment certified by US EPA, CARB, or SCAQMD as meeting a certain emission level, an appropriate emission factor equivalent to the certified emission level may be used provided the facility complies with the source test or maintenance requirements specified in paragraph 4.

d_i = The equipment-specific or category-specific fuel usage (mmscf/~~per~~ quarter or mgal/~~per~~ quarter).

n = The number of equipment exempt under Rule 219.

3. Missing Data Periods

The Facility Permit holder shall determine NO_x emissions for equipment exempt under Rule 219 using the substitute data procedures specified in Subdivision G of this Chapter for any quarter for which the Facility Permit holder did not obtain and record valid fuel consumption data as required by Subdivision F, Paragraphs 1 and 2 of this Chapter.

4. Source Testing and Maintenance

Each equipment exempt under Rule 219 with NO_x emissions determined using an alternative emission factor based on a US EPA, CARB, or SCAQMD certified emission level shall either be periodically source tested pursuant to F.4.a. or maintained pursuant to F.4 b.

a. Source Testing

i. Conduct periodic source tests to verify that emissions are less than or equal to the US EPA, CARB, or SCAQMD certified emission level. Each such source test shall comply with the provisions of Chapter 5 D.1. and D.2.

ii. Each device subject to this source testing requirement shall be tested on the same schedule as specified in Table 5-B for Process Unit with Concentration Limit, except in cases where a facility has multiple devices subject to this source testing requirement, all with the same US EPA, CARB, or SCAQMD certification. In such cases the facility operator may conduct the source testing of at least half of the devices with the same certification each five-year period provided each device is source tested at least once every two successive five-year periods.

iii. If a source test determines that an equipment exempt under Rule 219 with NO_x emissions quantification using an emission factor equivalent to the US EPA, CARB, or SCAQMD certified emission level has emissions greater than the emission factor used for emission quantification, emissions from that source and all other sources engaged in meter sharing with that source pursuant to subdivision E of this chapter shall quantify emissions using the appropriate equipment-specific or category-specific emission factor in Table 3-D from the start of the quarter in which the source test was conducted through the end of the quarter in which a subsequent source test demonstrates that the source's emissions are less than or equal to the emission factor.

b. Maintenance

i. Conduct annual maintenance on the equipment to ensure emissions remain at or below the US EPA, CARB, or SCAQMD certified emission level. Promptly after completing such maintenance, verify that the emissions from each device subject to this maintenance requirement remain at or below the US EPA, CARB, or SCAQMD certified emission level with a portable NOx, CO, and oxygen analyzer according to the Combustion Gas Periodic Monitoring Protocol for the Periodic Monitoring of Nitrogen Oxides, Carbon Monoxide, and Oxygen from Combustion Sources Subject to South Coast Air Quality Management District Rules 1110.2, 1146, and 1146.1.

ii. If an annual maintenance emission check with a portable analyzer determines that an equipment exempt under Rule 219 with NO_x emissions quantification using an emission factor equivalent to the US EPA, CARB, or SCAQMD certified emission level has emissions greater than the emission factor used for emission quantification, emissions from that source and all other sources engaged in meter sharing with that source pursuant to subdivision E of this chapter shall quantify emissions using the appropriate equipment-specific or category-specific emission factor in Table 3-D from the start of the quarter in which the portable analyzer emission check was conducted through the end of the quarter in which a subsequent portable analyzer emission check demonstrates that the source's emissions are less than or equal to the emission factor.

c. Recordkeeping

Each facility that elects to comply with subdivision 2 by implementing the procedures specified in paragraph 4.a. or 4.b. shall keep records of all testing, maintenance, and verification conducted pursuant to those paragraphs for at least three years and make such records available to the Executive Officer upon request.

G. SUBSTITUTE DATA PROCEDURES

1. For each process unit or process units using a common fuel meter, elapsed time meter, or equivalent monitoring device, the Facility Permit holder shall provide substitute data as described below whenever a valid quarter of usage data has not been obtained and recorded. Alternative data, based on a back-up fuel meter, elapsed time meter, or equivalent monitoring device, is acceptable for substitution if the Facility Permit holder can demonstrate to the Executive Officer that the alternative system is fully operational during meter down time and within + or - 2% accuracy. The substitute data procedures are retroactively applicable from the adoption date of the RECLAIM program.

2. Whenever data from the process monitor is not available or not recorded for the affected equipment or when the equipment is not operated within the parameter range specified in the Facility Permit, the Facility Permit holder shall calculate substitute data for each quarter, when valid data has not been obtained, according to the following procedures.

   a. For a missing data period less than or equal to one quarter, substitute data shall be calculated using the process unit(s) average quarterly fuel usage for the previous four quarters. If four quarters of data are not available, substitute data shall be calculated as if the facility has no records.

   b. For a missing data period greater than one quarter, substitute data shall be calculated using the process unit(s) highest quarterly fuel usage data for the previous four quarters. If four quarters of data are not available, substitute data shall be calculated as if the facility has no records.

   c. If the facility has no records, substitute data shall be calculated using 100% uptime during the substitution period and the process unit(s) maximum rated capacity and uncontrolled emission factor for each quarter of missing data.

   d. For a process monitor which uses a gas chromatograph or equivalent continuous method to continuously determine the F-factor and higher heating value of the fuel (Rule 2012, Appendix A, Chapter 4, Subdivision B.4.a.i), the Facility Permit holder shall use the stack gas flow rate missing data substitution procedure for major sources (Rule 2011 or 2012, Appendix A, Chapter 2, Subdivision E.2).

QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES

TABLE OF CONTENTS

ATTACHMENT C - QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES

A. Quality Control Program....................C-1

B. Frequency of Testing....................C-2

ATTACHMENT C

QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES

A. Quality Control Program

Develop and implement a quality control program for the continuous emission monitoring systems and their components. As a minimum, include in each quality control program a written plan that describes in detail complete, step-by-step procedures and operations for each of the following activities:

1. Calibration Error Test Procedures

   Identify calibration error test procedures specific to the CEMS that may require variance from the procedures used during certification (for example, how the gases are to be injected, adjustments of flow rates and pressures, introduction of reference values, length of time for injection of calibration gases, steps for obtaining calibration error, determination of interferences, and when calibration adjustments should be made).

2. Calibration and Linearity Adjustments

   Explain how each component of the CEMS will be adjusted to provide correct responses to calibration gases, reference values, and/or indications of interference both initially and after repairs or corrective action. Identify equations, conversion factors, assumed moisture content, and other factors affecting calibration of each CEMS.

3. Preventative Maintenance

   Keep a written record of procedures, necessary to maintain the CEMS in proper operating condition and a schedule for those procedures.

4. Audit Procedures

   Keep copies of written reports received from testing firms/laboratories of procedures and details specific to the installed CEMS that were to be used by the testing firms/laboratories for relative accuracy test audits, such as sampling and analysis methods. The testing firms/laboratories shall have received approval from the District by going through the District's laboratory approval program.

5. Record Keeping Procedures

Keep a written record describing procedures that will be used to implement the record keeping and reporting requirements.

Specific provisions of Section A-3 and A-5 above of the quality control programs shall constitute specific guidelines for facility personnel. However facilities shall be required to take reasonable steps to monitor and assure implementation of such specific guidelines. Such reasonable steps may include periodic audits, issuance of periodic reminders, implementing training classes, discipline of employees as necessary, and other appropriate measures. Steps that a facility commits to take to monitor and assure implementation of the specific guidelines shall be set forth in the written plan and shall be the only elements of Section A-3 and A-5 that constitute enforceable requirements under the written plan, unless other program provisions are independently enforceable pursuant to other requirements of the NO_X protocols or District or federal rules or regulations.

B. FREQUENCY OF TESTING

There are three situations which will result in an out-of-control period. These include failure of a calibration error test, failure of a relative accuracy test audit, and failure of a BIAS test, and are detailed in this subdivision. Data collected by a CEMS during an out-of-control period shall not be considered valid.

The frequency at which each quality assurance test must be performed is as follows:

1. Periodic Assessments

For each monitor or CEMS, perform the following assessments on each day during which the unit combusts any fuel or processes any material (hereafter referred to as a "unit operating day"), or for a monitor or a CEMS on a bypass stack/duct, on each day during which emissions pass through the bypass stack or duct. These requirements are effective as of the date when the monitor or CEMS completes certification testing.

a. Calibration Error Testing Requirements for Pollutant Concentration Monitors and O_2 Monitors

Test, record, and compute the calibration error of each NO_X pollutant concentration monitor and O_2 monitor at least once on each unit operating day, or for monitors or monitoring systems on bypass stacks/ducts on each day that emissions pass through the bypass stack or duct. Conduct calibration error checks, to the extent practicable, approximately 24 hours apart. Perform the daily calibration error test according to the procedure in Paragraph B.1.a.ii. of this Attachment.

For units with more than one span range, perform the daily calibration error test on each scale that has been used since the last calibration error test. For example, if the emissions concentration has not exceeded the low-scale span range since the previous calendar day, the calibration error test may be performed on the low-scale only. If, however, the emissions concentration has exceeded the low-scale span range since the previous calibration error test, perform the calibration error test on both the low- and high-scales

i. Design Requirements for Calibration Error Testing of NO_x Concentration Monitors and O_2 Monitors

Design and equip each NO_x concentration monitor and O_2 monitor with a calibration gas injection port that allows a check of the entire measurement system when calibration gases are introduced. For extractive and dilution type monitors, all monitoring components exposed to the sample gas, (for example, sample lines, filters, scrubbers, conditioners, and as much of the probe as practical) are included in the measurement system. For in situ type monitors, the calibration must check against the injected gas for the performance of all electronic and optical components (for example, transmitter, receiver, analyzer).

Design and equip each pollutant concentration monitor and O_2 monitor to allow daily determinations of calibration error (positive or negative) at the zero-level (0 to 20 percent of each span range) and high-level (80 to 100 percent of each span range) concentrations.

ii. Calibration Error Test for NO_x Concentration Monitors and O_2 Monitors

Measure the calibration error of each NO_x concentration analyzer and O_2 monitor once each day according to the following procedures:

If any manual or automatic adjustments to the monitor settings are made, conduct the calibration error test in a way that the magnitude of the adjustments can be determined and recorded.

Perform calibration error tests at two concentrations: (1) zero-level and (2) high level. Zero level is 0 to 20 percent of each span range, and high level is 80 to 100 percent of each span range. All calibration gases used during certification tests and quality assurance and quality control activities shall be NIST/EPA approved standard reference materials (SRM), certified reference materials CRM), or shall be certified according to "EPA Traceability Protocol for Assay and Certification of Gaseous Calibration Standards," September 1997, EPA 600/R-97/121 or any subsequent version published by EPA.

Introduce the calibration gas at the gas injection port as specified above. Operate each monitor in its normal sampling mode. For extractive and dilution type monitors, pass the audit gas through all filters, scrubbers, conditioners, and other monitor components used during normal sampling and through as much of the sampling probe as practical. For in situ type monitors, perform calibration checking all active electronic and optical components, including the transmitter, receiver, and analyzer. Challenge the NO_x concentration monitors and the O_2 monitors once with each gas. Record the monitor response from the data acquisition and handling system. Use the following equation to determine the calibration error at each concentration once each day:

$$CE = \frac{|R-A|}{S} \times 100 \qquad \text{(Eq. C-1)}$$

Where:

CE = The percentage calibration error based on the span range

R = The reference value of zero- or high-level calibration gas introduced into the monitoring system.

A = The actual monitoring system response to the calibration gas.

S = The span range of the instrument

b. Calibration Error Testing Requirements for Stack Flow Monitors

Test, compute, and record the calibration error of each stack flow monitor at least once within every 14 calendar day period during which at anytime emissions flow through the stack; or for monitors or monitoring systems on bypass stacks or ducts, at least once within every 14 calendar day period during which at anytime emissions flow through the bypass stack or duct. Introduce a zero reference value to the transducer or transmitter. Record flow monitor output from the data acquisition and handling systems before and after any adjustments. Calculate the calibration error using the following equation:

$$CE = \frac{|R - A|}{S} \times 100 \qquad \text{(Eq. C-2)}$$

Where:

CE = Percentage calibration error based on the span range

R = Zero reference value introduced into the. transducer or transmitter.

A = Actual monitoring system response.

S = Span range of the flow monitor.

c. Interference Check for Stack Flow Monitors

Perform the daily flow monitor interference checks specified in Paragraph B.1.c.i. of this Attachment at least once per operating day (when the unit(s) operate for any part of the day).

i. Design Requirements for Flow Monitor Interference Checks

Design and equip each flow monitor with a means to ensure that the moisture expected to occur at the monitoring location does not interfere with the proper functioning of the flow monitoring system. Design and equip each flow monitor with a means to detect, on at least a daily basis, pluggage of each sample line and sensing port, and malfunction of each resistance temperature detector (RTD), transceiver, or equivalent.

Design and equip each differential pressure flow monitor to provide (1) an automatic, periodic backpurging (simultaneously on both sides of the probe) or equivalent method of sufficient force and frequency to keep the probe and lines sufficiently free of obstructions on at least a daily basis to prevent sensing interference, and (2) a means to detecting leaks in the system at least on a quarterly basis (a manual check is acceptable).

Design and equip each thermal flow monitor with a means to ensure on at least a daily basis that the probe remains sufficiently clean to prevent velocity sensing interference.

Design and equip each ultrasonic flow monitor with a means to ensure on at least a daily basis that the transceivers remain sufficiently clean (for example, backpurging the system) to prevent velocity sensing interference.

d. Recalibration

Adjust the calibration, at a minimum, whenever the calibration error exceeds the limits of the applicable performance specification for the NO_x monitor, O_2 monitor or stack flow monitor to meet such specifications. Repeat the calibration error test procedure following the adjustment or repair to demonstrate that the corrective actions were effective. Document the adjustments made.

e. Out-of-Control Period – Calibration Test

An out-of-control period occurs when the calibration error of an NO_x concentration monitor exceeds 5.0 percent based upon the span range value, when the calibration error of an O_2 monitor exceeds 1.0 percent O_2, or when the calibration error of a flow monitor exceeds 6.0 percent based upon the span range value, which is twice the applicable specification. The out-of-control period begins with the hour of completion of the failed calibration error test and ends with the hour of completion following an effective recalibration. Whenever the failed calibration, corrective action, and effective recalibration occur within the same hour, the hour is not out-of-control if 2 or more valid readings are obtained during that hour as required by Chapter 2, Subdivision B, Paragraph 5.

An out-of-control period also occurs whenever interference of a flow monitor is identified. The out-of-control period begins with the hour of the failed interference check and ends with the hour of completion of an interference check that is passed.

f. Data Recording

Record and tabulate all calibration error test data according to the month, day, clock-hour, and magnitude in ppm, DSCFH, and percent volume. Program monitors that automatically adjust data to the calibrated corrected calibration values (for example, microprocessor control) to record either: (1) the unadjusted concentration or flow rate measured in the calibration error test prior to resetting the calibration, or (2) the magnitude of any adjustment. Record the following applicable flow monitor interference check data: (1) sample line/sensing port pluggage, and (2) malfunction of each RTD, transceiver, or equivalent.

2. Semi-annual Assessments

a. For each CEMS, perform the following assessments once semi-annually thereafter, as specified below for the type of test. These semi-annual assessments shall be completed within six months of the end of the calendar quarter in which the CEMS was last tested for certification purposes (initial and recertification) or within three months of the end of the calendar quarter in which the District sent notice of a provisional approval for a CEMS, whichever is later. Thereafter, the semi-annual tests shall be completed within six months of the end of the calendar quarter in which the CEMS was last tested. For CEMS on bypass stacks/ducts, the assessments shall be performed once every two successive operating quarters in which the bypass stacks/ducts were operated. These tests shall be performed after the calendar quarter in which the CEMS was last tested as part of the CEMS certification, as specified below for the type of test.

Relative accuracy tests may be performed on an annual basis rather than on a semi-annual basis if the relative accuracies during the previous audit for the NO_X pollutant concentration monitor, flow monitoring system, and NOx emission rate measurement system are~~is~~ 7.5 percent or less.

b. For CEMS on any stack or duct through which no emissions have passed in two or more successive quarters, the semi-annual assessments must be performed within 14 unit operating days after emissions pass through the stack/duct.

c. The due date for a semi-annual or annual assessment of a major source may be postponed to within 14 unit operating days from the first re-firing of the major source if the major source is physically incapable of being operated and all of the following are met:

i. All fuel feed lines to the major source are either disconnected or opened and either flanges or equivalent sealing devices are placed at both ends of the disconnected or opened lines, and

ii. The fuel meter(s) for the disconnected or opened fuel feed lines are maintained and operated and associated fuel records showing no fuel flow are maintained on site.

This paragraph applies separately for each unrelated, independent event. For any hour that fuel flow records are not available to verify no fuel flow, NOx emissions shall be calculated using the maximum valid hourly emissions from the last 30 days of operation.

Prior to re-starting operation of the major source, the Facility Permit Holder shall: (1) provide written notification to the District no later than 72 hours prior to starting up the source, (2) start the CEMS no later than 24 hours prior to the start-up of the major source, and (3) conduct and pass a Cylinder Gas Analysis (CGA) prior to the start-up of the major source. The emissions data from the CEMS after the re-start of operations is considered valid only if the Facility Permit Holder passes the CGA test. Otherwise, for a non-passing CGA, the CEMS data is considered invalid until the semi-annual or annual assessment is performed and passed. As such, NOx emissions shall be calculated using the maximum valid hourly emissions from the last 30 days of operation commencing with the hour of start up and continuing through the hour prior to performing and passing the semi-annual or annual assessment.

d. An electrical generating facility that either only operates under a California Independent System Operator (Cal ISO) contract or is owned and operated by a municipality may postpone the due date for a semi-annual or annual assessment of a major source to the next calendar quarter provided that the facility shows:

i. The semi-annual or annual assessment was scheduled to be performed during the first 45 days of the calendar quarter in which the assessment was due;

ii. The assessment was not completed due to lack of adequate operational time; and

iii. A CGA was conducted and passed within the calendar quarter when the assessment was due.

e~~a~~. Relative Accuracy Test Audit

Perform relative accuracy test audits and bias tests semi-annually and no less than 3 months apart for each NO_X pollutant concentration monitor, stack gas volumetric flow rate measurement systems, and the NO_X mass emission rate measurement system in accordance with Chapter 2, Subdivision B, Paragraphs 10, ~~Chapter 2, Subdivision B, Paragraph~~ 11, ~~and Chapter 2, Subdivision B, Paragraph~~ 12, and 18. The relative accuracy of the pollutant concentration monitor and the mass emission rate measurement system shall be less than or equal to 20.0 percent, and the relative accuracy of the stack gas volumetric flow rate measurement system shall be less than or equal to 15.0 percent. For monitors on bypass stacks/ducts, perform relative accuracy test audits once every two successive bypass operating quarters in accordance with Chapter 2, Subdivision B, Paragraphs ~~2.B.~~10, ~~2.B.~~11, ~~and 2.B.~~12, and 18.

f~~b~~. Out-of-Control Period – Relative Accuracy Test Audit

An out-of-control period occurs under any of the following conditions: (1) The relative accuracy of an NO_X pollutant concentration monitor or the NO_X emission rate measurement system exceeds 20.0 percent; (2) the relative accuracy of the flow rate monitor exceeds 15.0 percent; or (3) failure to conduct a relative accuracy test audit by the due date for a semi-annual assessment. The out-of-control period begins with the –hour of completion of the failed relative accuracy test audit and ends with the hour of completion of a satisfactory relative accuracy test audit.

g~~c~~. Out-of-Control Period – BIAS Test

An out-of-control period occurs if all the following conditions are met:

i. Failure of a bias test as specified in Attachment B of this Appendix;

ii. The CEMS is biased low relative to the reference method (i.e. Bias Adjustment Factor (BAF), as determined in Attachment B of this Appendix, is greater than 1); and

iii. The Facility Permit holder does not apply the BAF to the CEMS data.

The out-of-control period begins with the hour of completion of the failed bias test audit and ends with the hour of completion of a satisfactory bias test.

h~~d~~. Alternative Relative Accuracy Test Audit

i. The Facility Permit holder of a major source, that has received written approval from the Executive Officer as an intermittently operated source, may postpone the due date for a semi-annual assessment to the end of the next calendar quarter if the Facility Permit holder:

I. operated the source no more than 240 cumulative operating hours and no more than 72 consecutive hours during the calendar quarter when a semi-annual assessment is due; and

II. conducted a relative accuracy test audit on the CEMS serving the source during the previous four calendar quarters and meeting the accuracy criteria as set forth under Subparagraph B.2.e~~a~~.; and

III. conducted an alterative relative accuracy test audit on the CEMS serving the source during the calendar quarter when a semi-annual assessment is due and meeting the criteria specified under Clause B.2.h~~d~~.iii.

If any of the requirements under Subclauses B.2.h~~d~~.i.I, II and III is not met and the source did not have passing RATA during the calendar quarter when the semi-annual assessment is due, emissions from the source shall be determined pursuant to the Missing Data Procedures as specified under Rule 2012, Appendix A, Chapter 2, Subdivision E after the semi-annual assessment due date until the hour of completion of a satisfactory relative accuracy test audit.

ii. The Facility Permit holder may submit a written request to designate a major source as an intermittently operated source provided the Facility Permit holder demonstrates that:

I. During any calendar quarter within the previous two compliance years, the source was operated no more than 240 cumulative operating hours and no more than 72 consecutive hours; or

II. During any calendar quarter within the next two compliance years, the source will be operated no more than 240 cumulative operating hours and no more than 72 consecutive hours.

iii. An alternative relative accuracy shall consist of a Cylinder Gas Analysis (CGA) method as defined under 40 CFR, Part 60, Appendix F, combined with a flow accuracy verification. For sources equipped with stack flow monitors, the flow accuracy shall be verified by calibrating the transducers and transmitters installed on the stack flow monitors using procedures under Paragraph B.3 of this attachment. For sources equipped with fuel flow meters and no stack flow monitors, the flow accuracy shall be verified by calibrating the fuel flow meters either in-line or offline in accordance with the procedures outlined in 40CFR Part 75, Appendix D. Passing flow accuracy verification results that were obtained within the past 4 quarters may be used in lieu of performing a flow accuracy verification during the calendar quarter when a semi-annual assessment is due. The calculated accuracy for the analyzer responses for NO_x and O_2 concentration shall be within 15 percent or 1 ppm, whichever is greater, as determined by the CGA method as defined under 40 CFR, Part 60, Appendix F. Successive alternative relative accuracy test audits shall be performed no less than 45 days apart.

3. Calibration of Transducers and Transmitters on Stack Flow Monitors

All transducers and transmitters installed on stack flow monitors must be calibrated every two operating calendar quarters, in which an operating calendar quarter is any calendar quarter during which at anytime emissions flow through the stack. Calibration must be done in accordance with Executive Officer approved calibration procedures that employ materials and equipment that are NIST traceable.

When a calibration produces for a transducer and transmitter a percentage accuracy of greater than ± 1%, the Facility Permit holder shall calibrate the transducer and transmitter every calendar operating quarter until a subsequent calibration which shows a percentage accuracy of less than ± 1% is achieved. An out-of-control period occurs when the percentage accuracy exceeds ±2%. If an out-of-control period occurs, the Facility Permit holder shall take corrective measures to obtain a percentage accuracy of less than ±2% prior to performing the next RATA. The out-of-control period begins with the hour of completion of the failed calibration error test and ends with the hour of completion of following an effective recalibration. Whenever the failed calibration, corrective action, and effective recalibration occur within the same hour, the hour is not out-of-control if two or more valid data readings are obtained during that hour as required by Chapter 2, Subdivision B, Paragraph 5, Subparagraph a.

SOUTH COAST AIR QUALITY MANAGEMENT DISTRICT

Draft Final Staff Report

Proposed Amendments to Regulation XX
Regional Clean Air Incentives Market (RECLAIM)
NOx RECLAIM

~~October 6~~~~November~~ December 4, 2015

Executive Summary

Background

On October 15, 1993, the South Coast Air Quality Management District (SCAQMD) Governing Board adopted Regulation XX - REgional Clean Air Incentives Market (RECLAIM). Regulation XX includes rules that specify the applicability and procedures for determining NOx and SOx facility emissions allocations, program requirements, as well as monitoring, reporting, and recordkeeping requirements for sources located at RECLAIM facilities. RECLAIM was designed to provide equivalent emission reduction in the aggregate for the facilities in the program compared to what would occur under a command-and-control approach, with flexibility for each facility to find the most cost-effective strategy to meet their emission reduction targets. The program requires robust monitoring to ensure compliance. Over the past more than 20 years, the program has resulted in significant emission reductions. The RECLAIM program started with 392 NOx facilities in 1993. By the end of compliance year 2013, there were 275 facilities in the NOx RECLAIM universe.

Best Available Retrofit Control Technology for RECLAIM

When the NOx RECLAIM program was first adopted, the NOx RECLAIM facilities were issued NOx annual allocations (also known as facility caps), which declined annually from 1993 until 2003 and remained constant after 2003. The annual allocations issued to the NOx RECLAIM facilities reflected the levels of Best Available Retrofit Control Technology (BARCT) envisioned to be in place at the RECLAIM facilities, and were the result of a BARCT analysis conducted in 1993. A BARCT reassessment is required by the California Health & Safety Code (H&SC) §40440 to assess the advancement in control technology and to ensure that RECLAIM facilities achieve the same emission reductions that would have occurred under a command-and-control approach and that emission reductions from the program contribute to the efforts in the Basin to achieve the federal National Ambient Air Quality Standards (NAAQS). The SCAQMD staff conducted a BARCT reassessment for NOx in 2005 and another for SOx in 2010, and subsequently amended the RECLAIM rules to reduce the facility annual allocations. RECLAIM facilities have the flexibility to install air pollution control equipment, change their operations, or purchase RECLAIM Trading Credits (RTCs).

Ozone Non-Attainment Status

On March 12, 2008, the EPA strengthened its ground-level 8-hour ozone standard from 0.08 parts per million (ppm) to 0.075 ppm. On May 21, 2012, the EPA classified two areas in the country, the South Coast and the San Joaquin Valley, as “Extreme” non-attainment areas with respect to the 2008 8-hour ozone standard. The attainment dates for the 1997 and 2008 ozone standards are

June 15, 2024 and July 20, 2032, respectively with emissions reductions and attainment required in the previous calendar year. NOx is a precursor for ozone. Significant reductions in NOx emissions are necessary for the Basin to attain the *federal* 24-hour PM2.5 standard ~~in~~ *by* 2019 and the *federal* ozone ambient air quality standards in 2023 and 2031.

2012 Air Quality Management Plan and Control Measure CMB-01

The SCAQMD developed and adopted the 2012 Air Quality Management Plan (AQMP) in partnership with CARB, U.S. EPA, SCAG and stakeholders throughout the region to outline the strategy to meet and maintain the state and federal air quality standards. The 2012 AQMP identified control measures needed to attain the federal 24-hour standard for PM2.5 by 2014 and provided updates on progress towards meeting the 8-hour ozone standard in 2023. Control Measure CMB-01 – Further NOx Reduction for RECLAIM is one of the control measures included in the 2012 AQMP. Control Measure CMB-01 called for a reassessment of BARCT for NOx RECLAIM facilities and estimated that a total of 2-3 tons per day (tpd) of NOx emission reductions could be achieved in 2014 for Phase I with an additional of 1-2 tpd NOx in 2020 for Phase II following the BARCT analysis. CMB-01 Phase I served as a PM2.5 SIP contingency measure for the 2012 AQMP, and if emission reductions were not needed in Phase I, the RTC reductions estimated for Phase I would be combined with the total reductions that could be achieved in Phase II. It was anticipated that NOx emissions reductions from both phases would also contribute to meeting the ozone standards in 2024 and 2032.

Current Emissions and RTC Holdings

The 2011 audited actual emissions were 20 tons per day (tpd) for the RECLAIM universe (59% from the refineries and 41% from the non-refinery sector). For ~~electrical~~ electricity generating facilities, staff used 2012 emissions instead of 2011 due to several reasons: 1) local ~~electrical~~ electricity generating facilities in the region operated more in 2012 to make up for the closure of the San Onofre Nuclear Generation Station (SONGS), 2) the commissioning of new ~~electrical~~ electricity generating facilities in the region was reflected more accurately in 2012, and 3) a recent shift in the use of renewable energy sources, such as wind, solar, and water, and their inherent intermittency resulted in the use of peaking units with increased numbers of startups and associated emissions. The 2011/2012 baseline emissions for the NOx RECLAIM universe in this analysis were 20.7 tpd.

The RECLAIM Trading Credit (RTC) holdings for the RECLAIM universe were 26.5 tpd, of which the refinery sector held 51% of the RTCs, ~~electrical~~ electricity generating facilities 21%, investors 4% and other RECLAIM facilities 24%.

Proposed BARCT, Emission Reductions, and RTC Reductions

The BARCT analysis resulted in the BARCT levels and incremental emission reductions by 2023 shown in Table EX.1. For the refinery sector, a new level of BARCT is proposed for fluid catalytic cracking units, boilers/heaters >40 mmbtu/hr, gas turbines, coke calciners, and sulfur recovery and tail gas incinerators. For the non-refinery sector, a new BARCT level is proposed for container glass melting furnaces, cement kilns, sodium silicate furnaces, metal melting furnaces >150 mmbtu/hr, gas turbines and ICEs not located on the outer continental shelf (OCS). No new BARCT is proposed for ~~electrical~~ electricity generating facilities.[1]

Table EX. 1 - Summary of Proposed BARCT (May 2015)

Refinery Sector	2015 BARCT Level	Incremental Emission Reductions from 2000/2005 BARCT (tpd)
Fluid Catalytic Cracking Units	2 ppmv at 3% O2	0.43
Refinery Boilers and Heaters >40 mmbtu/hr	2 ppmv or 0.002 lb/mmbtu	0.94
Refinery Gas Turbines	2 ppm at 15% O2	4.14
Coke Calciner	10 ppmv at 3% O2	0.17
Sulfur Recovery Units Tail Gas Incinerators	2 ppmv at 3% O2 or 95% reduction	0.32
	Total	**6.00**

Non-refinery Sector	2015 BARCT Level	Incremental Emission Reductions from 2000/2005 BARCT (tpd)
Container Glass Melting Furnaces	80% reduction	0.24
Sodium Silicate Furnace	80% reduction	0.09
Metal Heat Treating Furnaces >150 mmbtu/hr	9 ppmv at 3% O2	0.56
Gas Turbines (non-OCS)	2 ppmv at 15% O2	1.04
Internal Combustion Engines (non-OCS)	11 ppmv at 15% O2	0.84
Cement Kilns	0.5 lbs/ton	1.29 (note)
	Total	**2.77**

Note: The 1.29 tpd emission reductions from cement kilns were not included in the 2.77 tpd emission reductions because the cement facility was not in operation in 2011. Cement kilns were the highest emitting stationary source of NOx emissions in 2008, thus staff conducted a BARCT analysis for cement kilns and reduced the remaining emissions projected to the 2023 level for the cement facility to the BARCT level.

[1] Staff conducted a BARCT analysis focusing on the top 37 NOx emitting facilities in 2011, and a cement plant which was the highest NOx emitting stationary source in 2008. The BARCT analyses with detailed information are in the appendices (Appendices A-J of Part I for the refinery sector, and Appendices M-S of Part II for the non-refinery sector.)

As shown in Table EX.1, the total BARCT-equivalent emission reductions are 8.8 tpd (6.00 tpd for the refinery sector and 2.77 tpd for the non-refinery sector.) Due to projected growth,[2] the remaining emissions in 2023 at these proposed 2015 BARCT levels would be 10.2 tpd (2.76 tpd for the refinery sector and 7.47 tpd for the non-refinery sector.) Staff has added a 10% compliance margin to the 2023 remaining emissions. In addition, staff has added the remaining emissions from shutdown glass and cement facilities at BARCT levels, thereby adding to the compliance margin, as well as the emissions for new facilities entering RECLAIM program since 2005 to the total remaining emissions. Staff has provided some adjustments to account for uncertainties that arose in the BARCT analysis and for additional 2011 activity level adjustment. This results in total proposed NOx RTC reductions of 14 tpd from the current RTC holdings of 26.5 tpd in 2023.[3] The remaining RTCs for the NOx RECLAIM universe would be 12.5 tpd (26.5 tpd – 14 tpd = 12.5 tpd), which is 2.3 tpd or almost ~~23~~22.5% above the projected remaining emissions from RECLAIM NOx sources in 2023. See Figure EX.1.

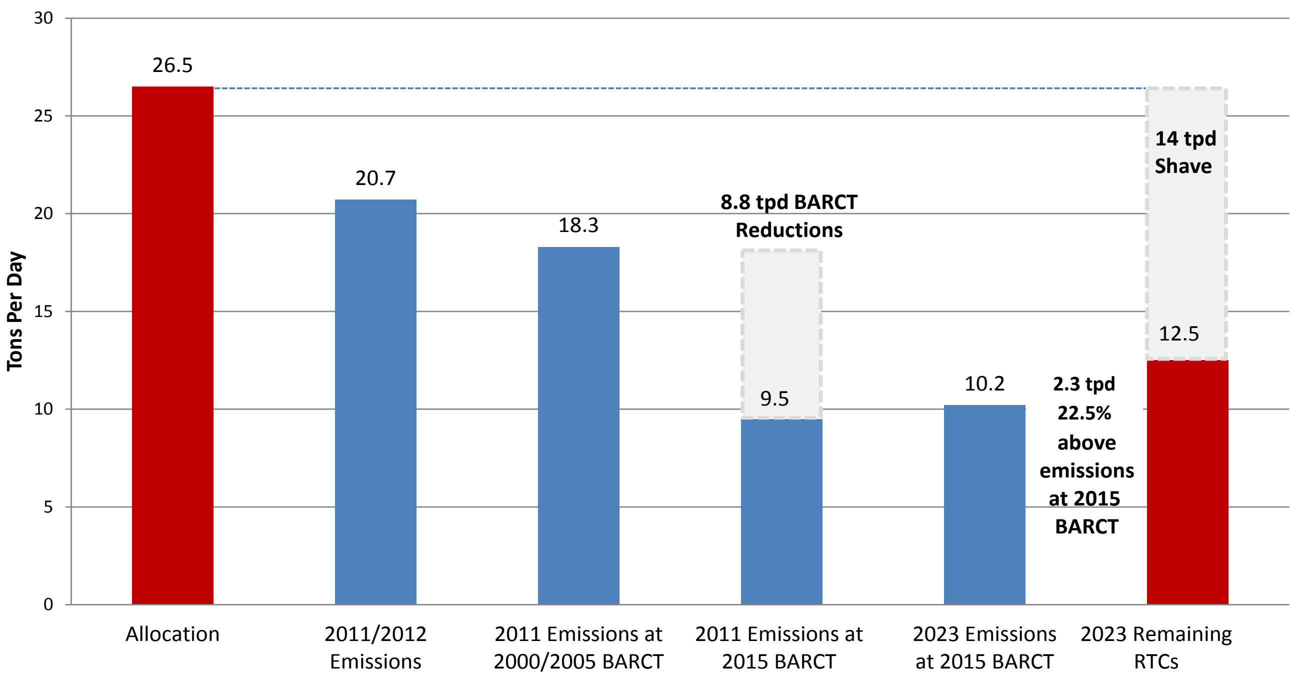

Figure EX. 1 – Audited Emissions and RTC Holdings

---

[2] The growth factor for the refineries is 1. Electric generating facilities are expected to be more efficient with growth factor of 0.89 (2014 California Gas Report). The average growth factor for other non-refinery facilities is 1.1 (Southern California Association of Government (SCAG)).

[3] RTC Reductions = RTC Holdings – Remaining Emissions in 2023 - Adjustments = 14 tpd. Refer to Chapter 5 and Appendix U of Part III for detailed information.

Staff is proposing to distribute the 14 tpd NOx RTC reductions to 56 facilities and investors that hold 90% of the 26.5 tpd RTCs. Investors are grouped with the refineries and treated as a facility for shave purposes. The remaining 219 facilities that hold 10% of the 26.5 tpd RTC are not proposed to be shaved because there was limited or no new BARCT for the types of equipment and operation at these facilities.[4] Staff's current proposal is to weight the amount of shave considering the technology available to different facility types as summarized below:

66% shave for 9 refineries and investors
49% shave for 21 ~~electrical~~ electricity generating facilities
49% shave for 26 other major facilities
0% shave for 219 remaining facilities

The 2023 remaining emissions after installing BARCT, the RTC holdings after the shave, and the surplus or deficit RTCs after the shave for each industry sector are presented in Table EX.2. After the shave, the 9 refineries, the investors, and the 21 ~~electrical~~ electricity generating facilities would have surplus RTCs. Some facilities in the 26 non-~~electrical~~ electricity generating facilities and the 219 remaining facilities would not be subject to any shave however their emissions would grow above the RTC holdings that they currently have and they would have to purchase RTCs from other industry sectors to reconcile their projected emissions. Overall, there is a net of 2.3 tpd surplus RTCs for the entire RECLAIM universe.

Table EX. 2 – Summary of 2023 RTC Holdings and 2023 Emissions After BARCT

	9 Refineries	**15 Investors**	**21 ~~Electrical~~ Electricity generating facilities**	**26 Non-~~Electrical~~ Electricity generating facilities**	**219 Other Facilities**	**Net Total**
Current RTC Holdings (tpd) (note)	14.15	0.42	5.63	3.45	2.86	26.5
% Shave	66%	66%	49%	49%	0%	
RTC Holdings After Shave (tpd)	4.81	0.14	2.87	1.76	2.86	12.5
2023 Emissions After BARCT (tpd)	2.76	0	2.04	1.93	3.5	10.2
Surplus or Deficit RTCs (tpd)	2.05	0.14	0.83	(0.17)	(0.64)	2.3

Note: RTC Holdings as of September 22, 2015

Staff is proposing to implement the 14 tpd RTC reductions over a 7-year period from 2016 to 2022 but as expeditiously as possible to help the Basin meet the PM2.5 standard deadlines as well as the ozone standards in 2023 and 2031. Staff is proposing the following implementation schedule for NOx RTC reductions:

2016 – 4 tons per day

[4] The ICEs and small boilers or heaters in the remaining 219 facilities could be subject to additional BARCT but the potential emission reductions totaled less than 0.1 tpd.

2018 – 2 tons per day
2019 – 2 tons per day
2020 – 2 tons per day
2021 – 2 tons per day
2022 – 2 tons per day

Over the past five years from 2009-2013, the unused RTCs in the NOx RECLAIM program ranged from 5 tpd to 8 tpd. Staff is proposing a 4 tpd RTC reduction in 2016. Additional BARCT implementation will take about 2 - 4 years for planning, permitting, and construction, and thus staff is proposing the remaining shave of 10 tpd to take place over five years from 2018 to 2022.

The BARCT analyses are described in Chapter 3, the costs and cost effectiveness of the proposal are described in Chapter 4 and are summarized in Table EX.3. The total Present Worth Values (PWVs) of the project range from $728 M to $1.1 B, and the overall cost effectiveness values of the project as a whole range from $9 K to $14 K per ton NOx reduced. Individual category cost-effectiveness is set forth in the table below. The RTC reductions are estimated in Chapter 5, and the proposed changes in rule language are described in Chapter 6.

Table EX. 3 - Summary of Costs and Cost Effectiveness

	2015 BARCT	Incremental Emission Reductions from 2000/2005 BARCT (tpd)	Number of Affected Facilities	Estimated No of Control Devices	PWVs ($M)	Incremental Cost Effectiveness (thousand dollars/ton)
Refinery Sector						
FCCUs	2 ppmv	0.43	5	5 SCRs (or 2 SCRs + 3 LoTOx/WGS)	152 - 391	3 - 13
Boilers and Heaters	2 ppmv	0.94	8	~~75~~ 73 SCRs	237	28
Refinery Gas Turbines	2 ppm	4.14	5	7 SCRs and adding catalysts to 4 SCRs	53 - 98	1 - 3
Coke Calciner	10 ppmv	0.17	1	1 UltraCat (or 1 LoTOx/WGS)	40 - 91	22 - 35
SRU/TG Incinerators	2 ppmv	0.32	4	6 SCRs (or 1 SCRs + 5 LoTOx/WGS)	83 - 106	28 - 40
Refinery Total		**6.00**		**~~92~~ 91 SCRs + 1 UltraCat (or ~~84~~ 83 SCRs and 9 LoTOx/WGS) and adding catalysts to SCRs**	**565 - 923**	**10 - 17**
Non-Refinery Sector						
Glass Melting Furnaces	80% red	0.24	1	2 SCRs (or 1 UltraCat)	6 - 15	3 - 7
Sodium Silicate Furnace	80% red	0.09	1	1 SCR (or 1 UltraCat)	3 - 5	4 - 8
Metal Heat Treating	9 ppmv	0.56	1	1 SCR	8 - 10	3 - 4
Gas Turbines (non-OCS)	2 ppmv	1.04	3	14 SCRs	~109	5 - 36
ICEs (non-OCS)	11 ppmv	0.84	7	16 SCRs	~37	5 - 8

Non-Refinery Total (w/o Cement Kilns)	**2.77**		**34 SCRs (or 31 SCRs and 2 UltraCat)**	**163 - 176**	**6 - 7**
Overall	**8.8**		**~~127~~ 125 SCRs + 1 UltraCat (or ~~115~~ 114 SCRs + 9 LoTOx/WGS + 2 UltraCat)**	**728 - 1099**	**9 - 14**

Public Process

The public process for PAR XX – NOx RECLAIM is summarized in Table EX.4. Staff began this rulemaking process in the 4th quarter 2012. In 2013, staff formed a RECLAIM Working Group to discuss potential amendments to the NOx RECLAIM program that included members representing NOx RECLAIM facilities, the Western States Petroleum Association (WSPA), the environmental community, as well as CARB and U.S. EPA. The first meeting was conducted on January 31, 2013. A list of participants is shown in Table EX.5.

To gather pertinent information for rule development, staff sent out Survey Questionnaires to 38 facilities, including the top 37 emitting facilities in 2011 and a cement facility which was the highest NOx stationary emission sources in 2008. Since January 2013, ~~eleven~~ *fourteen* Working Group Meetings were held to discuss potential BARCT levels for major NOx sources ~~at the top 37 and cement facilities~~, the emissions inventory, potential for emission reductions, and proposals for RTC reductions.[5] In addition, in September 2014, SCAQMD staff contracted with two consultants (Environmental Technology Services, Inc. (ETS) and Norton Engineering Consultants Inc. (NEC)) to conduct independent BARCT analyses. The consultants and staff visited a glass manufacturing facility, a cement manufacturing facility, and six refineries to assess the availability of space for the installation of additional controls and to discuss BARCT issues and concerns with the stakeholders. The consultants completed their analyses in December 2014, and staff held the 8th Working Group Meeting in January 7, 2015 to report on the consultants' findings to the stakeholders. A CEQA and Socioeconomic scoping session was held in January 8, 2015 and staff received ten comment letters. From January to March 2015, staff reviewed the consultants' analyses and addressed comments received in response to the CEQA and Socioeconomic scoping session. Staff also extended the contract for NEC to allow time to produce the confidential proprietary information reports for each refinery, and this task was completed in April 2015.

In addition to the ~~twelve~~ fourteen Working Group Meetings, staff participated in over ~~30~~ *50* meetings *held* with various stakeholders individually or in groups to discuss the BARCT analysis and the proposed allocation reduction distribution (shave) methodology. Staff also met with a

[5] The Survey Questionnaires for the refineries and non-refineries are in Appendix L and Appendix T, respectively. The detailed BARCT analyses are in the relevant appendices (Appendices A-J for refinery sector and Appendices M-S for non-refinery sector.) Staff focused on the top 37 emitting facilities contributing more than 85% of the 2011 emissions and the cement plant which was the highest NOx stationary emission source in 2008. Staff looked at other sources in the remaining facilities: the emission reductions from ICEs and small boilers and heaters at these facilities would generate less than 0.1 tpd emission reductions and staff did not identify any more stringent BARCT for other equipment at these facilities.

number of air pollution control manufacturers to discuss control technologies, and invited the manufacturers to write manuscripts and give presentations at the 2014 Air & Waste Management Association annual conference in Long Beach. Several refinery representatives participated in the discussions at the conference.

A Public Workshop was conducted on July 22, 2015, a Public Consultation Meeting was conducted on September 29, 2015, the draft Program Environmental Assessment was released on August ~~13~~14, 2015 for 75 days public comments, and the draft socioeconomic analysis was released on September 9, 2015. ~~Three~~ Four Stationary Source Committee meetings were held on March 21, 2014, July 24, 2014, ~~and~~ October 14, 2015, and November 20, 2015 including a special session requested by industry devoted to RECLAIM discussion. The Public Hearing is scheduled for ~~November 6~~December 4, 2015.

Table EX. 4 - Summary of Public Process

Calendar Year 2013	
January 31, 2013	RECLAIM Working Group was formed. The 1st RECLAIM Working Group Meeting was conducted
March 20, 2013	2nd RECLAIM Working Group Meeting
June 13, 2013	3rd RECLAIM Working Group Meeting. Staff conducted a Survey to gather information for rule development.

Chapter 1 – Background

Legislative Authority

The California Legislature created the SCAQMD in 1977 as the agency responsible for developing and enforcing air pollution control rules and regulations in the South Coast Air Basin (Basin). The H&SC requires the SCAQMD to adopt an AQMP outlining how the Basin will achieve and maintain state and federal ambient air quality standards by the earliest practicable date. In addition, the SCAQMD is required to adopt rules and regulations to implement the AQMP. The SCAQMD's rules and regulations must contain BARCT for existing sources. The SCAQMD staff is required to conduct a BARCT reassessment on a regular basis to capture the advancement in control technology and to ensure that RECLAIM facilities achieve the emission reductions that would have occurred under a command-and-control approach and that emission reductions from the program contribute to the Basin achieving the federal and state ambient air quality standards. The relevant H&S provisions, including a definition of BARCT, are cited below:

H&SC §40460(a): "*… the south coast district board shall adopt a plan to achieve and maintain the state and federal ambient air quality standard.*"

H&SC §40440(a): "*The south coast district board shall adopt rules and regulations that carry out the plan and are not in conflict with state law and federal laws and rules and regulations*."

H&SC §40440(b)(1): "*~~-~~The rules and regulations adopted … shall … require the use of best available control technology for new and modified sources and the use of best available retrofit control technology for existing sources*."

H&SC §40406: "*…best available retrofit technology means an emission limitation that is based on the maximum degree of reduction achievable taking into account environmental, energy, and economic impacts by each class or category of source.*"

Non-Attainment Status

Relative to the ozone and PM2.5 NAAQS promulgated by the U.S. EPA to protect public health and the environment, the Basin is currently classified as an "extreme" non-attainment area for ozone and is a non-attainment area for annual and 24-hour PM2.5. Scientific studies have found an association~~s~~ between exposure to particulate matter and ozone and significant health problems, including asthma, chronic bronchitis, reduced lung function, irregular heartbeat, heart attack, and premature death in people with heart or lung disease. Individuals particularly sensitive to air pollution exposure include older adults, people with heart and lung disease, and children.

There are six criteria pollutants that contribute to ambient air pollution for which there are federal NAAQS: ozone, carbon monoxide, lead, particulate matter, sulfur dioxide, and nitrogen dioxide. The effect of reducing emissions of each of these pollutants varies by area depending on the composition of the atmosphere, concentrations of these pollutants and other area-specific factors. The federal EPA requires the SCAQMD to implement all reasonably available control measures (RACM) and reasonably available control technology (RACT) considering economic and technical feasibility and other factors to reduce criteria air pollutants.

On March 12, 2008, the EPA strengthened its ground-level 8-hour ozone standard from 0.08 ppm to a level of 0.075 ppm. On May 21, 2012, the EPA classified two areas in the country, the South Coast and the San Joaquin Valley, as "Extreme" non-attainment areas with respect to the 2008 8-hour ozone standard. The attainment dates for the 1997 and 2008 ozone standards are June 15, 2024 and July 20, 2032, respectively, with emission reductions and attainment required in the previous calendar year. NOx is a major precursor of ozone and PM2.5, and reducing NOx is essential for the Basin to attain the ozone ambient air quality standards while also helping to meet PM2.5 standards. The SCAQMD staff is currently developing the 2016 AQMP to address ozone and PM2.5 attainment strategies.

Control Measure CMB-01 of the 2012 AQMP

Control Measure CMB-01 – *Further NOx Reductions from RECLAIM* is one of the control measures specified in the 2012 AQMP. The control measure CMB-01 has 2 phases: Phase I has an estimated reduction of 2–3 tpd NOx and serves as a contingency measure for PM2.5 attainment. A contingency measure is a measure that will be automatically implemented if the basin fails to meet the PM2.5 standards by the attainment date. Based on recent data, the Basin will fail to meet the 24-hour PM2.5 ambient air quality standard by the original attainment date of 2014 as well as the revised attainment date of 2015. Therefore, the SCAQMD has asked EPA to reclassify the Basin as "serious" non-attainment for the 24-hour standard, and will be required to submit a new attainment plan. If Phase I was not triggered, CMB-01 anticipated that Phase I reductions would be rolled into Phase II to help attain the ozone standards. In combination, Phase I and Phase II together had estimated reductions of 3-5 tpd with the lower end of emission reduction range committed to in the State Implementation Plan (SIP) yet to be acted on by U.S. EPA. The adoption date and implementation date for Control Measure CMB-01 were estimated to be 2015 and 2020, respectively. The analysis done for these amendments resulted in significantly more reductions than those identified in the control measure. The control measure emission reduction estimates are based on information available at that time, and the emission reductions proposed for a rule that implements a control measure can be more or less than the control measure estimate based on additional analysis of available cost effective technologies. The control measure CMB-01 mentioned that additional reductions would be sought if required to implement BARCT, and that all feasible reductions are needed to attain the ozone standards.

Current NOx RECLAIM Program

On October 15, 1993, the SCAQMD's Governing Board adopted the RECLAIM program and Regulation XX. Regulation XX includes 11 rules that specify the applicability, NOx and SOx allocations, general requirements, as well as monitoring, reporting, and recordkeeping requirements. The RECLAIM program started with 392 NOx facilities in 1993, dropped to 281 facilities in 2011, with 275 facilities by end of the 2013 compliance year. Under the RECLAIM program, facilities are issued SOx and NOx annual allocations, also known as facility caps. The facility caps decline annually to reflect the levels of BARCT that were envisioned to be in place at the RECLAIM facilities. To meet their annual declining allocations, RECLAIM facilities have the flexibility of installing pollution control equipment, changing operations, or purchasing RECLAIM Trading Credits. It was envisioned that a BARCT analysis would be conducted periodically to capture the advancement in control technology and to assure that the RECLAIM program would achieve emission reductions equivalent to command and control approaches and as expeditiously as possible. Throughout the years, there have been a number of amendments to the RECLAIM rules, including BARCT reassessments for NOx in 2005 and SOx in 2010. As a result of the January 2005 amendment, NOx RTCs were reduced by 7.7 tpd, approximately 22.5%, applied all 281 RECLAIM facilities. This reduction was implemented in phases: 4 tpd by 2007 and an additional 0.925 tpd in each of the following 4 years. Figures 1.1 - 1.3 show the historical trend of NOx emissions, RTC allocations, and RTC price for compliance years 1994 - 2013 reflecting the fact that the NOx reductions specified by the January 2005 amendment did not upset the market or cause RTC prices to rise above the $15,000 per ton, which is the level specified in Rule 2015 that would require a program review.

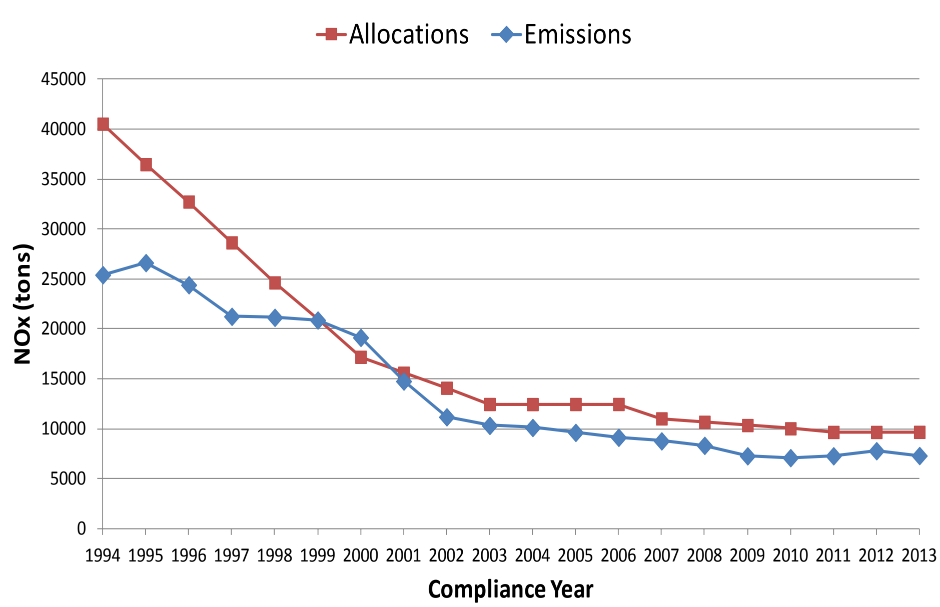

Figure 1. 2 – Audited Emissions and RTC Holdings

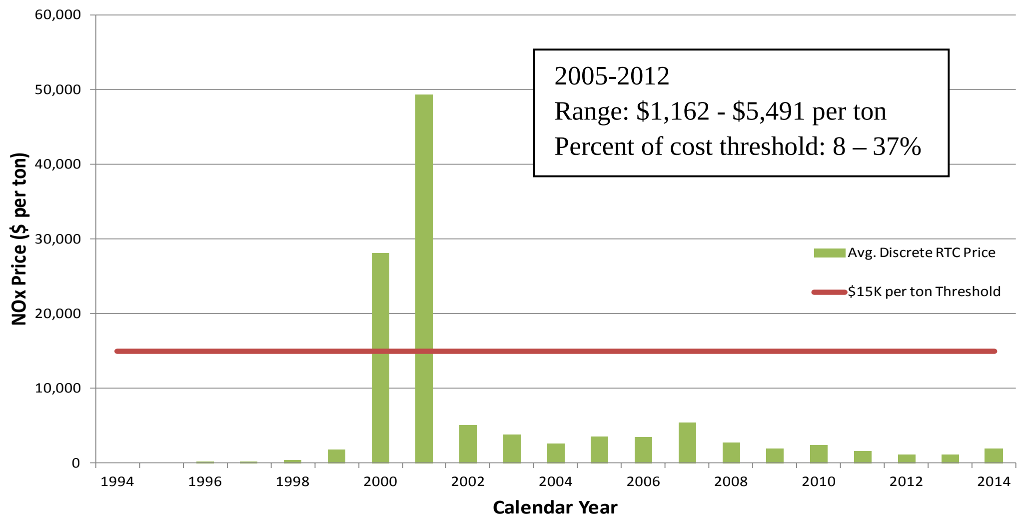

Figure 1.3 – NOx Discrete RTC Price versus Threshold

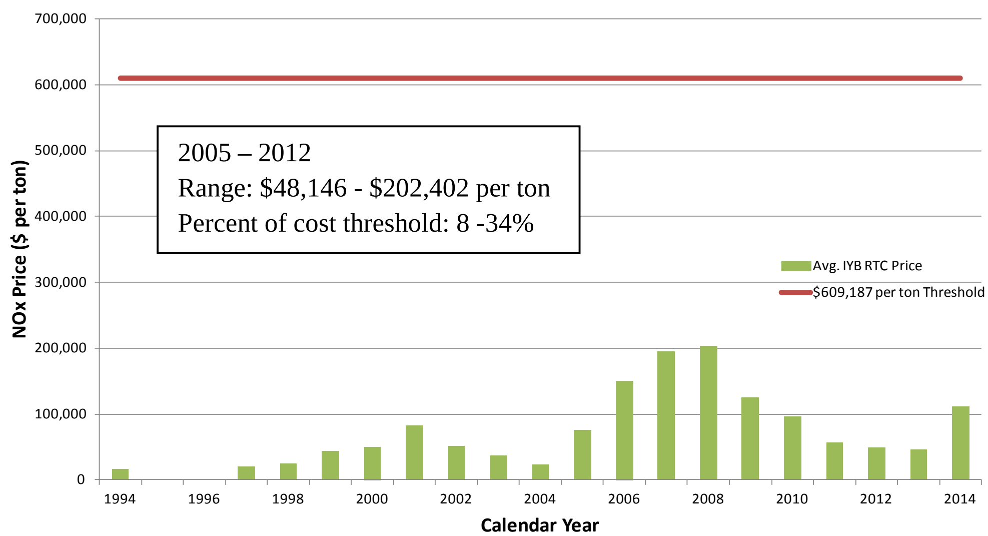

Note: IYB cost threshold is adjusted annually by CPI

Figure 1.4 – NOx Infinite Year Block (IYB) RTC Price versus Threshold

According to the RECLAIM Annual Audit Reports, the vast majority of the RECLAIM facilities complied with their NOx RTC allocations and their aggregate RECLAIM NOx emissions remained below their NOx allocations for each compliance year since 2005. RECLAIM facilities had a high rate of compliance for covering emissions with RTCs. The same was true for all other years of the program except for 2000 and 2001 when there was a California power crisis. The audited annual NOx emissions, NOx RTCs allocated for the universe, and unused RTCs are summarized in Table 1.1. Data show that approximately 21–30% RTCs in each of the past 5 years were not used, approximately 5.45 tpd – 8.41 tpd.

Table 1. 1 – Audited Emissions, RTC Holdings and Unused RTCs from 2009-2013

Compliance Year	Audited emissions (tons)	RTC Holdings (tons)	Unused RTCs (tons)	Unused RTCs (%)
2009	7,306	10,377	3,071	30%
2010	7,121	10,053	2,932	29%
2011	7,302	9,690	2,388	25%
2012	7,691	9,689	1,988	21%
2013	7,326	9,699	2,373	24%

Reference: Table 3-2, page 3-4, Annual RECLAIM Audit Report for 2013 Compliance Year

NOx RECLAIM Facilities

There were ~~281~~ *276* facilities in RECLAIM as of June 2011 and 275 by the end of compliance year 2013. These facilities either elected to enter the program or had NOx emissions greater than or equal to four tons per year in 1990 or any subsequent year. The distribution of the 20 tpd audited 2011 emissions and the 26.5 tpd RTC allocations for 2020 are shown in Figures 1.5 and 1.6.

The top 37 facilities emitted 17.10 tpd NOx in 2011, more than 85% of emissions. The NOx emissions from RECLAIM facilities are generated from a wide range of equipment, and the top NOx emitting sources at the 37 facilities are refinery coke calciners, refinery fluidized catalytic cracking units, refinery and non-refinery gas turbines, refinery boilers and heaters, glass melting furnaces, sodium silicate furnaces, metal heat treating furnaces, internal combustion engines, and refinery sulfur recovery and tail gas incinerators. Cement kilns were the highest emitting stationary NOx source in 2008. The 2011 inventory did not include the cement kilns in the inventory since they were non-operational and subsequently shut down in 2012. However staff did identify a new BARCT level for this operation and removed the equivalent amount of emissions from the remaining emissions in 2023 from the cement kiln.

Figure 1.6 shows the amount of RTC holdings by sector for Compliance Year 2020 without considering 2015 BARCT levels and the proposed amendments. Refineries hold over half of the RTCs with the second most predominant RTC holding industry being ~~electrical~~ electricity generating facilities.

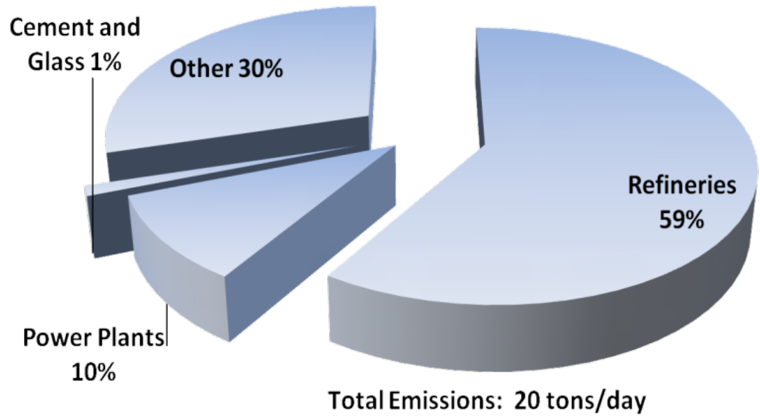

Figure 1. 5 – Distribution of 20 tpd NOx Emissions (End of Compliance Year 2011)

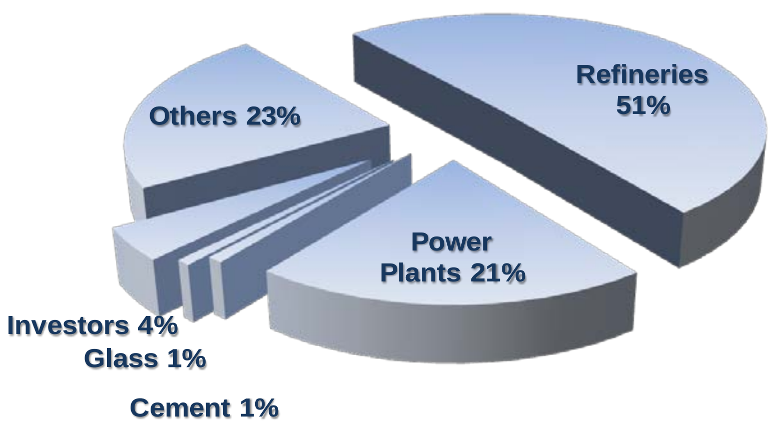

Figure 1. 6 – Distribution of 26.5 tpd RTC Holdings (End of Compliance Year 2020)

Chapter 2 – Facility Emissions and RTC Holdings

Projected Emissions and Emission Reductions

As stated in the 2012 AQMP and summarized in Table 2.1 below, NOx emissions from the RECLAIM facilities were projected to be about 27 tpd by 2023 (26.51 tpd total allocation rounded up to 27 tpd in the 2012 AQMP), representing 37% of the NOx emissions from stationary sources. Collectively, RECLAIM is the fourth largest source of NOx emissions in the Basin in 2023 as shown in Table 2.2.

The 3-5 tpd of reductions for CMB-01 were estimated during the development of the 2012 AQMP, however staff's analysis of BARCT shows that additional reductions from RECLAIM NOx sources are possible. Staff is proposing that the RECLAIM program can contribute 14 tpd additional NOx emissions reductions by 2023.

Audited Facility Emissions and RTC Allocations

The ~~281~~ *276* RECLAIM facilities, as of June 2011, emitted 20.0 tpd NOx in 2011 adjusted to 20.7 tpd NOx using the ~~electrical~~ electricity generating facilities' emissions in 2012 instead of 2011 emissions. Table 2.3 below lists the top 37 emitting facilities that contributed 17.10 tpd NOx emissions in 2011, more than 85% of the emissions from the entire NOx RECLAIM universe. The cement facility, the highest emitting NOx facility from 2008 to 2010, was not in operation in 2011.

At the beginning of the RECLAIM program, the NOx RECLAIM universe was granted 40,534 tons per year (111 tpd) RTCs. This original amount of RTCs gradually dropped to a level of 12,486 tons per year (34.2 tpd) in 2005. In 2005, the RECLAIM rules were amended to implement a BARCT assessment that resulted in a cumulative RTC reduction of 7.7 tpd that was fully implemented in 2011. For compliance year 2011 and beyond, the RTC holdings for the NOx universe remain at a constant level of 9,677 tons per year (26.5 tpd).

Major NOx Sources at Top Emitting Facilities

RECLAIM Rule 2012 establishes the requirements for monitoring, reporting and recordkeeping of NOx emissions under the RECLAIM program and classifies the NOx emitting equipment at the RECLAIM facilities into three categories: major NOx sources, large NOx sources, and NOx process units. RECLAIM facilities are required to monitor the emissions for each major NOx source with a Continuous Emissions Monitoring System (CEMS) and report the emissions electronically on a daily basis via a remote terminal unit to the SCAQMD Central Station. The emissions for each large source are calculated based on fuel usage or exhaust gaseous flow rates and reported electronically on a monthly basis to the SCAQMD Central Station. The emissions from all process units are reported on a quarterly basis.

Table 2.4 shows that major NOx sources contributed 88% of the NOx emissions from the NOx RECLAIM universe; large NOx sources and process units generated only 12% of the NOx RECLAIM emissions. Thus, staff focused on the major NOx sources at the top 37 emitting facilities to evaluate potential BARCT and emission reductions.

The major NOx sources at the top 37 emitting RECLAIM facilities subject to new 2015 BARCT analysis are refinery fluid catalytic cracking units, refinery boilers and heaters >40 mmbtu/hr, refinery and non-refinery gas turbines, cement kilns, glass melting furnaces, sodium silicate furnaces, metal heat treating furnaces >150 mmbtu/hr, refinery sulfur recovery and tail gas incinerators, and internal combustion engines.

Table 2. 4 - NOx Emissions per Source Classification

Source Categories	NOx (tons per day)	Number of Equipment	Percentage of Emissions
Major NOx Sources	17.5	415	88%
Large sources and Process Units	2.6	>1000	12%
Total	**20.0**		**100%**

Chapter 3 – 2015 Proposed BARCT and Emission Reductions

Previous BARCT Determinations

At the inception of the RECLAIM program, NOx starting allocations for 1994 and ending allocations for 2000 were based on the starting and ending emissions factors listed in Table 1 of Rule 2002 – *Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx).* For the 2003 ending allocations, 2000 ending allocations were adjusted to be equal to the 1991 AQMP projected inventory for RECLAIM sources in 2003. The 2005 future year allocations were set equal to the 2003 allocations. In 2005, the SCAQMD staff conducted a BARCT assessment, and the rules were amended to reduce the RTCs by 7.7 tpd implemented by 2011. Table 3 of Rule 2002 was added to record the 2005 BARCT levels. The BARCT levels were kept at the 2000 ending emission factors as shown in Table 2 of Rule 2002 for individual equipment categories where improved control technologies were not yet deemed applicable or cost-effective in the 2005 BARCT assessment.

Proposed 2015 BARCT

Staff is proposing the BARCT levels tabulated in Table 3.1 and estimating that these 2015 BARCT levels will provide about 8.8 tpd in NOx emission reductions (6.00 tpd for refinery sector and 2.77 tpd for non-refinery sector) beyond what could be achieved by the 2005 BARCT levels for each category of major emitting sources at the top emitting facilities. Further discussions of NOx control technologies, proposed BARCT levels, estimated emission reductions, costs and cost effectiveness values are discussed in Part I of this staff report for the refinery sector and Part II for the non-refinery sector. The RTC reductions to implement BARCT are 14 tpd. See Chapter 5 and Part III of this staff report.

Part I – BARCT Analyses for Refinery Sector:

Appendix A	Fluid Catalytic Cracking Units
Appendix B	Boilers and Heaters, >40-100 mmbtu/hr
Appendix C	Refinery Gas Turbines
Appendix D	Coke Calciner
Appendix E	Sulfur Recovery Units Tail Gas Incinerators

Part II – BARCT Analyses for Non-Refinery Sector:

Appendix M	Cement Kilns
Appendix N	Container Glass Melting Furnaces
Appendix O	Sodium Silicate Furnace

Appendix P	Metal Melting Furnaces > 150 mmbtu/hr
Appendix Q	Non-Refinery Gas Turbines
Appendix R	Non-Refinery, Non-~~Electrical~~ Electricity Generating Facility Internal Combustion Engines
Appendix S	Non-Refinery Boilers > 40 mmbtu/hr

Table 3. 1 - 2015 Proposed BARCT Levels and Emission Reductions

Refinery Sector	2015 BARCT Level	Incremental Emission Reductions Beyond 2000/2005 BARCT (tpd)
Fluid Catalytic Cracking Units	2 ppmv at 3% O2	0.43
Boilers and Heaters >40 mmbtu/hr	2 ppmv or 0.002 lb/mmbtu	0.94
Gas Turbines	2 ppm at 15% O2	4.14
Coke Calciner	10 ppmv at 3% O2	0.17
Sulfur Recovery Units Tail Gas Incinerators	2 ppmv at 3% O2 or 95% reduction	0.32
	Total	**6.00**

Non-refinery Sector	2015 BARCT Level	Incremental Emission Reductions Beyond 2000/2005 BARCT (tpd)
Cement Kilns	0.5 lb/ton clinker	1.29 (note)
Container Glass Melting Furnaces	80% reduction	0.24
Sodium Silicate Furnace	80% reduction	0.09
Heat Treating Furnaces >150 mmbtu/hr	9 ppmv at 3% O2	0.56
Gas Turbines (non-OCS)	2 ppmv at 15% O2	1.04
ICEs (non-OCS)	11 ppmv at 15% O2	0.84
	Total	**2.77**

Note: The 1.29 tpd emission reductions from cement kilns were not included in the 2.77 tpd emission reductions because the cement facility was not in operation in 2011. Cement kilns were the highest source of NOx emissions in 2008, thus staff conducted a BARCT analysis for cement kilns and reduced the remaining emissions projected to the 2023 level for the cement facility to the BARCT level.

Co-Benefits of Energy Efficiency Projects

For the refinery sector, in addition to the 6.00 tpd emission reductions shown in Table 3.1, there are about 0.6 to 0.7 tpd NOx emission reductions that are expected to have occurred concurrently with the energy efficiency projects to reduce greenhouse gases as shown in Table 3.2. According to CARB staff, these co-benefits reductions were not yet included in the baseline and SCAQMD staff did not include the co-benefits in this proposal. See Appendix K for further details.

Table 3. 2 - Co-Benefits of Emission Reductions for Energy Efficiency Projects

Projects	Emission Reductions (tpd)
Completed and ongoing (2007-2011)	0.6
Scheduled	0.05
Under investigation	0.07 - 0.08
Total	**0.7**

Chapter 4 – Costs and Cost Effectiveness

This chapter discusses both the preliminary analysis in December 2014 and the revised analysis in 2015.

Staff's Preliminary Estimates

Staff preliminary analyses as of December 2014 for costs and cost effectiveness are discussed in Part I, Appendices A – E, for the refinery sector and Part II, Appendices M – S, for the non-refinery sector, respectively. A summary of the methods used for costs and cost effectiveness analyses and the results of these detailed analyses are provided in this Chapter.

The Present Worth Value~~s~~ (PWV) of a control device are the total costs to install and operate the control device estimated at the present currency value. The PWV consists of the Total Installed Costs (TIC) and Annual Operating Costs (AC) during the entire economic life of the control equipment using the Discounted Cash Flow (DCF) Method as follows:

$$PWV = TIC + (15.62 \times AC)$$

Where:

PWV = Present Worth Value, $
TIC = Total Installed Costs, $
AC = Annual Operating Costs, $
15.62 = a factor to estimate the cumulative annual operating costs during a 25-year life of a control device

The incremental cost effectiveness value of a control device is estimated as follows:

$$CE_{\text{incremental}} = (PWV_{2015\ BARCT} - PWV_{2000/05\ BARCT}) / (ER_{2015\ BARCT} - ER_{2000/05\ BARCT})/25/365$$

Where:

$CE_{\text{incremental}}$ = Incremental Cost Effectiveness, \$/ton
$PWV_{2015\ BARCT} - PWV_{2000/05\ BARCT}$ = Incremental costs to achieve additional control to meet the 2015 BARCT level from the 2000/2005 BARCT level
$ER_{2015\ BARCT} - ER_{2000/05\ BARCT}$ = Incremental emission reductions to achieve the 2015 BARCT level from the 2000/2005 BARCT level

The incremental costs and cost effectiveness were calculated based on the 2011-2012 baseline emissions and the DCF method. Staff also presented the cost effectiveness estimated with the

Levelized Cash Flow (LCF) method. In the cost effectiveness analysis using the DCF method, staff used a cutoff level of $50,000 per ton. The $50,000 per ton cutoff is based on the policy developed during the 2008 – 2010 SOx RECLAIM rule amendment that was adopted by the District Governing Board. The results of staff's preliminary estimates in 2014 for PWVs and cost effectiveness values are summarized in Tables 4.1 and 4.2; and the revised estimates are summarized in Tables 4.3 and 4.4.

Consultants' Estimates

In the Fall of 2014, the SCAQMD staff contracted with two consultants, NEC and ETS, to conduct independent studies on costs and cost effectiveness. The consultants' reports are included as separate documents (Addenda 1 and 2). Table 4.1 below shows a comparison between staff's and NEC's estimates for the refinery sector, and Table 4.2 shows a comparison between staff's and ETS's estimates for the non-refinery sector.

Refinery Sector

For the refinery sector, as shown in Table 4.1, NEC and staff recommended BARCT levels of 2 ppmv for gas turbines, FCCUs, boilers/heaters, and SRU/TG incinerators. For the refinery coke calciner, NEC recommended a BARCT level of 5 - 10 ppmv instead of 2 ppmv previously recommended by staff. Staff agreed with NEC's recommendation and changed the recommendation to 10 ppmv BARCT for the coke calciner. Different approaches were used to estimate the SCR costs for FCCUs, boilers/heaters and SRU/TG incinerators, an adjustment was made to the proposed shave amount to account for the different engineering and cost assumptions. Please refer to Part I, Appendix F - J, for further discussion. Table 4.3 shows the ranges of PWVs and cost effectiveness values for the refinery sector based on the revised proposal.

Table 4. 1 – Initial Proposal - BARCT Levels, Costs and Cost Effectiveness - Refinery Sector (December 2014)

Equipment Category	Proposed 2014 BARCT	Staff's Estimates		Estimates Using NEC's Information		Incremental DCF Cost-Effectiveness
		Incremental Reductions (tpd)	**PWVs ($M)**	**Incremental Reductions (tpd)**	**PWVs ($M)**	**$/ton NOx Reduced**
Gas Turbines	2 ppmv	4.14	97.7	4.14	52.7	1K - 3K
FCCUs	2 ppmv	0.43	152	0.43	211	3K - 18K
Coke Calciner	5 ppmv	0.21(1)	22 - 61	0.17(2)	39.5	11K - 25K
Boilers/Heaters >40 mmbtu/hr	2 ppmv	1.05	254.5	0.61	162	27K - 29K
SRU/TG Incinerators	2 ppmv	0.35	49 - 68	0.32	120	15K - 48K
Total		**6.18**	**575 - 633**	**5.67**	**585**	**7K - 12K (3)**

Note: 1) Based on 5 ppmv BARCT, 2) Based on 10 ppmv BARCT, 3) Weighted average by NOx reductions

Non-Refinery Sector

For the non-refinery sector, ETS agreed with the proposed BARCT levels- recommended for all categories. ETS's estimated costs and incremental costs were slightly higher than staff's estimates as shown in Table 4.2. Table 4.4 shows the revised ranges of PWVs and cost effectiveness values for the non-refinery sector.

Table 4. 2 – Initial Proposal - BARCT Levels, Costs and Cost Effectiveness - Non-Refinery Sector (December 2014)

	Proposed 2014 BARCT	**Incremental Reductions (tpd)**	**Staff's PWVs ($M)**	**ETS's PWVs ($M)**	**Incremental DCF CE $/ton NOx Reduced**
Cement Kilns	0.5 lb/ton clinker	1.32	34 - 107	36 - 112	3 - 10K
Container Glass	0.24 lb/ton pulled	0.24	4 - 14	6 - 15	3 - 7K

ICEs	11 ppmv @15% O2	0.84	0.9 - 4	0.9 - 4	5 - 8K
Boilers >40 mmbtu/hr	No new BARCT	0	0	0	
Total		**6.18**	**53 - 154**	**57 - 160**	**4 - 15 K (1, 2)**

Note: 1) LCF ranges from $5 K - $57 K per ton, 2) Weighted average by NOx reductions

Staff Recommendations

After the facility visits and the consultants' analyses were completed, staff revisited the cost estimations and made modifications to the preliminary proposals. Staff's revised recommendations are presented below.

Refinery Sector

Staff's current recommendations for the refinery sector are tabulated in Table 4.3. Please refer to Part I, Appendices A-J for additional information.

Table 4. 3 - Staff's Revised Recommendation for Refinery Sector (May 2015)

	2015 BARCT	Incremental Reductions (tpd)	PWVs ($M)	Incremental Cost Effectiveness ($K/ton DCF)	Note
FCCUs	2 ppmv	0.43	152 – 391	3 – 13	1
Gas Turbines	2 ppmv	4.14	53 – 98	1 – 3	2
Boilers/Heaters >40 mmbtu/hr	2 ppmv	0.94	237	28	3
Coke Calciner	10 ppmv	0.17	40 - 91	19 – 25	4
SRU/TG Incinerators	2 ppmv	0.32	83 - 106	28 – 40	5
Total		**6.00**	**565 – 923**	**10 – 17**	6

Notes:

1) See Appendix A. The PWV of $152M are for the case where all 5 refineries would install SCRs. The PWV of $391 M are for the case where SCRs would be installed at Ref 5 and 6 and LoTOx and scrubbers at Ref 4, 7 and 9 to reduce both NOx and SOx.
2) See Appendix C. The PWV of $53 M was estimated by NEC for adding catalysts to all SCRs. The PWV of $98 M was derived by SCAQMD staff for adding catalysts to Ref 1's SCRs and new SCRs to Ref 4 - 7.
3) See Appendix B.
4) See Appendix D. The PWV of $40M was estimated by NEC for LoTOx technology and $91 M was staff's estimates for Tri-Mer technology
5) See Appendix E. The PWV of $83 M was for SCRs and $106 M for LoTOx applications
6) Incremental cost effectiveness is the weighted average by NOx reductions. Low end of incremental cost effectiveness = $565 M/ (6*25*365) = $10,320 per ton NOx reduced. High end of incremental cost effectiveness = $923 M/ (6*25*365) = $16,858 per ton NOx reduced.

Non-Refinery Sector

Table 4.4 tabulates staff's current recommendations for the non-refinery sector. Please refer to Part II, Appendices M-R for further information.

Table 4. 4 - Staff's Recommendation for Non-Refinery Sector (May 2015)

	2015 BARCT	Incremental Reductions (tpd)	PWVs ($M)	Incremental Cost Effectiveness ($K/ton DCF)	Note
Cement Kilns	0.5 lb/ton clinker	1.29	61 - 152	5 - 11	1
Container Glass Melting Furnaces	0.24 lb/ton glass pulled	0.24	6 - 15	3 - 7	2
Sodium Silicate Furnace	1.28 lb/ton glass pulled	0.09	3.0 - 4.6	4 - 8	3
Metal Heat Treating Furnace > 150 mmbtu/hr	9 ppmv at 3% O2	0.56	8 - 10	3 - 3.8	4
Gas Turbines	2 ppmv at 3% O2	1.04	~109	5 - 36	5
ICEs	11 ppmv at 15% O2	0.84	~37	5 - 8	6
	Total	**4.06**	**224 - 328**	**6 - 9**	7, 8, 9, 10

Note:

1) Refer to Appendix M
2) Refer to Appendix N
3) Refer to Appendix O
4) Refer to Appendix P
5) Refer to Appendix Q
6) Refer to Appendix R
7) Incremental costs effectiveness is the weighted average by NOx reductions. With cement kilns: low end of incremental cost effectiveness = $224 M/ (4.06*25*365) = $6 K per ton NOx reduced, and high end of incremental cost effectiveness = $328 M/ (4.06*25*365) = $9 K per ton NOx reduced.
8) The incremental emission reductions would be 4.06 tpd including the incremental reductions for the cement kilns. Without the cement kilns, the incremental emission reductions would be 2.77 tpd.
9) The range for PWVs would be $224 M – $328 M including the PWVs for the NOx control device for cement kilns. The range of PWVs would be $163 M - $176 M without the control devices for cement kilns.
10) Incremental costs effectiveness is the weighted average by NOx reductions. Without cement kilns: low end of incremental cost effectiveness = $163 M/ (2.77*25*365) = $6 K per ton NOx reduced, and high end of incremental cost effectiveness = $176 M/ (2.77*25*365) = $7 K per ton NOx reduced.

Chapter 5 - RTC Reductions

Remaining Emissions

As discussed in the Public Process section, staff started the discussion with stakeholders on the calculation method that would be used to estimate the RTC reductions in 2013. One of the parameters used in the calculation for the RTC reductions is the remaining emissions projected to 2023. The 2023 remaining emissions estimates by staff were first presented to the stakeholders at the January 22, 2014 Working Group Meeting. Staff later refined the numbers and presented them to the stakeholders in the July 31, 2014 and April 29, 2015 Working Group Meetings. The changes made are summarized below.

Refinery Sector

Table 5.1 tabulates the estimated 2023 remaining emissions for each NOx source category in the refinery sector. In 2014, staff estimated the total 2023 remaining emissions to be 2.56 tpd. In 2015, staff revised the number to 2.76 tpd as a result of the following changes:

- The BARCT level for coke calciner was changed from 2 ppmv to 10 ppmv. As a result, the remaining emissions for coke calciner increased to 0.08 tpd.

- The costs of control for boilers/heaters and SRU/TG incinerators were revised to be higher. As a result, the cost effectiveness for several boilers/heaters and one incinerator became higher than the policy threshold of $50,000 per ton, and these units were excluded from the equipment that contributed to the emission reductions. The remaining emissions for the boilers/heaters >40 mmbtu/hr increased to 0.85 tpd, and the remaining emissions for the SRU/TG incinerators increased to 0.11 tpd.

Table 5. 1 - Remaining Emissions for Refinery Sector

	Total No of Units	2011 Emissions (tpd)	2000/2005 BARCT	2011 Emissions at 2000/2005 BARCT (tpd)	2015 BARCT	2011 Emissions at 2015 BARCT (tpd)	2023 Emission Reductions Beyond 2000/2005 BARCT (tpd)	2023 Emission at 2015 BARCT with GF = 1 (tpd)
FCCUs/CO Boilers	8	1.08	85% control	0.60	2 ppmv	0.17	0.43	0.17

Total	**265**	**11.50**		**8.76**		**2.76**	**6.00**	**2.76**

Non-Refinery Sector

Table 5.2 tabulates the estimated 2023 remaining emissions for each NOx source category in the non-refinery sector. In 2014, staff estimated the 2023 remaining emissions for the non-refinery sector to be 8.77 tpd. In 2015, staff revised the number to 7.47 tpd as a result of the following changes:

- The baseline for ~~electrical~~ electricity generating facilities was changed from 2011 to 2012. The 2011 and 2012 baseline emissions were 1.45 tpd and 2.50 tpd, respectively. Staff also used either the BACT level or the level stated in the permit conditions to estimate the emission reductions beyond the levels that could be achieved by the 2005 BARCT. In addition, staff used the most recent growth factor of 0.868 to estimate the remaining emissions for the ~~electrical~~ electricity generating facilities. As a result of these changes, the 2023 remaining emissions for ~~electrical~~ electricity generating facilities were changed to 2.04 tpd.

- The remaining emissions from non-~~electrical~~ electricity generating facilities were changed to 1.37 tpd; and

- The remaining emissions from other sources were changed to 4.06 tpd.

Table 5. 2 - Remaining Emissions for Non Refinery Sector (May 2015)

****CPCC's emissions and emission reductions have NOT been included in the totals, this facility did not have any emissions in CY2011. CY2008 emissions were used to calculate the emission reductions.**

*****Includes Non-Refinery, Non-Power Plant Process Units in the Top 37 and all other sources outside the Top 37.**

Calculation Method for RTC Reductions

The RTC reductions are calculated as follows:

RTC Reductions = RTC Holdings – (Remaining Emissions x Compliance Margin)

Where

RTC Holdings = 26.5 tpd
Remaining Emissions = ($R_{Refinery}$ + $R_{Non\text{-}Refinery}$ + $R_{Adjustment}$)
$R_{Refinery}$ = Remaining emissions for refinery sector x Growth Factor
$R_{Non\ Refinery}$ = Remaining emissions for non-refinery sector x Growth Factors
$R_{Adjustment}$ = Potential adjustments set aside for new ~~electrical~~ electricity generating facilities
Compliance margin = 10% as provided in the previous RECLAIM amendments

An example shown below was presented at the April 29, 2015 Working Group Meeting:

$R_{Refinery}$ = 2.76 tpd including growth factor of 1 as shown in Table 5-1
$R_{Non\ Refinery}$ = 7.47 tpd including growth factor of 1.1 as shown in Table 5-2
$R_{Adjustment}$ = 0.07 tpd potential adjustments for new ~~electrical~~ electricity generating facilities due to SONGS shutdown and 0.29 and 0.10 for CPCC and other shutdown facilities
RTC Reductions = 26.5 – ([(2.76 + 7.47 + 0.07) x 1.1] + (0.29 + 0.10))
= 26.5 – 11.7 = 14.8 tpd

Regional NSR Holding Account for Electric*ity*~~*al*~~ Generating Facilities

Staff has received input from several electric*ity*~~*al*~~ generating facility operators that have concerns with concurrent compliance with the RTC allocation shave and the new source review (NSR) holding requirements per Rule 2005. New facilities that entered into RECLAIM after October 15, 1993 must hold RTCs for all of their equipment at the permitted potential to emit (PTE) level at the beginning of every compliance year. Pre-RECLAIM power producing facilities only need to hold RTCs for one year if their PTEs increase, unless their new PTEs exceed their initial 1993 allocation. Electric*ity*~~al~~ ~~producing~~ generating facilities often operate at a capacity factor well below the PTE level during any given compliance year. The combustion equipment for these facilities is also already at the BARCT or BACT emission level. These facilities would be shaved and be subject to complying with the NSR holding requirements as well as their annual emission reconciliation requirements.

Staff has proposed the creation of a Regional NSR Holding Account to help address the NSR holding requirements programmatically for all post-1993 electric*ity*~~al~~ ~~producing~~ *generating* facilities. This account would reduce the individual facility NSR hold requirements by the amount that they were shaved and would be comprised of the shaved RTCs from these facilities as discrete credits. All electric*ity*~~al~~ generating facilities would be allowed to access this account to offset emissions (rather than just satisfy NSR holding requirements) if the Governor of California declares a state of emergency regarding reliable energy supply or grid stability in the Basin. The size of the Regional NSR Holding Account would be equivalent to the RTCs shaved from the affected post-1993 ~~electrical~~ electricity generating facilities. This approach serves two purposes. First, it provides relief from the different and burdensome NSR holding requirements for these newer facilities relative to older electric*ity*~~al~~ ~~generation~~ generating facilities. Second, it provides an emergency source of RTCs to be accessed in the case of a power crisis. Any new electric*ity*~~al~~ generating facility that enters RECLAIM after the proposed amendment would still be subject to the full multi-year NSR holding requirements.

Staff Proposal and CEQA Alternatives

Table 5.3 summarizes the staff proposal which includes a NOx RTC shave of 14 tpd rather than the 14.8 tpd calculated above. The 0.8 tpd difference is to account for comments received from stakeholders regarding uncertainties in the BARCT analysis, and to provide some additional compliance margin. Staff is currently proposing that the 14 tpd RTC reductions be distributed to 56 facilities and investors that collectively hold about 90% of the 26.5 tpd RTCs. The 56 affected facilities include 9 major refineries, 21 ~~electrical~~ electricity generating facilities, and 26 other top emitting facilities as shown in Table 5.5. Staff is proposing not to shave the remaining 219 facilities that hold only 10% of the 26.5 tpd RTCs because there was limited or no new BARCT identified for other types of equipment and operations there. Other approaches to determine the RTC reductions as shown in Table 5.4 were analyzed as project alternatives in the CEQA analysis. For further information, please refer to Part III, Appendix U of this staff report.

Staff is proposing the following implementation schedule:

2016: 4 tons per day
2018: 2 tons per day
2019: 2 tons per day
2020: 2 tons per day
2021: 2 tons per day
2022: 2 tons per day

As shown in Table 1-1 of Chapter 1, in the past five years from 2009-2013, the unused RTCs in the NOx RECLAIM program ranged from 5.5 to 8 tpd, and thus staff is proposing a reasonable initial 4 tpd RTC reduction in 2016. Additional BARCT implementation will take about 2 – 4 years for planning, permitting, and construction, and staff is proposing that the remaining shave of 10 tpd take place between 2018 and 2022.

Table 5. 3 - Staff Proposal - Affected Facilities and Percent Shave

	Major Refineries and Investors	Non-~~Electrical~~ Electricity generating facilities	~~Electrical~~ Electricity generating facilities	Bottom 10% of RTC Holders	Total
No of facilities	9	26	21	219	275
Current RTCs	14.6	9.1		2.8	26.5
RTC Reductions	9.6	4.4		0	**14.0**
Remaining RTCs	5	4.7		2.8	12.5
Percent Shave	9.6/14.6 = 66%	4.4/9.1 = 49%		0%	

Note that investors are counted as one facility and grouped with the refineries.

Table 5. 4 - Alternatives for CEQA Analysis

	Alternative	Major Refineries + Investors	Non-Major Refineries/ Facilities	~~Electrical~~ Electricity Generating Facilities	Bottom 10% of RTC Holders
1	Shave 14 tpd uniformly across all 275 facilities	53%	53%	53%	53%
2	Shave 15.87 tpd (w/o 10% compliance margin) uniformly across all 275 facilities	60%	60%	60%	60%
3	Shave 8.8 tpd (the difference in emission reductions between previous BARCT and 2015 BARCT) uniformly across all 275 facilities	33%	33%	33%	33%
4	No project	0%	0%	0%	0%
5	Shave 14 tpd weighted by BARCT reduction contribution and distributed to all 275 facilities	66%	37%	37%	37%

Chapter 6 – Summary of the Proposed Changes in Rule Language and Draft Program Environmental Assessment

Appendix X contains more detailed information regarding the changes described below.

Rule 2001 (g)(1) to (4) and (i)(1)(K) and (i)(2)(O) – Electricity Generating Facilities Opt-out of NOx RECLAIM

Rule 2001 includes a provision that would allow the owner or operator of an electricity generating facility (EGF) to opt out of the NOx RECLAIM program. An opt-out plan would need to demonstrate that at least 99 percent of the EGF's NOx emissions for the most recent 3 compliance years are at current BARCT or BACT. The rule specifies how New Source Review requirements would be met, how RTCs will be handled, and that Facility Permit amendments would be required to ensure that BARCT or BACT levels would be maintained. The EGF operator would need to comply with any source specific rule limits as quickly as possible, but no later than 3 years after approval of their opt-out plan. The owner or operator at multiple EGFs under common control would have one opportunity to apportion the NOx limits among its facilities. Monitoring, reporting, and recordkeeping requirements of Rule 2012 and its associated protocols would continue to apply unless the Executive Office approves an alternative plan that is sufficient to determine compliance with all applicable rules.

As mentioned above, an EGF may opt out of RECLAIM provided it meets certain criteria. Specifically, the facility will be subject to a condition limiting the facility's NOx emissions, for a facility existing as of October 1993, to the amount of RTCs held by the facility as of September 22, 2015, and for a facility built after October 1993, to the amount of RTCs required to be held pursuant to Rule 2005. However, if the operator has more than one facility subject to RECLAIM upon removing all of the facilities from RECLAIM simultaneously, the operator has a single opportunity to re-distribute the RTCs holdings among the various facilities in such a way that the RTCs held for each facility will not exceed the maximum emissions that can be generated by the equipment permitted at that facility based on the existing permit conditions.

Once the facility is re-issued its permit without RECLAIM requirements, subsequent modifications to the facility will be subject to provisions of Regulation XIII – New Source Review for NOx, as well as other pollutants. There are four possible scenarios that may trigger New Source Review (NSR) provisions for NOx. The table below shows the potential conditions that may be imposed for each scenario:

Scenario	Offset Exemption	Emission Limiting Conditions
Replacement of existing equipment with other equipment that is functionally equivalent and no increase in maximum emissions	1304 (a)(1)	Facility annual emission limit remains; no need for additional individual equipment limit for the remaining existing equipment
Replacement of an electric utility steam boiler with combined cycle gas turbine(s), intercooled, chemically-recuperated gas turbines, other advanced gas turbine(s); solar, geothermal, or wind energy or other equipment, to the extent that such equipment will allow compliance with Rule 1135 or Regulation XX rules	1304 (a)(2)	Facility annual emission limit remains; no need for individual equipment limit for the remaining existing equipment
Concurrent modification or replacement of existing equipment or removal and addition of different equipment that result in a net decrease in emission potential	1304 (c)(2)	Facility annual emission limit remains; no need for individual equipment limit for the remaining existing equipment
Modification or replacement of existing equipment that result in a net increase of emissions, or construction of new equipment	None	May apply for individual equipment limits prior to applying for modification or new construction; Facility annual emission limit will be updated to account for offset provided for new or modified source

Rule 2002 (f)(1) – BARCT Proposed Levels and RTC Reductions

The staff proposal of the new BARCT levels for the refinery and non-refinery sectors are summarized in Table 6 of Rule 2002.

The proposal would result in a programmatic reduction of 14 tons per day RTC holdings over 7 years. Four tons per day would be reduced in 2016 and the remainder would be reduced in equal increments from 2018 to 2022. There would be no reductions proposed for the year 2017. These reductions are reflected in subparagraphs (f)(1)(B) and (f)(1)(C). Subparagraph (f)(1)(B) includes all of the Major Refineries and Investors. The Major Refineries are listed in Table 7 of Rule 2002. Subparagraph (f)(1)(C) includes all other facilities subject to the reduction in NOx RTCs. These facilities are listed in Table 8 of Rule 2002.

The remaining NOx RTCs after a shave for any compliance year would be the Tradable/Usable NOx RTC Adjustment factor in (f)(1)(B) multiplied by the RTC holdings (as of September22, 2015) of all the Major Refineries listed in Table 7 plus the Tradable/Usable NOx RTC Adjustment factor in (f)(1)(C) multiplied by the RTC holdings (as of September 22, 2015) of all the facilities listed in Table 8. Please see Appendix U for further explanation on how the factors in subparagraphs (f)(1)(B) and (C) were derived. Appendix U also contains the list of facilities including NOx RTC holders not designated as Facility Permit Holders as of September 22, 2015, except any NOx RTC holders listed in Table 8.

Since the RTC reductions specified in subparagraph (f)(1)(A) have been realized, the conversion of non-tradable/non-usable NOx RTCs to tradable/usable NOx RTCs is no longer applicable to the RTC reductions specified in this subparagraph. The tradable/usable NOx RTCs specified in subparagraph (f)(1)(A) would remain intact and used for calculating RTC reductions for facilities entering the RECLAIM program. However the same approach in converting adjustment factors previously specified in subparagraph (f)(1)(A) would now be applied to the RTC reductions specified in subparagraphs (f)(1)(B) and (f)(1)(C).

Subparagraphs (f)(1)(B) and (f)(1)(C) also include adjustment factors to obtain Non-tradable/Non-usable holdings. The quantity of Non-tradable/Non-usable NOx RTCs is equal to the incremental shave amount in the given compliance year. Subparagraph (f)(1)(G) and (f)(1)(H) specify that shaved RTCs from newer ~~electrical~~ electricity generating facilities listed in Table 9 will be used to fund a Regional NSR Holding Account that can be used, along with their Non-tradable/Non-usable holdings, by these facilities to help meet their ongoing NSR holding requirements.

Subparagraph (f)(1)(E) updates the 12-month rolling average trigger to $22,500 per ton for discrete credits. A trigger level of $35,000 per ton has been added for a 3-month rolling average in subparagraph (f)(1)(I). If RTC prices exceed either of these levels, a report to the Board and a program review are required. Subparagraph (f)(1)(J) includes a 12-month rolling average for Infinite Year Block (IYB) RTCs of $200,000 per ton. If credit prices are lower than this amount beginning in 2019, then a report to the Board is also required.

Subparagraph (f)(1)(I) describes provisions for conversion of Non-tradable/Non-usable holdings to Tradable/Usable NOx RTCs if the 12-month rolling average RTC price exceeds $22,500 per ton. This trigger corresponds to the adopted 2012 AQMP cost effectiveness threshold that triggers additional analysis of proposed rules. Similarly, (f)(1)(I) also requires that the Executive Officer's report to the Board on the trigger price also include a commitment and schedule to conduct a more rigorous cost-effectiveness, market analysis, and socioeconomic impact assessment of the RECLAIM program.

Subparagraph (f)(1)(~~L~~M) clarifies the method for determining allocations for existing facilities that enter RECLAIM after the date of adoption of the proposed amendments.

Rule 2002 (f)(4) and (f)(5) – Regional NSR Holding Account and State of Emergency Related to ~~Electrical~~ Electricity Generating Facilities

A new electricricity~~al~~ generating facility (EGF), along with all new RECLAIM facilities, must hold sufficient RTCs to offset their entire potential to emit (PTE) for one year prior to commencement of operation and at the beginning of every compliance year thereafter. These requirements are triggered in cases where a facility incurs an emission increase as defined under Rule 2005(d) – Emission Increase. ~~Electrical generating facilities~~EGFs often~~m~~ have PTEs that far exceed their actual emissions, and cannot readily reduce their PTEs given that they must be available for grid support if called upon. Given this burdensome requirement, staff is proposing to create ~~an~~a Regional NSR Holding Account, held by the SCAQMD, that would be used for the purpose of helping such facilities comply with the NSR requirements specified in Rule 2005. These proposed requirements are specified in Rule 2002 paragraph (f)(4). The RTCs in the Regional NSR Holding Account would not be available to offset actual emissions, except for the situation described below.

Staff is proposing in paragraph (f)(5) that during a State of Emergency declared by the Governor related to electricity demand or power grid stability in the Basin, any ~~electrical generating facility~~EGF can use their Non-tradable/Non-usable NOx RTC holdings to offset their emissions after exhausting their Tradable/Usable holdings. Furthermore, if their Non-tradable/Non-usable NOx RTC holdings are exhausted, they may apply for the use of NOx RTCs in the Regional NSR Holding Account on a quarterly basis. Subparagraphs (f)(4)(i) – (iii) describe the criteria that the Executive Officer must consider in determining the amount and the distribution of these RTCs. If the total RTCs requested exceeds the supply in the Account, the RTCs will be distributed proportionately according to the verified offset needs of the requesting facilities

The RTCs in the Regional NSR Holding Account would be 0.827 tons per day for 2023 & beyond (See Appendix U). These RTCs would be derived from the RTC reductions applied to the newer ~~electrical~~ electricity generating facilities listed in Table 9.

Rule 2002 (i) – RTC Reduction Exemption

Given that no facilities in the history of the RECLAIM program have applied for an exemption pursuant to subdivision (i), and given the unlikelihood that a facility could meet the stringent requirements listed therein, staff is proposing to remove the subdivision in its entirety.

Rule 2002 (i) – Facility and Equipment Shutdowns

The proposed rule includes provision to address the retirement of RTCs from complete facility closure or equipment shutdowns that represent twenty-five percent or more of a facility's emissions for any quarter within the previous 2 compliance years. This would apply to any facility listed in Table 7 or 8 of Rule 2002. Permits associated with the equipment being shut down would be surrendered, and the RTCs for future years would be retired from the RECLAIM program.

Rule 2005 – Requirements for New ~~Electrical~~ Electricity Generating Facilities

Rule 2005 sets forth requirements for new or modified equipment or processes at RECLAIM facilities. The purpose of the rule is to ensure that the RECLAIM program is equivalent to the federal and state NSR program requirements. One of the requirements is to ensure that the facility must hold sufficient RTCs to offset emission increases for one year prior to commencement of operation and at the beginning of every compliance year thereafter. For an RECLAIM facility existing prior to the adoption of the RECLAIM program, the amendments made in June 3, 2011 required the RECLAIM facility to hold adequate RTCs for the first year of operation prior to commencement of operation of a new or modified source, but will not require the facility to hold RTCs at the commencement of subsequent compliance years, provided that the facility emission level remains below its starting Allocations plus non-tradable credits. However, a new RECLAIM facility will have to continue to hold adequate RTCs equal to the amount of emission increases at the beginning of each compliance year. Any unused RTCs cannot be sold until the end of the compliance year, or the applicable quarters if the facility has permit conditions to cap its emissions during each quarter, thus allowing sale of unused RTCs at the end of the quarter. To remedy this burdensome RTC holding requirement for new ~~electrical generating facilities~~EGFs that cannot change their allowable NOx emissions in their Facility Permit, staff is proposing a Regional NSR Holding Account described in Rules 2002(f)(4) above. Proposed changes in Rule 2005 would assure that the RTCs in the Account would only be used the for the purpose of complying with the NSR requirements (other than access during a power crisis as also described in 2002(f)(4)) . Please see Appendix X for further explanations.

Other Administrative Amendments

Besides the changes described in Rule 2002 and 2005 described above, staff also proposes administrative amendments to Regulation XX to clarify the rule language and to ensure effective and consistent implementation of the RECLAIM program.

Rule 2002(b)(5) - 5-Year Limitation on Amending Annual Emission Reports

Some facilities entering the RECLAIM program have sought to amend their past AERs, which dated as far back as 1989, in ways that increase the initial SOx and/or NOx allocations previously determined pursuant to Rule 2002. The longer the time that has elapsed between the reporting period and the submittal of the amendment, the more problematic the process of validating the proposed changes and the supporting documentation. In fact, such validation has been infeasible in some cases. Therefore, staff is proposing to add language to Rule 2002(b)(5) to provide clarity on which annual report submittals and/or revisions may be considered by staff in determining facility allocations.

Rule 2002 (Table 4) – Minor Typographical Edit

Rule 2002's Table 4 – RECLAIM SOx Tier III Emission Standards includes a row for Diesel Combustion, which includes a BARCT Emission Standard of "15 ppmv as required under Rule 431.2." However, the standard in Rule 431.2 is actually "15 ppm by weight" rather than 15 ppmv (*i.e.*, 15 ppm by volume). The staff proposal would correct the Table 4 entry to "15 ppm by weight as required under Rule 431.2," consistent with the definition of Low Sulfur Diesel at Rule 431.2(b)(5).

Rules 2011 and 2012 - Delayed RATA Tests due to Extenuating Circumstances

Rules 2011 and 2012 set forth monitoring, reporting, and recordkeeping requirements for sources of SOx and NOx at RECLAIM facilities. The accompanying Appendices A to these rules outline in greater detail the technical specifications required for monitoring, reporting, and recordkeeping for RECLAIM sources such as the timing and frequency of Semi-Annual Assessments in the form of Relative Accuracy Test Audits (RATAs) for CEMS. RATAs must be conducted while the equipment is in operation. Equipment monitored by CEMS at some RECLAIM facilities, however, may experience extenuating circumstances that prevent them from conducting RATA tests in a timely manner.

Additionally, facilities under contract with the California Independent System Operator (CalISO), as well as ~~electrical~~ electricity generating facilities owned and operated by municipalities, have experienced difficulties in meeting RATA deadlines because their equipment operates based on current energy demand and may not operate long enough (or at all) to conduct a RATA in the quarter in which RATA is due. ~~Electrical~~ Electrcity generating facilities with equipment under contract with CalISO or owned and operated by municipalities often do not know when demand for electricity will result in generation equipment being required to operate until a day prior, creating scheduling difficulties in conducting RATAs and precluding the use of non-operational status. The inherent inconsistent operational nature of such equipment at electric generating facilities sometimes causes a need to postpone their RATAs.

Under current rule requirements, facilities having such extenuating circumstances seek variances for indeterminate amounts of time. The proposed amendments would, under specific conditions and criteria, allow RECLAIM Facility Permit Holders of equipment experiencing these extenuating circumstances to postpone RATAs. The specific conditions and criteria are further explained in details in Appendix X.

Proposed Amended Rules 2011, Appendix A, Attachment E and 2012, Appendix A, Attachment F – *Clarification of "Standard Gas Conditions"*

Proposed amendments to Rule 2011, Appendix A, Attachment E and 2012 Appendix A, Attachment F would clarify standard gas conditions by giving each facility operator the option to use either the 60 ºF standard or the 68 ºF standard provided one or the other is used consistently throughout the facility for RECLAIM purposes.

-**Rules 2011 and 2012 - Typographical Edits**

Staff also proposes to make several typographical clarifications and corrections in Rules 2011 and 2012 Appendix A, Attachment C B.2.b and Rule 2011 Appendix A, Attachment C B.2.e. Please see Appendix X for further explanations.

Draft Program Environmental Assessment (PEA)

A Notice of Preparation/Initial Study (NOP/IS) was released for a 57-day public review and comment period from December 5, 2014 to January 30, 2015. Eight comment letters were received from the public regarding the preliminary analysis in the NOP/IS. These comment letters and responses to individual comments are included in Appendix G of the Draft Program Environmental Assessment (PEA). In addition, on January 8, 2015, a CEQA and Socioeconomic Scoping Meeting was held. CEQA comments raised at the Scoping Meeting have been summarized and responded to in Appendix H of the Draft PEA. Socioeconomic comments raised at the Scoping Meeting and in the two comment letters specific to socioeconomic issues received are addressed in the Draft Socioeconomic Analysis. The Draft PEA was released on August 13, 2015, and the commenting period was extended until October 6, 2015. The Draft Socioeconomic Analysis was released on September 9, 2015.

Draft Findings under California Health and Safety Code

California Health and Safety Code § 40727 requires that prior to adopting, amending or repealing a rule or regulation, the AQMD Governing Board shall make findings of necessity, authority, clarity, consistency, non-duplication, and reference based on relevant information presented at the public hearing and in the staff report.

Necessity
A need exists to amend Rules 2002 – Applicability, 2002 – Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx), 2005 – New Source Review for RECLAIM, 2011 – Requirements for Monitoring, Reporting, and Recordkeeping for Oxides of Sulfur (SOx) Emissions (Protocol), and 2012 – Requirements for Monitoring, Reporting, and Recordkeeping for Oxides of Nitrogen (NOx) Emissions (Protocol) to seek additional emission reductions from RECLAIM relative to the 2012 AQMP (Control Measure CMB-01), to demonstrate BARCT equivalence pursuant to California Health and Safety Code §40440, and to make changes necessary for the ongoing administration of the program.

Authority
The AQMD Governing Board has authority to amend existing Rules 2001 – Applicability, 2002 – Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx), 2005 – New Source Review for RECLAIM, 2011 – Requirements for Monitoring, Reporting, and Recordkeeping for Oxides of Sulfur (SOx) Emissions (Protocol), and 2012 – Requirements for Monitoring, Reporting, and Recordkeeping for Oxides of Nitrogen (NOx) Emissions (Protocol), pursuant to California Health and Safety Code §§ 39002, 40000, 40001, 40440, 40440.1, and 40702.

Clarity
The proposed amended rules are written or displayed so that their meaning can be easily understood by the persons directly affected by them.

Consistency
The proposed amended rules are in harmony with and not in conflict with or contradictory to, existing statutes, court decisions or state or federal regulations.

Non-Duplication
The proposed amended rules will not impose the same requirements as any existing state or federal regulations. The amendments are necessary and proper to execute the powers and duties granted to, and imposed upon, AQMD.

Reference

By adopting the proposed amended rules, the AQMD Governing Board will be implementing, interpreting and making specific the provisions of the California Health and Safety Code §§ 39002, 40001, 40440 (a), 40440.1, 40702, and 40725 through 40728.5; and Title 42 U. S. C. Sections 7410 and 7511a.

Comparative Analysis

H&S Code §§ 40727 and 40727.2 require a written analysis comparing the proposed amended rule with existing regulations. The §40727.2 analysis is traditionally applied to source-specific rules requirements affecting equipment subject to a command-and-control regulatory approach. RECLAIM varies from this regulatory approach in that it is based on a mass cap approach with a declining balance. This regulatory program decreases emission credit holdings, which caps emissions at a facility, as opposed to application of equipment-specific requirements. Therefore, this comparative analysis differs from the traditional comparative analysis. A comparative analysis for the RECLAIM program was provided for Rule 2002, amended on January 7, 2005 (NOx RECLAIM sources) and November 5, 2010 (SOx RECLAIM sources).

A comparative analysis, as required by H&S Code §40727.2, compares individual pieces of equipment to any applicable standard. The key to this analysis is to demonstrate non-duplication of new or amended regulatory requirements on an affected source. The current proposed RECLAIM amendment primarily seeks to reduce RTCs in the market and NOx emissions. There are no significant changes proposed to the other program elements, such as enforceable procedures, operating parameters or work practice requirements. In addition, amendments to the monitoring, recordkeeping, and reporting requirements are administrative in nature, as they do not affect or otherwise change an emissions limitation or add a significant requirement. On this basis, this comparative analysis focuses only on the determination of a new BARCT standard for the equipment under RECLAIM.

Relative to the derivation of new BARCT standards, all of the equipment categories listed in Tables 1 and 3 of Rule 2002 were examined by staff and presented to stakeholders for comments and feedback. However, as shown in Table 3.1 of this staff report, new BARCT was only determined for fluid catalytic cracking units, refinery boilers and heaters greater than 40 million British thermal units per hour (mmbtu/hr), refinery gas turbines, coke calciner, sulfur recovery units/tail gas incinerators, cement kilns, container glass melting furnaces, sodium silicate furnace, heat treating furnaces greater than 150 mmbtu/hr, non-refinery gas turbines, and internal combustion engines. In making the BARCT determinations, as discussed in Appendices A through S, a systematic approach of analysis was undertaken to derive any new control standards. This analysis included review of potentially applicable requirements from other air pollution control districts or agencies, applicable AQMD rules, as well as emission controls achieved in practice or otherwise technologically and economically feasible that would have otherwise been required under a command-and-control regulatory approach in the absence of RECLAIM. The results of the BARCT analysis are presented by equipment category in Appendices A through S.

The proposed programmatic reductions are based on the determination of new BARCT for certain emission sources. The resulting equipment-level reductions that would have occurred if applied with the same percentage under a command-and-control regulatory program are subsumed and spread among the RECLAIM facilities which hold 90 percent of the RECLAIM Trading Credits (RTC). The RTCs are proposed to be reduced at a rate of 66 percent for the larger refineries and investors and 49 percent among the remaining facilities that comprise those facilities holding 90 percent of the RTCs. As RECLAIM is a market-based program with facility-level mass emissions caps there are no specific air pollution control requirements (i.e., equipment specific emission limits) for these sources that must be met by these RECLAIM facilities holding 90 percent of the RTCs. Facilities are allowed the flexibility to meet their reduction requirements by whatever means they choose, such as equipment modifications, installation of control equipment, or purchasing RTCs.

Notwithstanding the aforementioned discussion, RECLAIM facilities are subject to the requirements of other AQMD regulations not subsumed by the program, including requirements under Regulation II – Permits, and Regulation IV – Prohibitions, such as Rule 401 – Visible Emissions, Rule 402 – Nuisances, and Rule 403 – Fugitive Dust. It should be noted that there are federally mandated programs, such as New Source Review (BACT/LAER), Prevention of Significant Deterioration, and Standards of Performance for New Stationary Sources, which are also applicable to the RECLAIM program and incorporated within the program. RECLAIM also complies with federal policy regarding start-up, shutdown, and malfunctions. In addition, there is not a comparable state or federal program for a cap and declining balance of NOx emissions. However, RECLAIM, as it currently exists, is in the SIP and complies with federal requirements applicable to market-type air pollution control programs, such as the Economic Incentive Program (EIP) guidelines.

Consequently, RECLAIM stands on-its-own and does not contain any duplicative or conflicting regulatory requirements.

Incremental Cost-Effectiveness

Health and Safety Code Section 40920.6 requires an incremental cost-effectiveness analysis for Best Available Retrofit Control Technology (BARCT) rules or emission reduction strategies when there is more than one control option that would achieve the emission reduction objective of the proposed amendments, relative to NOx. The proposed control option is what was analyzed in the BARCT analysis, while the alternative control option is BARCT control to a less stringent level.

To determine the incremental cost effectiveness, the calculated difference in the dollar cost between the two control options is divided by the difference in their emission reduction potentials.

The control costs for the staff proposal used the average cumulative present worth values for each source category. The control costs for the alternative project used the same costs for the control equipment because it is assumed that a majority of the same costs to build and construct a control system despite a higher emission level would still apply.

The emission reductions of the alternative project are calculated by using the higher BARCT level applied to each source category. The emission reductions of the proposed control option are also factored into the final calculation.

The difference of the PWV of the alternative control option and the proposed control option (the PWV is the same in this case) is divided by the difference in the emission reduction potentials for both projects. If “a” is the alternative control option and “p” is the proposed control option, then the incremental cost effectiveness is:

$$(C_a – C_p) / (E_a – E_p) = \$ \text{ costs /per ton}$$

When calculated across all the source categories subject to BARCT for NOx RECLAIM, the incremental cost effectiveness for the source categories ranged from $53,000/ton to $917,000/ton. The table below lists the incremental cost effectiveness values calculated for all the source categories subject to the BARCT analysis.

Source Category	**Incremental Cost Effectiveness ($/ton)**
FCCUs	$117,000
Refinery Gas Turbines	$60,000
Boilers/Heaters >40 MMBTU/hr	$61,000
Coke Calciner	$897,000
SRU/TG Incinerators	$63,000
Container Glass Melting Furnaces	$78,000
Sodium Silicate Furnace	$122,000
Metal Heat Treating Furnace >150 MMBTU/hr	$61,000
Non-Refinery, Non-~~Electrical~~ Electrcity Generating Facility Gas Turbines	$917,000
Non-Refinery, Non-~~Electrical~~ Electrcity Generating Facility IC Engines	$53,000

The calculated values clearly indicate that the alternative control option is not viable when compared to the proposed controls.

Part I – BARCT Analyses for Refinery Sector

Part I contains the information related to the BARCT analyses for the refinery sector. Part I includes 10 Appendices from Appendix A to Appendix J that discuss 1) the NOx control technologies, 2) costs and cost effectiveness analyses for major NOx sources at the refineries, and 3) the consultant's analyses. The NOx reductions co-benefits of the energy efficiency projects at the refineries are summarized in Appendix K. The Survey Questionnaires sent to the refineries in ~~2003~~ 2013 to collect pertinent information for this BARCT analyses are included in Appendix L.

Appendix A - Refinery Fluid Catalytic Cracking Units

Process Description

There are five refineries that operate six fluid catalytic cracking units (FCCU) in the SCAQMD: Chevron, ExxonMobil, Tesoro (Carson and Wilmington), Phillips66, and Valero. The FCCUs are classified as major sources of emissions in RECLAIM, and as such, the NOx emissions from FCCUs are required to be monitored with a continuous emission monitoring system (CEMS), and reported on a daily basis electronically to the SCAQMD. A brief description of the process is presented below.

An FCCU converts heavy oils into more valuable gasoline and lighter products. A schematic of the process is shown in Figure A.1. The process uses a very fine catalyst that behaves as a fluid when aerated with a vapor. The fluidized catalyst is circulated continuously between a reactor and a regenerator and acts as a vehicle to transfer heat from the regenerator to the oil feed in the reactor. The cracking reaction is endothermic and the regeneration reaction is exothermic. The fresh feed is preheated by heat exchangers to a temperature of 500-800 degrees Fahrenheit and enters the FCCU at the base of the feed riser where it is mixed with the hot regenerated catalyst. The heat from the catalyst vaporizes the feed and raises it to the desired reaction temperature. The mixture of catalyst and hydrocarbon vapor travels up the riser into the reactor. The cracking reaction starts in the feed riser and continues in the reactor. Average reactor temperatures are in the range of 900-1,000 degrees Fahrenheit. As the cracking reaction progresses, the catalyst surface is gradually coated with carbon (coke), reducing its efficiency. While the cracked hydrocarbon vapors are routed overhead to a distillation column for separation into lighter components, the oil remaining on the catalyst is removed by steam stripping before the spent catalyst is cycled to the regenerator.

In the regenerator, spent catalyst is reactivated (regenerated) by burning the coke off the catalyst surface. The regenerated catalyst is generally steam-stripped to remove adsorbed oxygen before being cycled back to the reactor. The regenerator exit temperatures for catalyst are about 1,200-1,450 degrees Fahrenheit. The regenerator can be designed and operated to either partially burn the coke on the catalyst to a mixture of carbon monoxide (CO) and carbon dioxide (CO_2), or completely burn the coke to CO_2. The regenerator temperature is carefully controlled to prevent catalyst deactivation by overheating and to provide the desired amount of carbon burn-off. This is done by controlling the air flow to give a desired CO_2/CO ratio in the exit flue gases or the desired temperature in the regenerator. The flue gas containing a high level of CO is routed to a supplemental-fuel fired CO boiler if needed to completely burn off the CO to CO_2. The FCCUs in the SCAQMD are currently operated in a completely burn mode; what used to be the CO boilers are used as heat recovery devices without any supplemental fuel.

It is during the regeneration cycle that some of the catalyst is lost in the form of catalyst fines, and NOx, SOx and other pollutants are formed. The FCCU is a major source of sulfur oxides (SOx), nitrogen oxides (NOx), particulate matter (PM10, PM2.5), as well as ammonia (NH3), hydrogen cyanide (HCN) and other pollutants in the refinery. Approximately 90% of the NOx generated from the FCCUs are from the nitrogen in the feed that is accumulated in the coke which is then burned-off in the regenerator. This portion of the NOx is called "fuel" NOx. "Fuel" NOx is a combination of nitric oxide (NO), nitrogen dioxide (NO_2), and nitrous oxide (N_2O). The remaining 10% of the NOx generated from the FCCUs are "thermal" NOx which is generated in the high temperature zones in the regenerator, and "prompt" NOx generated from the reaction between nitrogen and oxygen in the combustion air. The NOx emissions from the FCCU are typically controlled with selective catalytic reduction (SCR), LoTOx scrubbers, and/or NOx reducing additives.

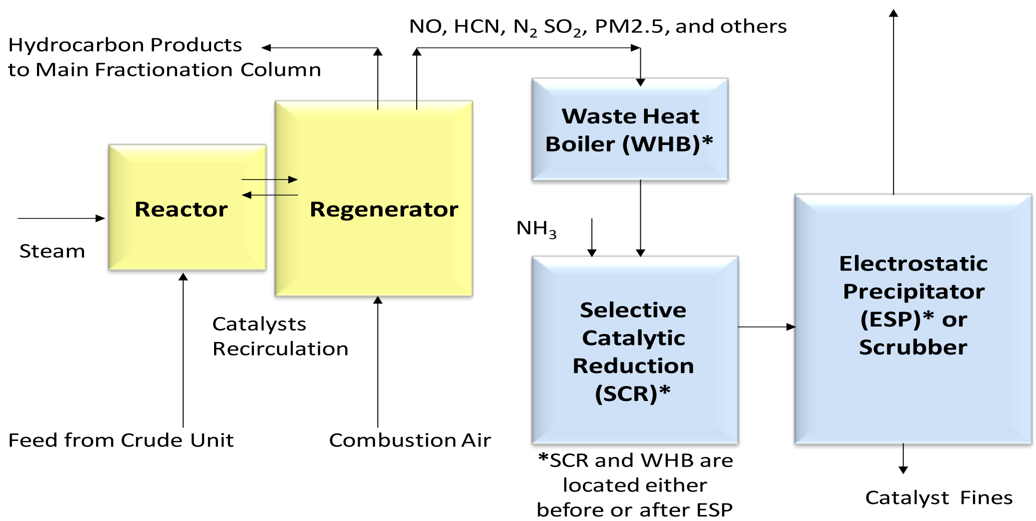

Figure A. 1 - Simplified Schematic of FCCU Process

Emission Inventory

As shown in Table A.1, the total 2011 NOx emissions from the six FCCUs (two with downstream CO boilers/heat exchangers) located in the SCAQMD are 1.08 tons per day.

Three FCCUs at Refinery 6, 1 and 5 use SCRs installed in 2000, 2003 and 2008, respectively to control NOx emissions. Three FCCUs at Refinery 4, 7 and 9 have no NOx controls.

As shown in Table A.1, Refinery 1's FCCU with SCR currently emits at a level under 2 ppmv NOx (with a 5 ppmv ammonia slip.) The NOx concentrations from other FCCU/CO units vary from 6 to 45 ppmv. Figure A.2 graphically shows the 2011 NOx emissions and the regenerator exhaust gas NOx concentrations for the six FCCUs in the SCAQMD. Comparing the data of the six FCCUs, Refinery 1's FCCU operating with SCR installed in 2003 has the lowest NOx emissions and the lowest NOx concentrations at below 2 ppmv.

As previously mentioned, 90% of the NOx emissions from the FCCUs are generated from the nitrogen in the FCCU feed (or coke in the regenerator.) Figure A.3 shows the NOx emissions compared to the FCCU feed rates. Comparing the data of the six FCCUs, Refinery 1 has the highest feed rate but achieves the lowest emissions with the use of an SCR.

Table A. 1 - 2011 Emissions for Refinery FCCUs

Facility ID	Device ID	Device	Process/NOx Control	2011 Emissions (lbs)	Current NOx ppmv @ 3% O2
5	203	REGEN1	FCCU/SCR	119,724	14.84
1	164	REGEN2	FCCU/SCR	16,686	1.21
6	151	REGEN3	FCCU/SCR	123,008	5.62
6	164	CO BOILER	FCCU/SCR	20,038	5.62
4	112	CO BOILER	FCCU/no control	157,150	21.0 - 27.6
4	96	REGEN4	FCCU/no control	in CO Boiler	21.00
7	1	REGEN5	FCCU/no control	101,648	12.88
9	36	REGEN6	FCCU/no control	249,277	35.5 - 45
			Total	**1.08 tons per day**	

Achieved-In-Practice Level for FCCU

Refinery 1 FCCU's SCR has demonstrated that a level of 2 ppmv NOx at 5 ppmv ammonia slip is achieved in practice. [Reference 1]

— The SCR was installed and operated since 2003. It was designed with a NOx inlet of 155 ppmv to achieve a level of 10 ppmv NOx outlet concentration (>90% control efficiency)

— At normal operations, the inlet NOx concentrations range from 40 - 80 ppmv, and the outlet NOx concentrations are typically below 2 ppmv with 5 ppmv ammonia slip (95% - 98% control efficiency). The SCR is capable of having three catalyst layers, each 29 ft x 29 ft x 4.5 ft deep; and is operated with two layers to reach 95% - 98% control. Catalyst life is 5 to 6 years.

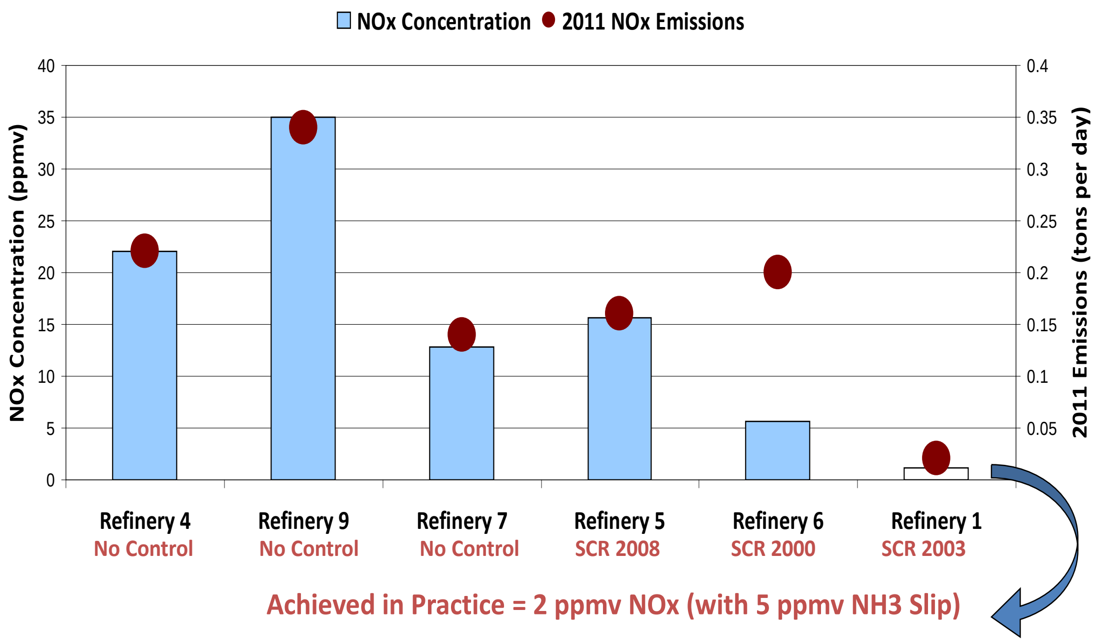

Figure A. 2 - 2011 NOx Emissions and NOx Concentrations for Refinery FCCUs

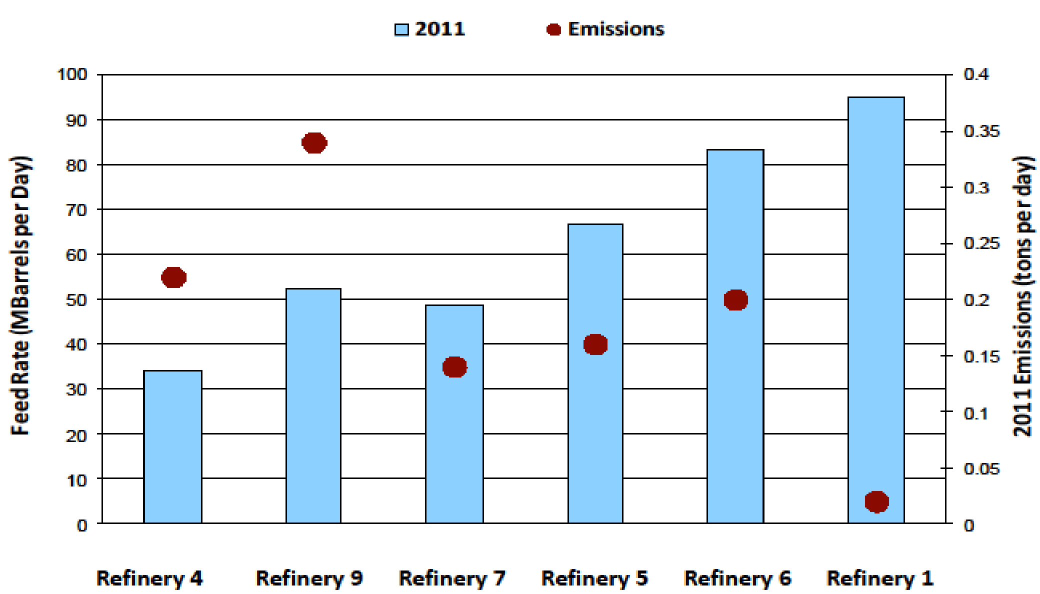

Note: Refinery feed rates are from source test reports and the U.S. Energy Information Administration Website – Refinery Capacity Report www.eia.gov

Figure A. 3 - 2011 NOx Emissions and Feed Rates for Refinery FCCUs

Control Technology

The commercially available control technologies for NOx are discussed below.

Selective Catalytic Reduction (SCR)

For the past two decades, SCR technology has been used successfully to control NOx emissions. The technology is considered mature and commercially available. SCRs can be designed to reduce 95%-98% NOx emissions from the FCCUs and achieve 2 ppmv NOx while maintaining a low ammonia slip of less than 5 ppmv. [1-17]

SCR is an effective control technology for NOx which uses ammonia (NH_3) to selectively reduce NOx to nitrogen through the following reactions: [2 - 4]

$4\ NH_3 + 4\ NO \rightarrow 4\ N_2 + 6\ H_2O$ (Reaction 1)
$4\ NH_3 + 2\ NO + 2\ NO_2 \rightarrow 4\ N_2 + 6\ H_2O$ (Reaction 2)

It should be noted that, at temperatures above 797 ^oF, ammonia can be oxidized to form NO and N_2O. These are undesirable reactions since NO and N_2O will ultimately convert to NOx and increase the NOx emissions. [5]

$4\ NH_3 + 5\ O_2 \rightarrow 4\ NO + 6\ H_2O$ (Reaction 3)
$4\ NH_3 + 4\ NO + 3\ O_2 \rightarrow 4\ N_2O + 6\ H_2O$ (Reaction 4)

A successful SCR catalyst can facilitate the reduction of NH_3 (Reaction 1 and 2) while subsiding the NH_3 oxidation reactions (Reaction 3 and 4). Typically, the SCR catalysts are vanadium, titanium, and/or zeolite based with different sizes and shapes, and have various ranges of operating temperatures: [5 – 8, 18]

Conventional SCR catalysts:	400 degrees F - 800 degrees F
Low temperature SCR catalysts:	300 degrees F - 400 degrees F
High temperature SCR catalysts:	800 degrees F - 1100 degrees F

The ~~stochiometric~~stoichiometric amount of ammonia required is 1 mole of NH_3 per mole of NOx reduced (NH_3/NOx = 1). Ammonia injection and mixing are critical since a non-uniform distribution and mixing of ammonia can result in inadequate NOx conversion and extensive ammonia slip.

To reduce the ammonia slip caused by imperfect ammonia distribution and mixing, SCR manufacturers have developed the Ammonia Slip Catalyst (ASC), a layer of catalyst which can be installed downstream of the SCR catalyst. Early generation of ASCs were based on precious metal which is highly active for NH_3 oxidation. The current newly developed ASCs selectively favor the NH_3 reduction over the NH_3 oxidation: NH_3 is partially oxidized to NO (Reaction 3) and NO is then quickly reduced to N_2 (Reaction 1 and 2). In addition, the advanced ACSs highly support the oxidation of CO to CO_2. Other advantages of ASCs are summarized below: [5, 9-10]

- Enhancing the selective reduction of NO to N2 and supporting the oxidation of CO to CO2 while suppressing the oxidation of NH3 to NOx;
- Allowing for operations at higher NH_3/NOx ratios to ensure complete NOx conversion;
- Maintaining low ammonia slips; and
- Reducing the overall SCR catalyst volume while maintaining the high NOx control efficiency.

In the SCAQMD, aqueous ammonia is required to be used with SCRs instead of anhydrous ammonia due to safety reasons. In general, aqueous ammonia has lower risks and higher operating costs than anhydrous ammonia. A larger volume of aqueous ammonia will be required to achieve the same NOx reduction, thus increasing the costs of deliveries (e.g. for 29% aqueous ammonia, the delivery costs is in transporting 71% water with the ammonia.) Aqueous ammonia requires either compressed air for atomization or vaporizers to evaporate the water. The costs for operating with aqueous ammonia are approximately two times higher than the costs for operating with anhydrous ammonia. [11-13]

Sulfur dioxide (SO_2) to sulfur trioxide (SO_3) conversion and ammonium bisulfate (ABS) formation are undesirable reactions in the SCR process. SO_3 and ABS can cause plugging at downstream components. However, the main factors affecting the formation of ABS, such as temperature, the amount of ammonia slip, molar ratio of ammonia to NOx, the SO_3 concentrations, and fly ash contents; and the methods to control SO_3 ABS formation to reduce its negative effects have been well investigated, documented, and implemented by the SCR manufacturers as well as the SCR users. In addition, ABS is unlikely to be a problem for low flue gas sulfur units. [14]

LoTOx™ Application with Scrubber

LoTOx™ stands for "Low Temperature Oxidation" process in which ozone is used to oxidize insoluble NOx compounds to soluble NOx compounds. These soluble compounds can then be removed by absorption in caustic solution, lime or limestone. The LoTOx™ process is a low temperature operating system, optimally operating in a range of 140 - 325 degrees F. The LoTOx™ is a registered trademark of Linde LLC. (previously BOC Gases) and was later licensed to BELCO of Dupont for refinery applications. The LoTOx application is explained below. [19 - 27]

A typical combustion process produces about 95% NO and 5% NO_2. Both NO and NO_2 are relatively insoluble in aqueous solution, and thus a wet gas scrubber is not efficient in removing these insoluble compounds from the flue gas stream. However, with the introduction of ozone, NO and NO_2 can be easily oxidized to highly soluble compounds N_2O_5 (Reaction 5 and 6) and subsequently converted to nitric acid HNO_3 (Reaction 7). The nitric acid is then rapidly absorbed in caustic solution (Reaction 8), limestone or lime (Reaction 9 and 10), and removed from the wet scrubbers. In addition, the rates of oxidizing reactions for NOx (Reaction 5 and 6) are fast compared to SO_2 oxidation reaction (Reaction 11), and as a result, there is no ABS or SO_3 formation. The LoTOx process can be integrated with any types of wet scrubbers (e.g. venturi, packed beds), semi-dry scrubbers, or wet electrostatic precipitators (ESPs).

$NO + O_3 \rightarrow NO_2 + O_2$	(Reaction 5 - Fast)
$2\ NO_2 + O_3 \rightarrow N_2O_5 + O_2$	(Reaction 6 – Fast)
$N_2O_5 + H_2O \rightarrow 2\ HNO_3$	(Reaction 7)
$HNO_3 + NaOH \rightarrow NaNO_3 + H_2O$	(Reaction 8)
$2HNO3 + CaCO3 \rightarrow Ca(NO_3)_2 + H_2O + CO_2$	(Reaction 9)
$2HNO3 + Ca(OH) \rightarrow Ca(NO_3)_2 + 2H_2O$	(Reaction 10)
$SO_2 + O_3 \rightarrow SO_3 + O_2$	(Reaction 11 - Very slow)

The LoTOx process requires oxygen supply and ozone generation. Oxygen is used to generate ozone on site. Typically oxygen is stored as liquid in vacuum jacketed vessels or is delivered by pipeline. Ozone is an unstable gas and it is typically generated on demand using an ozone generator. An ozone generator is shaped similar to a shell and tube heat exchanger. A corona discharge is used to dissociate oxygen into individual atoms; and the oxygen atoms combine with other oxygen molecules to form ozone. An ozone injection manifold should be designed to achieve uniform distribution and complete mixing. A ratio of NOx/O_3 of about 1.75 – 2.5 is needed to achieve 90% to 95% NOx conversion and reduction. Since sulfites are ozone scavengers, the LoTOx process typically has a very low ozone slip of 0-3 ppmv.

Several advantages of LoTOx application in comparison to SCR are:

- LoTOx is a low temperature operating system, meaning that it does not require heat input to maintain operational efficiency and enables maximum heat recovery of high temperature combustion gases.

- LoTOx can be an integrally connected to a wet (or semi-wet) scrubber, and become a multi-component air pollution control system that can reduce NOx, SOx and PM in one system whereas SCR is primarily designed to reduce only NOx

- There is no ammonia slip, SO_3, and ABS issues associated with LoTOx application.

BOC Gases received a grant funded partially by the California Air Resources Board to demonstrate the LoTOx technology at a reverbertory furnace used for lead smelting, operated by Quemetco Inc., City of Industry in California. The demonstration was successful, accomplishing > 90 percent NOx removal which led to a full scale system installation in 2001.[23] Today, there are more than 50 applications engineered by Linde since 1997,[19] and more than two dozen applications with EDV™ scrubbers engineered by BELCO since 2007.[26] EDV™ is a registered trademark of BELCO. LoTOx with EDV™ scrubber is shown in Figure A.4.

Table A.2 contains a list of the LoTOx applications for FCCUs, boilers, furnaces, and other combustion equipment. This is not an inclusive list. Applications in gas-fired and high sulfur coal-fired units met 95% control (2 ppmv - 5 ppmv). Current installations in refineries have achieved NOx level of 8 ppmv -10 ppmv (85% - 95% control efficiency). Manufacturers have confirmed that LoTOx can be designed to achieve 2 ppmv NOx from current inlet concentrations (85%-95% control efficiency) for FCCUs.

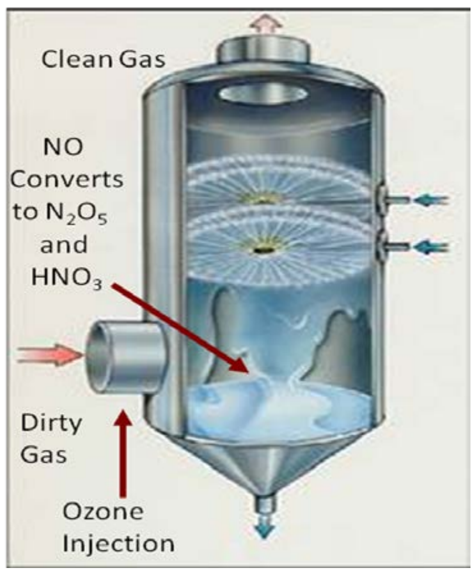

Figure A. 4 - EDV Scrubber with LoTOx Application

Table A. 2 – List of LoTOx Applications

No	Application	Exhaust Gas Flow (scfm)	NOx Inlet (ppmv)	NOx Outlet (ppmv)	% Control	Startup Date
1	400 HP natural gas fired boiler *	4,000	30-70	2	97%	1997-98
2	Stainless steel pickling	4,000	3400	100	97%	2000
3	25 MW coal fired boilers	90,000	200	10-20	95%	2001
4	Lead recovery furnace	26,000	50-150	10	93%	2002
5	1000 HP natural gas fired boiler *	10,000	20-40	4	90%	2001
6-10	Five (5) FCCUs in the U.S.	40,000-260,000	70-120	8-20	80%	2007
11-12	Sulfuric acid plants in the U.S.	2 x 16,800	90	10	90%	2008
13-23	Nine (9) FCCUs and 2 LoTOx ready installations in the U.S.	12,000 – 310,000	30-250	10-18.5	93%	2008-15
24-40	Ten (10) FCCUs, a refinery boiler, 6 LoTOx ready installations in China	90,000-390,000	100-350	20-73	80%	2012-15
41-42	FCCUs in Thailand & Romania	43,000-135,000	230-250	20-73	80%	2015-19

Note: See Reference 19. * Units are in Southern California.

NOx Reduction Additives

The combustion in the FCCU regenerator generates a dozen of various pollutants (NO, N_2O, NO_2, HCN, NH_3, CO, SO_2 ~~etc~~etc.) and the dynamic interaction of these compounds with each other is complex. A simplified version of the chemical reactions in the FCCU regenerator is shown in Figure A.5. “Fuel” nitrogen in the coke is first converted to HCN. HCN is thermodynamically unstable and it is converted to NH_3, N_2, NO, N2O, NO_2 compounds. The rates of these reactions depend heavily on the regenerator temperatures and the regenerator configuration. NOx reduction additives can be used to promote the conversion of NOx, HCN, and NH_3 to N_2 and reduce NOx emissions. The removal efficiency for NOx Reduction Additives is reported to vary from 50% to 80%. [28-38]

No	Application	Capacity (bpsd)	NOx Inlet (ppmv)	NOx Outlet (ppmv)	% Control	Startup Date
1	FCCU, Arkansas	20,000	70-100	10	86%	2007
2	FCCU, Texas City, TX	130,000	100-200	10	95%	2007
3	FCCU, Texas City, TX, retrofit	60,000	100-150	8	95%	2007
4	FCCU, Texas City, TX, retrofit	52,000	70-100	10	90%	2007
5	FCCU, Houston, TX, retrofit	58,000	100-150	10	93%	2007
7	FCCU, St. Charles, LA, retrofit	100,000	Confidential			2010
8	FCCU, Corpus Christi, TX, retrofit	45,000				2010
9	FCCU, Delaware, DE, retrofit	75,000				TBD
10	FCCU, El Dorado, KS	40,000	150	20	86%	TBD
11	FCCU, Ardmore, Oklahoma	40,000	TBD			TBD
12	FCCU, Three Rivers, Texas	28,000				TBD
13	FCCU, Placid Refining, LA	30,000				TBD

Note: Refer to Reference 20 for additional installations inside and outside of the U.S. Some scrubbers have built in ready for LoTOx retrofit but ozone generators have not yet been installed as of May 2013.

Manufacturers of the NOx reduction additives such as BASF, INTERCAT and Grace Davidson recommended the following best practices to minimize the NOx formation with the use of their additives, and at the same time, promote the conversion of CO to CO2:

- Minimizing excess oxygen,
- Reducing feed nitrogen, and
- Utilizing non-platinum CO promoters

Figure A.6 shows outlet NOx concentrations of a FCCU with and without the use of NOx Reduction Additives. Data in Figure A.6 shows that higher excess oxygen favors the formation of NOx rather than N_2, and NOx Reducing Additives are capable of removing 60% of NOx emissions. NOx Reduction Additives cannot yet reduce NOx to 2 ppmv levels, however additives may be used in combination with other control technologies to reach the targeted levels. Two manufacturers indicated that NOx additives generally would cost about $15-$20 per pound and would be used at a rate between 1-3% of the FCC fresh catalyst addition rate. The NOx control effectiveness of the NOx Reducing Additives would be very specific for each FCCU application.

Figure A. 6 - NOx Reduction Additive Reduces NOx Emissions by 60%

Costs and Cost Effectiveness for SCRs

Several methodologies were used to estimate the costs and ensuing cost effectiveness of installing or modifying the SCR's for the FCCU controls to 2 ppmv NOx. These included direct cost estimates from refiners, scaling cost estimates based on flue gas flow rates, using U.S. EPA's guideline approach, an upper range industry cost factor and a consultant's independent assessment.

Refinery 1

The refinery 1 SCR achieved 2 ppmv NOx and 5 ppmv NH_3 slip. Refinery 1 provided staff with the total installed costs, ammonia costs, and catalysts replacement costs for their SCR. [1] Staff estimated Present Worth Value (PWV) for Refinery 1 SCR using the equations below assuming 4% interest rate and 25-years SCR life. The PWV of Refinery 1 SCR was estimated to be $41 million dollars.

$$PWV_{Ref\ 1} = TIC_{Ref\ 1} + (15.62 \times AC_{Ref\ 1}) + (2.52 \times CR_{Ref\ 1}) \qquad \text{(Equation 1)}$$

Where:

$PWV_{Ref\ 1}$ = Present Worth Value, $
$TIC_{Ref\ 1}$ = Total Installed Costs, $
$AC_{Ref\ 1}$ = Annual Operating Costs, $
$CR_{Ref\ 1}$ = Catalysts Replacement Costs, $

Refinery 5, 6 and 7

Costs for the SCRs at Refineries 5, 6 and 7 were derived based on Refinery 1's data. The PWV of Refinery 5, 6, and 7 SCRs were estimated using the PWV of Refinery 1 SCR and the ratios of their appropriate inlet flue gas flow rates to the 0.7 power as follows. The PWVs of SCRs for Refinery 5, 6 and 7 were estimated to be $33 million, $57 million and $27 million respectively as shown in Table A.3.

$$PWV_{Ref\ 5} = PWV_{Ref\ 1} \times (\text{Flow Rate}_{Ref\ 5} / \text{Flow Rate}_{Ref\ 1})^{\wedge 0.7} \qquad \text{(Equation 2)}$$
$$PWV_{Ref\ 6} = PWV_{Ref\ 1} \times (\text{Flow Rate}_{Ref\ 6} / \text{Flow Rate}_{Ref\ 1})^{\wedge 0.7}$$
$$PWV_{Ref\ 7} = PWV_{Ref\ 1} \times (\text{Flow Rate}_{Ref\ 7} / \text{Flow Rate}_{Ref\ 1})^{\wedge 0.7}$$

Refineries 5 and 6 installed their SCRs in 2008 and 2000 respectively. In order to meet the 2 ppmv NOx proposed level, they may choose to 1) retrofit their existing SCRs, or 2) add additional catalysts to their existing SCRs if space is available (Note: Refinery 1 only utilizes 2 layers out of 3 layers of catalysts to meet 95% - 98% control), or 3) change the existing catalysts to a more effective catalyst type. As shown in Table A.3, the PWVs in these scenarios can be potentially less than \$33 million and \$57 million dollars for Refineries 5 and 6, respectively.

Refinery 4 and 9

Refinery 4 and Refinery 9 FCCUs have no controls for NOx emissions. Several manufacturers provided costs information for the SCRs at Refinery 4 and Refinery 9 to achieve 2 ppmv and 5 ppmv NOx.[15 - 17] One manufacturer indicated that the flue gas exist temperatures at the two refineries must be raised to 650 degrees F to avoid SO2/SO3 and ABS related problems; and estimated that this would add about 10% to the overall costs of the equipment.

The EPA's OAQPS Guidelines' approach was used to estimate the following costs: [4]

Instrumental = 10% x Equipment Cost
Sales Tax = 9% x Equipment Cost
Freight = 5% x Equipment Cost
Thus, Total Equipment Cost = 1.24 x Equipment Cost = 1.24 EC
Installed Costs = 50% of Total Equipment Costs

Total Installed Costs (TIC) = (1.24 EC) + 0.5(1.24 EC) = 1.86 EC (Equation 3)

Based on its reported data, the annual operating costs of Refinery 1's SCR during its 25-year life is about 20% of the total installed costs. Staff used this 20% factor to estimate the 25-year operating costs for the new SCRs at all the refineries. Staff added a contingency factor of 1.5 to cover additional uncertainties for both the TIC and the annual operating costs.

$PWV_{\text{Ref 4, Ref 9}}$ = 1.5 [(1.86 EC) + 0.2 (1.86 EC)] = 3.35 EC (Equation 4)

Using the EPA OAQPS Guidelines' approach, the PWVs would become \$16 million and \$19 million for Refinery 4 and 9 as shown in Table A.3, respectively.

Cost effectiveness (CE) was estimated as follows and is summarized in Table A.3:

CE = PWV / (ER x 365 days x 25 years) (Equation 5)
Where:

CE = Cost Effectiveness, \$/ton
PWV = Present Worth Value, \$
ER = Emission Reductions, tpd

The cost effectiveness in Table A.3 is estimated using Discounted Cash Flow (DCF) method. The cost effectiveness calculated based on the Levelized Cash Flow (LCF) method is about 1.65 times higher than the cost effectiveness estimated by the DCF method (e.g. $18K per ton DCF compared to $30K per ton LCF.)

Table A. 3 - Costs and Cost Effectiveness for SCRs (December 2014)

Fac ID	Emissions (tpd)	NOx (ppmv)	% Control	Emission Reduction (tpd)	PWV ($M)	CE ($/ton)
1	0.02	<2	95%	-	(41)	(10,181)
5	0.16	15	87%	0.14	< 33	< 25,259
6	0.20	6	64%	0.13	< 57	< 49,408
7	0.14	13	84%	0.12	27	25,455
4	0.22	21-23	91%	0.20	16	8,961
9	0.34	34-52	95%	0.32	19	6,537
Total reductions for Ref 4,9,5,6 and 7				**0.91**	**152**	**Avg <18,422**

Emissions for all 6 refineries = 1.08 tpd. Remaining emissions from FCCUs at BARCT for all 6 refineries = 1.08 – 0.91 = 0.17 tpd

Consultant's Analysis for SCRs and Staff's Revised Estimates for SCRs

In 2014, staff contracted Norton Engineering Consultants (NEC) to conduct a BARCT analysis for the refinery sector. [39] The NEC's analysis is included in Addendum 1. Table A.4 shows a comparison between NEC's and staff's estimates:

Table A. 4 – Comparison of SCR Costs Estimated by Staff and NEC (December 2014)

Facility ID	Staff's Estimates (note 1) ($M)	NEC's Estimates ($M)	NEC's Feed Rate Adjusted Estimates ($M)
5	<33	<46 (note 2)	<43
6	<57	<46 (note 2)	<50
7	27	42 (note 3)	37
4	16	38	38
9	19	39	37
Total	**152**	**211**	**195**

Note: 1) Staff's estimates were presented at the Jan 22, 2014 Working Group Meeting. For a 2-layer SCR configuration; 2) Estimates reflect a new SCR installation and are over-estimated because the FCCUs already have SCRs installed; 3) This FCCU will be dismantled.

NEC recommended SCRs with 3 layers of catalysts compared with staff's analysis based on refinery FCCU SCR applications currently operating with 2 layers of catalyst in the Basin. The NEC cost estimate included 2 layers of markup factors applied to the equipment costs and an overall 4.5 factor to project the total installed cost to the cost of material and labor.[6] NEC further added the cost of waste heat boiler modifications, new CEMS and additional ammonia storage. The resulting cost information was used to generate a curve to express PWV as a function of feed rate.

NEC's initial estimation of PWV was conducted using a set of refinery FCCU feed rates that were not consistent with those reported in the 2010 SOx RECLAIM staff report or by the January 22, 2014 RECLAIM Working Group presentation. The third column in Table A.4 provides the adjusted cost estimate to account for the representative refinery feed rates.

Catalyst Layers

Staff used a different approach than NEC to estimate the SCR costs because Refinery 1 had achieved an emissions rate of 2 ppmv NOx with only 2 layers of catalysts. This resulted in a significant difference in the cost estimates based on 2 catalyst layers (staff) and 3 catalyst layers (NEC). To address this difference, staff adjusted the manufacture's proposed 60 barrels/day 3 catalyst-layer SCR configuration used by NEC in their estimate to a 2 catalyst-layer model. The adjustment included a 27 percent reduction in the base price to account for the 2-layer configuration (at 10 ft. per second) but then followed NEC's pricing including the 1.35 bid conditioning factor, the 1.75 labor factor and a 4.5 factor applied to the equipment cost. The adjusted estimate added the costs of the waste heat boiler modifications, additional ammonia storage, added CEMS, maintenance and catalyst replacement costs. The projected PWV for the adjusted manufacturers estimate for the 2-catalyst layer configuration is listed in Table A.5 totaling $163 million for five FCCU's.

Range of Costs and Cost Effectiveness for SCRs

In its report, NEC indicated that the factors in the EPA OAQPS Guidelines (Equation 3) were not sufficient to cover retrofitting applications at the refineries. The refineries also indicated the factors relating equipment costs to TIC should be at least 4, or higher. To reconcile this difference, staff presents the PWVs as a range of costs and cost effectiveness in Table A.5.

---

[6] NEC first marked-up the costs provided by the manufacturer by 35%. NEC named this markup as "bid conditioning factor" to cover the "low" bid provided by the manufacturer. NEC then added 75% increase in labor costs to the costs provided by the manufacturer. NEC did not provide any references to their markup factors and simply stated that the factors were based on their own experience.

The staff cost effectiveness estimate is based on a 2-catalyst layer FCCU SCR application that is operating at Refinery 1. The PWV calculated for the five units totaled $152 million establishing the lower end average of the cost effectiveness at $18,000 per ton NOx reduced. The upper cost effectiveness listed in Table A.5 is derived from the PWV totals from the manufacturers adjusted 2-layer estimate averaging $20,000 per ton NOx reduced.

As previously stated, the 2-layer catalyst SCR application has been demonstrated to reach 2.0 ppmv at Refinery 1, in the Basin. Since NEC's proposed model is based on a 3-layer catalyst application it is not included in the cost effectiveness calculation presented in Table A.5. Regardless, the cost effectiveness calculated for the NEC model would place the FCCU SCR application for the 5 units at an average CE of $29,000. Thus, using the NEC 3-layer catalyst assumption, the cost effectiveness is still less than the $50,000 threshold used in the current BARCT analysis and less than the $30,800 threshold established for SCR control equipment established for boilers greater than 75 mmBtu/hr in SCAQMD Rule 1146.

Note that Refinery 4's FCCU is scheduled to be shut down in the near future which would result in lowering the costs estimated for the FCCU category.

Table A. 5 – Revised Costs and Cost Effectiveness for SCRs (March 2015)

Fac ID	Emission Red (tpd)	Staff's 2-Layer Estimate PWV ($M)	Manufacturers Adjusted 2-Layer With no Mark-Up Estimates ($M)	Manufacturers Ajusted 2-Layer with 2 Mark-Ups Estimates PWV ($M)	Range of PWV ($M)	CE ($/ton)
5	0.14	<33	<34	<36	<33 – 36	<25K - $27K
6	0.13	<57	<40	<42	<57 – 42	<49K – 36K
7	0.12	27	29	31	27 – 31	25K – 29K
4	0.20	16	22	23	16 – 23	9K – 13K
9	0.32	19	29	31	19 – 31	7K – 11K
Total	**0.91**	**152**	**154**	**163**	**152 - 163**	**18K – 20K**

Costs and Cost Effectiveness for NOx Reduction Additives

NOx reduction additives can reduce about 10% - 70% NOx emissions depending on the FCCU regenerator configuration and operating condition. The use of NOx reducing additives may not achieve the ultimate goal of 2 ppmv, but may help the refineries achieve the future facility overall shave. Cost effectiveness for NOx reducing additives were estimated to be about $6,460 per ton of NOx reduced using DCF method ($10,660 per ton using LCF method.) The inputs and results were summarized in Table A.6.[38]

Table A. 6 - Costs and Cost Effectiveness for NOx Reduction Additives

Inputs	
Baseline NOx	40 ppmv
NOx reduction	50%
Cost of NOx Reduction Additives	$15 per lb
NOx Reduction Additives	1.5% of total catalysts
Catalyst Addition Rate	4 ton per day
FCCU Rate	70 million barrels per day
Results	
NOx Reduction Additives Costs	1800 $/day
NOx Reduction	348 lbs/day
Cost Effectiveness for NOx Reducing Additives	**6,460 $/ton**

Costs and Cost Effectiveness for LoTOx Scrubbers

The FCCUs at Refinery 4 and Refinery 9 currently have no control. Refinery 7's FCCU has a scrubber. Process data for these three refineries' FCCUs were provided to a manufacturer, and the manufacturer provided estimates for the total installed costs and annual operating costs. [27]

The total installed costs provided by the manufacturer included the ozone generator, the associated closed loop chiller, cooling pump, ozone injection lances. The installed costs also included the associated platforms and access steel, some interconnecting piping and supports, valves and instruments and freight to the job site. The manufacturer did not include oxygen storage and vaporization (which was only necessary if the refinery did not yet have oxygen at the site for other uses), or the cost of electrical equipment and foundation. Staff added a contingency factor of 2 to markup the costs provided by the manufacturer to account for any additional modifications needed at the site and any variations in annual operating costs such as electricity or oxygen.

The PWV for Refineries 4, 7 and 9 LoTOx applications were estimated as follows:

$$PWV_{\text{Ref 4, 7 and 9}} = \text{Contingency Factor x } (TIC_{\text{Ref 4, 7 and 9}} + (15.62 \text{ x } AC_{\text{Ref 4, 7 and 9}}))$$

Where:

$PWV_{\text{Ref 4, 7 and 9}}$ = Present Worth Value $
$TIC_{\text{Ref 4, 7 and 9}}$ = Total Installed Costs provided by vendor, $
$AC_{\text{Ref 4, 7 and 9}}$ = Annual Operating Costs provided by vendor, $

Contingency Factor = 2

Refineries 5 and 6 currently employ SCRs to reduce their FCCU's NOx emissions. Scrubbers may be needed to reduce the SOx emissions from their FCCUs, and LoTOx can be installed concurrently with the scrubbers to further reduce NOx emissions. The PWV for LoTOx applications at Refineries 5 and 6 were estimated based on the PWV for LoTOx applications at Refineries 4 and 7 and the ratios of their appropriate inlet flue gas flow rates to the 0.7 power as follows:

$PWV_{Ref\ 5} = PWV_{Ref\ 5} \times (\text{Flow Rate}_{Ref\ 5} / \text{Flow Rate}_{Ref\ 4})^{\wedge 0.7}$
$PWV_{Ref\ 6} = PWV_{Ref\ 7} \times (\text{Flow Rate}_{Ref\ 6} / \text{Flow Rate}_{Ref\ 7})^{\wedge 0.7}$

The present worth values and cost effectiveness values are summarized in Table A.7. The average cost effectiveness is $15 K per ton using DCF method and $25 K per ton using LCF method.

The manufacturer estimated that a plot space needed for the ozone generator and accessories to be about 25 ft x 35 ft. The first LoTOx application was put in service in 1997. At that time, required a large foot print (e.g. 1st generation LoTOx application at a Texas refinery required a foot print of 30 ft x 80 ft.) The newer generation LoTOx application has a much smaller footprint (e.g. an equivalent unit to the Texas refinery application now requires only 25 ft x 30 ft).

Table A. 7 - Costs and Cost Effectiveness for LoTOx Applications (December 2014)

Fac ID	Emissions (tpd)	NOx (ppmv)	% Control	Emission Reduction (tpd)	PWV ($M)	CE ($/ton)
4	0.22	21-23	91%	0.20	19	10,767[JW1]
7	0.14	13	84%	0.12	16	15,199
9	0.34	34-52	95%	0.32	32	10,631
5	0.16	15	87%	0.14	24	18,590
6	0.20	6	64%	0.13	34	29,502
Total for Ref 4,9,5,6 and 7				**0.91**	**125**	**Avg <15,124**

Staff did not include the costs for scrubbers and waste water treatment in Table A.7. Since Refinery 5 and 6 already have SCRs, they will likely to use their SCRs to control NOx. Staff included the costs for scrubbers with waste treatment for Refineries 4, 7 and 9. Staff also estimated the overall cost effectiveness for the LoTOx/scrubbing multi-component air pollution control as shown in Table A.8.

Table A. 8 – Revised Costs and Cost Effectiveness for LoTOx Scrubbers (March 2015)

Fac ID	NOx Emission Reductions (tpd)	SOx Emission Reductions (tpd)	PWV for LoTOx ($M)	PWV for Scrubbers ($M)	Total PWV ($M)	CE (K$/ton)
4	0.20	0.20	19	91	110	30
7	0.12	0.87	16	51	67	7
9	0.32	0.58	32	90	121	15

Note: 1) SOx emission reductions were taken from Table 3-11, Chapter 3, SOx RECLAIM Staff Report, dated November 2, 2010. [40] 2) PWVs for scrubbers including waste treatment were based on information provided on Table 3-12, Chapter 3, SOx RECLAIM Staff Report, dated November 2, 2010, and a Marshall Swift Index of 1.1. [40] 3) It is assumed that retrofitting existing scrubber for Refinery 7 would cost about half of the costs estimated for the installation of the new scrubber under SOx RECLAIM project.

Incremental Costs and Cost Effectiveness

The BARCT level for the FCCUs in 2005 was set at 85% reduction. The costs for SCRs to meet 85% reductions were estimated to be $111.1 million. The emission reductions were estimated to be 0.48 tons per day. A Marshall index of 1.25 was used to raise the costs of $111.1 million dollars to current dollars of $138.88 million.

Table A.9 presents the Staff estimated the overall PWVs for 2 cases:

Case 1: Assume all 5 refineries will use SCRs to achieve the proposed BARCT level of 2 ppmv. Using the low end costs for SCRs in Table A-5, the total PWVs to achieve 2 ppmv NOx level would be $152 million.

Case 2: Assume Refineries 5 and 6 will use SCRs (using the high end costs for SCRs in Table A.5) and Refineries 4, 7 and 9 will use LoTOx and scrubbers (Table A-8) for multi-component control. The total PWVs would be $375 million.

Table A. 9 – Present Worth Values of SCRs and LoTOx/Scrubbers for FCCUs (March 2015)

Fac ID	Case 1 - PWV ($M)	Case 2 - PWV ($M)
5	<33 (SCR)	<36 (SCR)
6	<57 (SCR)	<57 (SCR)
7	27 (SCR)	67 (LoTOx and Scrubber)
4	16 (SCR)	110 (LoTOx and Scrubber)
9	19 (SCR)	121 (LoTOx and Scrubber)
Total	**152 (all SCRs)**	**391 (SCRs and LoTOx/Scrubbers)**

Incremental cost effectiveness to achieve a more stringent of 2 ppmv NOx from a less stringent level of 85% control during 25-years life of the control device is listed in Table A.10. CE is estimated as follows:

$$CE_{\text{incremental}} = (PWV_{2\text{ ppmv}} - PWV_{85\%\text{ control}}) / ((ER_{2\text{ ppmv}} - ER_{85\%\text{ control}}) \text{ x } 25 \text{ yrs x } 365 \text{ days})$$

Where:

$CE_{\text{incremental}}$ = Incremental Cost Effectiveness, $/ton
$PWV_{2\text{ ppmv}}$ = Sum of all SCR (or LoTOx) costs to meet 2 ppmv, $
$PWV_{85\%\text{ control}}$ = Sum of all SCR costs to meet 85% reduction, $ = $139 M
$ER_{2\text{ ppmv}}$ = Total emission reductions achieved at 2 ppmv NOx, tpd
= 0.91 tpd estimated from 2011 baseline
$ER_{85\%\text{ control}}$ = Total emission reductions achieved with 85% control, tpd
= 1.08 tpd – 0.60 tpd = 0.48 tpd

Table A. 10 – Incremental Cost Effectiveness of SCRs and LoTOx Scrubbers for FCCUs (March 2015)

	Emission Reductions (tpd)	PWV ($M)
SCR for 85% control	0.48 tpd NOx	139
SCR for 2 ppmv for all 5 Refineries	0.91 tpd NOx	152
SCR for 2 ppmv for Ref 5, 6 and LoTOx/Scrubber for Ref 4,7, 9	0.91 tpd NOx and 1.65 tpd SOx	391
Case 1 – Incremental Emission Reductions = 0.91 – 0.48 = 0.43 tpd NOx Incremental Cost Effectiveness: SCR – SCR for all 5 Refineries (152 - 139) / (0.91 – 0.48) / 25 / 365 = 3,444 $/ton DCF and 5,683 $/ton LCF		
Case 2 – Incremental Cost Effectiveness: SCR – SCR for Ref 5, 6, and SCR - LoTOx for Ref 4, 7, 9 (391 – 139) / (0.91 + 1.65 – 0.48) / 25 / 365 = 13K $/ton DCF and 23K $/ton LCF		

Staff's Recommendation

Staff proposes a BARCT level of 2 ppmv NOx for FCCUs because 1) Refinery 1 FCCU's SCR has achieved-in-practice 2 ppmv NOx at 5 ppmv NH3 slip; and 2) NOx control technologies such as SCR, LoTOx, and NOx reduction additives are commercially available and can be used in conjunction to achieve 2 ppmv NOx in a cost-effective manner.

The cost information submitted by SCR and LoTOx manufacturers support that a BARCT level of 2 ppmv NOx is feasible and cost-effective for FCCUs in the SCAQMD. It should also be noted that NOx reducing additives, which can reduce 50% or more of NOx emissions, can be used in parallel with SCRs and LoTOx applications if needed.

In summary:

Case 1:
Total PWVs: $152 M with SCRs for all 5 refineries
Total incremental costs: $13 M
Incremental emission reductions: 0.43 tpd NOx
Incremental cost effectiveness with SCRs: 3,444 $/ton DCF or 5,700 $/ton LCF

Case 2:
Total PWVs: $391 M with SCRs for Refineries 5 and 6 and LoTOx/scrubbers for Refineries 4, 7 and 9
Total incremental costs: $252 M
Incremental emission reductions: 0.43 tpd NOx and 1.65 tpd SOx for 5 FCCUs
Incremental cost effectiveness: 13K$/ton DCF or 23K $/ton LCF

Appendix B – Refinery Boilers and Process Heaters

Process Description

Boilers and process heaters are used extensively in almost all of the processes in refinery such as distillation, hydrotreating, fluid catalytic cracking, alkylation, reforming, and delayed coking. Figure B.1 provides a simplified diagram of the processes where boilers and heaters are used. There are 23 boilers and 189 heaters in the refineries classified as major or large NOx sources. The refinery heaters and boilers primarily burn refinery gas which is generated at the refinery. Most of these boilers and heaters use natural gas as back-up or supplemental fuel. Liquid fuel or solid fuel is rarely used in refinery boilers and heaters. The combustion of fuel generates NOx, primarily "thermal" NOx with small contribution from "fuel" NOx and "prompt" NOx.

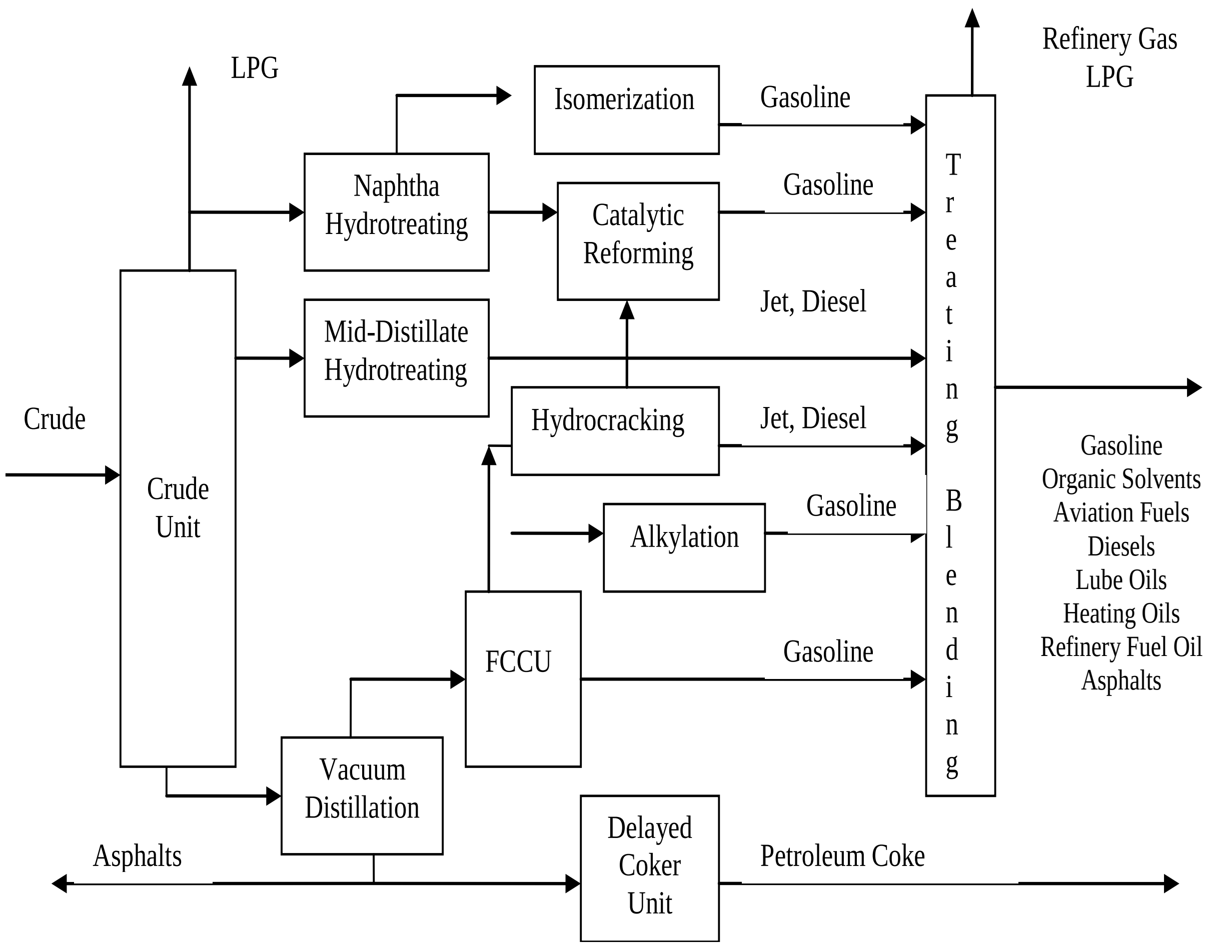

Figure B. 1 - Refinery Processes

Emission Inventory

There are a total of 212 boilers and heaters classified as major and large NOx sources at the refineries. The distribution of boilers and heaters and their emissions are shown in Table 5.1. Collectively, the 212 boilers and heaters emitted about 7.39 tons per day in 2011. Their NOx concentrations at the stack vary from 1.6 ppmv for units equipped with selective catalytic reduction (SCR) to 120 ppmv for units with no control.

The 2005 RECLAIM amendments set BARCT levels between 5 ppmv to 12 ppmv for various categories of boilers and heaters. A comprehensive list of equipment specific NOx emission limits is provided in Table 3 of the SCAQMD Rule 2002, amended January 7, 2005. As a component of the BARCT assessment, the decision was made to retain the 2000 BARCT level for boilers/heaters with maximum input rating between 40-100 mmBtu/hr at 25 ppmv. In 2005, it was estimated that 51 boilers/heaters would require SCRs to be installed to reduce NOx emissions. Only 4 pieces of equipment were retrofitted with SCRs; these were in response to either an EPA consent decree or an order of abatement. If all of the boilers and heaters had complied with the 2005 BARCT emissions from boilers and heaters would be reduced from 7.39 tons per day to 1.92 tons per day, approximately 74% reduction in emissions.

Achieved-In-Practice NOx Levels for Boilers and Heaters

The following is a summary of refinery boilers and heaters that have very low emission levels:

- Fourteen process heaters using refinery fuel gas in the SCAQMD ranging from 22 to 653 mmBtu/hr equipped with SCRs have achieved 1.6 - 3.5 ppmv NOx at 3% O_2;

- Two boilers, 400 HP and 1000 HP, using natural gas, equipped with LoTOx scrubbers have achieved 2 - 5 ppmv NOx at 3% O_2;

- A crude heater using refinery fuel gas rating at 10 mmBtu/hr in Coffeyville refinery Kansas has been operated at 3 - 8 ppmv NOx at 3% O_2 with Great Southern Flameless technology without the use of SCR.

All of the control technologies mentioned above are commercially available and can be designed to reach 2 ppmv NOx at 3% O_2.

Control Technology

Commercially available control technologies are SCRs, Great Southern Flameless Heaters, and LoTOx applications with scrubbers. Other potential technologies on the horizon are ClearSign, Cheng Low NOx and KnowNOx. SCR, Great Southern Flameless burners and ClearSign burner technologies are discussed below. Cheng Low NOx, LoTOx and KnowNOx technologies are discussed in other Appendices. Other common control technologies such as Low NOx burners, Ultra Low NOx burners, or Selective Non Catalytic Reduction (SNCR) are not discussed here.

Selective Catalytic Reduction

SCR is an effective control technology for NOx which uses ammonia (NH_3) to selectively reduce NOx to nitrogen through the following reactions.

Great Southern Flameless Heaters

In 2012, Coffeyville Resources purchased the world's first flameless crude heater designed by Great Southern Flameless for their Coffeyville refinery in Kansas to comply with a Consent Decree issued by the U.S. EPA. The flameless heater has been in operation for over one year and has achieved-in-practice 5 ppmv NOx at 3% O2 with pilots in operation, and 3 ppmv NOx without pilots for flameless technology. Great Southern Flameless confirmed the following: [18-21]

- Flameless heaters can be designed to achieve:
  - 5 ppmv NOx at 3% O_2; or
  - 2 ppmv NOx at 3% O_2 with pilots off during flameless firing and with a fuel mix of 25% natural gas and 75% refinery gas.

- Oxy-fuel flameless heaters can be designed to achieve:
  - 2 ppmv NOx at 3% O_2; or
  - 1 ppmv with pilots off during flameless firing

Great Southern Flameless can supply flameless heaters or oxy-fuel flameless heaters with maximum rating from 10 mmBtu/hr to 320 mmBtu/hr (240 mmBtu/hr process duty.) Their production capacity is 30 heaters per year. The modules are designed and fabricated in Oklahoma, shipped in pieces to be field, and assembled at the site. The heaters can use the same foundation of the conventional heaters. The flameless heater designed by Great Southern Flameless for the Coffeyville refinery has the following characteristic:

- The heater is a polygon with the process coil (heat exchanger tubes) in the center and two "Flameless Nozzle Grouping" (FNG) located on the wall which fire tangentially. Each FNG consists of 2 conventional nozzles, 2 flameless fuel nozzles, 4 air nozzles and 1 nozzle for pilot fuel.

- To pin the flue gas in circulation against the wall, Great Southern Flameless developed and patented a proprietary design for the heater's interior wall. The interior wall of the heater has a dimple pattern in the refractory which holds the flue gas to the wall and allows the flue gas to circulate in high volume and velocity around the heater until it eventually rotates out to the center of the heater, and up through the uptake ducts and into the convection section of the heater. This unique wall design eliminates hot gas impingement on the process coil located in the center of the heater and assures even heat radiation from the heater walls to the heat exchanger tubes.

- Great Southern Flameless also developed and has a patent pending for an automated 3-way switching valve. This valve allows the heater to be operated in three different firing modes:
  - Conventional firing mode when all fuel gas is diverted to the 2 conventional nozzles;
  - Staged firing mode when half of the fuel gas goes to the 2 conventional nozzles and the other half goes to the 2 flameless nozzles; and
  - Flameless firing mode when all fuel gas goes to the 2 flameless nozzles and the combustion is sustained by the high temperatures of the combustion air.

- The heater has a balanced draft air-preheat system which generates high temperature combustion air. High temperature combustion air is required for the staged firing mode and the flameless firing mode to maintain the high auto-ignition temperature required for combustion.

From cold start, the heater is brought up in natural draft mode in the same manner as any typical conventional heater. The firing rate of the heater is gradually increased to the required level while the combustion air is gradually increased to 850 degrees F. Once the combustion air temperature exceeds 850 degrees F, it will sustain the automatic ignition of fuel, and the heater is transitioned into the staged fuel firing mode with pilots off-line. The heater is operated in the staged firing mode until steady state operation is achieved. At this point, the heater is transitioned into flameless firing mode. Visible flame from the conventional nozzles disappears and NOx emissions decreases significantly in the flameless mode operation.

Table B.1 below tabulates the temperature profile inside the heater under the three modes of firing. With more even temperature distribution, the flameless firing mode results in 4 ppmv NOx compared to 77 ppmv NOx under conventional firing and 49 ppmv under staged firing mode. The Coffeyville heater average NOx emissions are in the levels of 3 – 8 ppmvd without the use of high temperature high energy SCR system.

The heater can be designed for combustion with oxygen. Combustion with oxygen in place of air will eliminate "prompt" NOx and reduce CO_2 emissions. Figure B.2 shows a flameless heater modified for oxygen combustion. Table B.2 lists the predicted performance of an oxy-flameless heater. Flameless and oxy-flameless heaters come in modules and can be stacked up to 320 mmBtu/hr rating.

Table B. 1– Temperature Zones and NOx Emissions of Great Southern Flameless Heater

	Conventional Firing	Staged Firing	Flameless Firing
Combustion Air Temperature, degrees F	804	893	909
Average Radiant Upper Level Temp, degrees F	1544	1740	1714
Average Radiant Mid Level Temp, degrees F	2050	1826	1476
Average Radiant Lower Level Temp, degrees F	1488	1627	1669
Excess Oxygen, %	3.7	2.6	2.4
NOx, ppmv	77	49	4

	Traditional Heater	Flameless Heater	Oxy-Flameless Heater
NOx, ppmv	31	4-8	0-1
Excess Oxygen, %	3	3	3
NOx, lb/mmBtu		0.0106	0.0021 or below

ClearSign Technology

ClearSign Combustion Corporation in Seattle has developed two technologies applicable for boilers and heaters: DUPLEX™ technology and Electrodynamic Combustion Control (ECC™). ClearSign expected that these technologies would generate low concentrations of NOx and CO without the need for flue gas recirculation (FGR), SCR or high excess air operation.

DUPLEX™ technology can be installed in new boilers or heaters, or retrofit in existing boilers and heaters. The DUPLEX technology comprises a proprietary DUPLEX tile installed downstream of conventional burners. The hot combustion flame from the conventional burners impinges onto the DULEX tile, and the tile helps radiate heat evenly with high emissivity to the combustion products. DUPLEX operation also creates more mixing and shorter flames. Since the flame length is one parameter that limits the total heat release in a furnace, decreased flame length can allow for significantly higher process throughputs. DUPLEX tile is expected to have a 3- to 5-year life. A demonstration project with San Joaquin Air Pollution Control District and efforts of scaling up the technology to heaters of 5 - 50 million BTU/hr are underway. [20]

The Electrodynamic Combustion Control (ECC™) uses an electric field to effectively shape the flame, accelerate flame speed, and improve flame stability. The total electrical field power required to generate such effects is less than 0.1% of the firing rate.

Bench test performance estimates for DUPLEX and ECC indicated that NOx and CO were less than 5 ppmv, when furnace temperatures were steady maintained between 1200 and 1800 ^{o}F. Beside the benefits of reducing air pollution, ClearSign believes that their burners will provide substantial economic benefits from more uniform heat distribution, improved process throughput, and potentially reduced maintenance costs. [22-23]

Costs and Cost Effectiveness for SCRs

Staff developed a cost curve that plots the PWV of the control devices as a function of boiler/heaters' maximum rating utilizing the following sets of data:

- Refinery Survey Data
- Refinery Consultant's Analysis
- Data provided by three SCR manufacturers, Great Southern Flameless and ClearSign.

The PWVs determined from the cost curve were used to estimate the costs and cost effectiveness for all 212 boilers/heaters at the refineries. The details follow.

Survey Data

As a component of the RECLAIM BARCT evaluation, a survey was submitted to the refineries in 2013 requesting cost information for their boilers and heaters operated with SCRs. There are 14 heaters at the refineries that currently achieve between 1.6 ppmv and 3.5 ppmv NOx at 3% oxygen with the use of SCRs. Table B.3 lists several key characteristics of the heater/SCR combination including: the 2011 emissions, the NOx concentration measured at the stack, the heater maximum rating, and the year of SCR installation, the equipment costs (in the year of installation), installation costs (in the year of installation), and annual operating costs reported by the refineries. [13] A Marshall Index was used to bring the reported costs to the present dollars. Several heaters share a control device. Where this occurs, staff apportioned the reported costs for SCRs into individual SCR costs for each heater based on their relative maximum input ratings. The PWV of individual heaters are estimated using Equation 1 and 2.

$$PWV = (TIC + (15.62 \times AC)) \times \text{Marshall Index} \qquad \text{(Equation 1)}$$

Where:

PWV = Present Worth Value, $
TIC = Total Installed Costs, $
AC = Annual Operating Costs, $. The catalyst replacement costs were reported as a part of the annual operating costs

$$PWV_{\text{Heater A}} = PWV * R_{\text{Heater A}} / R_{\text{All Heaters}} \qquad \text{(Equation 2)}$$

Where:

$PWV_{\text{Heater A}}$ = Present Worth Value of Heater A
$R_{\text{Heater A}}$ = Maximum Rating of Heater A
$R_{\text{All Heaters}}$ = Total Maximum Rating of All Heaters

From the set of all 14 data points above, staff obtained the following ratios:

Installation Costs = 2.807 x Equipment Costs
Total Installed Costs = 3.870 x Equipment Costs
Present Worth Values = 4.072 x Equip Costs = 1.052 x Total Installed Costs (Equation 3).

Table B. 3 – Costs of SCRs Estimated Based on Information Submitted by Refinery

Device	Process	mmBtu/ hr	2011 Emissions (Tons)	Existing NOx ppmv at 3% O2	Shared Control	PWV ($M)

Refinery's Consultant Study

A refinery provided information to SCAQMD staff from a study conducted by their consultant. This study estimated actual costs to install SCRs for 18 heaters at the refinery. The heaters have capacity ranging from 39 - 352 mmBtu/hr. Several heaters were to share a common SCR. The estimated PWVs for these 18 heaters were calculated using the refinery consultant's estimates for the total installed costs and a multiplier factor of 1.052 (Equation 3). The PWVs of common SCRs were apportioned as individual SCR costs for individual heaters using the heater maximum ratings. The PWVs for 18 heaters are summarized in Table B.4. [14]

Table B. 4 – Performance and Cost Information of SCRs for Process Heaters from Refinery Survey

Process	mmBtu/hr	2011 Emissions (Tons)	Year of Installation	Existing NOx ppmv (3% O2)	Shared Control	Equipment Cost ($M)	Installation Cost ($M)	Marshall Index	PWV ($M)

Crude	83	0.86	2001	2.7	No	7.5	22.5	1.42	43.27
Hydrotreating	78	0.27	2003	2.3	No	4.98	14.93	1.38	28.11

Note: Staff used all 14 data points to estimate the ratios of 2.807, 3.870 and 4.072 in Equation 3 however staff did not include data point #13 and #14 on Figure B.3 since the costs of these data points are out of the norm (e.g. data point #13 of $43 million for a 83 mmBtu/hr heaters as compared to data point #12 of $44 million for 653 mmBtu/hr heater.)

SCR Manufacturers

All SCR manufacturers that staff contacted confirmed the following:

- It is feasible to achieve 2 ppmv NOx at 5 ppmv ammonia slip; and
- The costs for SCRs to achieve 2 ppmv NOx is about 10% higher than the costs of SCRs to meet 5 ppmv NOx.

Three SCR manufacturers provided SCR equipment costs. Staff used a multiplication factor of 4 to estimate the PWVs using Equation 3 and the actual reported costs from several refineries submitted in response to the SCAQMD survey.

After refinery visits, a multiplication factor of 4 was used to estimate the TIC (not PWV) as recommended by several refineries to reflect the difficulty of installing SCR for retrofit applications. [15-17] In addition, the following costs were added to the TIC of the SCRs listed in Table B.5:

- Induced draft fans:
  - $1.26 M for 100 mmBtu/hr heater,
  - $1.69 M for 163 mmBtu/hr, and
  - $2.67 M for 350 mmBtu/hr as estimated by NEC [24]
- Ammonia tanks: $1.5 M per NEC recommendation [24]
- CEMS: $100,000 based on data submitted to the SCAQMD in previous CEMS applications.

Great Southern Flameless

Great Southern Flameless provided costs data based on the following assumptions, and the results are summarized in Table B.6 and Table B.7. [20-21]

- 5 ppmv NOx outlet concentration for standard flameless heater
- 3 ppmv NOx outlet for standard flameless heater with pilots off during flameless firing
- 2 ppmv NOx outlet for standard flameless heater with pilots off during flameless firing and fuel conditioning (25% natural gas and 75% fuel gas)
- 1 ppmv NOx outlet concentration for standard oxy-fueled flameless heater
- The equipment costs include burner management system (BMS) control
- Oxygen costs is estimated at $70 per ton for 93% oxygen concentration
- There is no difference in costs between the 2 ppmv and 5 ppmv NOx flameless heaters
- The PWV was estimated based on 4% interest rate and 20-25 years life for heaters
- The PWV for standard flameless includes the savings due to increase in efficiency (83% to 91%) over the conventional heaters
- The PWV for standard oxy-fuel flameless is based on 20% (mass) injection of O2 and includes the savings due to operating efficiency increase (83% to 93.5%)

Table B. 5 - Costs of SCRs Estimated Based on Information from SCR Manufacturers

	Unit Rating (mmBtu/hr)	NOx in (ppmv)	NOx out (ppmv)	Equip Cost ($ M)	PWV ($ M)	NH3 (lb/hr)
A	163	80	2	0.13	0.52 – 3.81 (note 7)	10
	163	80	2	0.10 (NH_3 Slip Cat)	0.4 – 3.99 (note 7)	10
B	100	100	5	0.27 (note 1)	1.08 – 3.94 (note 7)	17
	100	100	2	0.30	1.30 – 4.16 (note 7)	17.5
	350	100	5	0.33 (note 2)	1.30 – 6.0 (note 7)	57
	350	100	2	0.38	1.50 – 6.0(note 7)	59
C	100	100	5	0.20 (note 3)	0.80 – 4.0 (note 7)	5.8
	100	100	2	0.22	0.88 – 4.0 (note 7)	6.0
	350	100	5	0.65 (note 4)	0.26 – 4.53 (note 7)	17.5
	350	100	2	0.70	0.28 – 4.55 (notes 5,7)	17.8

Note: 1) SCR replacement costs were estimated to be $10,000 - $15,000 every 3 – 5 years; 2) SCR replacement costs were estimated to be $20,000 - $25,000 every 3 – 5 years; 3) SCR replacement costs were estimated to be $23,000 - $24,000 every 6 to 7 years ; 4) SCR replacement costs were estimated to be $70,000 - $72,000 every 6 to 7 years; 5) Manufacturer C also estimated annual operating costs based on ammonia costs of about $800 per ton, and using this data, the PWV of the SCR for the 350 mmBtu/hr heater to meet 2 ppmv would be $2,218,040 million which is in the range of $2,800,000 estimated by using the multiplier factor of 4 and the equipment costs provided by the manufacturer. 6) Ammonia slip is 5 ppmv in all categories listed in Table B-6. 7) The high end of the range includes the costs of SCR, induced draft fan, ammonia tank, and new CEMS.

Table B. 6 – Costs for Great Southern Flameless Heaters

Fired Duty HHV (mmBtu.hr)	Equipment Costs ($)	Installation Costs ($)	Total Installed Costs ($)
32	1,909,005	3,818,010	5,727,015
117	3,813,040	7,626,080	11,439,120

321	5,332,800	10,665,600	15,998,400

Table B. 7 - Costs for Great Southern Flameless Heaters with Fuel Savings

Fired Duty HHV (mmBtu/hr)	PWV for Flameless Heater 2 ppmv NOx ($ M)	PWV for Oxy-Fuel Flameless 1 ppmv NOx ($ M)
32	4.9	10
117	7.8	22
187	7.0	32
321	5.5	50

ClearSign

ClearSign provided the estimates summarized in Table B.8 for DUPLEX burners to achieve 5 ppmv NOx and also 2 ppmv NOx. Note that their estimates did not yet include the economic benefits for more uniform heat distribution or improved process throughput and potential reduced maintenance costs. ClearSign indicated that their cost estimates were conservative and can be adjusted due to market demand. In addition, ClearSign provided an analysis showing the revenue savings of about $36,000 per ton NOx reduced using DUPLEX burners compared to SCR to achieve the proposed BARCT levels. [23]

Table B. 8 - Costs for DUPLEX Burners

Maximum Input Rating (mmBtu/hr)	PWV for 2 ppmv DUPLEX ($ M)	PWV for 5 ppmv DUPLEX ($ M)
12	0.442	0.102
24	0.884	0.204
48	1.767	0.408
96	3.535	0.815
150	5.523	1.274
200	7.292	1.682
400	14.728	3.397

Present Worth Values and Cost Effectiveness

The aggregated control equipment cost data for the boilers and heaters was sorted into 5 categories based on maximum firing rate and a representative maximum PWV for the control equipment in the category was set. Two sets of costs per firing rate were developed: one set for a 5 ppmv emissions rate and a second group for a 2 ppmv emissions limit.

For 5 ppmv SCR:

$5 M for ≤ 100 mmBtu/hr boilers and heaters
$10 M for > 100 – 200 mmBtu/hr boilers and heaters
$20 M for > 200 – 400 mmBtu/hr boilers and heaters
$30 M for > 400 – 600 mmBtu/hr boilers and heaters
$45 M for > 600 mmBtu/hr boilers and heaters

Per manufacturer's recommendation, the representative PWV cost for each category was multiplied by a factor of 1.1 for the 2 ppmv limit. A cost curve was then constructed relating the PWV for the control devices as a function of boiler/heater maximum rating determined from the five sets of data shown above. Figure B.3 illustrates the linear cost curve and distribution of control equipment by PWV/firing rate. PWVs were estimated for each boiler/heater (from the 212 pieces of equipment in the inventory) using the linear equation.

For 2 ppmv SCR:

$5.5 M for units with maximum rating ≤ 100 mmBtu/hr
$11 M for units with maximum rating > 100 – 200 mmBtu/hr
$22 M for units with maximum rating > 200 – 400 mmBtu/hr
$33 M for units with maximum rating > 400 – 600 mmBtu/hr
49.5 M for units with maximum rating > 600 mmBtu/hr

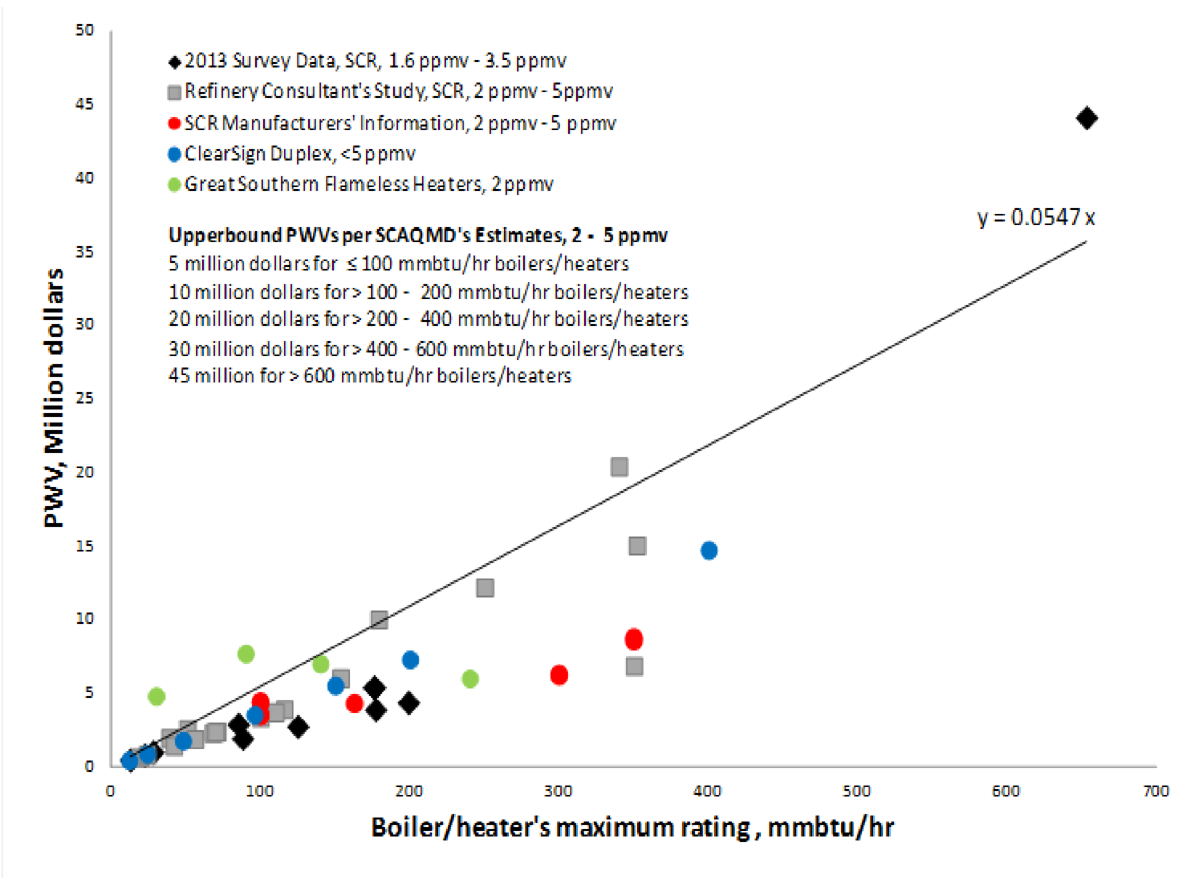

Figure B. 3 – Revised PWVs of Control Devices for Refinery Boilers/Heaters (March 2015)

Incremental Cost Effectiveness was estimated as follows based on the Discounted Cash Flow (DCF) method. A multiplication factor of 1.65 was used to estimate the cost effectiveness using the Levelized Cash Flow (LCF) method:

CE = PWV / (ER x 365 days x 25 years)

Where:

CE = Incremental Cost Effectiveness, $/ton
PWV = Present Worth Value, $
ER = Incremental Emission Reductions, tpd

Units with cost effectiveness exceeding $50,000 per ton were excluded from estimating the total emission reductions and the average cost effectiveness for the category of boilers and heaters. Staff estimated there would be 103 units that would be cost effective with total PWVs of $254.5 Million and an average cost effectiveness of $27 K per ton NOx reduced as of December 2014.

Consultant's Analysis for SCRs

NEC concurred that the 2 ppmv BARCT level is feasible for refinery boilers/heaters >40 mmBtu/hr. However, NEC recommended using SCRs with 4 layers of catalysts. NEC stated:

> "NEC feels that 2 ppmv NOx at 3% O_2 and 5 ppmv ammonia slip is an achievable BARCT level. If the refinery heaters and boilers were only burning natural gas, this 2 ppmv NOx level could be achieved by installing three SCR catalyst beds in series. However, to improve the NOx removal efficiency while burning RFG, which is necessary as all of the heaters routinely operate in this mode, NEC recommends the addition of an Ammonia Slip Catalyst (ASC) bed downstream of the third SCR bed to enhance performance. The ASC bed will permit the SCR to operate with higher ammonia loadings when needed and still guarantee the 5 ppmv ammonia slip. An additional complication in controlling the NOx level on refinery heaters is that many of them have duties that change significantly over short periods of time due to process and feed variations. The ASC bed will also alleviate this difficulty."[24]

NEC estimated their cost profile based on data provided by a manufacturer for a FCCU's SCR, upgrading the base cost for a 2-catalyst layer SCR to a 4-catalyst layer model. As with the FCCU example, the manufacturer's cost proposal was adjusted by a 1.35 factor for bid conditioning followed by a 1.75 factor for labor and a 4.5 factor to estimate the total installed cost. The NEC 4-catalyst layer model added the costs of an induced draft fan, CEMS and an ammonia injection system to their prototype SCR. The resulting profile was sized for a series of heating rates to establish cost curve that related PWV to mmBtu. Their cost equation was applied to the same boiler heater data set to estimate the cost effectiveness of achieving a 2 ppmv emissions rate.

The difference between the staff and NEC cost estimates are greatest for the units less than 200 mmBtu/hr where the staff estimate is roughly half of the NEC estimate (e.g., for 125 mmBtu/hr, staff: $11 million and NEC: $18 million). For heating values approximately 300 mmBtu/hr and higher the costs estimate converge (e.g., for 525 mmBtu/hr, staff: $33 million and NEC: $32.7 million). The impact of applying the NEC algorithm resulted in higher costs for the units with lower firing rates and as a result only 48 heaters/boilers became cost-effective. A comparison between NEC and staff's results are tabulated in Table B.9.

Table B. 9 - Comparison of NEC's and Staff's Cost Estimates for SCRs (December 2014)

	Staff's Estimates	**Staff's Estimates with NEC's Cost Information**
Total Boilers and Heaters	212	212
Number of Cost-Effective Units	103	48
Total PWVs for Cost-Effective Units	$254.5 M	$162 M
Total Emission Reductions	1.05 tpd	0.61 tpd
Average Cost Effectiveness	$27 K per ton DCF	$29 K per ton DCF

It is important to acknowledge that the two approaches were similar in relating firing rate to PWV to estimate cost effective SCR applications. However the underlying the costs, including the sizing of the SCR catalyst layer configuration (1 to 4 layers) were distinctly different. Both assumptions yield estimates to achieve a 2 ppmv emissions target. The average cost effectiveness is essentially the same and less than the $30,800 thresholds established for SCR control equipment established for boilers greater than 75 mmBtu/hr in SCAQMD Rule 1146. The difference in total emissions reduced by the two methodologies is 0.44 TPD.

Upon review of NEC's analysis, staff agreed with the following recommendations from the refineries and revised its cost analysis accordingly:

1. The refineries requested staff to use a factor of 4 (not of 3, which was a combination of the 1.86 factor recommended in the EPA OAQPS Guidelines and 50% added contingency) to estimate the installed costs from the equipment costs provided by the manufacturers. Staff agreed with this recommendation and revised the calculated PWVs based on the manufacturers' information. Revised PWVs are included in Figure B.3 above.

2. For heaters <110 mmBtu/hr with existing SCRs, the refineries requested staff to consider the full costs of SCR installations, not the "incremental" costs in estimating the cost effectiveness values. Staff concurred with this request.

Staff's revised costs and cost effectiveness estimate are summarized in Table B.10. Table B.11 provides the details of the application of the revised methodology to the affected boilers and heaters. The revised analysis results in slightly lower incremental emission reductions and a nominal increase in cost. This revision modified the difference in total NOx emissions reduced by the staff and NEC methodologies to a new total of is 0.33 TPD. Note that an adjustment is proposed to reduce the overall NOx RECLAIM shave amount to account for uncertainties in the BARCT analysis related to these different methodologies. The proposed adjustment is significantly larger than 0.33 TPD.

Table B. 10 – Revised Cost Estimates of SCRs for Boilers and Heaters

Total Boilers and Heaters	212
No of Cost-Effective Units (<50,000 $/ton)	82
No of SCRs	75 (24 upgraded, 51 new)
Total PWVs for Cost-Effective Units	237
Total Emission Reductions	0.94 ton per day
Average Cost Effectiveness	28 K $/ton DCF, 45 K $/ton LCF

Staff's Recommendation

Staff proposes to set a new BARCT level of 2 ppmv NOx for refinery boilers/heaters >40 mmBtu/hr because NOx control technologies such as SCR, LoTOx, Great Southern Flameless heaters are either commercially available, achieved-in-practice and/or can be designed to achieve 2 ppmv NOx in a cost-effective manner.

Incremental Emission Reductions beyond 2005 BARCT level: 0.94 tons per day
Total Incremental Costs: $ 237 M
Average Incremental Cost Effectiveness: $28 K/ton (DCF) and $45 K/ton LCF)

Table B. 11 – Details of Cost Estimates for Boilers and Heaters

Summary of CE for Boilers/Heaters

Results:

Total units = 23 boilers + 189 heaters = 212 units

Cost-effective units = 82. Not cost-effective units = 130
Total SCRs = 75 (24 upgraded, 51 new)

Total PWVs = 237 millions. Total emission reductions = 0.94 tpd.

Average cost effectiveness = 27,710 $/ton DCF = 45 K $/ton LCF

Appendix C – Refinery Gas Turbines

Process Description

Gas turbines are used in refineries to produce both electricity and steam. Frame gas turbines are exclusively used for power generation and continuous base load operation ranging up to 250 MW with simple-cycle efficiencies of approximately 40% and combined-cycle efficiencies of 60%. Aero-derivative gas turbines are adapted from aircraft engines. These turbines are lightweight and more efficient than frame turbines however the largest units are available for up to only 40-50 MW. The existing gas turbines at the refineries in the SCAQMD range from 7 MW to 83 MW. Most are all operated with duct burners, heat recovery steam generator (HRSG), Selective Catalytic Reduction (SCR), CO catalysts and some units have Ammonia Slip Catalysts (ASC), Cheng Low NOx (CLN), and Dry Low NOx (DLN) or Dry Low Emissions (DLE) combustors. Figure C.1 shows a typical layout of a turbine, duct burner, HRSG, and control system.

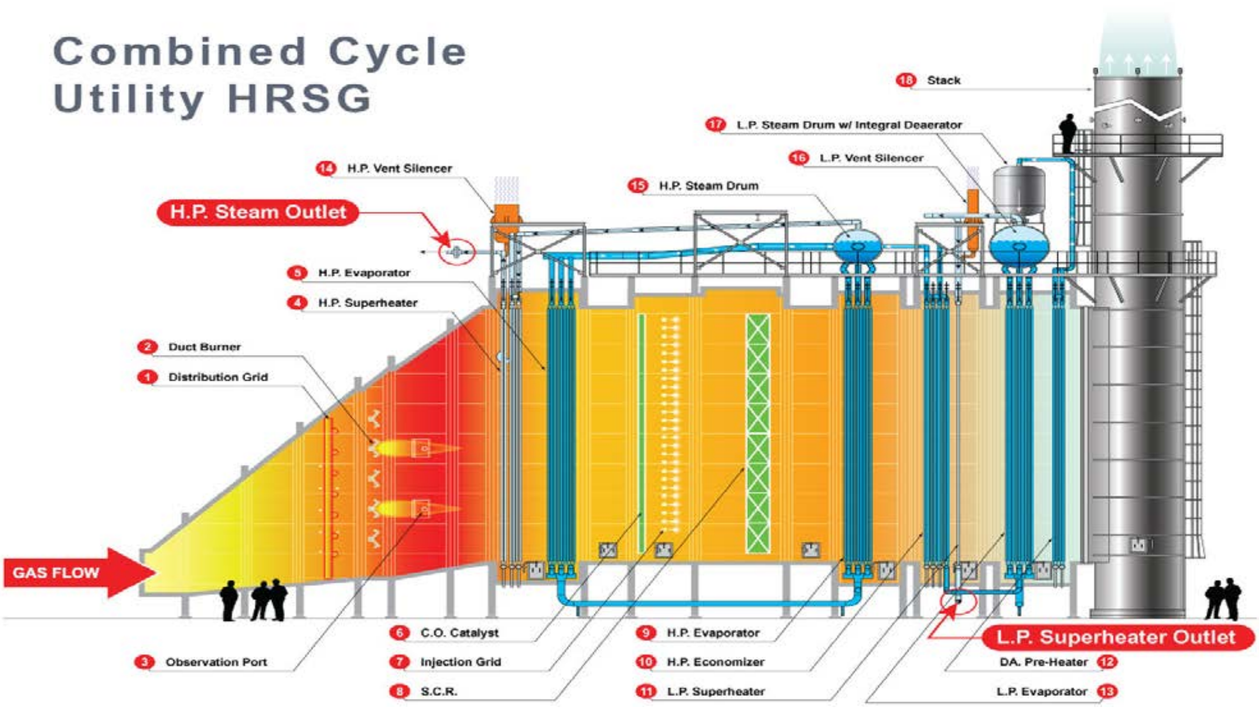

Figure C. 1 - Gas Turbine with Duct Burner (victoryenergy.com)

Emission Inventory

There are a total of 21 gas turbines/duct burners classified as major NOx sources at the refineries in the SCAQMD. Collectively, the 21 gas turbines/duct burners emitted about 1.33 tons per day in 2011 as shown in Table C.1. Table C.1 also includes information on the type and size of equipment, what controls are in place, and the year the controls were installed. NOx levels at the stack vary from 1.67 ppmv at 15% O2 for units with SCR and ASC to 5.95 ppmv for units with SCR and water injection. [1]

It should be noted that at the inception of the RECLAIM program, the SCAQMD staff provided allocations for the gas turbines based on the 2000 BARCT level of 62.27 lbs/mmscft. If all gas turbines/duct burners were operated at the 2000 BARCT level of 62.27 lb/mmscft, the emissions from these turbines would amount to about 4.86 tons per day. In addition, these units are subject to either BACT limits or permit conditions that limit the annual mass emissions at the time the permits were issued: Refinery 1's gas turbines/duct burners have a BACT limit of 8 ppmv NOx; Refinery 5, 6 and 7's units have a BACT limit of 9 ppmv; and units at Refinery 4 are subject to a limit of 583 tons per year of NOx emissions. If these gas turbines/duct burners were operated at the BACT levels or at the levels specified in the permit conditions at the time the permits were issued, the emissions would be 5.99 tons per day, higher than 4.86 tons per day of the 2000 BARCT. All of the gas turbines are currently emitting at a level below their allocations and below the levels at the time their permits were issued. Technology improvements with time and the implementation of BACT levels have recently changed emissions to 2 ppmv for frame turbines and 2.5 ppmv for aero-derivative units.

Achieved-In-Practice NOx Levels for Gas Turbines

- Refinery 10's 7 MW aero-derivative gas turbine/duct burner with Cormetech SCR and ASC operating under a permit condition of 2.5 ppmv NOx, 15% O_2 has actually achieved the levels below 2 ppmv NOx at 15% O_2. [1, 6, 9, 25]

- In 2010, Refinery 5 received a permit to construct a new 46 MW frame gas turbine/duct burner with DLN, SCR and CO catalysts. The permit has a limit of 2 ppmv NOx, 15% O_2 and 5 ppmv NH3 slip. This unit has been in operation since 2012. [28-29]

- In 2011, Refinery 1 received a permit to construct for ~~a~~an 85 MW gas turbine /duct burner with DLN, SCR and CO catalyst. The permit condition required the turbine to be operated at a BACT level of 2 ppmv NOx, 15% O2. Regardless of the permit, Refinery 1 did not install the gas turbine. [7]

The above 7 MW aero-derivative, 46 MW and 85 MW frame gas turbines/duct burners demonstrate the feasibility of the proposed level of 2 ppmv NOx, 15% O2, annual average, for gas turbines using natural gas as well as refinery gas. The limits stated in the permit conditions are based on short-term averages (e.g. 1-hour average), which is more stringent than the proposed BARCT at 2 ppmv, annual average.

Table C. 1 - 2011 Emissions for Refinery Gas Turbines/Duct Burners

Control Technology

Gas turbines/duct burners are capable of emitting very low NOx emission levels. Currently most of the units at the refineries in SCAQMD are emitting less than 5 ppmv NOx using commercially available control technologies such as water or steam injection, DLN, DLE, CLN, SCR, CO catalysts and ASC.

Water or Steam Injection

Most of the NOx generated in the gas turbine/duct burner is "thermal" NOx. Water or steam injected into the high temperature frame zone quench the temperature down and reduce NOx to approximately 25 ppmv at 15% O2. However, water/steam injection tends to increase the CO emissions appreciably.

Dry Low NOx (DLN) and Dry Low Emissions (DLE)

DLN/DLE is based on a concept of lean premixed combustion – gaseous fuel is premixed with combustion air at the air to fuel ratio two times higher than the stoichiometric ratio. The lean mixture reduces peak flame temperature in the combustion zone and suppresses "thermal" NOx formation. The premixing chamber for the combustion air and gaseous fuel must be specifically designed for each type of turbines and integrated into the turbine design. Every 4 to 5 years, the combustion liners of the DLE/DLN combustors are deteriorated and must be replaced. Table C.2 shows potential performance of DLN/DLE in certain models of GE frame and aero-derivative turbines. A few models of natural-gas-fired turbines can reach as low as 3-5 ppmv NOx. Maintaining the low NOx emission levels from the turbines from full to low load, or from turbines with varying load swings coupled with the emissions from the duct burners remain a challenge for DLN/DLE combustor technology. Most manufacturers would guarantee a level of 15-25 ppmv for DLE/DLN combustors. [14-16]

Table C. 2 – Performance of DLN and DLE

Combustion System	Frame Type	Potential NOx Level
DLN1	GE 3/5/6B/7/9E	9-25 ppmv
DLN1	GE 6B/7E/9E	3-5 ppmv
DLN2.6	GE 6F/7F	9 ppmv
DLN2.6	GE 9F	9 ppmv
Combustion System	**Aero-derivative Type**	**Potential NOx Level**
DLE	GE LMS100 (100 MW)	25 ppmv (gaseous fuel)
DLE	GE LM6000 (40-55 MW)	15-25 ppmv (gaseous fuel) 100 ppmv (liquid fuel)
DLE	GE LM2500 (28 – 34MW)	15-25 ppmv (gaseous fuel) 100 ppmv (liquid fuel)

Cheng Low NOx (CLN)

Cheng Low NOx is an alternative to DLN/DLE. [17-23] In lieu of premixing air to fuel, CLN premixes steam with fuel prior to combustion. The difference in the CLN and the traditional steam injection technology is that CLN can deliver a uniform homogenous mix of steam and fuel to the combustion chamber. A schematic diagram for the CLN is shown in Figure C.2.

The effect of homogeneity on CO and NOx emissions is shown in Figure C.3. With careful mixing, the steam to fuel ratio can be extended to 4 to 1 without causing any flameout and increasing CO emissions. The NOx level can theoretically be lowered to 1 ppmv without the use of SCR. The CO level can be reduced to below 2 ppmv without the use of CO catalyst. [17-20]

The CLN technology was developed by Cheng Power Systems, Inc. It was patented in 2002. Since 2005, the CLN technology has been running continuously on a 6 MW Allison Rolls Royce (RR) KB5S at the Stanford Research Institute (SRI) in Menlo Park. In 2009, it was demonstrated on a GE LM2500 at Calpine Corporation's Agnews Cogeneration Plant. The newest CLN was installed in the GE LM2500PH gas turbine. Table C.3 below shows a list of CLN installations in the past decade.

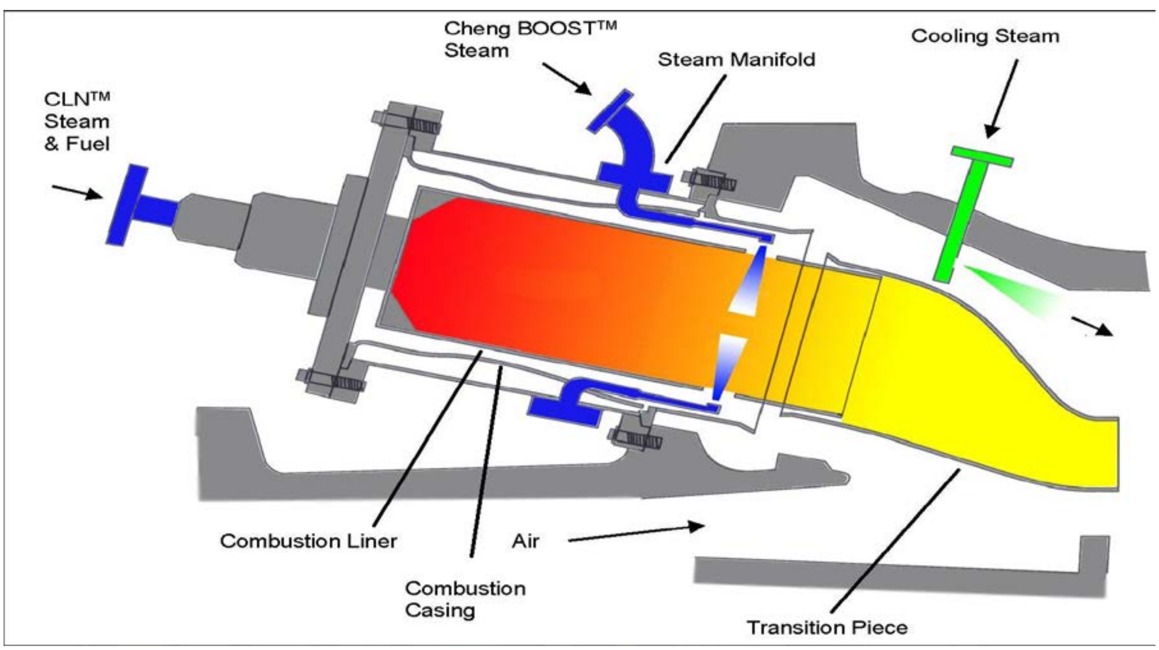

Figure C. 2 - Cheng Low NOx (Reference 22)

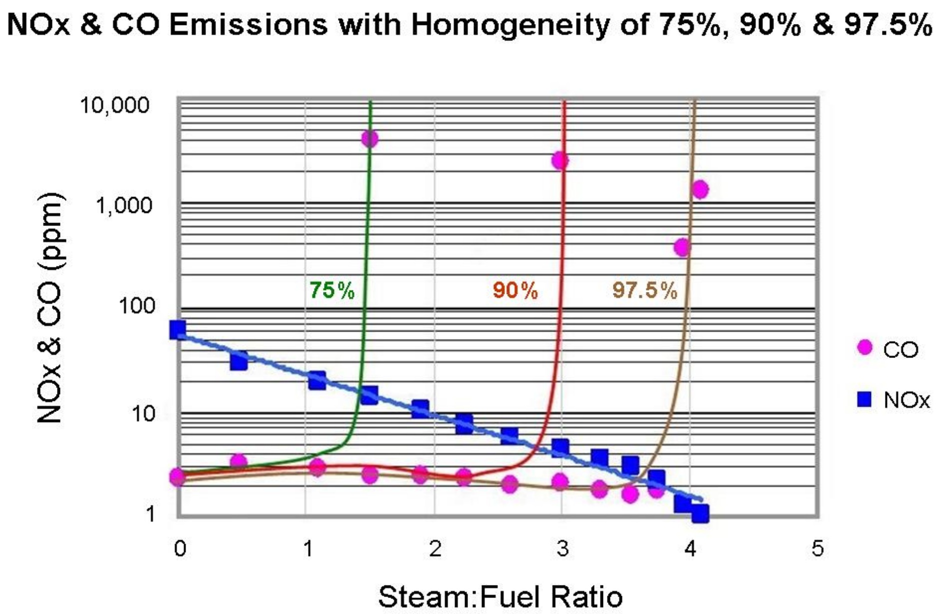

Figure C. 3 - Effect of Homogeneity and Steam to Fuel Ratio in CLN Application (Reference 22)

Table C. 3 – Installations of CLN

Engine	Rated Power, MW
RR 501 KH	6.2
RR 501 KB7S	5.2
RR 501 KB5	3.9
RR Avon 1535	15
GE LM2500	22
GE 6B	39.5
LM 6000 PC	43
GE 7EA	85

Figure C.4 below shows some of the test results of CLN. Additional test results can be found in References 18-20. It should be noted that, CLN was put in operation on two GE Frame 6B turbines at a refinery in the SCAQMD. Actual test data at the refinery site in the SCAQMD shows a level of 17.7 ppmv NOx at 15% O2 at the steam to fuel ratio of 1.5. [18-19] In addition to lowering NOx and CO emissions, additional benefits that CLN provide are lowering the heat rate and increasing power output.

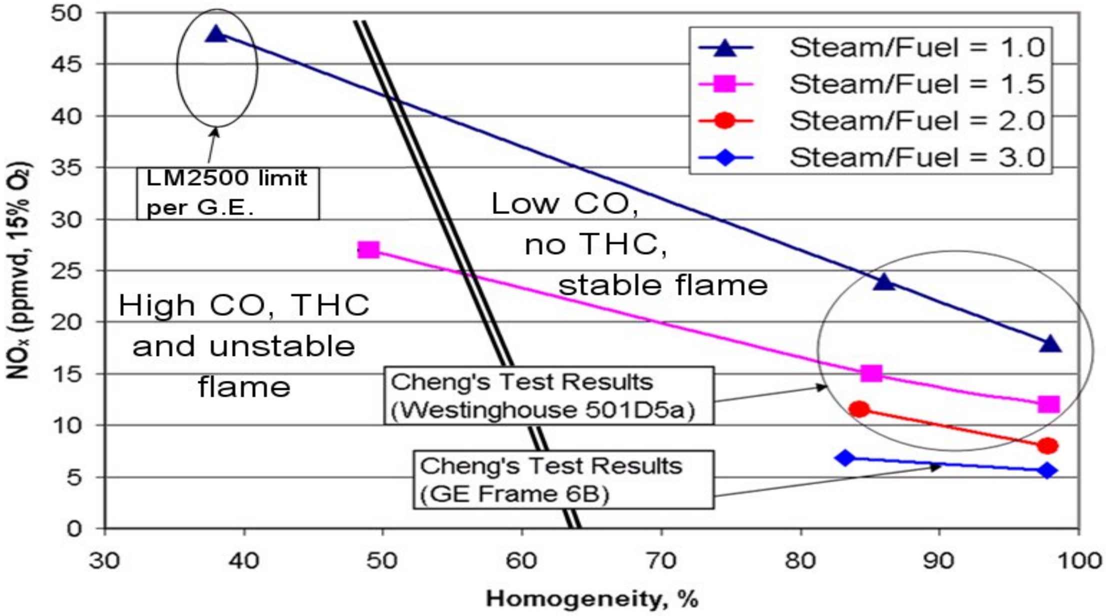

Figure C. 4 - Effect of Homogeneity and Steam to Fuel Ratio on NOx Emissions in CLN Application

In summary, CLN with a steam to fuel ratio of 1.75 to 1 is proven viable to reduce NOx emissions to 9 ppmv or 15 ppmv. SCR can be used in combination with CLN to reach 2 ppmv NOx and CO levels. The current CLN system comes with automatic adjustment software to continuously monitor and optimize the amount of steam to fuel ratio. Cheng Power projects that with a steam to fuel ratio of 3 or 4 to 1, CLN would be able to reach 2 ppmv NOx without the use of SCR.[21-23]

Selective Catalytic Reduction

SCR is an effective control technology for NOx which uses ammonia (NH_3) to selectively reduce NOx to nitrogen. Please refer to Appendix A for further descriptions.

All SCR manufacturers that staff contacted confirm that SCRs can be designed to reduce 95%-98% NOx emissions when used in combination with DLE/DLN, CLN, CO catalysts, ASC, or water/steam injection. Two ppmv NOx can be achieved while maintaining low ammonia slips of less than 5 ppmv.

Cormetech indicated that they have achieved less than 2 ppmv NOx and 2 ppmv NH_3 in 10 gas turbines. In addition one of the full scale demonstration projects is a 7 MW cogeneration unit located at a refinery in the Los Angeles Basin (startup in 2003) that achieved <2 ppmv NOx at <0.1 ppmv ammonia slip. [25] BASF advertised that their vanadia/titania catalysts have 99% NOx removal efficiency in the optimum temperature range of 550 – 800 degrees F, and their zeolite catalysts have 99% removal efficiency in the optimum temperature range of 675 - 1075 degrees F, and they also supply ASC that can reduce both ammonia and NOx. [27]

The CO catalysts are used in conjunction with SCR catalysts to concurrently reduce NOx to nitrogen and oxidize CO and hydrocarbon to CO2 and water. The CO catalysts are typically made of platinum, palladium or rhodium, and have about 90% removal efficiency for CO and remove 85% to 90% of hydrocarbon or hazardous air pollutants.

Costs and Cost Effectiveness

It has been reported that the costs of SCR catalysts have dropped significantly over time – catalyst innovations have been the principle driver, resulting in a 20 percent reduction in catalyst volume and costs with no change in performance. [10] Staff developed a cost curve that plots the PWV of the control devices as a function of gas turbines' maximum rating utilizing the following sets of data:

- Refinery data
- EPA and DOE data
- Data provided by SCR manufacturers and Cheng Low NOx

Staff then used the PWVs from the cost curve to estimate the cost and cost effectiveness for all 21 turbines/duct burners at the refineries. The details are explained below.

Refinery 1's Cost Information for SCR

In 2011, Refinery 1 received a permit to construct for an 85 MW gas turbine/duct burner. It was planned as the fifth cogeneration unit at this site. SCR and CO catalysts were proposed to control NOx and CO emissions from a DLN combustor. The total installed costs for SCR and CO provided in their application for permit was estimated to be \$5.9 million. Staff used a Marshall Index factor of 1.2 to adjust to current dollars. [7]

This refinery has four existing cogeneration units at the site emitting between 2.52 ppmv to 3.50 ppmv NOx. The refinery reported through a survey conducted in 2013 that the annual operating costs were \$375,000 per year, and catalyst replacement costs were \$950,000 every 10 years. [8]

Using Equation 1 below with a Marshall Index adjustment factor of 1.2 to bring the costs to present dollars, staff estimated the PWV for the SCR/CO catalysts were approximately \$15.50 million.

PWV = Adjustment Factor x (TIC + (15.62 x AC) + (1.14 x CR)) (Equation 1)

Where:

PWV = Present Worth Value, $
TIC = Total Installed Costs, $
AC = Annual Operating Costs, $
CR = Catalyst Replacement Costs, $

Refinery 10's Cost Information for SCR

This refinery has a 7 MW cogeneration unit that is using SCR and ASC (installed in 2002) to achieve a level of 1.67 ppmv NOx at 15% O2. The refinery reported total installed costs, annual operating costs, and catalyst replacement costs every 10 years. Using Equation 1 with Marshall Index of 1.4, staff estimated the PWV for SCR/ASC catalysts of approximately $3.8 million. [6, 9]

Costs Information from SCR Manufacturers

All SCR manufacturers that staff contacted confirmed that it is feasible to achieve 2 ppmv NOx at 5 ppmv ammonia slip for natural gas as well as refinery gas applications using SCRs, or combinations of SCRs with CO, or ammonia slip catalysts.

Manufacturer B provided the cost to add catalyst and increase the ammonia usage to the SCR of Refinery 1 to achieve 2 ppmv NOx. In this conservative estimate, Manufacturer B assumed that the existing NOx levels were at 10 ppmv. Manufacturer B believed that with the current SCR system at Refinery 1, the refinery could meet 2 ppmv NOx just by adding ammonia. [5]

Additional catalysts = $234,000 ($250 per cubic foot)
Additional ammonia = $11,000 based on $900 per ton ammonia

Manufacturer A provided several sets of cost information for 1) conventional SCRs and for 2) an advanced SCR with ASC for 83 MW and 7 MW cogeneration units with inlet NOx concentrations at 35 ppmv and 50 ppmv to get to 2 ppmv and 5 ppmv outlet NOx concentrations. The costs are summarized in Table C.4 below: [4]

Table C. 4 – Costs of SCR and ASC for 83 MW and 7 MW Cogeneration Units

Engine	Rated Power 83 MW	Rated Power 83 MW	Rated Power 83 MW	Rated Power 7 MW
Exhaust Flow, lb/hr	2,653,000	2,653,000	2,653,000	140,000

CO Conversion, %	92	92	67	92
NH3 Slip, ppmv	5	5	5	5
Costs	$986,000	$1,100,000	$650,000	$60,000

Note: 8 ppmv NOx is the existing permit condition of Refinery 1's cogeneration unit.

The SCR, CO and ASC have a catalyst replacement frequency of 10 years. Manufacturer B assumed that the existing ammonia storage tanks and injection systems can be used. Associated equipment such as pumps, control valves and vaporizer capacity may increase costs however, this equipment was not included in the cost estimate. Installation and duct modifications were also not included in the cost estimate. Staff used a multiplier factor of 1.6 to add the costs of modifications and installation based on Refinery 10 data. Assuming the entire existing SCR and CO catalysts were replaced with SCR and ASC using the costs provided by Manufacturer B, staff estimated the SCR/ASC's PWVs would be approximately of $19 million for the 83 MW turbine and $2 million for the 7 MW turbine.

SCR Cost Information in Literature

Reference 2 contains extensive cost information for SCR catalysts to achieve 80% - 90% reduction from various inlet concentrations to 9 ppmv NOx outlet concentration. The gas turbines in the SCAQMD currently have inlet NOx concentrations in the range of 6 to 2.5 ppmv. An incremental reduction of 80% - 90% is needed to reach 2 ppmv NOx. Staff assumed that the entire SCR costs in Reference 2 can be used to estimate the "incremental" costs for the SCRs at the refineries to reach 2 ppmv. The estimated PWVs based on Reference 2 are $4.13 million for an SCR for a 7 MW turbine, and $22.44 million for an SCR for ~~a~~an 83 MW turbine.

Reference 3 contains the total installed costs and annual operating costs for conventional SCR to reach 79% NOx removal efficiency for a 4.2 MW, 23 MW and 161 MW turbines. Staff assumed that these costs can be used to reflect the "incremental" costs for the scenarios in the SCAQMD. Staff's estimate of the incremental PWVs for SCRs would be $4 million for the 4.2 MW gas turbine, $11 million for the 23 MW gas turbines, and $41 million for the 161 MW gas turbines.

Costs for Cheng Low NOx

Cheng Power Systems provided the following information on costs for CLN to meet 2 ppmv NOx.[20-21] In a presentation to the SCAQMD staff, Cheng compared the costs to operate a simple cycle 85 MW gas turbine with a Cheng cycle gas turbine to show that within a year of operation, the CLN would generate $9 million savings by reducing heat rate and increasing power, and that savings would offset the $5.5 million installation costs for the CLN.[21] The costs for Cheng Low NOx are listed in Tables C.5 and C.6.

Table C. 5 - Projected Income Gain Due to Power Increase for Cheng Low NOx

Engine	Power (MW)	Percent Power Increase
RR 501 KB series	5.2	20%
RR Avon 1535	15	20%
GE LM2500	22	20%
GE 6B	39.5	20%
LM 6000 PC	43	16%
GE 7EA	85	20%

Note: For GE 6B, the increase in power during summer was from 34 MW to 42MW.

Table C. 6 - Equipment and Installation Costs for Cheng Low NOx for Various Types of Gas Turbines

Engine	Power (MW)	Hardware	Installation/Software	Total
RR 501 KB series	5.2	$250,000	$125,000	$375,000
RR Avon 1535	15	$500,000	$350,000	$850,000
GE LM2500	22	$950,000	$650,000	$1,600,000
GE 6B	39.5	$1,700,000	$700,000	$2,400,000
LM 6000 PC	43	$1,800,000	$700,000	$2,500,000
GE 7EA	85	$3,000,000	$2,500,000	$5,500,000

Note: The above price assumes a CHP or Combined Cycle Plant with steam heat recovery system available. The extra costs of engine refurbishment or upgrade is to be determined based on a case by case basis and is not included in the above list.

Present Worth Values and Cost Effectiveness

Figure C.5 depicts a cost curve constructed relating the PWVs for the control devices as a function of turbine MW rating. The PWVs were then estimated for all gas turbines/duct burners to achieve 2 ppmv NOx with SCR/CO catalysts or SCR/ASC. See Table C.7. The PWVs with CLN/SCRs could be less if the savings resulting from increasing power would offset the CLN costs.

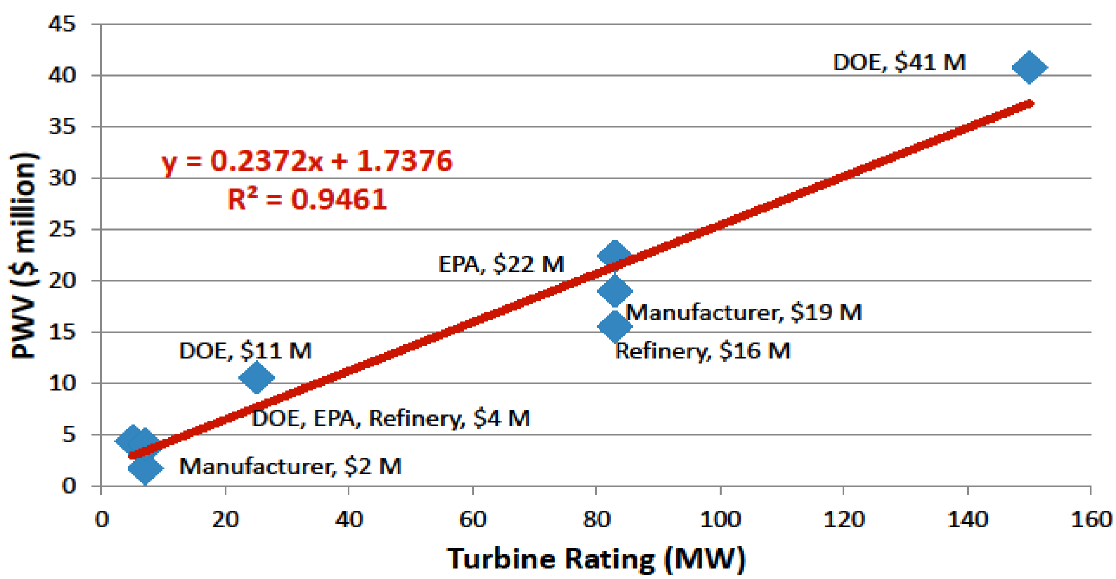

Figure C. 5 - Present Worth Values for Gas Turbines

Table C. 7 – Present Worth Values and Cost Effectiveness for Gas Turbines (December 2014)

No of Units	Rating (MW)	Current NOx Level (ppmv)	Incremental Emission Reduction per Unit from 2005 BARCT (tpd)	Staff's Estimate PWV per Unit ($M)	Incremental Cost Effectiveness ($/ton)
1	59	5.7	0.21	15.7 (new SCR)	8,210
3	46	3-4	0.31	12.6 (new SCR)	4,472
2	30	6	0.20	8.9 (new SCR)	4,851
1	23	5.7	0.14	7.2 (new SCR)	5,631
4	83	2.5-3.5	0.60	4.8 (add catalysts)	870
Total for all 10 units			**4.14**	**97.68**	

Incremental cost effectiveness values were estimated as follows based on the Discounted Cash Flow (DCF) method. A multiplication factor of 1.67 (to account for 25 years life of the SCR/CO/ASC system with frequency of catalyst replacement every 10 years) was used to convert the cost effectiveness estimated using DCF method to the Levelized Cash Flow (LCF) method:

CE = PWV / (ER x 365 days x 25 years)

Where:

CE = Incremental Cost Effectiveness, $/ton
PWV = Present Worth Value, $
ER = Incremental Emission Reductions, tpd

It should be noted that the cost estimates in Table C.7 above are conservative for several refineries as discussed below:

- Refinery 5's gas turbines A, B, and C currently emit 3.5 - 4.5 ppmv NOx at 15% O_2. Refinery 5 recently changed the catalysts used in Turbine A and Turbine B from Hitachi to Cormetech, and reduced the catalyst's volume from 2700 cubic feet to 667 cubic feet. The catalyst's volume of Turbine C is 950 cubic feet. The new Turbine D at Refinery 5 uses only 300 cubic feet of Cormetech catalysts to reach 2 ppmv NOx. Turbine D has DLN. Turbines A, B have CLN with steam injection at steam to fuel ratio of 1.5. Turbine C has steam injection at a steam to fuel ratio of 1.3. It should be noted that the steam to fuel ratio for Turbines A and B was permitted at 2.1 – 2.6. Refinery 5 has several options to reach 2 ppmv NOx: 1) add additional catalysts or change to more effective catalysts, 2) increase the steam to fuel ratio, or 3) retrofit with CLN or DLN. Increasing the steam to fuel ratio could add more power to the system and return the investments within a couple years of operation. [20, 28-29]

- Refinery 7 also changed the catalysts to Haldor Topsoe and Cormetech. With the use of more efficient SCR and ASC and additional ammonia, Refinery 7 may be able to reduce the catalyst volume and NOx emissions from 5 ppmv to 2 ppmv NOx without compromising the ammonia slip. [11, 25, 26, 31]

- Refinery 4's two 30 MW turbines currently use water injection, SCR and CO catalysts to achieve 5-6 ppmv NOx. The turbines have permit conditions limiting them to 96 ppmv NOx and 5 ppmv ammonia slip, and 583 tons per year NOx. Refinery 4 can retrofit the unit with steam injection or CLN technology, increase the power and reduce NOx without compromising the ammonia slip. Alternatively, the refinery may change to more effective SCR catalyst type and use ASC to reduce catalyst volume and increase NOx reduction effectiveness without compromising the ammonia slip. [11, 20, 25, 26]

- Refinery 10's gas turbine/duct burner is already at levels below 2 ppmv, thus no incremental costs were estimated for this refinery.

In conclusion, staff proposes to set a new BARCT level of 2 ppmv NOx for refinery gas turbines, aero-derivative as well as frame turbines, because NOx control technologies such as DLE/DLN, CLN, SCR with CO catalysts, SCR with ASC are commercially available and can be used together to achieve 2 ppmv NOx in a cost-effective manner. A level of 2 ppmv NOx is achieved-in-practice for an aero-derivative 7 MW gas turbine/duct burner using SCR and ASC. Two 46MW and 83 MW frame cogeneration units with SCR and CO catalysts were given permits to constructs since 2011 with permit conditions limiting to 2 ppmv NOx, 2 ppmv CO and 5 ppmv ammonia slip.

Consultant's Estimates for SCRs

NEC agreed with staff's proposal of 2 ppmv BARCT level for gas turbines using refinery gas. They proposed adding catalyst to the existing SCRs of the gas turbines to achieve 2 ppmv NOx. Their estimates are generally lower than the staff estimate since they assumed that more catalyst would be used rather than the addition of new SCRs. NEC's estimates are compared to the staff estimate in Table C.8. [33]

Table C. 8 - Comparison of Staff's and NEC's Estimates for Gas Turbines

No of Units	Rating (MW)	Current NOx Level (ppmv)	Incremental Emission Reduction per Unit from 2005 BARCT (tpd)	Staff's Estimate PWV per Unit ($M)	NEC's Estimate PWV per Unit ($M)
1	59	5.7	0.21	15.7 (new SCR)	5.1 (add catalysts)
3	46	3-4	0.31	12.6 (new SCR)	4.0 (add catalysts)
2	30	6	0.20	8.9 (new SCR)	2.6 (add catalysts)
1	23	5.7	0.14	7.2 (new SCR)	2.0 (add catalysts)
4	83	2.5-3.5	0.60	4.8 (add catalysts)	7.1 (add catalysts)
Total for all units			**4.14**	**97.68**	**52.7**

Staff's Recommendation

Staff recommends to set a new BARCT level of 2 ppmv NOx for refinery gas turbines since NOx control technologies such as DLE/DLN, CLN, SCR with CO catalysts, SCR with ASC are commercially available and can be used together to achieve 2 ppmv NOx in a cost-effective manner. A level of 2 ppmv NOx is achieved-in-practice for a turbine/duct burner 1,7 MW cogeneration unit using SCR and ammonia slip catalysts. An 83 MW cogeneration with SCR and CO catalysts was given a permit to construct since 2012 with a permit condition of 2 ppmv NOx.

In summary:

- Incremental Emission Reductions beyond 2005 BARCT level: 4.14 tons per day
- Total Estimated Incremental Costs Range: $52.7 (NEC) - 97.68 M (Staff)
- Average Incremental Cost Effectiveness: 1,452 – 2,692 $/ton (DCF) and 2K – 4.5K $/ton (LCF)

Appendix D - Coke Calciner

Process Description

Tesoro operates the sole coke calciner in the SCAQMD. Coke calcining is a process to improve the quality and value of "green coke" produced at a delayed coker in a refinery. The green feed, produced by the nearby Carson Refinery, is screened and transported to the coke calcining facility by truck, where it is stored under cover in a coke storage barn. The screened and dried green coke is introduced into the high end of the rotary kiln, 3 ft diameter x 270 ft long, is tumbled by rotation, and moves down the kiln countercurrent to a hot stream of combustion air produced by the combustion of natural gas or oil. The kiln temperatures are in a range of 2000 – 2500 degrees Fahrenheit. The green coke is retained in the kiln for approximately one hour to drive off the moisture, impurities, and hydrocarbon. After discharging from the kiln, the calcined coke drops into a cooling chamber, where it is quenched with water, treated with dedusting agents for dust control, and carried by conveyors to storage tanks. Later, the calcined coke is transported by trucks to the Port of Long Beach for export, or is loaded into railcars for shipments to domestic customers. A simplified process diagram of the calcining process is shown in Figure D.1.

The coke calciner produces approximately 400,000 tons per year of calcined products. This plant is a global supplier of calcined coke to the aluminum industry, and they provide fuel grade coke to the fuel, cement, steel, calciner, and specialty chemicals businesses. [1]

Emission Inventory

The 2011 NOx emissions from the coke calciner and current NOx outlet concentration are listed in Table D.1. The total 2011 emissions are 0.55 tons per day. The NOx outlet concentration at 65 ppmv is higher than the 2005 BARCT level of 30 ppmv (0.036 lb/mmBtu).

Table D. 1 - 2011 Emissions for Coke Calciner

Fac ID	Device ID	Device	2011 Emissions (lbs)	Current NOx at 3% O_2 (ppmv)
2	C67	Afterburner	390,625	65
2	D20	Rotary Kiln	11,400	65
Total (tpd)			**0.55**	

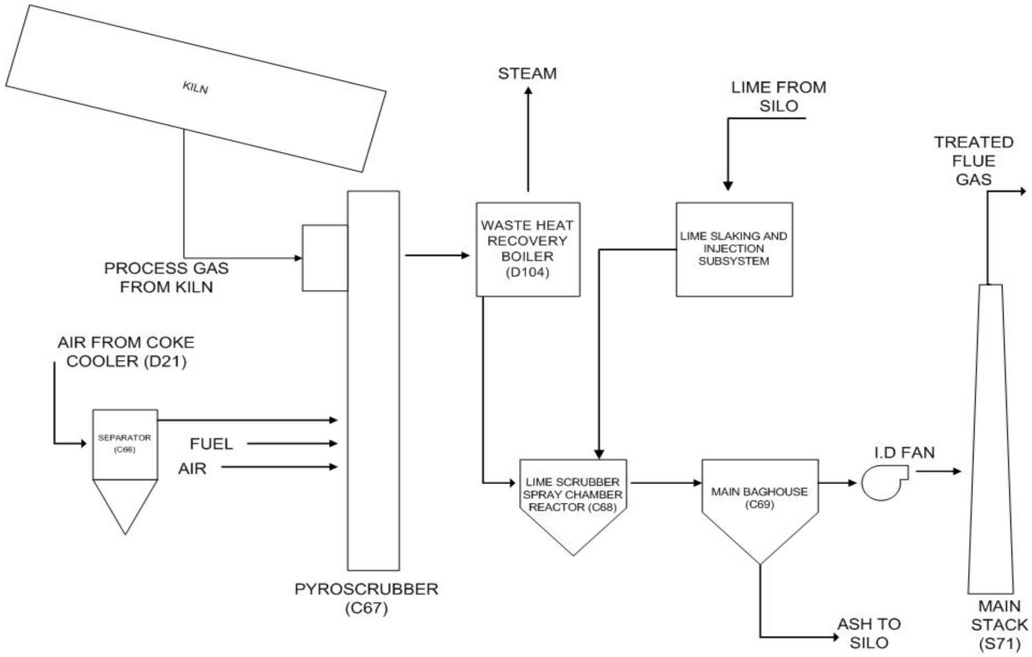

FIGURE 1: SIMPLIFIED PROCESS FLOW DIAGRAM

Figure D. 1 - Coke Calciner Process (Reference 1)

Control Technology

The commercially available control technologies for NOx emissions for the coke calciner are LoTOx and UltraCat, two commercially available multi-pollutant control technologies for low temperature removal of NOx.

LoTOx™ Application

LoTOx™ stands for "Low Temperature Oxidation" process where ozone is used to oxidize insoluble NOx compounds to soluble NOx compounds. LoTOx -is a low temperature operating system, meaning that it does not require heat input to maintain operational efficiency and enables maximum heat recovery of high temperature combustion gases. In addition, LoTOx can be used with a wet (or semi-wet) scrubber, and together the system becomes a multi-component air pollution control system that can reduce NOx, SOx and PM concurrently. There are more than 50applications engineered by Linde LLC. since 1997, and more than two dozen applications with EDV™ scrubbers engineered by BELCO Dupont since 2007. [2-3] Applications in gas-fired and high sulfur coal-fired units met 2-5 ppmv. Current installations in refineries met 8-10 ppmv. The technology can be applied to coke calciner, and the manufacturer confirmed that LoTOx can be designed to achieve 2 ppmv NOx from current inlet concentrations of the coke calciner.

The 2010 SOx RECLAIM amendments set a BARCT level of 10 ppmv SOx for the coke calciner. It was determined that wet scrubbers engineered by BELCO, Tri-Mer and MECS were all feasible and cost effective. LoTOx application can be integrated in any of these scrubbers to reduce NOx, SOx, PM and other toxic pollutants. The footprint needed for scrubbers and associated equipment was estimated to be about 30 ft x 40 ft. The facility has not yet installed any scrubber since the adoption of the SOx RECLAIM amendments in 2010.

UltraCat™ Application

UltraCat is also a multi-component air pollution control technology developed by Tri-Mer. UltraCat catalyst filters are composed of fibrous ceramic materials embedded with proprietary catalysts that can remove NOx, SO_2, PM, HCl, Dioxins, and HAPs. The optimal operating temperatures are approximately 350 to 750 degrees F. Aqueous ammonia injected upstream of the catalytic filters is used to remove NOx. NOx removal efficiency is about 95%. Dry sorbent such as hydrated lime, sodium bicarbonate or trona injected upstream of the catalytic filters is used to remove SO_2, HCl, and other acid gases with a removal efficiency of 90% - 98%. Particulate control to a level of 0.001 grains/dcsf and mercury control are also possible. UltraCat filters are arranged in a baghouse configuration with low pressure drop, about 5" water column, and it has a reverse pulse-jet cleaning action (the filters are back flushed with air and inert gas to dislodge the particulate deposited on the outside of the filter tubes). Catalytic filter tubes are replaced every 5 to 10 years. The UltraCat catalytic filtering system is depicted in Figure D.2.

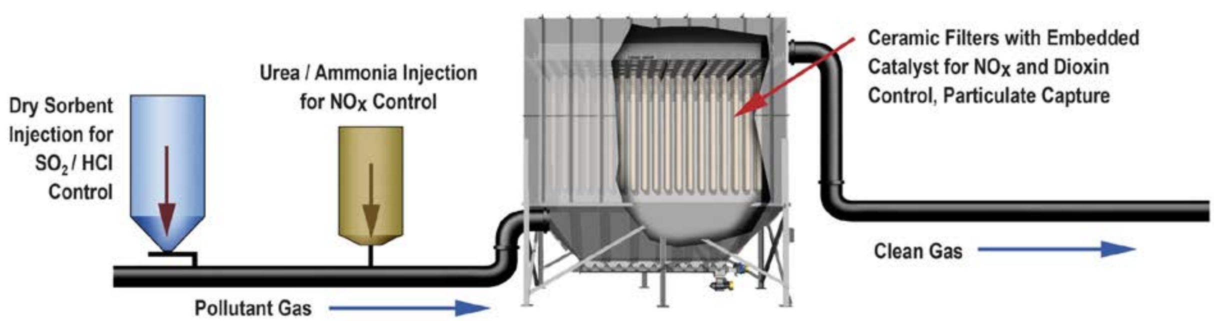

Figure D. 2 - Ultra-Cat Filters (Reference 5)[D2]

Costs and Cost Effectiveness

LoTOx™ Application

Table D.2 contains costs information provided by LoTOx manufacturer.[4] Staff estimated the PWV using the equations below for the Discounted Cash Flow (DCF) method assuming 4% interest rate and 25-years life for the control device. Staff applied a contingency factor of 1.5 to account for any additional costs that might occur. Incremental cost effectiveness was estimated as follows for the DCF method:

$$PWV = 1.5 \times (TIC + (15.62 \times AC)) \quad \text{(Equation 1)}$$
$$CE = PWV / (ER \times 365 \text{ days} \times 25 \text{ years}) \quad \text{(Equation 2)}$$

Where:

TIC = Total Installed Costs, $
AC = Annual Operating Costs, $
ER = Incremental Emission Reductions

In December 2014, the PWV and CE for LoTOx application were estimated to be $22 million and $10,347 per ton NOx reduced per DCF method as shown in Table D.3. The CE would be $17,073 per ton NOx reduced per Levelized Cash Flow (LCF) method.

UltraCat™ Application

Table D.2 contains costs information provided by UltraCat manufacturer.[6] In December 2014, staff estimated the TIC based on the OAQPS EPA Guidelines, i.e. TIC = 1.86 * Equipment Costs. Staff also applied a contingency factor of 1.5 to account for any additional costs that might occur. The PWV assuming 4% interest rate and 25-years life for the control device and the CE were estimated using Equations 1 and 2 shown above. The incremental emission reductions for Ultra-Cat system were estimated to be 0.23 tpd NOx and 0.28 tpd SOx

In December 2014, the PWV and incremental cost effectiveness for UltraCat application were estimated to be $61 million and $13,071 per ton NOx and SOx reduced estimated using DCF method as shown in Table D.3. The incremental cost effectiveness would be $13 K per ton NOx and SOx reduced estimated with the DCF method.

Table D. 2 – Costs of LoTOx and UltraCat for Coke Calciner (December 2014)

2011 NOx emissions	0.55 tons per day NOx
Current NOx concentration	64.95 ppmv NOx
2005 NOx BARCT level	30 ppmv NOx
2010 SOx BARCT level	10 ppmv SOx
2015 BARCT proposed level	2 ppmv NOx
2011 NOx emissions at 30 ppmv BARCT	0.25 tpd
2011 NOx emissions at 2 ppmv BARCT	0.02 tpd
Incremental NOx emission reductions	0.23 tpd
Flue Gas Temp	450 degrees F
Flue Gas Flow	6,806,770 dscfh (113,446 scfm)
Stack Oxygen	5%
Stack Moisture	29.8%
Coke Burned	81,471 tons per year
LoTOx Application for 2 ppmv NOx (97% control)	
Total Installed Costs	$6,250,000
Operating Costs	$544,300 per year
LoTOx Application for 5 ppmv NOx (92% control)	
Total Installed Costs	$6,200,000
Operating Costs	$516,800 per year
Ultra Cat Application for 2 ppmv NOx (97% control)	
Capital Costs of Emission Control	$7,531,774
Operating Costs – Utility, Catalysts, Labor, Maintenance	$1,721,490 per year
Filters replacement frequency	5 years at $215,600 per year

Table D. 3 - Cost and Cost Effectiveness Estimates for Coke Calciner (December 2014)

	Emission Reductions	PWV ($M)	Incremental CE ($/ton)
LoTOx	0.23 tpd NOx	22.13	10,374
UltraCat	0.23 tpd NOx + 0.28 tpd SOx	61.35	13,071

Consultant's Analysis for LoTOx and Staff's Revised Estimates for LoTOx and UltraCat

NEC suggested that a BARCT level of 2 ppmv was not feasible, and recommended 5 ppmv – 10 ppmv BARCT level for the coke calciner. NEC also suggested that a factor of 1.86 to estimate TIC and an adjustment of 1.5 were not conservative enough since space was extremely challenging at the coke calciner facility. A factor of 4.5 – 4.6 was more reasonable. Staff concurred with NEC recommendation and re-estimated the PWVs for the Ultra-Cat application as shown in Table D.4.

Table D. 4 – Revised Cost and Cost Effectiveness Estimates for Coke Calciner (March 2015)

	Staff's Estimates Using Factor of 4.5		NEC's Estimates
	BELCO	**Tri-Mer**	
BARCT Level	10 ppmv	92% control	10 ppmv
Incremental Reductions (tpd)	0.17	0.17+0.28=0.45	0.17
PWV ± 50% ($M)	54.29	91.17	39.50
Cost Effectiveness DCF ($/ton)	$35K/ton	$22K/ton	$25K/ton
Cost Effectiveness LCF ($/ton)	$58K/ton	$36K/ton	$42K/ton

Staff's Recommendation

Staff recommends setting a BARCT level of 10 ppmv NOx for coke calciners because NOx control technologies such as LoTOx and UltraCat are commercially available to achieve this level in a cost-effective manner.

2014 BARCT NOx = (0.08 tpd)(2000 lb/ton)(365 days/yr)/(81,471 ton coke/yr) = 0.8 lb/ton coke

- Total incremental emission reductions beyond 2005 BARCT: 0.17 ton per day
- Total incremental costs: $39.5 million - $91 million
- Total incremental cost effectiveness: $22 - $35 K/~~per~~ ton (DCF) or $36 - $58K/ton (LCF)

Appendix E - Sulfur Recovery Units/Tail Gas Incinerators

Process Description

A sulfur recovery unit and tail gas treatment unit (SRU/TGTU) at the refineries include a Claus unit followed by an amine absorption unit to recover the sulfur from various gaseous. The SRU (Claus unit) consists of a reactor and series of converters and condensers. Approximately 95% of sulfur from the gaseous streams is recovered after passing through the SRU. The tail gas is then sent to an amine absorption unit, or diethanol amine (DEA), SCOT, Wellman-Lord, and FLEXSORB to absorb and recover the remaining sulfur. Approximately 99% or the remaining sulfur is absorbed and recovered after the amine units. The tail gas is then vented to a thermal (or catalytic) oxidizer (incinerator) where the residual H_2S in the tail gas is oxidized to SO_2 before emitting to the atmosphere. The refinery SRU/TGTUs including their incinerators are classified as major sources of NOx and SOx.
Since the interception of the RECLAIM in 1993 until 2010, -no Best Available Retrofit Control Technology (BARCT) standards have been established for the SRU/TGTUs and incinerators. The 2010rule amendment included a new BARCT level for SOx at 5 ppmv, 0% O2. At that time, it was determined that Refineries 1, 5, and 6 could retrofit their SRU/TGTUs cost-effectively with wet gas scrubbers (WGS) to further reduce SOx emissions. The construction time was estimated to be about 3 years. [1] As of today, Refineries 1, 5 and 6 did not retrofit any of their existing SRU/TGTUs, instead they selected to purchase RECLAIM Trading Credits or reduce SOx elsewhere in the refinery to comply with their facility emission caps. In 2011, Refinery 5 installed a new SRU/TGTU at their refinery and evaluation of the performance is ongoing.

Emission Inventory

The 2011 NOx emissions from the SRU/TGTUs and incinerators in the SCAQMD and their current NOx outlet concentration are shown in Table E.1. The total 2011 emissions are 0.43 tons per day. The NOx concentrations at the stack vary widely from 6 ppmv to 70 ppmv. It should be noted that their SOx emissions also vary widely from 20 ppmv to 150 ppmv.

Table E. 1 - 2011 Emissions for SRU/TG Incinerators

Unit	Fac ID	Device ID	Device	2011 Emissions (lbs)	Existing NOx @ 3% O2
1	9	1260	INCINERATOR	7,696	66.81
2	6	952	INCINERATOR	41,066	6.57
3	5	911	INCINERATOR	28,379	29.00
4	5	913	HEATER	12,087	29.00
5	5	927	INCINERATOR	14,276	27.00
6	5	929	HEATER	6,080	29.00
7	5	955	INCINERATOR	40,313	29.83
8	5	957	HEATER	13,035	29.83

16	8	294	thermal INCINERATOR	49,563	32.00
17	8	292	catalytic INCINERATOR	1,010	not reported
			Total (tpd)	**0.43**	

Control Technology

Commercially available control technologies for NOx emissions are Selective Catalytic Reduction (SCR) and LoTOx. KnowNOx has been installed at two locations in the U.S. however has not yet been tested in any refinery applications. While SCR is considered a high temperature NOx reduction technology, LoTOx and KnowNOx are known for low temperature multi-pollutant control systems since they can be integrally connected with a WGS to reduce NOx, SOx, PM, VOCs, HAPs, and other toxic compounds.

Selective Catalytic Reduction

For the past two decades, SCR technology has been used successfully to control NOx emissions. The technology is considered mature and commercially available. The advanced SCRs can be designed to reduce 95%-98% NOx emissions from the SRU/TGTUs and incinerators and achieve 2 ppmv NOx while maintaining a low ammonia slip of less than 5 ppmv. [3-14]

LoTOx™ Application

LoTOx™ stands for "Low Temperature Oxidation" process where ozone is used to oxidize insoluble NOx compounds to soluble NOx compounds which can be subsequently removed by absorption in caustic solution, lime or limestone. Please refer to Appendix A for details. There are more than 50 LoTOx applications engineered by Linde LLC., and two dozen applications engineered by BELCO of Dupont for refinery FCCU applications.[15, 22] While BELCO's expertise is in the refinery FCCUs, its sister company MECS has engineered more than two dozen DynaWave scrubbers specifically designed for refinery SRU/TGTUs. Figure E.1 shows a schematic for a DynaWave scrubber. Figure E-2 contains a schematic for LoTOx process incorporated into the DynaWave scrubber.

Currently, LoTOx applications in the FCCU applications have achieved 8 ppmv - 10 ppmv NOx, and 2 ppmv – 5 ppmv NOx in gas-fired and high sulfur coal-fired units. [15, 22] LoTOx technology can be incorporated to the refinery SRU/TGTUs' incinerators and designed to achieve a level of 2 ppmv NOx outlet concentrations.[24]

Table E.3 has a list of the DynaWave installations in the U.S. [25] This is not an inclusive list. In addition to refinery SRU/TGTU applications, DynaWave scrubbers are used in numerous other industrial applications such as sulfuric acid plants, coke calciner, metallurgical plants, secondary aluminum or copper smelters, coal fired heaters and boilers, sulfur pits, platinum recovery plants, cement kilns, meat rendering plants, and medical waste incinerators. DynaWave scrubbers have been used in the industries since 1987.

A BARCT level for SOx was established at 5 ppmv, 0% O_2, annual average in 2010. In 2011, Refinery 5 installed a new SRU/TGTU with a DynaWave scrubber to meet a short-term BACT standard of 10 ppmv. The most recent source test data shows that the DynaWave scrubber meets <1 ppmv SOx, corrected to 0% O_2. Thus, concurrent reductions of NOx and SOx are feasible and cost-effective using a DynaWave and LoTOx combination application.

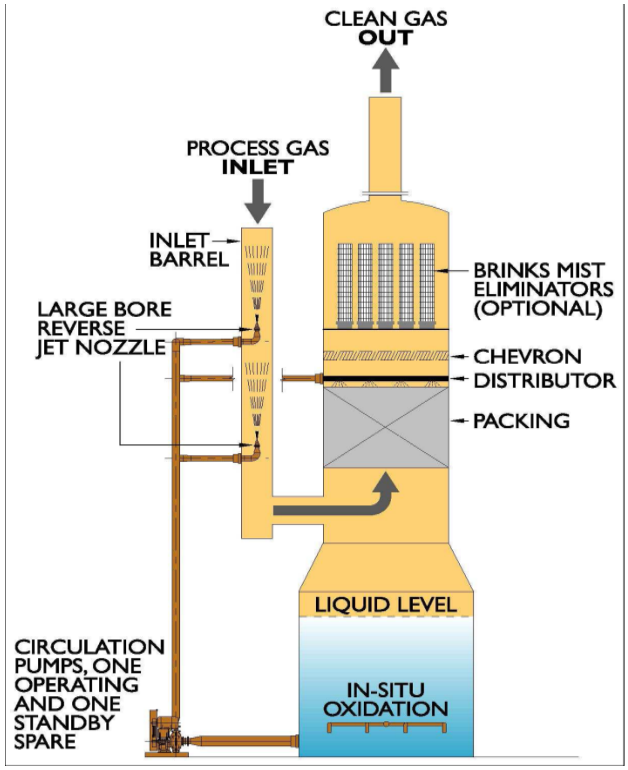

Figure E. 1 - DynaWave Scrubber (Reference 23)

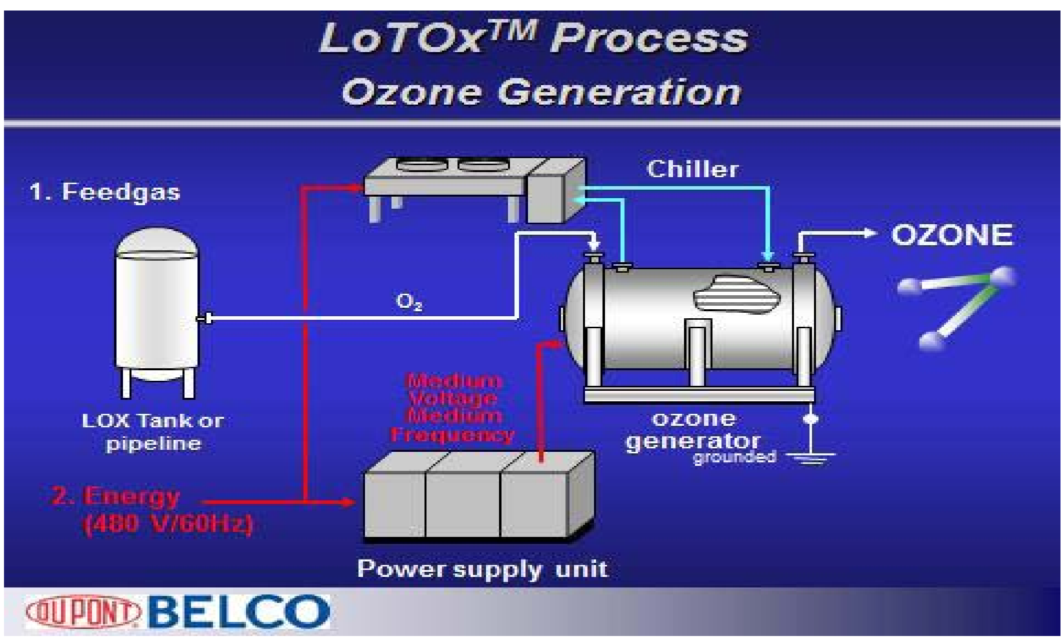

Figure E. 2 - Ozone Generation Process (Reference 23)

KnowNOx™ Application

In lieu of using ozone to convert NO and NO_2 to N_2O_5 and HNO_3, the KnowNOx technology uses chlorine dioxide ClO_2. The conversion reactions (Reactions 12 and 13) are in the gas phase, which can occur much faster than the liquid phase reactions with ozone (Reactions 5 and 6). It takes less than 0.5 seconds to achieve 99.8% or more conversion. The reactions require a smaller vessel in relative to the LoTOx reaction chamber. In addition, the KnowNOx process can simultaneously reduce NOx, SO_2, PM and other contaminants.[26-28]

$5\ NO + 2\ ClO_2 + H_2O \rightarrow 5\ NO_2 + 2\ HCl$	(Reaction 12 - Gas Phase)
$5\ NO_2 + ClO_2 + 3\ H_2O \rightarrow 5\ HNO_3 + 2\ HCl$	(Reaction 13 – Gas Phase)
$5\ SO_2 + 2\ ClO_2 + 6\ H_2O \rightarrow 5\ H_2SO_4 + 2\ HCl$	(Reaction 10)

The conceptual layout for the KnowNOx process is shown in Figure E.3. It includes a three-stages scrubbing system: SO_2 is scrubbed at the 1st stage with a DynaWave scrubber, ClO_2 injected to the 2nd stage converts NO and NO_2 to HNO_3 and other soluble salts, and H_2S generated in the 2nd stage is converted to soluble salts in the 3rd stage. The KnowNOx technology has been installed at two locations in the U.S., however, it has not yet been tested in any refinery applications, and may not yet have been proven at full scale operations.

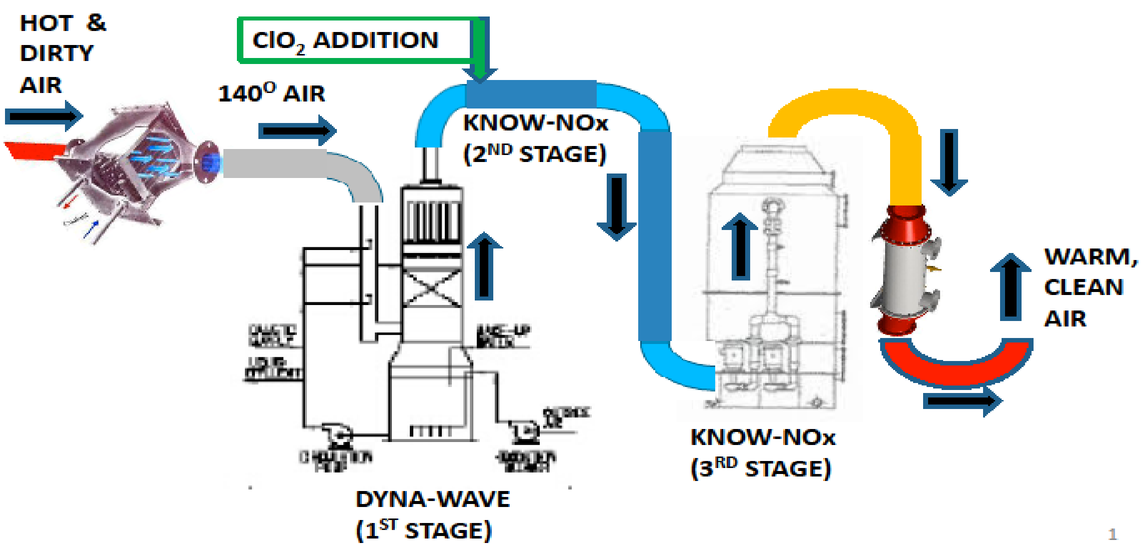

Figure E. 3 – KnowNOx Process (Reference 28)

Costs and Cost Effectiveness

Selected process conditions and the outlet NOx concentrations of the SRU/TGTUs at the refineries in the SCAQMD are listed in Table E.3. To obtain control equipment cost information, staff provided the manufacturers with the information for the three scenarios listed in Table E.4. These scenarios reflect the units with highest emissions and flue gas flow rates from the 17 SRU/TGTUs/incinerators in the SCAQMD.

Staff estimated the PWV for the control system using Equation 1 below assuming 4% interest rate and a 25-years life for the control device:

PWV = (Contingency Factor) x (TIC + (15.62 x AC) + (2.52 x CR)) (Equation 1)

Where:

PWV = Present Worth Value, $
TIC = Total Installed Costs, $
AC = Annual Operating Costs, $
CR = Catalyst Replacement every 5 years
Contingency factor = 1.5

Staff used the factors in the EPA OAQPS Guidelines to estimate the TIC and a- contingency factor of 1.5 was added to the TIC and AC to account for operational uncertainties. CE was estimated as shown in Equation 2 using the DCF method. For comparison, the incremental cost effectiveness would be about 1.65 higher if it was calculated using the LCF method:

CE = PWV / (ER x 365 days x 25 years) (Equation 2)

Where:

CE = Incremental Cost Effectiveness, $/ton
PWV = Present Worth Value, $
ER = Incremental Emission Reductions, tpd

Costs for SCRs

Manufacture A's estimates are summarized below: [13]

- It is feasible to achieve 2 ppmv NOx and 5 ppmv ammonia slip,
- All three scenarios would result in about the same costs,
- Costs for SCR catalysts would be about $600,000 and installation costs about $600,000,
- Add costs for heat exchangers in Scenario 1 and 2, and
- Inlet NOx could be higher but would not affect the overall cost estimates.

Table E. 3 - Process Information and NOx Emissions for SRU/TG Incinerators in SCAQMD

Unit	Fac ID	Device ID	Device	Max Rating (mmbtu/hr)	Flue Gas Flow rate (dscfm)	Flue Gas Temp (degree F)	Existing NOx (ppmv)
1	9	1260	INCINERATOR	36			66.81
2	6	952	INCINERATOR	100	34,640	1,080	6.57
3	5	911	INCINERATOR	30	12,500	515	29.00

17	8	292	catalytic INCINERATOR	15			

Table E. 4 – NOx and SOx Performance of SRU/TG Applications in SCAQMD

	Scenario 1 Refinery 6	Scenario 2 Refinery 1	Scenario 3 Refinery 5
Incinerator Rating	100 mmBtu/hr	45 mmBtu/hr	100 mmBtu/hr (note)
Average flue gas flow rate	36,000 dscfm	32,000 dscfm	14,500 dscfm
Temperature	1,100 degrees F	1,200 degrees F	520 degrees F
O2 %	2.5%	6% - 8%	4%
Current NOx concentration	21 ppmv	28 ppmv	30 ppmv
Current SOx concentration	40 ppmv	75 ppmv	20 ppmv

Note: Incinerator 58 mmBtu/hr and heater 41 mmBtu/hr are vented to a common stack

Manufacturer B's estimates are summarized below: [14]

- It is feasible to achieve 2 ppmv NOx and 5 ppmv ammonia slip,
- SCR costs for Scenario 1 and 2 were estimated to be about $461,000 for SCR at 80% NOx control efficiency. SCR costs for Scenario 3 would be about 10% less than Scenario 1 and 2.
- Costs for a system at 90% control efficiency would be about 5% higher than the costs for a system at 80% control efficiency.
- Costs for a system with 95% control efficiency would be about 10% higher than the costs for a system at 80% control efficiency.
- Estimated costs would not vary with inlet NOx concentration
- SCR footprint and dimension:
    - Catalysts with 1 layer and 1 module for a system with 85% control efficiency. Add 3 in of catalysts for a 95% control efficiency system
    - Add 2 ft in each direction for structural steel, and 6" for insulation
    - SCR overall dimension: 15 ft x 15ft x 15 ft
- Heat exchanger would be required for Scenarios 1 and 2 to lower the temperatures to the optimum temperatures of about 750 degrees F
    - Heat exchanger would cost about $100,000
    - Dimension for a horizontal flow heat exchanger: 6 ft Dia x 6ft - 10 ft L.
- Ammonia usage (19% aqueous ammonia):
    - 11.1 lb/hr for 80% removal, 12.1 lb/hr for 90% control, 12.6 lb/hr for 95% control
    - About $82,000 per year NH_3 costs and $40,000 miscellaneous for a 95% control
    - Dimension of 2000-gallons NH_3 storage tank: 4 ft D x 24 ft L, or 6 ft D x 10 ft L.
    - Ammonia storage tank costs $15,000 (30 days supply)
- Catalyst replacement would be every 5 years. Replacement frequency would depend on actual flue gas constituents and could be guaranteed for a turnaround cycle.

Costs for LoTOx™ Applications

MECS's cost estimates for LoTOx system to reduce NOx emissions are shown in Table E.5. MECS also provided costs for DynaWave and LoTOx in one system to reduce both NOx and SOx emissions as shown in Table E.5. [24]

Table E. 5 – Cost Information Provided by MECS

	Scenario 1		Scenario 2		Scenario 3	
	LoTOx	Dynawave LoTOx	LoTOx	Dynawave LoTOx	LoTOx	Dynawave LoTOx
Inlet Temp, degrees F	1,100	1,100	1,200	1,200	520	520
Inlet Flow, scfm	38,710	38,710	34,409	34,409	15,761	15,761
Outlet Temp, degrees F	158	158	161	161	139	139
Outlet Flow, scfm	52,782	52,782	48,329	48,329	18,021	18,021
Total Installed Costs, $	5,666,000	8,432,000	5,605.000	8,311,000	4,903,237	6,907,000
Operating Costs, $/yr	89,356	260,600	98,713	276,110	47,000	73,650

Costs for KnowNOx™ Applications

Costs provided by KnowNOx for its system to reduce only NOx emissions are shown in Table E.6. KnowNOx also provided costs for DynaWave scrubber in combination with its technology to reduce both NOx and SOx emissions.[29]

Table E. 6 – Cost Information Provided by KnowNOx

	Scenario 1		Scenario 2		Scenario 3	
	KnowNOx	Dynawave KnowNOx	KnowNOx	Dynawave KnowNOx	KnowNOx	Dynawave KnowNOx
Inlet Flow, scfm	36,000	36,000	32,000	32,000	14,500	14,500
Total Installed Costs, $	1,420,225	4,220,226	1,398,286	4,198,286	1,401,825	3,402,226
Operating Costs, $/yr	108,284	289,936	112,957	295,948	198,729	227,337

In 2014, staff estimated that SCRs, LoTOx and KnowNOx would be cost-effective for 10 SRU/TGTUs (out of 17 units) at Refineries 1, 5, 6 and 8. The PWVs for SCRs, LoTOx and KnowNOx were estimated to be $48.7 M, $68 M and $39 M respectively. The cost effectiveness for the 7 SCRs was estimated to be $15 K per ton NOx reduced (DCF) and $25 K per ton NOx reduced (LCF) as shown in Table E.7.

Consultant's Analysis for SCRs and Staff's Revised Estimates for SCRs and LoTOx

NEC confirmed that the 2 ppmv proposed BARCT level is feasible for the refinery SRU/TG incinerators. However, the consultants indicated that the factor of 1.86 from the EPA OAQPS Guidelines was low and suggested staff used a factor of 4.5. NEC also recommended using SCRs with 3 layers of catalysts and added the costs of waste heat boilers, new ammonia tanks and associated equipment. A comparison of NEC's and staff's estimates is shown in Table E.7.

Table E. 7 - Comparison of SCR Costs Estimated by Staff and NEC for SRU/TGTUs (December 2014)

	Staff's Estimates for SCRs	NEC's Estimates for SCRs
PWVs for SCRs	$ 48.7 M	$ 96.4 M
Cost Effective Units	10	9
Emission Reductions	0.35 tpd	0.32 tpd
Cost Effectiveness (DCF)	15,233 $/ton	33,014 $/ton

Staff revised the cost estimates using the factor of 4.5 recommended by NEC. The revised estimates are shown in Table E.8. Per these revised estimates, there would be 9 cost effective SRU/TG units with a total incremental emission reductions of 0.32 tpd at PWVs of $82.5 M for SCRs or $105.8 M for LoTOx applications.

Table E. 8 - Revised Cost and Cost Effectiveness Estimates for SCRs and LoTOx for SRU/TGTUs (March 2015)

Fac ID	Dev	SCR			LoTOx		
		AQMD ($M)	**Reductions (tpd)**	**AQMD CE ($/ton)**	**AQMD ($M)**	**Reductions (tpd)**	**AQMD CE ($/ton)**
6	D952	16.2	0.05	33,298	22.7	0.05	46,458
5	911/913	11.3	0.05	23,491	18.9	0.05	39,321
5	927/929	11.3	0.03	46,697	18.9	0.03	78,167*
5	955/957	11.3	0.07	17,818	18.9	0.07	29,826
1	910	17.3	0.06	34,379	22.7	0.06	45,127
1	*2413*	*16.9*	*0.03*	*63,593***	*22.7*	*0.03*	*85,404***
8	294	15.2	0.06	25,805	22.7	0.06	38,490
Total for cost-effective units		**82.5**	**0.32**	**28,270**	**105.8**	**0.29**	**39,963**

*this unit was cost effective using SCR technology thus was included in the revised analysis. ** this unit was not cost effective using either SCR or LoTOx thus was not included in the revised cost analysis.

Staff's Recommendation

Staff recommends to set a new BARCT level of 2 ppmv NOx for SRU/TG incinerators (95% control efficiency) because NOx control technologies such as SCR and LoTOx (or KnowNOx) with DynaWave scrubbers are commercially available and can de designed to achieve 2 ppmv NOx in a cost-effective manner.

In summary:

- Incremental Emission Reductions beyond 2005 BARCT level: 0.32 tons per day
- Number of cost effective units: 9
- Total Incremental Costs: $83 M ± 50% with SCRs - $106 M ±50% with LoTOx
- Average Incremental Cost Effectiveness (DCF method):
  - $28K per ton NOx reduced with SCRs
  - $40K per ton NOx reduced with LoTOx applications
- Average Incremental Cost Effectiveness (LCF method):
  - $46K per ton NOx reduced with SCRs
  - $66K per ton NOx reduced with LoTOx applications.

Appendix F - Comparative Analyses for FCCUs

This appendix provides a comparison of the selective catalytic reduction (SCR) design configuration, total installed cost (TIC) calculation and present worth value (PWV) estimation methodologies used in the staff and NEC cost effectiveness calculation for the FCCUs. Table F.1 summarizes the basic comparison. Variations in the SCR size, cost assumptions, TIC and PWV estimation methodology are provide in a side by side comparison for evaluation.

Table F.1 - Comparison of Staff and NEC Control Equipment Designs, TIC and PWV Estimation Methods

	Staff's Design	**NEC's Design**
SCR Configuration	2-Catalyst layers 3-Beds: 1-reserve	3-Catalyst layers 3-Beds: all used
Cost Models	SCR costs directly provided by Refinery 1 (2 catalyst layers) and the manufacturers (2-catalyst layers) SCR cost for Refinery 5, 6 and 7 scaled to Refinery-1 based on flow rate. SCR cost for Refinery 4 and 9 provided directly by the manufacturers.E	SCR cost provided by vendor (2 catalyst layers 12.8 feet per second). SCR vendor based costs curve (scaled for 3-layers, 10 feet per second) With NEC modifications and refinery input including: • 1.35 bid conditioning factor, • 1.75 labor factor, and • 4.5 TIC factor
Additional Costs		Waste Heat Boiler Modifications, New CEMS, NH3 Storage
Refinery Cost Application		
Refinery-1	Refinery -1 data	N/A
Refinery-4 & 9	EPA Methodology with 1.5 contingency for PWV. NEC additional costs assumed in the contingency factor.	Cost Curve
Refinery-5	Scaled to Refinery-1	Cost Curve
Refinery-6	Scaled to Refinery-1	Cost Curve
Refinery-7	Scaled to Refinery-1	Cost Curve
All Refineries	SCR cost provided by manufacturer (2 catalyst layers) with NEC additional costs included.	

Summary of Staff's Approach

Staff presented two approaches to estimate the SCR PWV for the 6 FCCUs operating in the Basin. (Note: two FCCUs are not controlled using SCRs). The first approach estimated PWV using data directly obtained from Refinery1 to establish PWV, while 3 additional SCR PWV were scaled from the Refinery 1 estimate. Two additional SCR PWV profiles were estimated using manufacturer provided cost information and the EPA cost model with a 150 percent contingency.

The second approach used the NEC model for the manufacturer's SCR designed for 2-catalyst layers. The two methods provided a range of PWV and CE as reported in Appendix A.

Approach #1

- Refinery 1 submitted capital costs and annual operating costs for their FCCU SCR in 2013. The FCCU SCR was installed in 2003 with 2 layers of catalysts and 1 spare layer and achieved 2 ppmv NOx.

- Using the cost information submitted directly by Refinery 1 to estimate the PWV would result in $41 M. Using the NEC equation (derived for a 3-catalyst layer SCR from data provided by a manufacturer) the PWV would result in $52 M. The PWV estimated based on NEC's approach and equation would be about 26% higher than that estimated using the actual costs submitted by Refinery 1.

- Staff scaled the Refinery 1 SCR PWV cost using the of Refinery 1 SCR and the ratios of their appropriate inlet flue gas flow rates to the 0.7 power to project PWV for Refineries 5, 6, and 7.

- PWV for Refineries 4 and 9 was estimated using SCR manufacturer cost data and the U.S. EPA Guideline approach with a 150 percent contingency markup.

Approach #2

Staff used the NEC approach to develop a cost curve based on the SCR manufacturer's design of 2-catalyst layers.

The NEC cost assumptions included:

- 1.35 for a bid conditioning factor
- 1.75 adjustment for labor
- 4.5 factor to relate the equipment costs to a TIC
- Staff added the NEC estimated costs of a waste heat boiler, new CEMS, and costs of ammonia storage tank.

PWV estimated for 2-catalyst layers vs. 3-catalyst layers

A comparison of the PWV estimates calculated for Refinery 9 using the manufacturer 2-layer SCR model (with and without selected cost markups) and the NEC 3-layer SCR model and the EPA methodology is presented in Table F.2.

Table F. 2 - Comparison of Cost Estimates for FCCU's SCR

	NEC's Design	Manufacturer's Design (note)				EPA Methodology
Layers of catalysts	3	2	2	2	2	with 50%
1.35 Markup	Yes	Yes	No	Yes	No	Contingency
1.75 Markup	Yes	Yes	Yes	No	No	
Total Installed Costs , $M	**31.6**	**26.4**	**21.5**	**18.3**	**15.5**	**16.13**
PWV, $M	**39**	**32**	**27**	**24**	**21**	**19**

Note: The TIC include the costs of SCR provided by vendor to NEC ($1.78 M) for a FCCU with a feed rate of 60 thousand barrels, the costs of waste heat boiler ($4.5 M) estimated by NEC, the costs of CEMS ($1.5 M) estimated by NEC, the costs of ammonia storage tank ($1.5 M) estimated by NEC, and annual operating costs estimated by NEC.

The PWV for the manufacturer's design with no markup ($21 M) was only 10% more than staff's estimates using the EPA methodology. With equivalent markup factors applied, the manufacturer's 2-layer model was approximately 22 percent lower in cost than the 3-layer model. This compares well with the 26 percent PWV adjustment between the NEC 3-catalyst layer model and staff's estimate for the 2-layer SCR noted for Refinery 1 in Approach #1. Also, for the EPA methodology, staff used a 50% contingency factor to account for the uncertainty in the complex refinery environment compared to the EPA OAQPS Guidelines recommended a level of 30%.

The cost curve described in Approach #2 was used estimate the PWV of the SCR system with two NEC markup factors for an SCR provided by vendor with 2 layers of catalysts, a new waste heat boiler, a new CEMS, and a new ammonia storage tank. The curve was applied to the boiler FCCU feed rates to estimate the PWVs of five SCRs at the refineries are listed in Table F.3.

Table F. 3 - Comparison of Cost Estimates for SCRs with and without Markups

	Feed Rate (10^3Barrels per Day)	AQMD's Estimates PWV ($M)	Manufacturer's costs with 2 layers of catalysts and 2 levels of markups PWV = 2.8013*(Feed Rate)$^{0.6}$ ($M)
Ref 5	71	33	36
Ref 6	90	57	42
Ref 7	55	27	31
Ref 4	34	16	23
Ref 9	55	19	31
Total		**152**	**163**

Summary of NEC's Approach

NEC based their estimation of PWV on a manufacturer's detailed cost profile for a 3-bed SCR for Refinery 9 where 2 layers were designated for catalyst loading. NEC's preferred engineering design required 3 catalyst layers (4-bed design with on bed in reserve) to meet the 2 ppmv emissions level. As such, the manufacturers design was scaled upward based on additional catalyst volume and associated costs as well as adjustments to the space velocity. The revised design was then subjected to the same cost assumptions stated in staff approach #2. PWV was estimated for the several feed rates to establish a distribution that was the basis for a power law cost curve. (See Addendum-1 to the staff report for NEC's analysis).

During the review of the NEC report, it was noted that the initial feed rates used by NEC in estimating PWV were not consistent with reported levels (Table F.4).

Table F. 4 - Refinery Feed Rates of FCCUs in SCAQMD

Refinery No.	**4**	**7**	**9**	**5**	**6**
Back-calculated feed rates used by NEC, 10^3 Barrels/Day	58	68	60	79	79
Feed rates reported in SOx RECLAIM, 10^3 Barrels/Day	30	55	55	71	90
Feed rates shown in the Jan 22 14 Working Group Meeting, 10^3 Barrels/Day	34	49	52	67	84

- The NEC 3-layer SCR model PWV estimates were recalculated using the reported feed rates and the revised PWVs were reduced by 26% to reflect the difference between the NEC cost curve estimate for Refinery 1 and the PWV determined by staff in Approach #1 above using the reported data.

- A comparison of the revised NEC cumulative PWVs adjusted by the 26 percent factor (2 vs. 3 catalyst layers for Refinery-1) with the staff approach #1 methodology were in good agreement (Table F.5).

Table F.5 – Estimates of Costs Adjusted to Refinery Feed Rates and Using the Refinery 1 26 Percent PWV Adjustment

	Feed Rate (10^3 Barrels/D)	Staff's Estimates ($M)	Revised NEC Estimates ($M)	Ratio Revised NEC/Staff's Estimates

Ref 6	90	57	40	0.70
Ref 7	55	27	29	1.07
Ref 4	34	16	22	1.38
Ref 9	55	19	29	1.53
Total		**152**	**154**	**1.01**

Summary of the Analysis

Staff based its cost estimates on the application of a 2-catalyst layer SCR design for each of the refineries. The analysis focused on Refinery 1 which had achieved in practice an emissions level of 2 ppmv with the 2-catalyst layer design.

NEC recommended a more conservative 3-catalyst layer design based upon their experience with refinery controls installations.

Both designs have nearly equivalent estimated PWV when the 3-to-2 catalyst layer assumption is normalized.

The costs estimated by staff provide a CE range between $18K and $20 K per ton of NOx reduced. Using the NEC 3-Layer approach, the upper value of -CE would be- $29K.

Appendix G - Comparative Analyses for Boilers & Heaters

This appendix provides a comparison of the control equipment design configuration, total installed cost (TIC) calculation and present worth Value (PWV) estimation used in the staff and NEC estimations for the boiler and heater cost effectiveness calculation. Table G.1 summarizes the basic comparison. Variations in the selective catalytic reduction (SCR) size, cost assumptions and TIC and PWV estimation methodology are provided in a side by side comparison for evaluation. As previously stated in Appendix B, the NEC design to reach 2 ppmv relies on the use of 3 layers of catalyst and 1 additional layer for an Ammonia Slip Catalyst (ASC) bed. Staff's estimate is based on existing SCR applications achieved-in-practice and alternate control methodologies identified in the analysis.

Table G.1 - Comparison of Staff and NEC Control Equipment Designs, TIC and PWV Estimation Methods

	Staff's Design	NEC's Design
SCR Configuration	1-Catalyst layers	3-Catalyst layers 1-ammonia bed 4-Beds: all used
Alternate Configurations	Great Southern Flameless Heaters ClearSign Duplex burners	
Cost Models	Refinery survey data, refinery consultant's data, cost estimates from SCR manufactures, Great Southern and ClearSIgn were used to construct maximum PWV of SCRs for 5 ppmv NOx for 5 ranges of boiler/heater firing rates.	SCR Vendor Based application (scaled for 4-layers) with NEC modifications and refinery input. Additional cost for induced draft fan
	CPWV of SCRs for 2 ppmv NOx = 1.1 * PWV of SCRs for 2 ppmv emissions limit for 5 ranges of boiler/heater firing rates	Individual PWV Costs curves for 5 ppmv and 2 ppmv emissions limits based on maximum firing rate
Refinery Application	83/212 Units ≤ $50,000/Ton	46/212 Units ≤ $50,000/Ton

Summary of Staff's Approach

- Cost data for all feasible control technologies including SCRs, LoTOx, Great Southern flameless heaters, and ClearSign duplex burners was analyzed.

- Three sets of cost data were used to construct the cost curve in Figure G.1:

    - Group 1 data set: Survey cost data provided directly by the refineries for SCRs that achieved 1.6 – 3.5 ppmv NOx was used. The refineries provided actual equipment costs, total installed costs (TIC) and annual operating costs. The actual costs were increased to 2014 dollars. From this set of actual costs: TIC = 3.87 x equipment costs, and PWV = 1.052 x TIC = 4.07 x equipment costs.

- Group 2 data set: Cost data estimated by the consultants for a refinery for future SCR projects was used. The consultants of the refinery applied a factor of 4.0 to estimate TICs for future projects (i.e. TIC = 4.0 x equipment costs), and staff estimated the PWVs consistently with the actual cost data in Group 1, PWV = 1.052 x TIC.

- Group 3 data set: Equipment costs provided by control equipment manufacturers for SCRs, Great Southern Flameless heaters, and ClearSign Duplex burners were used. TICs were estimated using a factor of 4.0, and PWVs were estimated using a factor derived from the Group 1 data set.

- Staff selected the upperbound PWVs shown in Figure G.1 for the costs of control devices that can achieve 5 ppmv NOx. Staff added another 10% to the upperbound costs in Figure 1 to derive the costs for control devices that can meet 2 ppmv NOx:

$5.5 M for units with maximum rating ≤ 100 mmBtu/hr
$11 M for units with maximum rating > 100 – 200 mmBtu/hr
$22 M for units with maximum rating > 200 – 400 mmBtu/hr
$33 M for units with maximum rating > 400 – 600 mmBtu/hr
$49.5 M for units with maximum rating > 600 mmBtu/hr

The upperbound PWVs derived were higher than all of the actual costs from the Group 1, 2 and 3 data sets. For example, the actual reported costs for a 650 mmBtu/hr heater was about $42 M and the upperbound PWV that staff derived based on this approach was $49.5 M.

Summary of NEC's Approach

NEC concurred that the 2 ppmv BARCT level is feasible for refinery boilers/heaters >40 mmBtu/hr. However, NEC stated their recommendation required using SCRs with 4 layers of catalysts [3-layers plus 1-layer of ammonia slip catalyst (ASC)].

- NEC used the approach described in Appendix F whereby a manufacturers design and quote for a 2-catalyst layer SCR (with 1-additional bed) was structured to accommodate a 4-layer SCR with 3-catalyst layers and an ammonium slip catalyst layer. Their estimate also included costs for a new CEMS, ammonia system and induced draft fan installation.

- NEC adjusted the manufacturer's design to 10 ft/sec velocity, increased the cross section area, added a 3rd and a 4th layer of catalysts, increased the SCR dimension to 20 feet width x 19.2 feet length x 44 feet height, and increased the equipment costs to $2.48 M.

NEC estimated annual costs for ammonia usage, utility, catalyst replacement, and miscellaneous maintenance and developed 2 sets of PWV cost curves based on applying the NEC SCR model to a range of firing rates.

The PWVs were estimated by NEC as follows:

PWV = 3.1354 x (Maximum rating of boiler or heater) $^{0.3947}$ for 5 ppmv SCRs
PWV = 3.4838 x (Maximum rating of boiler or heater) $^{0.3947}$ for 2 ppmv SCRs.

NEC provided two curves for 2 ppmv SCR and 5 ppmv SCR that staff could use to estimate the incremental costs for boilers/heaters >110 mmBtu/hr. Figure B.3 is revised below (Figure G.1) to include the NEC cost curves. The difference in the cost curve PWV project is most pronounced for the smaller units with maximum firing rates 200 mmBtu or less. As the firing rate increases beyond 500 mmBtu, the curves begin to converge.

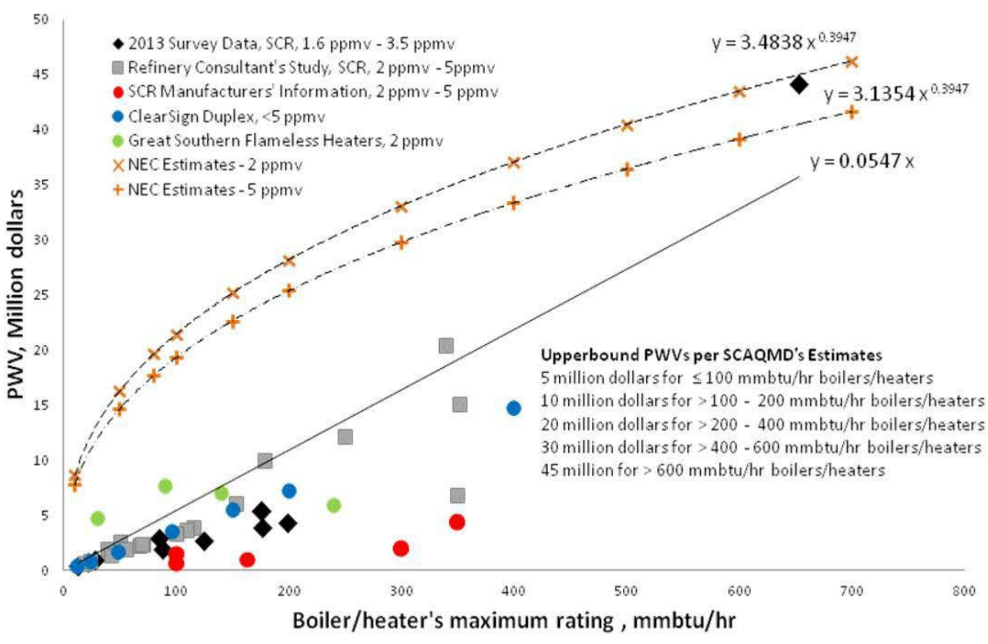

Figure G. 1 - Present Worth Values for SCRs (December 2014)

Summary and Discussion

The two methodologies employed to develop the PWVs for SCRs- are inherently different. The resulting number of units determined to be cost effective at 2 ppmv NOx at an under $50,000 per ton threshold varied from 48 using the NEC method to 103 units using the staff method. Using the NEC method resulted in 0.33 TPD less NOx reductions. As is noted in the following discussion, SCRs have achieved-in-practice 2 ppmv NOx in the Basin using the 1-catalyst layer SCR model. As a consequence of the uncertainty in PWV between the use of the two cost methodologies and CE estimation, staff is proposing to reduce the overall RECLAIM RTC reductions by the 0.33 TPD as a component of the overall adjustment from 14.8 to the 14.0 TPD proposal.

~~There are several heaters in the SCAQMD that have SCRs built to achieve 5 pppmv NOx, and these SCRs actually achieved 1.6 ppmv – 2.7 ppmv as reported by the refineries. All of these SCRs have 1 layer of catalysts. The catalyst depth is about 2 – 3 feet, and the catalyst volumes range from 62 – 623 cubic feet as shown in Table G-2. By comparison, the Refinery 1 FCCU SCR has 2 layers of catalyst with a total catalyst depth of 9 feet. The dimensions of the Refinery 1 FCCU SCR listed in Table G.2 are compared to the dimensions of the existing SCRs for refinery heaters. Refinery heater SCRs are more compact with smaller volumes of catalysts compared to FCCU SCRs. In contrast, Refinery 1 FCCU's feed rate is about 95,000 barrels per day (B/D) yet Refinery 1 FCCU SCR achieved less than 2 ppmv NOx using only 2-catalyst layers.~~

Table G. 1 – Performance Levels and Dimensions of Existing SCRs for Heaters in SCAQMD Compared to Existing SCR for an FCCU

	Ref 9 3 hydro treating heaters	Ref 5 isomax heater	Ref 5 crude heater	Ref 9 crude heater	Ref 5 3 coker heaters	Ref 5 4 ref-ormers	Ref 1 FCCU
Maximum rating, mmbtu/hr	63	78	83	85	528	589	95,000 B/D
NOx, survey, ppmv	**2.7**	**2.3**	**2.7**	**3.3**	**2.7**	**1.6**	**< 2ppmv**

SCR, Length, ft	6	7	6	7	18	16	29
SCR, Height, ft	4	6	3	12	20	3	49
Total SCR volume, ft3	110	798	note 1	1,380	6,300	note 1, 2	41,748
Existing catalyst volume, ft3	92	92	62	96	623	537	**6,210**
No of catalyst layers	1	1	1	1	1	1	**2 (1 spare)**
Catalyst depth, ft	3	2	3	2	2	3	**4.5**

Note:

1) The SCR height stated in the permit is likely for the catalsyts and not for the overall SCR .

2) District recently approved a change of catalysts for this SCR. New catalyst volume is 424 ft3, guarantee of <=5 ppmv NOx

Appendix H - Comparative Analyses for SRU/TGUs

This appendix provides a comparison of the proposed control equipment design configuration, total installed cost (TIC) calculation and present worth Value (PWV) estimation used in the staff and NEC estimations for the SRU/TGTU cost effectiveness calculation. Table H.1 summarizes the basic comparison. Staff evaluated selective catalytic reduction (SCR), LoTOx, and Know-NOx technologies while NEC expressed concerns on the effectiveness and applicability of technologies other than SCR. Where comparable, variations in the SCR size, cost assumptions and TIC and PWV estimation methodology are provide in a side by side comparison for evaluation.

Table H-1 - Comparison of Staff and NEC Control Equipment Designs, TIC and PWV Estimation Methods

	Staff's Design	NEC's Design
SCR Configuration	1-Catalyst layer 2	3-Catalyst layers 3-Beds: all used
Alternate Configurations	LoTOx ozone injection coupled with either a Belco EDV or DynaWave scrubber Know-NOx ClO2 injection coupled with a DynaWave scrubber	N/A N/A
Additional Equipment	Heat Exchanger	Waste heat boiler (heat exchanger)
Cost Models	Cost estimates: SCR manufacturers LoTOx and Know-NOx PWV estimated using EPA format (1.86 TIC) with 1.5 contingency factor Costs revised to reflect NEC PWV 4.5 factor	SCR Vendor Based application (scaled for 3-layers) with NEC modifications and refinery input.
Refinery Application	9 Units ≤ $50,000/Ton	9 Units ≤ $50,000/Ton

Summary of Staff's Approach

- Cost data for all feasible control technologies including SCR, LoTOx, and KnowNOx were analyzed. SCR and LoTOx are used in refinery applications such as boilers, heaters, and FCCU while KnowNOx currently does not yet have any refinery application.

- Process information for three representative scenarios was sent to 2 SCR manufacturers, MECS (LoTOx), and KnowNOx. Cost data provided by the manufacturers using the EPA

OAQPS Guideline methodology were used to estimate the TIC. This approach was used in the 2005 RECLAIM rule amendment.

Instrumental = 10% x Equipment costs
Sales Tax = 9% x Equipment costs
Freight = 5% x Equipment costs
Total Equipment Costs = 1.24 x Equipment costs
Installation = 50% x Total Equipment Costs
Total Installation Costs = (1.5) x Total Equipment Costs = 1.5 x 1.24 x Equipment Costs = 1.86 x Equipment Costs

- The SCR manufacturers also provided other pertinent information such as the SCR overall dimension and the number of catalyst layers needed to achieve 2 ppmv for a SRU/TG incinerator application.

- A contingency factor of 1.5 was used to cover any uncertainty in the estimated costs.

Summary of NEC's Approach

As previously described in Appendix F, NEC based their estimation of PWV on a manufacturer's detailed cost profile for a 3-bed SCR where 2 layers were designated for catalyst loading. NEC's preferred engineering design required 3 catalyst layers (4-bed design with one bed in reserve) to meet the 2 ppmv emissions level. As such, the ~~manufacturr's~~manufacturer's design was scaled upward based on additional catalyst volume and associated costs as well as adjustments to the space velocity. The revised design was then subjected to the cost assumptions stated in staff approach #2. PWV was estimated for the several feed rates to establish a distribution that was the basis for a power law cost curve. (See Addendum-1 to the staff report for NEC's analysis).

Summary

The staff and NEC approach to estimate the control costs differ. Addendum-1 of the Staff Report provides NEC's non-confidential "SCAQMD NOx RECLAIM – BARCT Feasibility and Analysis Review". A major difference between the two assessments revolves around the selection of control equipment analyzed. The SCAQMD analysis included multiple control technologies while NEC analysis relied solely on SCR implementation where design options and costs were prorated for the SRU/TG applications. Additionally, costs associated with CEMS, ammonia storage tanks and heat exchangers account for differences between the initial staff and NEC cost estimates. Note that the different approaches do not have an impact on the list of equipment that meet the $50,000 per ton cost effectiveness threshold for inclusion in the calculation of potential BARCT emission reductions from SRU/TGUs.

A second major difference between the two assessments occurs in the costing methodology to estimate TIC and PWV. Staff's use of the EPA methodology with a 1.5 contingency factor markup to estimate PWV is lower than the combined bid conditioning, labor adjustment and 4.5 installation mark-up used by NEC. (It is important to note that separate discussions with refiners and their consultants indicated that a mark-up factor of 4.0 or greater may be more representative).

As stated in Appendix E, in their final assessment, staff revised its cost estimate to reflect the higher TIC to PWV cost factor proposed by NEC which resulted in closing the gap between the two analyses.

Appendix I - Comparative Analyses for Coke Calciners

This appendix provides a comparison of the NOx emissions control design configuration, total installed cost (TIC) calculation and present worth Value (PWV) estimation used in the staff and NEC estimations for the Coke Calciner cost effectiveness calculation. Table I.1 summarizes the basic comparison. Variations in the equipment design, cost assumptions and TIC and PWV estimation methodology are provided in a side by side comparison for evaluation.

Table I.1 Comparison of Staff and NEC Control Equipment Designs, TIC and PWV Estimation Methods

	Staff's Design	NEC's Design
Proposed Control	LoTOx or UltraCat	LoTOx with modifications: taller or larger diameter scrubber, two vessels to enhance dry time, additional ozone usage and multiple ozone injection points
Target Emissions Limit	2 ppmv	5- 10 ppmv
Cost Basis	LoTOx TIC and UltraCat equipment costs provided by manufacturers	LoTOx equipment costs provided by manufacturers
	LoTOX PWV calculated by multiplying a 1.5 contingency factor to TIC and annual operating costs. UltraCat TIC estimated using the U.S. EPA 1.86 factor. PWA calculated by multiplying a 1.5 contingency factor to TIC and annual operating costs	TIC estimated as 1.35 factor applied to equipment cost to account for NEC proposed modifications. PWV calculated by multiplying a 3.44 contingency factor to TIC and annual operating costs

Summary of Staff's Approach

In order to collect cost data for all feasible control technologies, including LoTOx and UltraCat systems, staff sent the process information to the manufacturers, and the manufacturers provided equipment costs, annual operating costs, and foot print of the control devices. Staff used the approach in the EPA OAQPS Guidelines to estimate the Total Installed Costs (TIC = 1.86 x Equipment Costs.) This approach was used in the staff report of the 2005 RECLAIM rule amendment. Costs were increased by 50% to cover any uncertainty in the estimated TIC and annual operating costs.

Summary of NEC's Approach

NEC proposed 5 to 10 ppmv for BARCT. NEC used the costs provided to staff, and applied a factor of 4.67 to cover uncertainty in process development and installation costs. As a result, TIC = 4.67 x Equipment costs. Ultra-Cat was not considered a solution for the coke calciner.

Summary

Staff agrees that the coke calciner is a challenging application, and the BARCT level should be set at 10 ppmv as recommended by NEC. Addendum-1 of the Staff Report provides NEC's non-confidential "SCAQMD NOx RECLAIM – BARCT Feasibility and Analysis Review". Staff also agrees that a factor higher than the EPA OAQPS's factor of 1.86 would be reasonable for the coke calciner because of the space congestion situation at the site. Staff revised the calculation and used a factor of 4.5 instead of 1.86 for both LoTOx and Ultra-Cat technologies.

Appendix J - Comparative Analyses for Turbine/Duct Burners

This appendix provides a comparison of the control design configuration, total installed cost (TIC) calculation and present worth Value (PWV) estimation used in the staff and NEC estimations for the Turbine/ Duct Burner cost effectiveness calculation. Table J.1 summarizes the basic comparison. The cost assumptions for TIC and PWV estimation methodology are provided solely for the staff proposal since NEC recommendation was to add catalyst to achieve the 2 ppmv targeted emissions limit.

Table J.1 - Comparison of Staff and NEC Control Equipment Designs, TIC and PWV Estimation Methods

	Staff's Design	**NEC's Design**
Control Devise Configuration	Install new SCR with Ammonia Slip Catalysts and/or add catalyst to existing SCRs	Add catalyst to existing SCRs
Cost Basis	Cost information provide by several sources: • SCR costs directly provided by Refineries 1 and 10; • Costs also provided by vendor for SCR • US EPA SCR cost estimate from literature • Cheng Low NOx technology	Costs information provided by vendor and Refinery 1
Cost Models	Cost curve relating PWV to MW	Cost curve relating PWV to MW

Appendix K – Co-Benefits of Energy Efficiency Projects

Table K.1 below summarizes NOx reductions that are expected to occur as co-benefits of energy efficiency projects undertaken by the refineries in the Basin from the California Air Resources Board (CARB)'s report "Energy Efficiency and Co-Benefits Assessment of Large Industrial Sources – Refinery Sector Public Report, June 6, 2013.

CARB approved the Energy Efficiency and Co-Benefit Assessment of Large Industrial Facilities (EEA Regulation) on July 22, 2010. The regulation required the largest industrial sources in California to conduct a one-time assessment of fuel and energy consumption, and emissions of greenhouse gas, criteria pollutants, and toxic air contaminants. Affected facilities were also required to identify potential improvements in equipment, processes, or systems that could result in energy savings. http://www.arb.ca.gov/cc/energyaudits/energyaudits.htm#background.

CARB has a three-phase implementation plan to implement the EEA Regulation. Phase 1 was to develop the industrial sector public reports. From June 2013 to April 2015, CARB released five separate public reports compiling the information provided by the facilities subject to the EEA Regulation. The first report released in June 2013 was for the refinery sector. CARB is working on Phase 2 to develop the findings report, and Phase 3 to develop the Energy Efficiency Implementation Program. http://www.arb.ca.gov/cc/energyaudits/publicreports.htm.

CARB staff indicated that currently there was no requirement for the refineries to report the emissions stated in the public report released in June 2013 for inventory purposes. In addition, CARB had no process by which the inventory could be modified based on the estimates provided in the report. CARB did not know if the actual emission reductions would be different from the estimates in the report, and CARB had no plan to count these estimates as reductions to the current air quality. Thus, staff did not count the reductions in this proposal.

Table K. 1- Summary of Emission Reductions and Schedules of Energy Efficiency Projects

Valero identified 13 projects completed in 2007-2010 time frame (p.65)

Appendix L – Survey Questionnaires for Refinery Sector

In June 2013, staff developed Survey Questionnaire to collect pertinent information for the NOx RECLAIM rule development. The Survey Questionnaire was sent to the 37 top emitting facilities and California Portland Cement Company which was the #1 NOx emission source in the Basin in 2008. The Survey Questionnaire for the refinery sector and the non-refinery sector are shown below.

South Coast Air Quality Management
2013 NOx RECLAIM
Survey Questionnaire for Refineries
(Due Date: July 12, 2013)

Facility Contact

1. Please provide the facility contact for this project:
   Name: ________________________________
   Title: ________________________________
   Phone Number: _________________________
   Email Address: _________________________

Top NOx Emitting Equipment or Processes

(* The attached list may contain the information requested)

2. * Please verify the attached list for the top 10 NOx emitting equipment and processes at your facility in Compliance Year 2011 and their emissions.

3. Please mark on the attached list the NOx control equipment installed **after the 2005 NOx RECLAIM amendment**

Boilers, Heaters, Furnaces, Kilns, Turbines, and Cogeneration Units (Major and Large Sources)

4. For each major and large combustion source at your facility, please verify the following information in the attached list, and provide information if the attached list does not contain this specific information:
   a. * Device description, Device ID, Process Name
   b. * Emissions in CY 2011 (tons per day)
   c. * Maximum unit rating (MMBTU/hr)
   d. * Type of fuel used
   e. Fuel usage rate and BTU content of fuel
   f. Flue gas flow rate (million dry standard cubic feet), temperature, oxygen and water content

g. Representative flue gas analysis and fuel gas analysis
h. NOx concentration in the exhaust flue gas (ppmv at 3% O_2 or ppmv at 15% O_2). Please attach a copy of the most current source test reports/results.
i. Allowable back pressure
j. * Control technology used (e.g. LNB, SCR, NOx scrubber)

5. For the control technology identified in item #4 above:
   a. Device description, Device ID
   b. Manufacturer's name and performance. Please attach a copy of manufacturer's specification/guarantee
   c. Design parameters (e.g. maximum flue gas flow rate, inlet and outlet ppmv, ammonia slip)
   d. If the control device is shared between multiple NOx emitting sources, please identify all other sources that are vented to this control device
   e. Dimension of the add-on NOx control device (e.g. length, width, height of the SCR, catalyst volume)
   f. Cost information (capital costs, installation costs, and annual operating costs)
   g. Installation date (e.g. July 2005)

6. Provide drawings that show location and distances between the major and large NOx sources at the facility.

Fluid Catalytic Cracking Units

7. If the facility currently uses NOx reduction catalysts, please provide:
   a. Manufacturer's name
   b. Usage rate (e.g. lbs of catalysts added per day)
   c. Flue gas flow rate, temperature, oxygen, water content and flue gas analysis
   d. NOx in the exhaust flue gas (ppmv at 3% O2). Please attach a copy of the source test results
   e. Cost information (annual operating costs)

8. If the facility uses add-on NOx control device, please provide:
   a. Manufacturer's name and performance. Please attach a copy of manufacturer's specification/guarantee
   b. Design parameters (max flue gas flow rate, temperature, oxygen, water content, flue gas analysis)
   c. NOx in the exhaust flue gas (ppmv at 3% O2). Please attach a copy of the source test report/results
   d. Dimension of the add-on NOx control device
   e. Cost information (capital costs, installation costs, and annual operating costs)
   f. Installation date (e.g. July 2005)

Reports Submitted Under the U.S. EPA Consent Decree

9. If the facility must install control technology to reduce the NOx emissions under an U.S. Environmental Protection Agency (EPA)'s consent decree, please provide the District a copy of the most recent reports/test results submitted to the EPA related to this consent decree.

Feasible Control Approach Including Energy Efficiency Project

10. List any feasible control approach that your facility plans to install, including replacement of the existing units with higher energy efficient units, to further reduce your facility's NOx emissions and green-house gases. Provide a brief description of the control approach, manufacturer's name, estimated emission reductions, and cost information.

If you have any questions, please contact either:
Minh Pham, P.E. (909) 396-2613, mpham@aqmd.gov, or
Gary Quinn, P.E. (909) 396-3121, gquinn@aqmd.gov

Please submit information via e-mail by July 12, 2013
to Minh Pham and Gary Quinn.
Thank you for participating in the Survey.

Part II – BARCT Analyses for Non-Refinery Sector

Part II contains the information related to the BARCT analyses for the non-refinery sector. Part II includes 7 Appendices from Appendix M to Appendix S that discuss 1) the NOx control technologies, 2) costs and cost effectiveness analyses for the NOx emitting sources at the top 27 non-refinery facilities, and 3) staff's review of the consultant's costs and cost effectiveness analyses. The Survey Questionnaires for non-refinery facilities are included in Appendix T.

Appendix M – Cement Kilns

Process Description

In the NOx RECLAIM program there is one facility that operates cement kilns. This facility, under normal operation, has typically been among the highest NOx emitters in the RECLAIM program. This facility produces gray cement from limestone, sand, shale, and clay raw materials. The raw materials are processed into a mix that is fed into a long, dry kiln that goes through pyroprocessing. Pyroprocessing transforms the fine raw mix into cement clinker through physical and chemical reactions inside the kiln. The facility operates two of these long, dry kilns that rotate slowly and are inclined at an angle. The raw materials are fed at the higher end of the kiln and proceed through it under the high heat of the combustion gases that are produced by the kiln burners at the lower end. Once the material exits the kiln, it is considered clinker and is cooled, and further processed (ground, milled) into cement. The combustion fuels used in these kilns include petroleum coke, natural gas and tire-derived fuel (TDF). The flue gases exiting the kilns are then ducted to individual waste heat boilers that operate a steam generator for electricity. After the waste heat boilers, the flue gases from each kiln go to a dedicated baghouse which separates the solid particulate. The resultant flue gases then exit from individual stacks.

In 2005, there was no new BARCT proposed for this source category. The emission factor has remained unchanged from the 2000 (Tier 1) Level, which is 2.73 pounds of NOx per ton of clinker produced.

Current Emission Inventory

There are two long, dry cement kilns located at the subject NOx RECLAIM facility. This facility was not in operation in compliance year 2011 due to decreased production and has not been in operation since. Therefore, for the purposes of calculating the BARCT reductions, the baseline emissions from the 2012 AQMP base year (2008) were used for the emission reduction determination and cost effectiveness calculation.

Table M. 1 - 2011 Emissions for Cement Kilns

Equipment Type (at Top 37 Facilities)	Number of Units	2008 Emissions (tpd)
Long, Dry Cement Kiln	2	1.61

Control Technology

Long, dry cement kilns have achieved NOx reductions to the 2000 (Tier 1) level by utilizing low NOx burners and mid kiln firing with tire-derived fuel (TDF). With TDF, whole tires are introduced at an inlet location about midway along the kiln's calcining zone. TDF lowers NOx emissions by lowering the flame temperatures and reducing thermal NOx with the introduction of a slower burning fuel.

The facility began testing one of the kilns with a selective non-catalytic reduction system (SNCR) before it ceased operation. This approach involves injecting ammonia directly into the kiln heating zone, where NOx reduction occurs without the utilization of a catalyst. With SNCR, the temperature window is critical for successful treatment of NOx. With a long, dry cement kiln, this is often difficult to achieve with the different temperature zones along its length and the necessity to inject the reagent mid-kiln. NOx treatment is easier to achieve on more modern preheater/precalcining kilns with SNCR since they are often shorter in length and the temperature window lies towards the exit of the kiln at the lower part of the preheater tower. This allows for readily feasible reagent introduction. The testing of the SNCR system at the facility yielded about a 30% NOx reduction. As applied to other kilns, SNCR is capable of achieving between a 30 and 50% NOx reduction. In the case of this facility, a 45% NOx reduction would result in meeting the New Source Performance Standard (NSPS) level of 1.5 pounds of NOx per ton of clinker produced. This emission level is equivalent to that of a new precalciner kiln using SNCR for NOx control.

After discussions with several vendors, there is more than one technology available for effective treatment of NOx from this source category beyond the Tier 1 level. To effectively achieve the most significant NOx reduction, selective catalytic reduction (SCR) is a proven technology that is well suited for the flue gas treatment of NOx. This technology uses a precious metal catalyst that selectively reduces NOx in the presence of ammonia. Ammonia is injected in the flue gas stream where it reacts with NOx and oxygen in the presence of the catalyst to produce nitrogen and water vapor. The typical operating temperature of the exhaust gas is between 450 and 850 degrees F. In cement applications, the inherently high particulate load of the flue gas stream has created problems in the past for catalysts. The dust can plug the catalyst matrix openings and can also mask active sites which results in a degradation of performance. This obstacle can be overcome by utilizing sootblowers which blow off the accumulated particulates at timed intervals from the catalyst surface. There have been several installations of SCR systems on cement kilns in Europe that can handle high dust loads in the flue gas. The installation at Monselice, Italy has been in operation since 2006 and the installation at Mergelstetten has been in operation since 2010. An

SCR has also been installed on a long, dry kiln in Joppa, Illinois. It has been operating since 2013 and can achieve an 80% NOx reduction.

For cement applications, an alternate technology is available primarily for multi-pollutant control. The system utilizes Ultra Cat ceramic fiber filters. The flue gas is injected with ammonia that mixes with the gas and permeates across the ceramic filter wall. The filter material is embedded with catalyst which removes the NOx. Dry sorbent is injected in the flue gas to react with SOx. The resultant particulate, along with other particulate matter is captured at the outside of the filter walls.

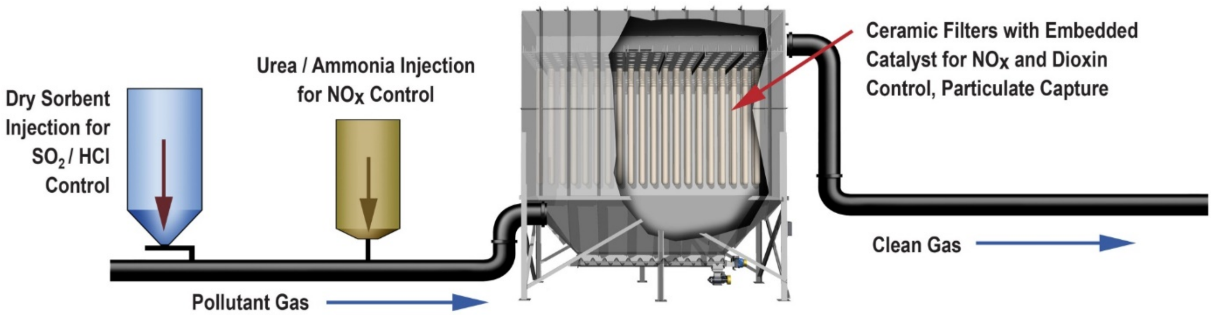

Figure M. 1 - Ultra Cat Ceramic Filter System

The accumulated solids on the filters are removed by a pulsed jet of air through the filter and the resultant solid waste is collected underneath the housing and is landfilled. This technology is guaranteed to achieve an 80% NOx reduction.

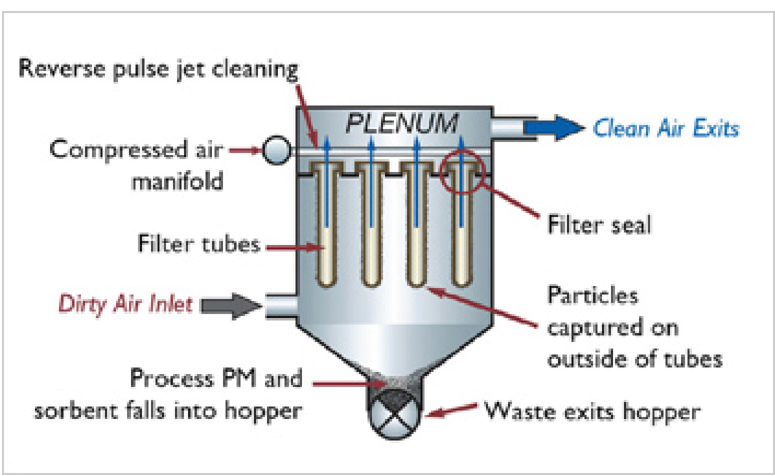

Figure M. 2 - Close-Up of Filter Housing and System Operation (~~Refernce~~Reference #2)

Another multi-pollutant control option for cement kilns is also possible that would reduce SOx and PM with a wet gas scrubber and treat NOx with SCR. A wet gas scrubber uses a liquid solution, typically caustic, as the absorbing agent for SO_2. The absorbed SO_2 is converted to sulfates and sulfites which are then captured in the liquid effluent treatment system where they are separated and then disposed. Solid particulates in the flue gas stream are removed by impaction with the liquid droplets inside the scrubber. The outlet flue gas stream is then processed by the SCR system for removal of NOx. Temperature control is extremely important for proper functioning of the pollutant control systems, primarily for SCR. The gas has to be hot enough after being processed by the scrubber for SCR treatment. This can be achieved by utilizing a heat exchanger ahead of the scrubber to reheat the gas to the proper temperature for SCR treatment. In this configuration, the scrubbing unit is installed ahead of the SCR for the purposes of removing SO_2 and preventing the formation of ammonium bisulfate (ABS). ABS formation is a result of sulfur compounds reacting with ammonia from the SCR system at a lower temperature below the dew point. ABS formation is reversible, and this involves heating the catalyst to evaporate it. When SO_2 is present in the flue gas stream, the minimum SCR process temperature is determined by the formation of ABS. With the removal of SO_2 from the flue gas stream by the scrubber, however, ABS formation is not an issue when operating the SCR system at the lower end of the normal temperature range.

Proposed BARCT level and Emission Reductions

SCAQMD command and control Rule 1112 set NOx limits for gray cement kilns. Last amended in 1986, the rule limits NOx emissions to 6.4 pounds per ton of clinker produced, averaged over any 30 consecutive day period. The 2005 NOx RECLAIM amendment proposed no new BARCT for cement kilns, so these units have been only required to meet the Year 2000 Tier 1 emission level. The Tier 1 emission level for cement kilns is 2.73 pounds of NOx per ton of clinker produced. When they were in operation, the two units in the NOx RECLAIM universe of facilities were compliant with the Tier 1 NOx emission level.

Based on vendor discussions, the proposed BARCT level for gray cement kilns is an 80% reduction and the control technology to achieve the NOx reductions is SCR or the Ultra Cat ceramic filter system. This would result in an emission level of about 0.5 pounds of NOx per ton of clinker produced.

The emission reductions achieved from the two long, dry cement kilns, based on the 2008 compliance year baseline emissions, amount to 1.29 tons per day. This is the incremental reduction from the Tier 1 emission level.

Cost Effectiveness

The total installed costs (TIC), which include equipment and installation costs were calculated by using vendor-supplied costs.

For an SCR installation on both kilns, the equipment costs include the SCR equipment, ductwork, steel, electrical, ammonia skid, sootblower air compressors, and insulation. The SCR system includes two layers of catalyst with a third layer for standby. A contingency value of 60% of the SCR equipment costs was estimated for the foundation civil work and other contingency. The SCR system for each kiln would be installed after the existing waste heat boiler and before the existing baghouse. This facility has specific plot space considerations that would require the installation of the SCR system between 5 and 30 yards from each waste heat boiler, depending on the kiln. The equipment would be placed on elevated platforms to allow for vehicle and/or railcar traffic underneath. There is no expected heat loss from the insulated ductwork. The annual operating costs include ammonia consumption and catalyst replacement costs, which for this installation were assigned a three year replacement interval.

For the Ultra Cat ceramic filter system, the equipment costs for both kilns include the emission control system, ammonia skid, booster fan, and engineering services, along with the installation. The annual operating costs include ammonia consumption, dry sorbent consumption, power consumption, labor, waste disposal, replacement filter costs. Since this facility is also a SOx source, dry sorbent injection for SOx removal will be required. This system would replace the existing baghouses at this facility.

The vendor-based equipment costs for the wet scrubber with heat exchanger and SCR for each kiln include the costs for the heat exchanger systems (ductwork, housing, dust collection hoppers), wet gas scrubber systems (venturi scrubber, pumps, structural steel, piping), and the SCR systems (2 layers of catalyst for each kiln, ductwork, ammonia skid, programmable logic control, sootblowers).

A contingency value of 60% of the equipment costs was estimated for the foundation and civil work, installation, and other contingency. The annual operating costs include ammonia consumption, catalyst replacement (3 year), caustic consumption, exhaust system fan power, scrubber pump power, and SCR dilution air fan and sootblower power. This system would replace the existing baghouses at this facility.

For all the scenarios, a present worth value (PWV) was calculated for the cement kilns using the TIC and annual costs (AC), and assumes a 4% interest rate and a 25-year equipment life per the equation below.

PWV = TIC + (15.622 x AC)

A cost effectiveness value was then calculated for each case scenario using the present worth value and dividing by the incremental emission reductions (ER, in tons per day) from the Tier 1 level over the control equipment life (25 years). This approach in calculating cost effectiveness utilizes the Discounted Cash Flow method (DCF).

Cost Effectiveness = PWV / (ER x 365 x 25 years)

Conversion to a Levelized Cash Flow (LCF) requires a calculation using the following equation:

LCF Cost Effectiveness = (TIC x CRF) + AC / (ER x 365),

where CRF is the Capital Recovery Factor assuming a 4% interest rate over an equipment life of 25 years.

Table M. 2 - Cost Effectiveness for Cement Kilns

Vendor 1: SCR system installed between waste heat boiler and baghouse. NOx removal only.			
Vendor 2: Dry scrubbing and ceramic filter system installed after the waste heat boiler and replacing the baghouse. NOx, SOx, and PM removal.			
Vendor 3: Wet gas scrubber and SCR system with heat exchanger installed after the waste heat boiler and replacing the baghouse. NOx, SOx, and PM removal.			
	Vendor 1	**Vendor 2**	**Vendor 3**
Capital Costs ($)	14,950,000	30,000,000	31,938,838
Annual Costs ($)	1,220,500	1,000,000	4,818,537
Present Worth Value ($)	34,016,651	45,622,000	107,214,017
Emission reductions (tpd)	1.287	1.287	1.287
DCF Cost Effectiveness ($/ton)	2,897	3,885	9,130
LCF Cost Effectiveness ($/ton)	4,635	6,216	14,609

To achieve an 80% NOx reduction, the cost effectiveness for cement kilns ranges from $2,900/ton to $9,100/ton ($4,600/ton to $14,600/ton, using LCF). Since the facility is also a SOx source, the calculated cost effectiveness combining NOx and SOx reductions equates to $3,300/ton for Vendor 2 and $7,600/ton for Vendor 3. This assumes a SOx reduction of 0.25 tons per day, as stated for the SOx RECLAIM amendment of 2010. All of the scenarios using the aforementioned NOx reduction technologies for flue gas treatment of cement kilns are considered cost effective.

Review of ETS's Analysis for Cement Kilns

ETS, Inc. was commissioned by SCAQMD staff to provide an independent evaluation of the previously described BARCT and cost analysis. ETS conducted a site visit at the facility to verify site specific considerations for the installation of control equipment.

For all the vendor installation estimates, a project scope contingency of 15% was applied to the total direct and indirect capital costs.

ETS concurs that there is sufficient plot space to install the control equipment for all three vendors and that an 80% NOx emission reduction is both feasible and cost effective.

Table M. 3 - ETS Revisions to Cost Effectiveness for Cement Kilns

Vendor 1: SCR system installed between waste heat boiler and baghouse. NOx removal only.			
Vendor 2: Dry scrubbing and ceramic filter system installed after the waste heat boiler and replacing the baghouse. NOx, SOx, and PM removal.			
Vendor 3: Wet gas scrubber and SCR system with heat exchanger installed after the waste heat boiler and replacing the baghouse. NOx, SOx, and PM removal.			
	Vendor 1	**Vendor 2**	**Vendor 3**
	Staff's Estimate (ETS's Estimate)	Staff's Estimate (ETS's Estimate)	Staff's Estimate(ETS's Estimate)
Capital Costs ($)	14,950,000 (17,192,500)	30,000,000 (34,500,000)	31,938,838 (36,729,664)
Annual Costs ($)*	1,220,500	1,000,000	4,818,537
Present Worth Value ($)	34,016,651 (36,259,151)	45,622,000 (50,122,000)	107,214,017 (112,004,843)
Emission reductions (tpd)	1.287	1.287	1.287
DCF Cost Effectiveness ($/ton)	2,897 (3,088)	3,885 (4,268)	9,130 (9,538)
LCF Cost Effectiveness ($/ton)	4,635 (4,941)	6,216 (6,829)	14,609 (15,262)

* No revisions made by ETS

The facility made several comments regarding the BARCT analysis and staff conducted further research that resulted in a refinement of the cost analysis. Further communications with Vendor 1 revealed that the original estimate capital costs should have been doubled, as the previous costs were clarified as being for only one kiln. The facility had a concern over the temperatures at the exit of the waste heat boiler, before entering the control equipment. The facility provided an updated temperature which was 100 degrees below what had been provided previously and was below the normal operating temperature for normal SCR operation. To address this change, additional costs for reheating the flue gas were incorporated into the estimate, along with the natural gas costs to fuel the added duct burner. This updated system would utilize a natural gas-fired duct burner with a heat exchanger to reheat the gas approximately 100-150 degrees to enable the SCR catalyst to operate normally. The project contingency and other contingencies were adjusted to reflect the updated costs. The capital and operational costs for reheating the flue gas were applied to all three vendor estimates. In addition, operational costs were incorporated into the Vendor 3 estimate for wastewater treatment of the wet gas scrubber effluent. Furthermore, costs for powering new induced draft (ID) fans were also incorporated into the vendor estimates.

Table M. 4 - SCAQMD Revisions to Cost Effectiveness for Cement Kilns

Vendor 1: SCR system installed between waste heat boiler and baghouse. NOx removal only.			
Vendor 2: Dry scrubbing and ceramic filter system installed after the waste heat boiler and replacing the baghouse. NOx, SOx, and PM removal.			
Vendor 3: Wet gas scrubber and SCR system with heat exchanger installed after the waste heat boiler and replacing the baghouse. NOx, SOx, and PM removal.			
	Vendor 1	**Vendor 2**	**Vendor 3**
	ETS's Estimate (Staff's Estimate)	ETS's Estimate (Staff's Estimate)	ETS's Estimate (Staff's Estimate)
Capital Costs ($)	17,192,500 (37,812,000)	34,500,000 (38,400,000)	36,729,664 (42,166,606)
Annual Costs ($)*	1,220,500 (2,029,048)	1,000,000 (1,430,116)	4,818,537 (5,722,253)
Present Worth Value ($)	36,259,151 (69,509,788)	50,122,000 (60,741,272)	112,004,843 (151,559,636)
Emission reductions (tpd)	1.287	1.287	1.287
DCF Cost Effectiveness ($/ton)	3,088 (5,919)	4,268 (5,172)	9,538 (11,203)
LCF Cost Effectiveness ($/ton)	4,941 (9,471)	6,829 (8,276)	15,262 (17,927)

To achieve the proposed BARCT level, the revised cost effectiveness for cement kilns ranges from $5,200/ton to $11,200/ton ($8,300/ton to $17,900/ton, using LCF). All of these scenarios using the aforementioned NOx reduction technologies for flue gas treatment of cement kilns are considered feasible and cost effective.

Appendix N – Container Glass Melting Furnaces

Process Description

In the NOx RECLAIM program there is one facility among the top 37 NOx emitting facilities that operates container glass melting furnaces. This facility produces container glass from dry, solid raw materials that are melted in the furnaces and then formed into glass container bottles.

In 2005, there was no new BARCT proposed for this source category. The emission factor has remained unchanged since 2000 (Tier 1), which is 1.2 pounds of NOx per ton of glass pulled.

Current Emission Inventory

There are two glass melting furnaces located at the subject NOx RECLAIM facility.

Table N. 1 - 2011 Emissions for Container Glass Melting Furnaces

Equipment Type	Number of Units	2011 Emissions (tpd)
Glass Melting Furnace (Container Glass)	2	0.30

Control Technology

Glass melting furnaces can achieve NOx reductions to the 2000 (Tier 1) level by utilizing oxy fuel firing. With oxy fuel firing, pure oxygen is used as the combustion reactant instead of nitrogen-laden ambient air. A higher temperature can be achieved for the batch melt based on the higher combustion efficiency in addition to achieving lower NOx emissions.

There is more than one technology available for effective treatment of NOx from this source category. To effectively achieve a significant NOx reduction, selective catalytic reduction (SCR) is a proven technology that is well suited for the flue gas treatment of NOx. This technology uses a precious metal catalyst that selectively reduces NOx in the presence of ammonia. Ammonia is injected in the flue gas stream where it reacts with NOx and oxygen in the presence of the catalyst to produce nitrogen and water vapor. The typical operating temperature of the exhaust gas is between 450 and 850 degrees F.

For glass melting applications, an alternate technology is available that has been achieved in practice, primarily for multi-pollutant control. The system utilizes Ultra Cat ceramic fiber filters. Please refer to Appendix M for further details. This technology is guaranteed to achieve an 80% NOx reduction and has been installed or is under construction at 12 glass manufacturing locations worldwide.

Proposed BARCT level and Emission Reductions

SCAQMD command and control Rule 1117 set NOx limits for glass melting furnaces. Last amended in 1984, the rule limits NOx emissions to 4.0 pounds per ton of glass pulled, effective in 1992. The 2005 NOx RECLAIM amendment proposed no new BARCT for container glass melting furnaces, so these units have been only required to meet the Year 2000 Tier 1 emission level. The Tier 1 emission level for container glass melting furnaces is 1.2 pounds of NOx per ton of glass pulled. The two units in the NOx RECLAIM universe are currently compliant with the Tier 1 emission level.
Based on vendor discussions, the proposed BARCT level for container glass melting furnaces is an 80% reduction and the control technology to achieve the NOx reductions is SCR or the Ultra Cat ceramic filter system. This would result in a NOx emission rate of 0.24 pounds per ton of glass pulled.

The emission reductions achieved from the two container glass melting furnaces, based on the reported value of emissions, amount to 0.24 tons per day. This is the incremental reduction from the Tier 1 emission level of 1.2 pounds of NOx per ton of glass pulled.

Cost Effectiveness

The total installed costs (TIC), which include equipment and installation costs were calculated by using vendor-supplied costs and the costs provided by the facility.

For the Ultra Cat ceramic filter system, the equipment costs were scaled from an existing vendor-based installation quotation for a sodium silicate glass melting furnace. The equipment costs which include the emission control system, ammonia skid, and booster fan were scaled by the heat input rate to the 0.6 power based on general chemical engineering cost estimating practice. The installation costs were calculated to be 40% of the equipment costs. The cost of installation as well as the cost of engineering services was scaled by the heat input rate. The annual operating costs (also scaled by heat input rate) include ammonia consumption, dry sorbent consumption, power consumption, labor, waste disposal, replacement filter costs. Since this facility is also a SOx source, dry sorbent injection for SOx removal will be required. This system would replace the existing dry scrubbing system and electrostatic precipitators (ESPs) at this facility.

For an SCR installation, two scenarios were considered. In the first scenario, one SCR chamber would handle the exhaust streams from the three ESPs. At this facility, three ESPs handle the exhaust from the two glass melting furnaces in which one ESP is operated as a backup. In the second scenario, one SCR would handle the exhaust from each ESP, so there would be a total of three SCR systems installed.

The vendor-based costs for the first option include the engineering, fabrication and field installation of a single SCR chamber sized to handle the exhaust from both furnaces. The SCR system includes one layer of catalyst with extra space for a second layer, supporting structure, ammonia skid, and programmable logic control (PLC) system. A contingency value of 80% of the SCR equipment costs was estimated for the foundation and ductwork to and from the existing stacks. This facility has specific plot space considerations that would require the installation of the SCR system roughly 30 yards from the ESPs and roughly 15 yards back to the stacks. The equipment would be placed on an elevated platform above the existing rail line. The annual operating costs include ammonia consumption and catalyst replacement costs, which for this installation were conservatively assigned an annual replacement interval. In addition, a 20% contingency was added to the annual costs for freight and installation.

The vendor-based costs for the second option include the engineering, fabrication and field installation of three SCR chambers as described for the first option, each sized to handle the exhaust from one furnace. A contingency value of 150% of the SCR equipment costs was estimated for the foundation and ductwork to and from the existing stacks. The annual operating costs were also derived as described for the first option. This option also included an additional 20% contingency.

The facility also provided an estimate for the retrofitting of one furnace that was based on the EPA cost manual for SCR installations for NOx removal. To expand this singular case to address the remaining furnace, two scenarios were considered for this approach. The first option would include the installation of two SCR systems, each sized to handle the exhaust of one furnace, manifolded to the existing three ESPs. The second option would include the installation of three SCR systems, each sized to handle the exhaust of one furnace. Each SCR would handle the exhaust from each ESP. For each option, the costs for additional SCRs were calculated by multiplying the facility-provided costs for a single unit with number of additional units required for each of the two options. Also for each option, a 15% contingency factor was applied to the direct and indirect costs. The annual operating costs for each option include operations and maintenance labor/materials, ammonia consumption, power consumptions and catalyst costs. In addition, an indirect annual cost factor was added and was calculated to be the capital costs multiplied by the capital recovery factor (CRF) for a 25 year installation at a 4% interest rate.

For all the scenarios, a present worth value (PWV) was calculated for the glass melting furnaces using the TIC and annual costs (AC), and assumes a 4% interest rate and a 25-year equipment life per the equation below.

$$PWV = TIC + (15.622 \times AC)$$

A cost effectiveness value was then calculated for each case scenario using the present worth value and dividing by the incremental emission reductions (ER, in tons per day) from the Tier 1 level over the control equipment life (25 years). This approach in calculating cost effectiveness utilizes the Discounted Cash Flow method (DCF).

$$\text{Cost Effectiveness} = PWV / (ER \times 365 \times 25 \text{ years})$$

Conversion to a Levelized Cash Flow (LCF) requires a calculation using the following equation:

$$\text{LCF Cost Effectiveness} = (TIC \times CRF) + AC / (ER \times 365),$$

where CRF is the Capital Recovery Factor assuming a 4% interest rate over an equipment life of 25 years.

Table N. 2 - Cost Effectiveness for Container Glass Melting Furnaces

Vendor 1: Dry scrubbing and ceramic filter system installed after the furnaces, replacing the dry scrubber and ESP. NOx, SOx, and PM removal.					
Vendor 2: SCR system installed post ESP. NOx removal only. Option 1: single chamber. Option 2: three chambers.					
Vendor 3: SCR system installed post ESP using costs provided by facility per EPA cost Manual. NOx removal only. Option 1: two chambers. Option 2: three chambers.					
	Vendor 1	**Vendor 2 Option 1**	**Vendor 2 Option 2**	**Vendor 3 Option 1**	**Vendor 3 Option 2**
Capital Costs ($)	5,134,891	2,070,000	5,000,000	4,096,959	6,145,439
Annual Costs ($)	567,686	132,500	180,750	560,123	840,185
Present Worth Value ($)	14,003,287	4,139,195	7,823,677	12,847,207	19,270,811
Emission reductions (tpd)	0.24	0.24	0.24	0.24	0.24
DCF Cost Effectiveness ($/ton)	6,442	1,904	3,599	5,910	8,865
LCF Cost Effectiveness ($/ton)	10,308	3,047	5,759	9,457	14,186

To achieve an 80% reduction, the cost effectiveness for container glass melting furnace ranges from $1,900/ton to $8,900/ton ($3,000/ton to $14,200/ton, using LCF). All of these scenarios using the aforementioned NOx reduction technologies for flue gas treatment of container glass melting furnaces are considered cost effective.

Review of ETS's Analysis for Container Glass Melting Furnaces

ETS, Inc. was commissioned by SCAQMD staff to provide an independent evaluation of the previously described BARCT and cost analysis. ETS conducted a site visit at the facility to verify site specific considerations for the installation of control equipment.

For the Vendor 1 estimates, the calculation of the installation costs were adjusted to reflect 40% of the equipment costs, instead of being scaled from the base equipment case. Additionally, a contingency of 15% of the capital costs was applied to the overall estimate.

The Vendor 2 estimates were also adjusted by ETS for several items. Foundation and ductwork costs were added, as well as costs for new stacks for both options (single and three SCRs). Operation and labor costs were added to the annual costs for both options as well as costs for power consumption with the addition of a booster fan. The annual catalyst replacement costs were also adjusted for both options to reflect labor costs to replace the catalyst, along with recycling/disposal costs for spent catalyst. Additionally, a contingency of 15% of the capital costs was applied to the overall estimate.

The Vendor 3 cost estimates were not evaluated by ETS because they felt that the cost estimates provided by the equipment vendors with actual field experience with NOx removal would provide better estimates than the EPA cost manual method. Also, there was a disparity in the costs with the vendor estimates versus the EPA cost manual method because economics of scale were not taken into consideration, such as volume cost savings for multiple pieces of equipment.

Since the glass melting furnaces at this facility are also SOx emission sources, the flue gas has to be at a sufficiently high temperature to prevent ammonium bisulfate formation (ABS) while also removing NOx emissions effectively. ABS forms when the SO_3 in the flue gas reacts with the ammonia in the SCR system to produce ammonium salts. If the flue gas temperature is above the dew point for ABS, it will remain in the gaseous phase. However, if the temperature of the flue gas falls below the dew point for ABS, it will precipitate and deposit as a sticky substance on the SCR catalyst matrix. The result is reduced activity of the SCR catalyst and it will need to be reheated to reverse the process and reactivate it. Upon speaking with the equipment vendors, the SOx emissions from the glass melting furnaces would not result in ABS formation as long as the flue gas temperature remains as high as possible, any heat loss from the ductwork is mitigated, and there is not an overly lengthy duct run constructed to the SCR. The current stack temperatures at the facility are adequately above the ABS dew point and, therefore, there is no foreseeable issue with ABS deposition on the SCR catalyst.

ETS concurs that the NOx emission levels that are achievable is 80% for this source category. Achieving this level would be feasible with both technologies evaluated (i.e., ceramic filtration system or SCR). The plot considerations at this facility are complex, leaving little room for the installation of control equipment. The Vendor 1 system would involve removing the existing SOx dry scrubbers to create additional space and would need to be tied in presumably under a facility shutdown period. The Vendor 2 system would be complex as well, but ETS concurs that there is sufficient plot space for the installation of SCR.

To achieve the proposed BARCT level, the revised cost effectiveness for container glass melting furnaces ranges from $3,000/ton to $8,900/ton ($4,700/ton to $14,200/ton, using LCF). All of these scenarios using the aforementioned NOx reduction technologies for flue gas treatment of container glass melting furnaces are considered feasible and cost effective.

Table N. 3 - ETS Revisions to Cost Effectiveness for Container Glass Melting Furnaces

Vendor 1: Dry scrubbing and ceramic filter system installed after the furnaces, replacing the dry scrubber and ESP. NOx, SOx, and PM removal.

Vendor 2: SCR system installed post ESP. NOx removal only. Option 1: single chamber. Option 2: three chambers.

Vendor 3: SCR system installed post ESP using costs provided by facility per EPA cost manual. NOx removal only. Option 1: two chambers. Option 2: three chambers.

Appendix O– Sodium Silicate Furnace

Process Description

In the NOx RECLAIM program there is only one facility that produces sodium silicate. Sodium silicate is a substance either in a solid or liquid form that has a variety of industrial uses. It is manufactured by heating soda ash and sand in a melting furnace. The materials react with heat to produce sodium silicate and carbon dioxide.

In 2005, there was no new BARCT proposed for this source category. The emission factor has remained unchanged since 2000 (Tier 1), which is 6.4 pounds of NOx per ton of glass pulled. This unit is considered a glass melting furnace, but since it processes sodium silicate, it is different than other types of glass melting furnaces such as container glass, flat glass, etc.

Current Emission Inventory

The single source sodium silicate melting furnace is a NOx major source.

Table O. 1 - 2011 Emissions for Sodium Silicate Furnace

Equipment Type	Number of Units	2011 Emissions (tpd)
Sodium Silicate Furnace	1	0.11

Control Technology

The raw material batch feed is delivered into the melting furnace which is fired by several natural gas-fired burners that melt the process feed. The flue gas then exits the furnace via a stack into the atmosphere. Combustion technology can often be employed to achieve some NOx reductions. Blower air staging, for example, can lower the temperature and result in lowering NOx emissions by around 15 to 20%.

To effectively achieve the largest reduction, however, selective catalytic reduction (SCR) is the technology that is best suited for significant flue gas treatment of NOx. This technology uses a precious metal catalyst that selectively reduces NOx in the presence of ammonia. Ammonia is injected in the flue gas stream where it reacts with NOx and oxygen in the presence of the catalyst to produce nitrogen and water vapor. The typical operating temperature of the exhaust gas is between 450 and 850 degrees F.

For glass melting applications, an alternate technology is available that has been achieved in practice, primarily for multi-pollutant control. The system utilizes Ultra Cat ceramic fiber filters. Please refer to Appendix M for further descriptions. This technology is guaranteed to achieve an 80% NOx reduction.

Proposed BARCT level and Emission Reductions

In command and control, SCAQMD Rule 1117 set limits for glass melting furnaces. Last amended in 1984, the rule limits NOx emissions to 4.0 pounds per ton of glass pulled, effective in 1992. The 2005 NOx RECLAIM amendment proposed no new BARCT for sodium silicate furnaces or other glass melting furnaces, so these units have been only required to meet the Year 2000 Tier 1 emission level. The Tier 1 emission level for sodium silicate furnaces is 6.4 pounds per ton of glass pulled.

The single unit in the NOx RECLAIM universe is currently compliant with the Tier 1 emission level. For sodium silicate furnaces based on vendor discussions, the proposed BARCT level for this source category is an 80% reduction and the control technology to achieve the NOx reductions is SCR or the Ultra Cat ceramic filter system.

The emission reductions achieved from the sodium silicate furnace, based on the reported value of emissions, amounts to 0.09 tons per day. This is the incremental reduction from the Tier 1 emission level and is almost equivalent to the Tier 1 emission level for container glass melting furnaces (1.2 lbs/ton of glass pulled).

Cost Effectiveness

The total installed costs (TIC), which include equipment and installation costs were calculated by using vendor-supplied costs. There are no site-specific conditions that would increase the installation costs dramatically.

For SCR, the equipment and installation costs include the SCR chamber, one layer of catalyst with extra space for a second layer, supporting structure, ammonia skid, programmable logic control system (PLC), and engineering/fabrication. The foundation and ductwork was estimated to be 60% of the equipment and installation costs. The annual operating costs include ammonia consumption and catalyst replacement costs, which for this installation were conservatively assigned an annual replacement interval. In addition, a 20% contingency was added to the annual costs for freight and installation.

For the Ultra Cat ceramic filter system, the equipment costs include the emission control system, ammonia skid, booster fan, and engineering services. The installation costs were calculated to be 40% of the equipment costs. The annual operating costs include ammonia consumption, power consumption, labor, waste disposal and replacement filter costs. Since this facility is not a SOx source, dry sorbent injection for SOx removal would not be required.

For both technologies, a present worth value (PWV) was calculated for the sodium silicate furnace using the TIC and annual costs (AC), and assumes a 4% interest rate and a 25-year equipment life per the equation below.

PWV = TIC + (15.622 x AC)

A cost effectiveness value was then calculated for each technology using the present worth value and dividing by the incremental emission reductions (ER, in tons per day) from the Tier 1 level over the control equipment life (25 years). This method of calculating cost effectiveness utilizes the Discounted Cash Flow method (DCF).

Cost Effectiveness = PWV / (ER x 365 x 25 years)

Conversion to a Levelized Cash Flow (LCF) requires a calculation using the following equation:

LCF Cost Effectiveness = (TIC x CRF) + AC / (ER x 365),

where CRF is the Capital Recovery Factor assuming a 4% interest rate over an equipment life of 25 years.

Table O. 2 - Cost Effectiveness for Sodium Silicate Furnace

Control Technology	TIC ($)	AC ($)	PWV ($)	ER (tpd)	DCF C.E. ($/ton)
SCR	1,600,000	76,315	2,792,193	0.09	3,470
Ultra Cat	1,986,161	166,016	4,579,663	0.09	5,691

The cost effectiveness for the sodium silicate furnace ranges from $3,500/ton to $5,700/ton ($5,600/ton to $9,100/ton, using LCF). This is to achieve an 80% NOx reduction. Both technologies for reducing NOx for the sodium silicate furnace are considered cost effective.

Review of ETS's Analysis for Sodium Silicate Furnace

ETS, Inc. was commissioned by SCAQMD staff to provide an independent evaluation of the previously described BARCT and cost analysis. ETS conducted an evaluation of the control technology and the costs for the installation of the control equipment.

For both vendor estimates, a contingency of 15% was applied the total direct and indirect capital costs. For the Vendor 2 estimate, the capital costs pertinent to SO_2 treatment were removed since this system would be removing NOx only.

To achieve the proposed BARCT level, the revised cost effectiveness for the sodium silicate furnace ranges from $3,800/ton to $5,700/ton ($6,000/ton to $9,200/ton, using LCF). Both scenarios using the aforementioned NOx reduction technologies for flue gas treatment of the sodium silicate furnace are considered feasible and cost effective.

Table O. 3 - ETS Revisions to Cost Effectiveness for Sodium Silicate Furnace

Appendix P – Metal Heat Treating Furnaces >150 MMBTU/hr

Process Description

In the NOx RECLAIM program there is one facility that operates these furnaces among the top 37 facilities. For the 2005 NOx RECLAIM amendment, a BARCT level of 45 ppm (0.055 lb/MMBTU) was established for metal heat treating furnaces.

Current Emission Inventory

Among the top 37 facilities in the NOx RECLAIM program, there are two furnaces above 150 MMBTU/hr that are metal heat treating furnaces for processing steel.

Table P. 1 - 2011 Emissions for Metal Heat Treating Furnaces >150 MMBTU/hr

Equipment Type (at Top 37 Facilities)	Number of Units	2011 Emissions (tpd)
Furnace >150 MMBTU/hr	2	0.49

Control Technology

As with all combustion sources, the type of burner used can affect the emissions. Some burners are lower NOx emitting than others. But for these types of furnaces, there are often dozens of burners that cumulatively require a high heat input. To achieve higher efficiency and to consume less fuel, recuperative and regenerative burners are used. These burners employ the principle of using preheated inlet air which is heated by the exhaust gases for more efficient combustion.

To effectively achieve a significant NOx reduction, however, selective catalytic reduction (SCR) is the technology that is best suited for the flue gas treatment of NOx. This technology uses a precious metal catalyst that selectively reduces NOx in the presence of ammonia. Ammonia is injected in the flue gas stream where it reacts with NOx and oxygen in the presence of the catalyst to produce nitrogen and water vapor. The typical operating temperature of the exhaust gas is between 450 and 850 degrees F.

Proposed BARCT level and Emission Reductions

In command and control, SCAQMD Rule 1147 set limits for metal heat treating furnaces at 60 ppm at 3% O_2 (0.073 lb/MMBTU). This rule was adopted in 2008 to address NOx emissions from miscellaneous sources. The 2005 NOx RECLAIM amendment proposed a BARCT level of 45 ppm at 3% O_2 (0.055 lb/MMBTU).

Based on vendor discussions for furnaces above 150 MMBTU/hr, the proposed BARCT level for this source category is an 80% reduction and the control technology to achieve the NOx reductions is SCR. An 80% NOx reduction from the 2005 BARCT level is equivalent to 9 ppm at 3% O_2.

The 2011 emissions adjusted to the 2005 BARCT level amount to 0.70 tons per day. The incremental reductions from each furnace from the 2005 BARCT level to the proposed BARCT level are 0.28 tons per day. One of the furnaces is already operating with an SCR system and is currently achieving around 20 ppm NOx. The source category incremental emission reductions achieved from the metal heat treating furnaces above 150 MMBTU/hr from the 2005 BARCT level amount to 0.56 tons per day.

Cost Effectiveness

The total installed costs (TIC), which include equipment and installation costs were calculated by using vendor-supplied costs and the costs from an existing installation.

For SCR, the vendor-based equipment and installation costs include the SCR catalyst, reactor and ductwork, ammonia skid, dilution air fan, civil work, and installation. A contingency value of 200% of the SCR equipment costs was used to estimate the installation, foundation, civil work, and other construction uncertainties. The annual operating costs include ammonia consumption, catalyst replacement costs (2 year replacement interval), power consumption, and maintenance.

The existing equipment-based equipment costs include installation, SCR catalyst system, ammonia skid, and control system. A 60% contingency value of the equipment and installation cost was used to estimate the costs for other ductwork. The annual operating costs include ammonia consumption, catalyst replacement costs (2 year replacement interval), and maintenance.

For both scenario cases, a present worth value (PWV) was calculated for the metal heat treating furnaces using the TIC and annual costs (AC), and assumes a 4% interest rate and a 25-year equipment life per the equation below.

$$PWV = TIC + (15.622 \times AC)$$

A cost effectiveness value was then calculated for each case scenario using the present worth value and dividing by the incremental emission reductions (ER, in tons per day) from the Tier 1 level over the control equipment life (25 years). This method of calculating cost effectiveness utilizes the Discounted Cash Flow method (DCF).

Cost Effectiveness = PWV / (ER x 365 x 25 years)

Conversion to a Levelized Cash Flow (LCF) requires a calculation using the following equation:

LCF Cost Effectiveness = (TIC x CRF) + AC / (ER x 365),

where CRF is the Capital Recovery Factor assuming a 4% interest rate over an equipment life of 25 years.

Table P. 2 - Cost Effectiveness for Furnaces > 150 MMBTU/hr

Control Technology	TIC ($)	AC ($)	PWV ($)	ER (tpd)	DCF C.E. ($/ton)
Vendor-based	2,800,152	440,631	9,683,684	0.28	3,800
Existing equipment-based	3,732,800	255,600	7,725,783	0.28	3,000

The cost effectiveness for furnaces above 150 MMBTU/hr ranges from $3,000/ton to $3,800/ton ($4,800/ton to $6,100/ton, using LCF). Achieving an 80% NOx reduction, SCR technology applied for reducing NOx for these furnaces is considered cost effective.

Review of ETS's Analysis for Metal Heat Treating Furnaces >150 MMBTU/hr

ETS, Inc. was commissioned by SCAQMD staff to provide an independent evaluation of the previously described BARCT and cost analysis. Based on staff's analysis and the review of technical information, ETS concurs that the NOx reduction level that can be achieved with SCR technology is 80%. No changes to the cost estimates were made.

Appendix Q – Non-Refinery, Non-~~Electrical~~ Electrcity Generating Facility Stationary Gas Turbines

Process Description

In the RECLAIM program, stationary gas turbines are used primarily to drive compressors or to generate power. In command and control, Rule 1134 limits the NOx emissions for all gaseous and liquid-fueled engines that are above 0.3 MW. Gas turbines operate either in simple cycle or combined cycle. Simple cycle units use the mechanical energy of shaft work that is transferred to and used by a gas compressor, for example, or to run an electrical generator to produce electricity. A combined cycle unit adds an additional element of heat recovery from its exhaust gases to produce more power by way of a steam generator. Combined cycle units are more efficient due to their use of two work cycles from the same shaft operation. Gas turbines can operate on both gaseous and liquid fuels. Gaseous fuels include natural gas, process gas, and refinery gas. Liquid fuels typically include diesel. The units in this category are not ~~electrical~~ electricity generating facility turbines (turbines that produce solely electric utility power). Some of these units are cogenerating units that, in addition to producing in-house power, also recover the useful energy from heat recovery for producing process steam. In 2005, there was no new BARCT proposed for this source category. The emission factor has remained unchanged since 2000 (Tier 1), which equates to 0.06 lb/MMBTU.

Current Emission Inventory

Among the top thirty seven non-~~electrical~~ electricity generating facility NOx emitting facilities in the RECLAIM universe, there are twenty gas turbines that are either major or large source units. Four of these units are currently utilizing some level of NOx control with selective catalytic reduction (SCR). The OCS turbines, which are fired on diesel or process gas, have the highest NOx emission concentrations in this source category. Six of these units are operated on an offshore oil drilling platform (outer continental shelf, or OCS).

Table Q. 1 - 2011 Emissions for RECLAIM Non-~~Electrical~~ Electrcity Generating Facility Gas Turbines

Turbine Type	Number of Units	2011 Emissions (tpd)
Total	20	1.92
Gas Compression	7	0.59
Cogeneration	6	0.75
Power Generation	1	0.09
OCS	6	0.49

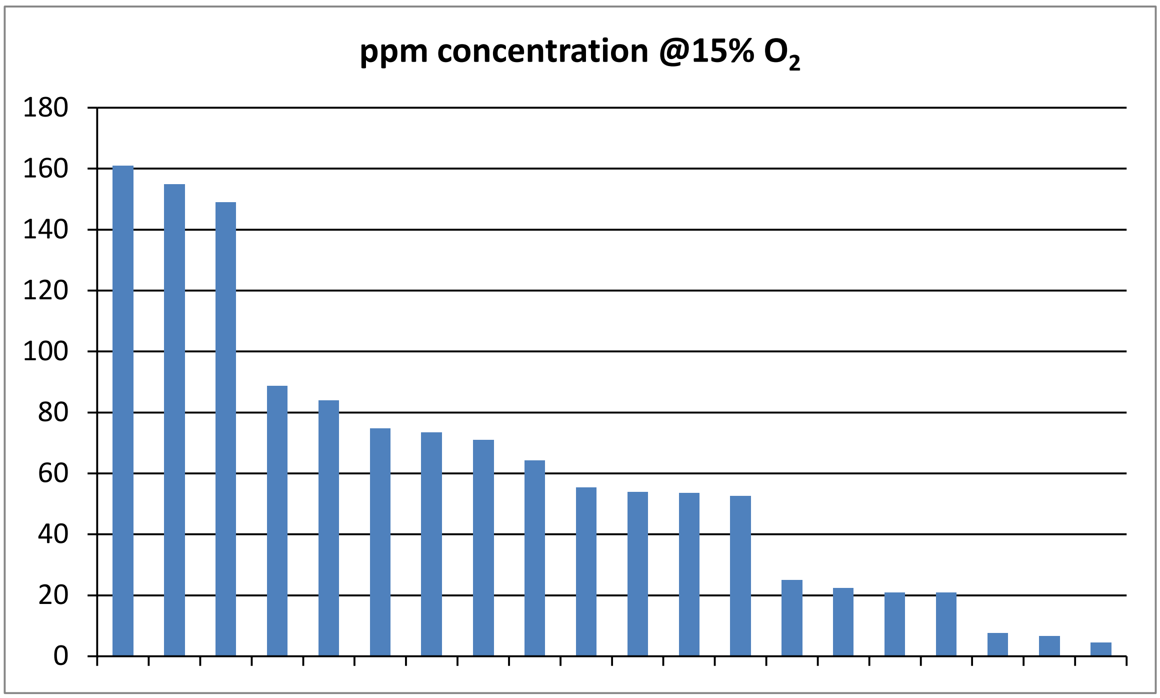

Figure Q. 1 - NOx Concentrations for Non-~~Electrical~~ Electrcity Generating Facility Gas Turbines at Top 37 Emitting Facilities

Control Technology

An uncontrolled unit will typically be emitting well over 100 ppm of NOx. There are several methods of NOx control for gas turbines, with differing levels of reduction.

Steam or water injection involves the introduction of either medium into the combustor flame zone to lower the flame temperature, thus reducing NOx formation. Typically, this will reduce NOx emissions up to 60%. Dry low emissions (DLE or DLN) is a type of dry control which involves a major modification to the turbine's combustion system. Unlike diffusion flames where the fuel and air mixes and combusts at the same time, DLE combustors are premixed, where the air and fuel mix first and then are combusted to produce a lower flame temperature. In addition, these systems operate under lean conditions, often with dual staged-combustion, further lowering NOx emissions. DLE technology can achieve NOx levels between around 10 and 45 ppm.

Selective catalytic reduction (SCR) is the most effective technology that can achieve ultra low NOx emissions. The technology uses a precious metal catalyst that selectively reduces NOx in the presence of ammonia. Ammonia is injected in the flue gas stream where it reacts with NOx and oxygen in the presence of the catalyst to produce nitrogen and water vapor. The typical operating temperature of the exhaust gas is between 450 and 850 degrees F.

Proposed BARCT level and Emission Reductions

In command and control, SCAQMD Rule 1134 set limits for gas turbines for a range of sizes (ratings), with the limits varying between 9 and 25 ppm, corrected to 15% oxygen content. The 2005 NOx RECLAIM amendment proposed no new BARCT for gas turbines, so these units have been only required to meet the Year 2000 Tier 1 emission level. The Tier 1 emission level for natural gas and diesel fueled gas turbines in equivalent to 0.06 lb/MMBTU, which corresponds to approximately 17 ppm at 15% O_2. This reference limit can be higher, depending on the efficiency of the unit. The majority of the RECLAIM units in this source category have not installed the controls to meet the Tier 1 emission level.

For the non-~~electrical~~ electricity generating facility, non-refinery gas turbines in the top 37 facilities and based on vendor discussions and achieved in practice BACT installations, the proposed BARCT level for this source category is 2 ppm @15% O_2, and the control technology to achieve the NOx reductions is SCR. For units that are emitting less than 40 ppm NOx at 15% O2, a 2 ppm emission level is achievable with SCR only. In Figure Q.1, this would apply to the 7 units to the right of the chart. However, for those units emitting at 40 ppm, a 95 percent reduction is achievable. For the remainder of these units, a 95% reduction would achieve around 3 to 4 ppm. The power generating offshore units would achieve 8 ppm at a 95% reduction for their current emission level since they have the highest emissions. The offshore gas compression turbines can achieve 5 ppm at a 95% reduction. A 2 ppm level would be achievable for the units emitting above 40 ppm if these units would install either wet or dry combustion controls to comply with the Tier 1 emission level. The single power generating gas turbine that is non-OCS currently operates with an SCR system permitted at 5 ppm for NOx. Staff believes that a replacement of the catalyst system would be sufficient to meet the 2 ppm BARCT level. As a worst case, a present worth value was calculated from the same curve derived from existing refinery power generating units for a complete replacement of the SCR catalyst and equipment.

The emission reductions achieved from both subsets of units emitting above and below 40 ppm in the non-OCS sector are 1.04 tons per day. This is the incremental reduction from the Tier 1 level. The OCS units would add an additional 0.07 tons per day.

Cost Effectiveness

The total installed costs (TIC), which include equipment and installation costs were calculated by using vendor-supplied costs. The vendor-supplied costs were for the SCR equipment only. This consists of the SCR housing, SCR catalyst, mixing ductwork, ammonia injection skid, PLC system, and CFD flow modeling.

Installation costs can vary due to the type of facility and any site-specific limitations. To derive a reasonable estimate, the installation costs were calculated to be double (or 200%) of the equipment costs. Since an SCR installation at an offshore facility could be more complicated than a typical onshore installation, the installation costs were calculated at four times the equipment costs to account for the unique site considerations for this type of installation. The annual operating costs include catalyst replacement (replacement interval of three years), ammonia consumption (19%), and electrical consumption.

A present worth value (PWV) was then calculated for each gas turbine using the TIC and annual costs (AC), and assumes a 4% interest rate and a 25-year equipment life per the equation below.

$$\text{PWV} = \text{TIC} + (15.622 \times \text{AC})$$

A cost effectiveness value was then calculated for each gas turbine using the present worth value and dividing by the incremental emission reductions (ER, in tons per day) from the Tier 1 level over the control equipment life (25 years). This method of calculating cost effectiveness utilizes the Discounted Cash Flow method (DCF).

$$\text{Cost Effectiveness} = \text{PWV} / (\text{ER} \times 365 \times 25 \text{ years})$$

Conversion to a Levelized Cash Flow (LCF) requires a calculation using the following equation:

$$\text{LCF Cost Effectiveness} = (\text{TIC} \times \text{CRF}) + \text{AC} / (\text{ER} \times 365),$$

where CRF is the Capital Recovery Factor assuming a 4% interest rate over an equipment life of 25 years.

The cost effectiveness for non-~~electrical~~ electricity generating facility, non-OCS gas turbines ranges from $4,700/ton to $35,900/ton ($7,500/ton to $57,500/ton, using LCF). This is to achieve a 95% reduction for those units emitting higher than 40 ppm and to achieve 2 ppm for those emitting lower than 40 ppm. For these gas turbines, the installation of SCR to treat NOx is cost effective. If the units emitting above 40 ppm install either wet or dry combustion controls to meet the Tier 1 emission level, then meeting 2 ppm is achievable.

The cost effectiveness for the offshore gas turbines ranges from $51,400/ton to $59,200/ton ($82,300/ton to $94,700/ton, using LCF). These figures reflect the power generating units achieving 8 ppm and the gas compression units meeting 5 ppm with SCR only. Since the cost effectiveness is above $50,000/ton and based on past rule makings, the OCS gas turbines are not considered cost effective in achieving the incremental NOx BARCT reductions from the Tier 1 level.

Table Q. 2 - Cost Effectiveness for Non-~~Electrical~~ Electrcity Generating Facility Gas Turbines

Unit	TIC ($)	AC ($)	PWV ($)	ER (tpd)	DCF C.E. ($/ton)

Review of ETS's Analysis for Metal Heat Treating Furnaces above 150 MMBTU/hr

ETS, Inc. was commissioned by SCAQMD staff to provide an independent evaluation of the previously described BARCT and cost analysis. ETS concurs with the costing information and the conservative approach taken for calculating the costs for the possibly varied installations, given the site-specific aspects. ETS also concurs with the achievability of the reductions using SCR technology and no changes to the cost estimates were made.

Appendix R – Non-Refinery Stationary Internal Combustion Engines

Process Description

Stationary Internal Combustion Engines (ICEs) are used primarily to drive pumps, compressors, or to generate power. In command and control, Rule 1110.2 limits the NOx emissions for all gaseous and liquid-fueled engines that are above 50 brake horsepower (bhp). There are generally two types of engines, spark-ignited (SI) or compression ignited (CI) engines. SI engines ignite the air/fuel mixture with a spark while CI engines use the heat of compression to ignite the fuel that is injected into the combustion chamber.

Engines can run at either stoichiometrically rich or lean conditions, depending on the air to fuel ratio. Rich combustion corresponds to an air /fuel ratio that is fuel-rich while lean combustion corresponds to a fuel-lean air/fuel ratio. Small SI engines typically run as rich burn, but many larger units as well as CI engines operate under lean conditions. Usually, more air is inducted than is required for complete combustion and the resultant exhaust oxygen level is high (over 5%). Rich burn engines typically operate very close to stoichiometric conditions by drawing only the necessary air to combust the fuel. Spark-ignited engines are typically fired on gaseous fuels such as natural gas, while compression-ignited engines are fired on liquid fuels such as diesel.

In 2005, there was no new BARCT proposed for this source category. Consequently, the emission factor has remained unchanged since 2000 (Tier 1), which equates to about 57 ppm at 15% O_2 for natural gas-fired engines. During the 2008 amendment of Rule 1110.2, most stationary ICEs outside of RECLAIM (with the exception of biogas engines) were required to meet a NOx emission limit of 11 ppm at 15% O_2 by July 1, 2011.

Current Emission Inventory

Among the top thirty seven NOx emitting facilities in the RECLAIM universe, there are thirty one engines that are either major or large source units. Nine of these units are controlled with NSCR (non-selective catalytic reduction) as these engines are rich burn. Sixteen of these engines are SI lean burn units, while the remaining six are CI lean burn units. The CI lean burn units are all operated on an offshore oil drilling platform (outer continental shelf, or OCS). Six of the SI lean burn units are two-stroke engines (See Table 1). The engine sizes range from a little over 700 bhp to 5,500 bhp.

Table R. 1 - 2011 Emissions for Internal Combustion Engines at Top 37 Facilities

Engine Type (at Top 37 Facilities)	Number of engines	2011 emissions (tpd)
Lean Burn (Spark-Ignited)	16	0.34
Lean Burn (Compression Ignited), OCS	6	0.03
Rich Burn (Spark-Ignited)	9	0.02
~~Electrical~~ <u>Electrcity</u> Generating Facility (2 stroke)	6	0.18
Total	37	0.56

There are also 6 additional ICEs that belong to a power producing facility, and the combined emissions from these engines were 0.18 tons per day in 2011. These engines are 2-stroke engines that are fired on diesel fuel due to the lack of access to natural gas.

CI engines, which are fired on diesel, have the highest NOx emission concentrations in this source category. 2-stroke SI engines have higher NOx emissions than 4-stroke SI engines since the higher efficiencies in 2-stroke engines translate to a hotter combustion temperature that can create more NOx.

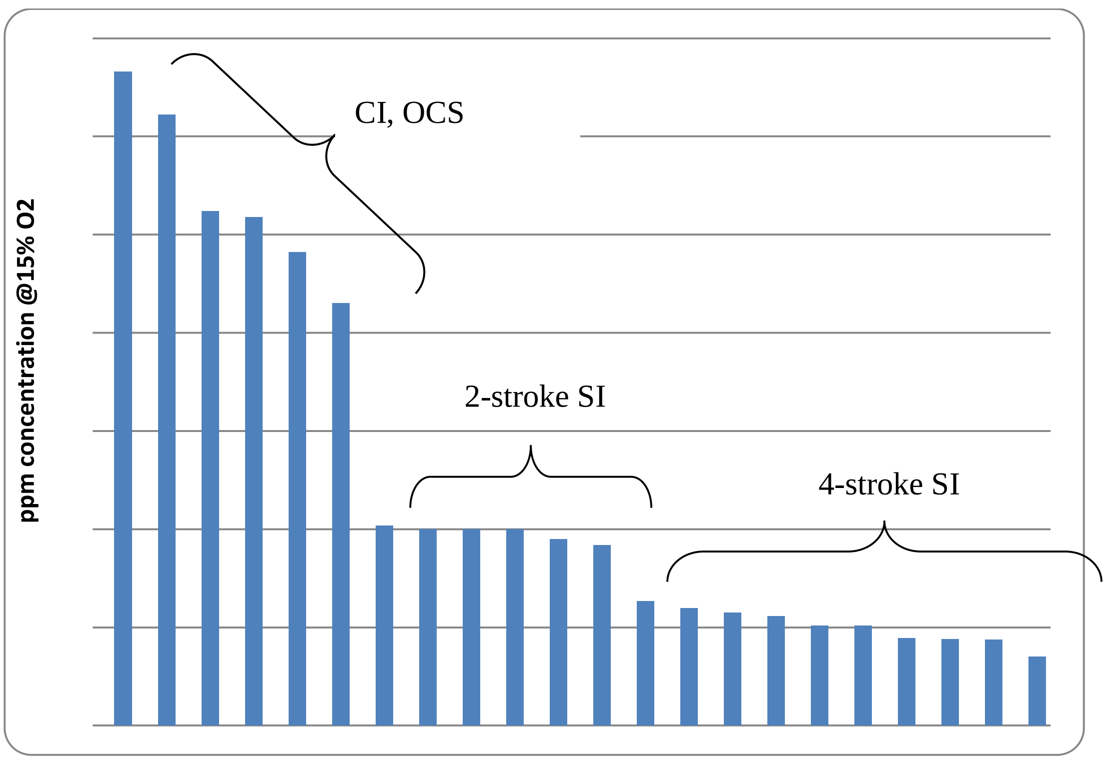

Figure R. 1 - NOx concentrations for Lean Burn ICEs at Top 37 Emitting Facilities

Control Technology

The flue gas from rich burn engines is typically very low in excess oxygen. This enables NOx reduction to take place via Non-Selective Catalytic Reduction technology (NSCR), which is inexpensive, readily installed, and simultaneously removes NOx, CO, and VOC. NSCR (or three-way) catalysts have been commercially available for many years and can achieve NOx removal efficiencies of over 90 percent. The catalyst reduces NOx to nitrogen and oxygen in the presence of CO and VOC, while simultaneously oxidizing CO and VOC to form carbon dioxide and water. Precise air/fuel ratio control is required since the catalytic reactions must occur within a narrow air/fuel ratio band.

With lean burn exhaust the higher oxygen content does not allow effective removal of NOx with NSCR. On this basis, CO and VOC will have a preferential reaction with the oxygen instead of the NOx. In this case, Selective Catalytic Reduction (SCR) is the technology of choice. Oxygen is an essential ingredient in the SCR reactions and the excess oxygen in the exhaust gas provides this. Ammonia (or urea) is injected in the flue gas stream where it reacts with NOx and oxygen in the presence of a catalyst to produce nitrogen and water vapor. The catalyst material is typically a base metal catalyst such as titanium dioxide or vanadium pentoxide, and operates within a temperature range of 450 to 850 F.

Proposed BARCT level and Emission Reductions

The 2008 amendment to Rule 1110.2 established a NOx emission level of 11 ppm @15% O_2 for most IC engines. The technology identified for rich burn engines was NSCR while the technology identified for lean burn engines was SCR. The effective date for complying with the final rule limit has been in effect for over four years. NSCR is feasible for rich burn engines and SCR is feasible for both two-stroke and four-stroke lean-burn engines.

The 2005 RECLAIM amendment proposed no new BARCT for IC engines, so these units have been only required to meet the Year 2000 Tier 1 emission level. For the non-~~electrical~~ electricity generating facility engines in the top 37 emitting facilities, the proposed BARCT level is 11 ppm @15% O_2. The rich burn engines in this category have all been retrofitted with NSCR and most of them meet the proposed BARCT level. These three way catalysts were installed to control CO and VOC for compliance with Rule 1110.2 requirements by July 1, 2011, since these pollutants are not governed under RECLAIM rules. There is an added benefit with three way catalysts because they also control NOx and this has resulted in emission reductions for these engines. For lean burn engines, however, the control technology to achieve the NOx reductions is SCR. If all the non-OCS engines in this category were to achieve the proposed BARCT level, the emission reductions from the Tier 1 level would be 0.84 tons per day. There is a portion of this reduction that is attributed to the rich burn engines and it amounts to 0.07 ton per day. Recent source tests indicate that the majority of these engines are already meeting the proposed BARCT level of 11 ppm. It is assumed that these engines will continue to meet the 11 ppm emission level.

The ~~electrical~~ electricity generating facility engines, since they are 2-stroke diesel engines, are more difficult in terms of reducing NOx emissions. These engines are isolated and there is no other fuel backup. The unique nature of these engines provides a challenge with regards to very low allowable backpressures, which makes SCR an inflexible treatment option. Therefore, there is no new proposed BARCT for ~~electrical~~ electricity generating facility ICEs.

The OCS engines in this category will not be subject to the new BARCT because the engines at offshore platforms run rig generators that are often variable in load. SCR systems need a more constant load so that the proper operating temperatures can be sustained for effective NOx removal.

Cost Effectiveness

The total installed costs (TIC), which include equipment and installation costs were calculated by using both vendor-supplied costs along with installation costs from an existing SCR installation on a lean-burn engine. The vendor-supplied costs were for the SCR equipment only. This consists of the SCR housing, SCR catalyst, mixing ductwork, expansion joint, urea injection skid (control system, pump, dosing unit), and an air compression/drying system.

Installation costs can vary due to the type of facility and any site-specific limitations. To derive a reasonable estimate, the costs from an achieved in practice SCR installation on a lean-burning engine were used. This engine is located at Orange County Sanitation District (OCSD), is fired on natural gas and digester gas, and is retrofitted with an oxidation catalyst and SCR. It was installed in 2009 and has been consistently been meeting the 11 ppm NOx limit of Rule 1110.2. The catalyst system had to be placed on an externally constructed platform because of the site constraints inside the engine building. These additional costs have been included as part of this analysis in anticipation of any supplemental support structures necessary to accommodate the SCR system. The 2009 dollar figures for the OCSD installation were raised to 2013 dollar values using the Marshall & Swift Index inflation factor. The installation costs for all the affected engines were scaled by horsepower based on the costs for this installation at OCSD.

The annual operating costs include catalyst replacement, reagent consumption, reagent delivery system maintenance, and electrical consumption. The annual costs for the OCSD installation assume a 3 year SCR catalyst replacement interval and were scaled for the engines in this source category by engine horsepower. For two-stroke engines, a very conservative replacement interval of one year was selected due to the potentially more contaminated exhaust gas stream (ash, soot) from this type of engine.

A present worth value (PWV) was then calculated for each engine using the TIC and annual costs (AC), and assumes a 4% interest rate and a 25-year equipment life per the equation below.

PWV = TIC + (15.622 x AC)

A cost effectiveness value was then calculated for each engine using the present worth value and dividing by the incremental emission reductions (ER, in tons per day) from the Tier 1 level over the control equipment life (25 years). This method of calculating cost effectiveness utilizes the Discounted Cash Flow method (DCF).

Cost Effectiveness = PWV / (ER x 365 x 25 years)

Conversion to a Levelized Cash Flow (LCF) requires a calculation using the following equation:

LCF Cost Effectiveness = (TIC x CRF) + AC / (ER x 365),

where CRF is the Capital Recovery Factor assuming a 4% interest rate over an equipment life of 25 years.

Table R. 2 - Cost Effectiveness for Lean-Burn, Non-OCS ICEs

Unit	TIC ($)	AC ($)	PWV ($)	ER (tpd)	DCF C.E. ($/ton)
1	890,182	36,625	1,462,338	0.036	4,500
2	890,182	36,625	1,462,338	0.033	4,900
3	890,182	36,625	1,462,338	0.033	4,800
4	890,182	36,625	1,462,338	0.034	4,700
5	890,182	36,625	1,462,338	0.035	4,600
6	1,386,291	82,640	2,677,289	0.043	6,900
7	485,628	25,696	887,048	0.019	5,000
8	485,628	25,696	887,048	0.019	5,000
9	1,307,772	77,475	2,518,084	0.038	7,300
10	485,628	25,696	887,048	0.019	5,100
11	1,307,772	77,475	2,518,084	0.037	7,500
12	2,319,249	100,719	3,892,680	0.084	5,000
13	2,319,249	100,719	3,892,680	0.084	5,000
14	2,319,249	100,719	3,892,680	0.085	5,000
15	2,319,249	100,719	3,892,680	0.083	5,200
16	2,319,249	100,719	3,892,680	0.084	5,000

The cost effectiveness for non-~~electrical~~ electricity generating facility IC engines ranges from \$4,500/ton to \$7,500/ton (\$7,200/ton to \$12,000/ton, using LCF). For these engines, the installation of SCR to treat NOx is cost effective.

Review of ETS's Analysis for Non-Refinery Stationary Internal Combustion Engines

ETS, Inc. was commissioned by SCAQMD staff to provide an independent evaluation of the previously described BARCT and cost analysis. ETS concurs with the costing information and the conservative approach taken for calculating the costs for the possibly varied installations, given the site-specific aspects. ETS also concurs with the achievability of the reductions using SCR technology and no changes to the cost estimates were made.

Appendix S – Non-Refinery Boilers >40 MMBTU/hr

In the top 37 emitting facilities, there are four boilers that are above 40 MMBTU/hr. They range between 49 and 247.3 MMBTU/hr. The 2005 BARCT level for these units was 9 ppm at 3% O_2. The incremental NOx reduction going from 9 ppm to a proposed BARCT level of 2 ppm would be 0.01 tons per day.

SCR would be the technology of choice for achieving NOx reductions for larger boilers. The costs for retrofitting these units were estimated from the ETS-adjusted vendor quotes for a similar sized installation for the sodium silicate furnace. The present worth value for the installation in on a 56.6 MMBTU/hr combustion furnace is $4,602,745. The present worth value for the largest unit was calculated from the cost curve developed for refinery boilers and heaters (Figure B-3).

The DCF cost effectiveness for all of the four units were calculated to be above $150,000 per ton of NOx. Therefore, retrofitting with SCR would not be cost effective. ETS concurs that the costs for installing SCR would not be cost effective for this source category.

Table S. 1 - Cost Effectiveness for Non-Refinery Boilers >40 MMBTU/hr

Unit	Rating (MMBTU/hr)	PWV ($)	Incremental Emission Reductions (tpd)	DCF Cost Effectiveness ($/ton)
1	57	4,602,745	0.003	182,107
2	62.5	4,602,745	0.003	153,938
3	49	4,602,745	0.0001	6,447,425
4	247.3	13,527,310	0.004	380,515

   Name: ______________________________
   Title: ______________________________
   Phone Number: ________________________
   Email Address: ________________________

Top NOx Emitting Equipment or Processes

(* The attached list may contain the information requested)

2. * Please verify the attached list for the top 10 NOx emitting equipment and processes at your facility in Compliance Year 2011 and their emissions.

3. Please mark on the attached list the NOx control equipment installed **after the 2005 NOx RECLAIM amendment**

Boilers, Heaters, Furnaces, Kilns, Turbines, and Cogeneration Units (Major and Large Sources)

4. For each major and large combustion source at your facility, please verify the following information in the attached list, and provide information if the attached list does not contain this specific information:
   k. * Device description, Device ID, Process Name
   l. * Emissions in CY 2011 (tons per day)
   m. * Maximum unit rating (MMBTU/hr)
   n. * Type of fuel used
   o. Fuel usage rate and BTU content of fuel
   p. Flue gas flow rate (million dry standard cubic feet), temperature, oxygen and water content
   q. Representative flue gas analysis and fuel gas analysis
   r. NOx concentration in the exhaust flue gas (ppmv at 3% O_2 or ppmv at 15% O_2). Please attach a copy of the most current source test reports/results.
   s. Allowable back pressure
   t. * Control technology used (e.g. LNB, SCR, NOx scrubber)

5. For the control technology identified in item #4 above:

h. Device description, Device ID
i. Manufacturer's name and performance. Please attach a copy of manufacturer's specification/guarantee
j. Design parameters (e.g. maximum flue gas flow rate, inlet and outlet ppmv, ammonia slip)
k. If the control device is shared between multiple NOx emitting sources, please identify all other sources that are vented to this control device
l. Dimension of the add-on NOx control device (e.g. length, width, height of the SCR, catalyst volume)
m. Cost information (capital costs, installation costs, and annual operating costs)
n. Installation date (e.g. July 2005)

6. Provide drawings that show location and distances between the major and large NOx sources at the facility.

Reports Submitted Under the U.S. EPA Consent Decree

7. If the facility must install control technology to reduce the NOx emissions under an U.S. Environmental Protection Agency (EPA)'s consent decree, please provide the District a copy of the most recent reports/test results submitted to the EPA related to this consent decree.

Feasible Control Approach Including Energy Efficiency Project

8. List any feasible control approach that your facility plans to install, including replacement of the existing units with higher energy efficient units, to further reduce your facility's NOx emissions and green-house gases. Provide a brief description of the control approach, manufacturer's name, estimated emission reductions, and cost information.

If you have any questions, please contact either:
Kevin Orellana (909) 396-3492, korellana@aqmd.gov, or
Gary Quinn, P.E. (909) 396-3121, gquinn@aqmd.gov

Please submit information via e-mail by July 12, 2013
to Kevin Orellana and Gary Quinn.
Thank you for participating in the Survey.

Part III – RTC Reduction Approaches

Part III contains information pertinent to the RTC reductions estimation. Part III contains three appendices: Appendix U contains a discussion on staff's approaches and calculation to determine the RTC reductions based on the 2015 BARCT levels assessed in Part I for the refinery sector and Part II for the non-refinery sector. Staff's calculation were also based on the 2011 audited NOx emissions for all NOx RECLAIM facilities except ~~electrical~~ electricity generating facilities. For ~~electrical~~ electricity generating facilities, staff used the 2012 baseline emissions. Appendix V contains the 2011 audited emissions, and Appendix W contains the 2012 baseline emissions for ~~electrical~~ electricity generating facilities.

Appendix U – Staff's Proposal and CEQA Alternatives

Staff has considered several options to determine the most appropriate RTC shave distribution to effect emission reductions that will protect the environment, satisfy the state and federal CAA requirements, and satisfy AQMP commitments, while concurrently providing for growth and safeguards for the continued functioning of the RECLAIM program. The RTC reductions with the application of BARCT total 14.79 tons per day. However, an adjustment is proposed to the total RTC reductions to account for issues that have been raised by stakeholders regarding the BARCT analysis. These issues primarily focused on the potential uncertainties of the control costs for refinery boilers and heaters and the reliability and consistency in maintaining controlled NOx concentrations for the coke calcining unit. With these adjustments, the RTC reduction that would be applied for the shave approaches would total 14 tons per day by 2023.

The shave proposals under consideration affect four major groups within the NOx RECLAIM universe:

- Major Refineries and Investors
- Top 90% of RTC Holders
- Others (Bottom 10 percent of RTC Holders)

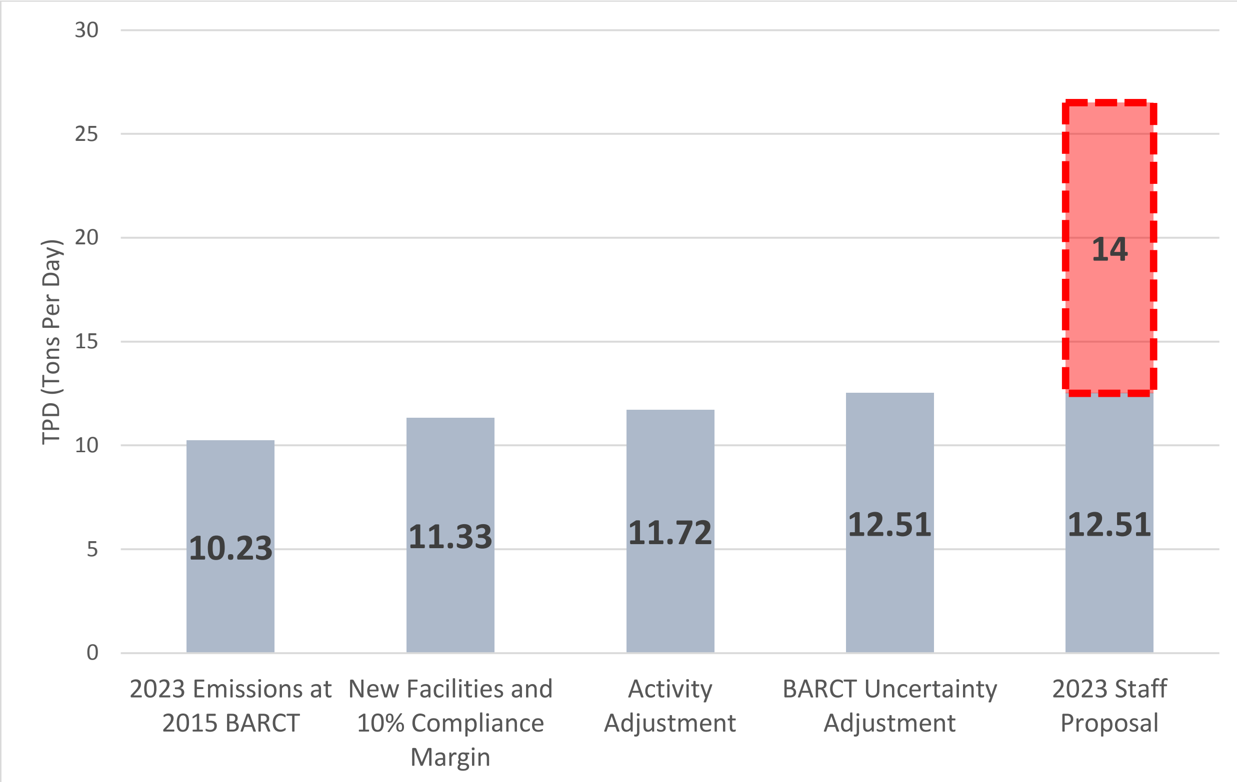
The bottom 10 percent of RTC holders would be exempted from an RTC reduction under the staff proposal. It should be noted that the newer ~~electrical~~ electricity generating facilities among the top 90% of RTC are subject to NSR holding requirements for their equipment, which is mostly at BACT. Staff is proposing a Regional NSR Holding Account for these facilities in order provide some relief given their ongoing NSR obligations of holding RTCs at the equipment's potential to emit level at the beginning of each compliance year.

Staff Proposal

Calculation of Remaining Emissions

The remaining emissions are determined by summing the calculated remaining emissions in 2023 with economic growth factors applied and with BARCT applied for both the refinery and non-refinery sectors (Tables 5.1 and 5.2). The remaining emissions total 10.23 tons per day. Emissions accounting for new RECLAIM facilities since the 2011 base year are added and a 10% compliance margin is applied, so the remaining emissions become 11.33 tons per day. Next, an activity adjustment, accounting for atypical operation conditions in 2011, is applied which results in 11.72 tons per day remaining. Lastly, a BARCT uncertainty adjustment is applied to account for uncertainties in the analysis. After all the adjustments, the total remaining emissions are 12.51 tons per day. This is equivalent to a 14 ton per day reduction from the allocation cap of 26.51 tons per day. Figure U.1 illustrates the adjustments and the total RTC reduction.

Figure U.1 – 2023 Adjustments and Allocation Target



The staff proposal for the shave would affect the top 90 percent of RTC holders, which includes major refinery facilities. Investors would also be shaved at this level. Refineries and Investors are designated as Category A facilities in Table U.1. Non-major refinery facilities in the top 90% of RTC holders and ~~electrical~~ electricity generating facilities among the top 90% of RTC holders would be included in the shave as Category B1 and B2 facilities, respectively. The reductions for the facilities subject to the shave would be weighted by the BARCT reduction contribution for major refineries and all other facilities, with investors grouped with the major refineries. RTC holdings for major refineries and investors would be shaved by 66 percent. For non-major refineries and all other facilities among the top 90 percent of RTC holders, the RTC holdings would be shaved by 49 percent. See Tables U.1 and U.2.

Table U.1 - List of 56 Affected Facilities Plus Investors

COUNTS

Category	Description	
A	Major Refineries	9
A	Investors (Counted as 1 Facility)	1
B1	Top 90% Holder, Non-~~Electrical~~ Electrcity Generating Facilities	26
B2	Top 90% Holder, ~~Electrical~~ Electrcity Generating Facilities	21
TOTAL		57

Table U.2 - RTC Reduction Calculation

Refinery Reductions Beyond 2005 BARCT, tpd	6.00
Non-Refinery Reductions Beyond 2005 BARCT, tpd	2.77
Total, tpd	8.77

Refinery Contribution to Emission Reduction (6.00 / 8.77 x 100)	68%
Non-Refinery Contribution to Emission Reduction (2.77 / 8.77 x 100)	32%

Total RTC Allocation in 2023	26.51
Remaining 2023 Emissions After BARCT and Growth	11.72
Minus BARCT Uncertainty Adjustment	0.79
Total RTC Reduction (26.51 - 11.72 - 0.79)	14

Weighted Reduction for Refinery (14.00 x 68%)	9.58
Weighted Reduction for Non-Refinery (14.00 x 32%)	4.42
Total Reduction	14

Major Refinery + Investor Holdings for Top 90%	14.57
Non-Major Facility Holdings + All ~~Electrical~~ Electrcity Generating Facility Holdings for Top 90%	9.09
RTC Holdings for Top 90% of Holders, Including Investors (14.57 + 9.19)	23.66

Remaining Major Refinery + Investor RTC Holdings (14.57 - 9.58)	4.99
% Shave to this Sub-Universe (9.58 / 14.57) x 100	66%

Remaining Non-Refinery RTC Holdings (9.09 - 4.42)	4.67
% Shave to this Sub-Universe (4.42 / 9.09) x 100	49%

RTC Reductions = Current Holdings (26.51 tpd) – Remaining Emissions in 2023 (11.72 tpd) = 14.79 tpd
Total RTC Reductions = 14.79 tpd – (BARCT adjustment of 0.79 tpd) = 14 tpd

CEQA Alternatives

CEQA Alternative 1: This approach would be an across the board RTC reduction and would affect all RECLAIM facilities and investors. The RTC holdings would be shaved by 53 percent overall.

CEQA Alternative 2: This approach, the most stringent, would also be an across the board RTC reduction affecting all RECLAIM facilities and investors, but would not include the 10 percent compliance margin or the BARCT adjustment for refinery equipment. The total RTC reduction would be 15.82 tons per day under this approach and the RTC holdings would be shaved by 60 percent overall.

CEQA Alternative 3: This approach has been proposed by industry representatives and is an across the board shave that would affect all RECLAIM facilities and investors. For this calculation, the base year emissions at the proposed BARCT level would be subtracted from the base year emissions at the previous BARCT level (Year 2000 or 2005). The result would be an RTC reduction of 33 percent to all RECLAIM facilities and investors.

CEQA Alternative 4: This is the "No Project" approach and no RTC reduction would be applied to any RECLAIM facility or investor.

CEQA Alternative 5: This approach would affect all RECLAIM facilities and investors. The RTC reductions would be weighted by the BARCT reduction contribution for major refineries and all other facilities, with investors grouped with the major refineries. RTC holdings for major refineries and investors would be shaved by 66 percent. For non-major refineries and all other facilities, the RTC holdings would be shaved by 37 percent.

Table U.3 - NOx RECLAIM Shave Options and CEQA Alternatives

		Major Refineries/ Investors	Non-Major Facilities	~~Electrical~~ Electrcity Generating Facilities	Bottom 10% of Holders
	Staff Proposal Under Consideration				
Staff Proposal	**Shave applied to 90% of RTC Holders (Weighted by BARCT Reduction Contribution)** *56 total facilities, plus investors as 1 company, and includes 47 non-major refinery facilities*	**66~~7~~%** **(9 Facilities)**	**49~~6~~%** **(26 Facilities)**	**49~~6~~%** **(21 Facilities)**	**0%** **(219 Facilities)**
	CEQA Alternatives Under Consideration				
CEQA Alternative #1	**Across the Board** *Affects all facilities and investors*	**53%**	**53%**	**53%**	**53%**
CEQA Alternative #2	**Most Stringent Approach** *Across the Board without 10% Compliance Margin*	**60%**	**60%**	**60%**	**60%**
CEQA Alternative #3	**Industry Approach** *Across the Board: Difference between previous BARCT and new BARCT*	**33%**	**33%**	**33%**	**33%**
CEQA Alternative #4	**No Project**	**0%**	**0%**	**0%**	**0%**

Tradable/Usable and Non-Tradable/Non-Usable Factors in Rule 2002(f)(1)(B) and (C)

The Tradable/Usable NOx Adjustment Factor is derived by dividing the amount of RTCs remaining after the shave for each compliance year by the total holdings prior to the beginning of the shave (September 22, 2015). For those facilities subject to subparagraph (f)(1)(B) [listed in Rule 2002 Table 7] the total Infinite Year Block (IYB) total holdings in 2022 prior to the beginning of the shave is 14.57 tons per day. Similarly, for those facilities subject to subparagraph (f)(1)(C) [listed in Rule 2002 Table 8] the total holdings prior to the beginning of the shave is 9.09 tons per day. Both of these values are presented in Table U.2 of this report.

The proposed RTC reduction for each compliance year is presented in Chapter 5 of this report are:

2016: 4 tons per day
2017: 0 tons per day
2018: 2 tons per day
2019: 2 tons per day
2020: 2 tons per day
2021: 2 tons per day
2022 2 tons per day

The proportion of RTC reductions based on initial holdings and remaining RTC for the Table 7 and Table 8 facilities are as follows:

Compliance Year	Table 7 Facilities		Table 8 Facilities	
	Reductions (TPD)	A_i Remaining (TPD)	Reductions (TPD)	B_i Remaining (TPD)
2016:	2.74	11.83	1.26	7.82
2017:	0	11.83	0	7.82
2018:	1.37	10.46	0.63	7.20
2019:	1.36	9.11	0.64	6.56
2020:	1.37	7.74	0.63	5.93
2021:	1.37	6.37	0.64	5.30
2022	1.38	4.99	0.63	4.67

The Tradable/Usable NOx Adjustment Factor is calculated as follows:

Table 7 Facilities = $A_i/14.57$

Table 8 Facilities = $B_i/9.09$

The Non-tradable/Non-usable NOx Adjustment Factor is derived by dividing the annual amount of RTC reductions starting in 2016 by the total holdings prior to the beginning of the shave. For the Table 7 and 8 facilities the annual amount of Non-tradable/Non-Usable holdings would be as follows:

Compliance Year	Table 7 Facilities RTC Reductions		Table 8 Facilities RTC Reductions	
	Annual (C_i) (TPD)	**Adjustment Factor**	**Annual (D_i) (TPD)**	**Adjustment Factor**
2015	0	0	0	0
2016	2.74	0.188	1.26	0.139
2017	0	0	0	0
2018:	1.37	0.094	0.63	0.069
2019:	1.37	0.093	0.63	0.07
2020:	1.37	0.094	0.63	0.069
2021:	1.37	0.094	0.63	0.07
2022	1.37	0.094	0.63	0.069
2023 and after	0	0	0	0

The Non-tradable/Non-usable NOx Adjustment Factor is calculated as follows:

Table 7 Facilities = $C_i/14.57$

Table 8 Facilities = $D_i/9.09$

Regional NSR Holding Account

In addition to the Non-tradable/Non-usable account, newer ~~electrical~~ electricity generating facilities subject to the shave with ongoing NSR holding requirements (entered RECLAIM after October 15, 1993) will have access to this account under specific circumstances, which will be funded by the shaved portion of each affected facility's holdings for every compliance year of the shave beginning in 2017. At the end of the shave, 49% of the holdings from newer ~~electrical~~ electricity generating facilities subject to NSR requirements will be held in the Regional account. For the first year of the shave, however, there will be no portion that will go into the account. The funding will begin on the second year, when the non-tradable account holdings expire. Access to credits for the purposes of NSR or compliance with annual emissions in the first year of the shave will be provided by the non-tradable account if the rolling average RTC threshold price trigger is reached or in a State of Emergency for power generation declared by the Governor in the Basin. The table below contains the yearly and cumulative holdings that will go into the account:

Compliance Year	Holdings for Regional NSR Holding Account (tpd)	Cumulative Balance (tpd)
2016	0	0
2017	0.237	0.237
2018	0	0.237
2019	0.118	0.355
2020	0.118	0.473
2021	0.118	0.591
2022	0.118	0.709
2023+	0.118	0.827

The total holdings that will be contained in the Regional NSR Holding Account programmatically will be 0.83 tons per day in 2023 and beyond.

The list of ~~electrical~~ electricity generating facilities in the top 90% of RTC holders that are subject to NSR holding requirements and are eligible to use the Regional Account for NSR purposes are as follows:

Facility ID	Facility Name
160437	SOUTHERN CALIFORNIA EDISON
152707	CPV SENTINEL LLC
146536	WALNUT CREEK ENERGY, LLC
128243	BURBANK CITY,BURBANK WATER & POWER,SCPPA
115314	LONG BEACH GENERATION, LLC
153992	CANYON POWER PLANT
155474	BICENT (CALIFORNIA) MALBURG LLC
127299	WILDFLOWER ENERGY LP/INDIGO GEN., LLC
129816/ 700126	INLAND EMPIRE ENERGY CENTER, LLC/ GENERAL ELECTRIC COMPANY

Table 9 in Rule 2002 lists these facilities and the specific yearly RTC balances that will go to the Regional NSR Holding account from compliance year 2016 and beyond. In 2023, the account would reach full funding and will carry over every year for the purposes of fully or partially fulfilling each facility's NSR demonstration.

Appendix V – 2011 Audited Emissions of 20 tons per day

The 2011 audited NOx emissions for the 281 facilities in RECLAIM are shown in Table V-1.

Table V. 1 - 2011 Audited Emissions

	Note: August 29, 2013 data from RECLAIM Admin team			

Appendix W – 2012 Emissions for ~~Power~~ Electricity Generating Sector

The base year for the BARCT analysis is compliance year 2011. However, the 2011 base year would not be appropriate for this source category due to the uniqueness of its operations. There have been several changes within recent years that have warranted the use of more recent base year data.

The San Onofre Nuclear Generating Station (SONGS) has not been in operation since early 2012 and is now undergoing decommissioning. The power deficit was to be made up by other natural gas fired units in the region. Other existing units are subject to the once-through-cooling (OTC) regulation and will have to be repowered. These repowered units are predicted to be more efficient units that consume less natural gas to produce the same amount of power as their predecessors. Other trends in the industry have begun to affect power availability such as the increased use of renewable power, like wind, water, and solar. The state of California must meet a 33% Renewable Portfolio Standard by 2020, and the inherent volatility of these renewable energy sources means that gas demand must be met almost in real time.

The growth factor for ~~electrical~~ electricity generating facilities came from the 2012 California Gas Report, consistent with what is used for the AQMP projections for these facilities. However, ~~B~~based on the 2014 California Gas Report, gas demand in the future is set to decrease slightly due to the utilization of more efficient ~~electrical~~ electricity generating facilities, greenhouse gas (GHG) reductions, and the increased use of renewable power. The projected emissions in 2023 using compliance year 2011 as the base year used growth factors from SCAG (Southern California Association of Governments) for non-~~electrical~~ electricity generating facilities.

Table W. 1 - Compliance Year 2011 ~~Power~~ Electricity Generating Sector Emissions

Compliance Year 2011 Emissions (tpd)	2011 Emissions at BARCT/BACT (tpd)	Growth Factor	2023 Emissions with Growth (tpd)
1.45	2.57	1.146	2.95

The figures above included those ~~electrical~~ electricity generating facilities among the top 37 NOx emitters in compliance year 2011. An additional 0.34 tons per day came from ~~electrical~~ electricity generating facilities outside the top 37 and was included as part of the “Other Sources” category with a different growth factor.

More recent base year data was obtained using calendar year AER (Annual Emissions Report) fuel usage data for 2012. The calendar year 2012 emissions include those for the major sources only belonging to electric generating facility source category (includes boilers, gas turbines, and ICEs). The emissions from process units and any Rule 219 equipment are almost negligible (the emissions from process units in 2011 were 0.006 tpd).

Table W. 2 - 2012 ~~Power~~ Electricity Generating Sector Emissions Based on Annual Emission Reports (AER) Fuel Usage

Calendar Year 2012 Emissions (tpd)	2012 Emissions at BARCT/BACT (tpd)	Growth Factor	2023 Emissions with Growth (tpd)
2.50	2.35	0.8683	2.04

The growth factor was extrapolated from the tables in the ~~2104~~ 2014 California Gas Report and it shows a slight decrease in demand for natural gas. There were nine ~~electrical~~ electricity generating facilities among the top 37 emitters in compliance year 2011. For this updated analysis, all ~~electrical~~ electricity generating facilities in RECLAIM were included (30 in total) and their emissions at the BARCT or BACT level were calculated. Most of the units are already meeting BARCT or BACT requirements, due to previous rule requirements.

Another unique aspect of the ~~power~~ electricityl generating sector is that many of the newer units are subject to new source review (NSR) holding requirements. Per Rule 2005, if a facility is new (received all its District permits on or after October 15, 1993), it must hold sufficient RTCs in advance of every year at the equipment's potential to emit level. Virtually all power generating units typically operate at a level far below its potential to emit, but the facility must still hold the RTCs to comply with the NSR demonstration. Stakeholders have brought to SCAQMD staff's attention their concern about the shave and whether a power generating facility can still comply with its emission allocation and NSR demonstration concurrently, especially when there is no cost effective method to retrofit their equipment to generate credits.

SCAQMD staff has proposed a safety valve for addressing the concerns of the ~~power~~ electricity generating sector. A Regional NSR Holding Account has been proposed that would consist of RTCs solely to meet the programmatic NSR holding demonstration. Under this approach, individual facility holding requirements would no longer be necessary. Concerns have also been raised in the event that a power emergency is experienced and there is an added demand for power production. SCAQMD staff has also proposed to allow access to the Regional NSR Holding Account if the Governor declares a state of emergency.

Appendix X – Proposed Changes in Rules 2001, 2002, 2005, 2011 and 2012

Rule 2001

Staff is proposing that the owner or operator of an electricity generating facility (EGF) would have the option of having their facility or facilities exit from the NOx RECLAIM program. This opting out of NOx RECLAIM is contingent on the submittal of a plan application subject to plan fees specified in Rule 306. To request this opting-out of the NOx RECLAIM program the following requirements are must be met as demonstrated in an opt-out plan submitted to the Executive Officer:

- At least 99 percent of the EGF's NOx emissions for the most recent three full compliance years are from equipment that meets current Best Available Control Technology (BACT) or Best Available Retrofit Control Technology (BARCT), for NOx.
- The EGF is subject to NOx RECLAIM as of the date of the amendment or has been subject to NOx RECLAIM for at least 10 years as of the plan submittal date.

For the purposes of Rule 2001, an EGF is defined as a NOx RECLAIM facility that generates electricity for distribution in the state or local grid system. However, this type of facility would not include a cogeneration facility. That is, a facility that sequentially produces electricity and another form of useful thermal energy (such as heat or steam) in a way that is more efficient than the separate production of both forms of energy.

Based on the timing that the EGF entered RECLAIM and as part of the opting-out procedures the EGF Facility Permit holder must submit applications to include in its permit and accept permit conditions that ensure all of the following apply:

- For an EGF~~s for which all permits were issued on or after January 1, 1994~~ that does not meet the definition of an existing facility, as defined in Rule 2000(c)(35), the quantity of NOx RTCs for all compliance years after the date of approval of the opt-out plan and required to be held by the facility pursuant to Rule 2005 – New Source Review for RECLAIM must be surrendered by the EGF, retired from the market, and used to satisfy any NOx requirements for continuing obligations under Regulation XIII – New Source Review. If needed to equal this amount, any Non-tradable/Non-usable RTCs and any RTCs corresponding to the EGF's contribution to the Regional NSR Holding Account may be used for this purpose and, if so used, would be removed from the Account.

- For existing EGFs, an amount of NOx RTCs equivalent to the facility's NOx holdings as of September 22, 2015 for all compliance years after the date of approval of the opt-out plan must be surrendered by the EGF, retired from the market.
- Any NOx RTCs held by an EGF beyond those referred above may be sold, traded, or transferred used by the EGF.

Other important requirements associated with EGFs opting-out of NOx RECLAIM include:

- That the EGF operator ensures that all equipment identified in the opt-out plan as meeting BACT or BARCT must not exceed at its respective BACT or BARCT levels of emissions or any existing permit condition limiting NOx emission that is lower than BACT or BARCT as of the date of the opt-out plan submittal.
- Limits on EGF Emissions ~~*For existing EGFs, total facility emissions shall be limited to the amount of Compliance Year 2015 RTCs held as of September 22, 2015. The facility NOx emission limit shall be apportioned to each NOx source in the same proportion as its share of the EGF's emissions during the three complete compliance years prior to the date of opt-out plan submittal.*~~

  - For existing EGFs the total facility emissions would be limited to the amount of Compliance Year 2015 RTCs held as of September 22, 2015.
  - For an EGF that does not meet the definition of an existing facility emissions from each NOx source would be limited to the amount of RTCs required to be held for that source pursuant to Rule 2005 as of the date of opt-out plan submittal.

The owner or operator of multiple EGFs under common control would have one opportunity to apportion the NOx emission limits among its facilities under common control, provided all of the facilities opt out concurrently. The apportionment must be described in the opt-out plan that shall be submitted to the Executive Officer. Each facility shall not have a limit that exceeds the amount of emissions that can be generated by all existing equipment located at the facility. For EGFs for which all permits were issued on or after January 1, 1994, emissions from each NOx source must be limited to the amount of RTCs required to be held for that source pursuant to Rule 2005 as of the date of the opt-out plan submittal.

- Subdivision (j) shall not be applicable to the EGF for any equipment installed or modified after the date of approval of the opt-out plan, and for existing equipment at the earliest practicable date but no later than three years after the date of the approved opt-out plan.
- The EGF operator must continue to comply with the requirements of Rule 2012 – Requirements for Monitoring, Reporting, and Recordkeeping for Oxides of Nitrogen (NOx) Emissions and its associated protocols unless the Executive Officer has approved an alternative monitoring and recordkeeping plan which is sufficient to determine compliance with all applicable rules.
- ~~o.~~ For EGFs not subject to Regulation XXX – Title V Permits, the EGF's permit must be re-designated as an "opt-out facility permit" and shall remain in effect, subject to annual renewal, unless expired, revoked, or modified pursuant to applicable rules. The EGF operator must continue to pay RECLAIM permit fees pursuant to Rule 301(l).
- After an EGF is removed out of NOx RECLAIM, Regulations XI and XIII would apply.

The Executive Officer would approve or deny the opt-out plan within 180 days of receipt of a complete plan, unless the EGF and the Executive Officer have mutually agreed upon a longer time period~~.~~ The Executive Officer will not approve the opt-out plan unless it has been determined that the abovementioned requirements are met (also see subparagraphs (g)(1)(A) and (g)(1)(B)) and the EGF accepts appropriate permit conditions to ensure proper compliance as specified above (also see subparagraphs (g)(2)(B) through (~~G~~H)). If, within 180 days or within the mutually agreed upon time period of receiving a complete opt-out plan, the Executive Officer does not take action on it, the EGF may consider it denied and petition the Hearing Board. The Executive Officer shall not re-issue the facility permit removing the EGF from RECLAIM unless the EGF surrendered the required amount of RTCs pursuant to subparagraph (g)(2)(A). Removal from RECLAIM of an EGF with an approved opt-out plan is effective upon issuance of a facility permit incorporating the conditions mentioned above (also see paragraph (g)(2)).

As currently specified no facility, on the initial Facility Listing or subsequently admitted to RECLAIM, may opt out of the program, unless approved by the Executive Officer according to above described requirements associated with an EGF.

The EGF option of exiting from the NOx RECLAIM program is also mentioned as one of the several exemptions in 2001(i)(1) and (2).

Rule 2002

The purpose of Rule 2002 is to establish the methodology for calculating facility Allocations and adjustments to RTC holdings for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx).

Rule 2002 provides an overview of the RECLAIM Allocations; the establishment of starting, year 2000 and 2003 Allocations, the annual Allocations for NOx and SOx and the adjustments to RTC holdings. Rule 2002 also specifies the requirement for establishing High Employment/Low Emissions (HILO) facilities, Non-Tradable Allocation Credits, and RTC Reduction Exemptions. In addition to these sections of the rule there are various tables specifying RECLAIM equipment emission factors and the identification of certain facilities status with regards to the RECLAIM Allocation adjustment.

The most substantive proposed rule amendments are found in subdivision (f) *Annual Allocations for NOx and SOx and Adjustments to RTC Holdings* as well as the additions of Table 7 - *List of NOx RECLAIM Facilities Referenced in Subparagraph (f)(1)(B)*, Table 8 - *List of NOx RECLAIM Facilities Referenced in Subparagraph (f)(1)(C)*, and Table 9 - *List of NOx RECLAIM Facilities for the Regional NSR Holding Account with Balances (in lbs).* ~~Staff is~~Other important proposed changes include updated and new RTC price threshold values removal of the ~~also proposing to remove subdivision (i)~~ *RTC Reduction Exemption*, and added a new requirement for facility and equipment shutdowns ~~from the Rule 2002~~.

The staff proposal calls for a programmatic reduction of 14 tons per day. Four tons per day would be reduced in 2016 and the remainder would be reduced in equal increments of 2 tons per day from 2018 to 2022. There would be no reductions proposed for the year 2017. These reductions are reflected in subparagraphs (f)(1)(B) and (f)(1)(C). Subparagraph (f)(1)(B) includes all of Major Refineries and Investors. The Major Refineries are listed in Table 7 of Rule 2002. Subparagraph (f)(1)(C) includes all other facilities subject to reductions in NOx RTCs. These facilities are listed in Table 8 of Rule 2002. These adjustment factors would also apply to subsequent owners of any of these facilities.

Thus the remaining NOx RTCs after a shave for any compliance year would be the Tradable/Usable NOx RTC Adjustment factor in (f)(1)(B) multiplied by the RTC holdings (as of September 22, 2015) of all the Major Refineries and Investors listed in Table 7 plus the Tradable/Usable NOx RTC Adjustment factor in (f)(1)(C) multiplied by the RTC holdings (as of September 22, 2015) of all the facilities listed in Table 8. For purposes of assigning the appropriate adjustment factor(s) for any RTC sold by an RTC holder that both purchased and sold RTCs between September 22, 2015 and the date of amendment will be based on a last in/first out basis. ~~at the time each transaction was registered.~~

Since the RTC reductions specified in subparagraph (f)(1)(A) have been realized the conversion of non-tradable/non-usable NOx RTCs to tradable/usable NOx RTCs is no longer applicable to the RTC reductions specified in this subparagraph. The tradable/usable NOx RTCs specified in subparagraph (f)(1)(A) would remain intact and used for calculating RTC reductions for facilities entering the RECLAIM program. However, a similar approach in applying adjustment factors previously specified in subparagraph (f)(1)(A) would now be applied to the RTC reductions specified in subparagraphs (f)(1)(B) and (f)(1)(C).

Many of the proposed amendments to Rule 2002 focus on what will be done to provide access to RTCs to affected ~~electrical~~ electricity generating facilities (EGF) in the RECLAIM program under a State of Emergency related to electricity demand or power grid stability ~~in the Basin~~within the SCAQMD jurisdictional boundaries. Other amendments focus on providing relief from burdensome New Source Review (NSR) holding requirement for newer ~~electrical~~ electricity generating facilities that entered RECLAIM after 1993.

New ~~electrical generating facilities~~ EGFs must hold sufficient RTCs to offset emission increases for one year prior to commencement of operation and at the beginning of every compliance year thereafter. These requirements are triggered in cases where a facility incurs an emission increase as defined under Rule 2005(d) – Emission Increase. Staff has identified ten (10) new ~~electrical~~ electricity generating facilities subject to this requirement. These facilities are listed in Table 9 of Rule 2002. Staff is providing in Table 9 the quantity of NOx RTCs commensurate to the shave amount for these ten new ~~electrical~~ electricity generating facilities. These RTCs would be placed in a Regional NSR Holding Account as per subparagraph (f)(1)(~~G~~F) for the specific purpose of helping to comply with the requirements specified in Rule 2005.

~~According to subparagraph (f)(1)(F), at the conclusion of any of the compliance years 2016 through 2022 if the NOx RTC prices have not exceeded the proposed $22,500 per ton threshold as specified in subparagraph (f)(1)(I) and a State of Emergency related to electricity demand or power grid stability in the Basin as specified in paragraph (f)(4) has not been declared by the Governor, then the Non-tradable/Non-usable NOx RTCs for that compliance year, except for those RTCs specified in subparagraph (f)(1)(G), shall be submitted as part of the State Implementation Plan commitment.~~ According to subparagraph (f)(1)(~~G~~F) the Executive Officer will transfer to a Regional NSR Holding account the amount of NOx RTCs holdings listed in Table 9 of this Rule from the corresponding facilities identified in the same table.~~.~~

The threshold of $15,000 per ton has been updated to $22,500 per ton, consistent with the cost-effectiveness threshold for additional analysis in the 2012 AQMP. (*2012 AQMP, Chapter 4: Control Strategy and Implementation, page 4-43*)

A companion provision to the abovementioned subparagraphs is subparagraph (f)(1)(~~H~~G) which states that for the purposes of meeting the NSR holding requirement as specified in subdivision (f) of Rule 2005, the facilities identified in Table 9 may use a combination of their Tradable/Usable and Non-tradable/Non-usable RTCs specified in subparagraph (f)(1)(C) and the amount for each facility listed in Table 9 which represent the RTCs in the Regional NSR Holding account.

~~Other than the updated price trigger, other proposed changes to subparagraph (f)(1)(I) require the Executive Officer to include in his report to the Governing Board a commitment and schedule to conduct a more rigorous analysis of the RECLAIM program.~~

The deletion of subparagraphs (f)(1)(D), (f)(1)(E), and (f)(1)(F) [existing rule designation] and proposed changes to subparagraphs (f)(1)(~~K~~L) and (f)(1)(~~L~~M) reflect the change from using the adjustment factors in (f)(1)(A) [previous NOx RECLAIM amendment] to the adjustment factors applied in this proposed amendment, as well as updated methods for determining allocations for existing facilities that enter RECLAIM.

Staff is proposing to add RTC price thresholds based on a 3-month averaging period and a minimum RTC price threshold based on a 12-month averaging period. As previously mentioned the current RTC price threshold based on a 12-month averaging period is proposed to be changed from $15,000 to $22,500 per ton.

With regards to the proposed 3-month averaging period staff will calculate the 3-month rolling average RTC price for all trades for the current compliance year. This running assessment will commence on May 1, 2016 with the NOx RTC prices averaged from January 1, 2016 through March 31, 2016. As with the 12-month rolling average staff will update the 3-month and once per month. [subparagraph (f)(1)(E)]

~~Notwithstanding the requirements of non-tradable/non-usable credits specified in subparagraphs (f)(1)(A), i~~In the event that the NOx RTC prices exceed ~~$15,000~~$22,500 per ton (*discrete* current compliance year credits) based on the 12-month rolling average, or exceed $35,000 per ton (*discrete* current compliance year credits) based on the 3-month rolling average calculated pursuant to subparagraph (f)(1)(~~B~~E), the Executive Officer will report the determination to the Governing Board. If the Governing Board finds that the 12-month rolling average RTC price exceeds ~~$15,000~~$22,500 per ton or the 3-month rolling average RTC price exceeds $35,000 per ton, then the ~~incremental~~ Non-tradable/Non-usable NOx ~~reductions~~ RTCs, as specified in subparagraphs (f)(1)(~~D~~B) and (f)(1)(C) valid for the period in which the RTC price is found to have exceeded the applicable threshold,*compliance year in which Cycle 1 facilities are currently operating* shall be -converted to Tradable/Usable NOx RTCs upon Governing Board concurrence. According to subparagraph (f)(1)(~~J~~F), in the event that the NOx RTC prices fall below $200,000 per ton (infinite year block) based on the 12-month rolling average staff will report the determination to the Governing Board. For the purpose of this rule, infinite year block refers to trades involving blocks of RTCs with a specified start year and continuing into the future for ten or more years.

In the event that the infinite year block NOx RTC prices fall below $200,000 per ton based on the 12-month rolling average, calculated pursuant to subparagraph (f)(1)(E) beginning in 2019 for the compliance year in which Cycle 1 facilities are operating, the Executive Officer will report the determination to the Governing Board.
For the purpose of this rule, infinite year block refers to trades involving blocks of RTCs with a specified start year and continuing into the future for ten or more years.

The addition of paragraph (f)(4) describes provisions to convert Non-tradable/Non-usable RTC~~S~~s and the Regional NSR Holding Account during a State of Emergency declared by the Governor related to electricity demand or power grid stability within the SCAQMD jurisdictional boundaries~~in the Basin~~. Specifically, such as a State of Emergency, the current compliance year Non-tradable/Non-usable NOx RTCs held by any electricity~~al~~ generating facilities that generate and distribute electricity to the grid system affected by the State of Emergency may be used to offset emissions after completely exhausting their own Tradable/Usable NOx RTCs.

If such a facility has completely exhausted their Non-tradable/Non-usable NOx RTCs, the owner or operator of the facility may apply for the use of the NOx RTCs in the Regional NSR Holding Account. The use of such RTCs in this Account would be based on availability at the end of each quarter. The owner or operator of each ~~electrical~~ electricity generating facility requesting NOx RTCs from the Regional NSR Holding Account would be required to submit a written request to the Executive Officer specifying the amount of RTCs needed and the basis for requesting the required amount.

The Executive Officer will determine the amount and distribution of the NOx RTCs from the Regional NSR Holding Account based on the requesting facility meeting the following criteria:

(i) The State of Emergency related to electricity demand or power grid stability within the SCAQMD jurisdictional boundaries~~in the Basin~~, as declared by the Governor, was the direct cause of the excess emissions.

(ii) The facility has been ordered to generate electricity in an increased amount and/or frequency due to the State of Emergency.

(iii) The facility has adequately demonstrated their need for the specific amount of RTCs from the Regional NSR Holding Account.

(iv) The facility owner or operator has not sold any part of their RTC holdings for the subject compliance year.

If the total RTCs requested exceed the supply of RTCs in this Account, the RTCs will be distributed proportionately according to the offset needs of the facilities on a quarterly basis. These RTCs will be non-tradable, but usable to offset emissions.

According to paragraph (f)(5) the Executive Officer will report to the Governing Board within 60 days of the end of the quarter in which the State of Emergency was declared~~declaration~~ by the Governor related to electricity demand or power grid stability within the SCAQMD jurisdictional boundaries~~in the Basin~~. Included in this report will be, as applicable:

(i) the quantity of RTCs from the Regional NSR Holding Account that were distributed for compliance with the requirement to reconcile quarterly and annual emissions;

(ii) any adverse impacts that the State of Emergency is having on the RECLAIM program; and

(iii) any potential changes to the RECLAIM program that will be needed to help correct these impacts.

There has also been some changes to paragraph (f)(1)(L~~M~~) that pertain to NOx Allocations for existing facilities that enter RECLAIM after the date of adoption. For this rule provision for Compliance Year 2016 and all subsequent years the amount determined pursuant to subparagraph (d)(1)(A) except the variable B2 shall be the lowest of:

(i) The applicable 2000 (Tier I) Ending Emission Factor for the subject source(s) or process unit(s), as specified in Table 1 multiplied by the percentage inventory adjustment pursuant to subdivision (e) (0.72);
(ii) The BARCT Emission factor for the subject source as specified in Table 3; and
(iii) The proposed BARCT Emission factor for the subject as specified in Table 6.

For those facilities that are permanently shutting down, staff is proposing that their NOx RTCs will be retired from the NOx Program.

~~To that end starting on the date of amendment it is proposed that the highest ranking official of any facility selling any infinite year block (IYB) RTCs must provide the Executive Officer a~~

~~written statement that there is no intention to shut down the facility. For the purpose of this rule, IYB refer to trades involving blocks of RTCs with a specified start year and continuing into the future for ten or more years. This will provide staff assurance that the trade in question is not related to a permanent shutdown.~~

~~It is proposed that any Facility Permit Holder of a facility listed in Table 7 or 8 in Rule 2002 that is permanently shutting down some or all equipment with emissions greater than or equal to 25 percent of the facility emissions for any quarter within the previous 2 compliance years must surrender:~~

- ~~NOx RTCs to the District for retirement from the RECLAIM Program; and~~
- ~~the permit(s) for the equipment that is shutdown.~~

Starting (*date of amendment*) the highest ranking official of any facility listed in Table 7 or 8 selling any infinite year block (IYB) RTCs shall provide the Executive Officer a written statement that there is no current intent~~*ion*~~ to shut down the facility within the next five years. For the purpose of this rule, IYB refer to trades involving blocks of RTCs with a specified start year and continuing into the future for ten or more years.

On or after [*2 years after date of amendment*], ~~*A*~~any Facility Permit Holder of a facility listed in Table 7 or 8 permanently shutting down ~~*some or all*~~one or more pieces of equipment with emissions greater than or equal to 25 percent of the facility's total NOx emissions for any quarter within the previous 2 compliance years shall surrender:

(A) NOx RTCs as determined under paragraph (i)(3) to the District for retirement from the RECLAIM Program; and

(B) the permit(s) for the equipment that is shutdown.

It should be noted that equipment will be deemed shut down and subject to the RTC and permit surrender requirements if it is non-operational for a period of two consecutive years or longer, unless the subject equipment is used in a cyclical operation with a cyclic period of two or more years. The reasons for non-operation cannot be attributed to economic circumstances.

The NOx RTCs to be surrendered must include those valid for all compliance years starting from the compliance year after the shutdown occurs and be equal to the NOx Allocations issued by the District to the facility multiplied by the maximum quarterly ratio in the previous 2 years. For the purposes of this rule, each quarterly ratio shall be calculated as follows:

$$Quarterly\ Ratio = \frac{Quarterly\ NOx\ emissions\ from\ the\ shutdown\ equipment}{Total\ \ facility\ \cancel{certified}\ quarterly\ NOx\ emissions\ for\ the\ same\ quarter}$$

The requirements related to the abovementioned facility and equipment shutdowns would not apply to shutdown equipment for which the equipment's operational capacity is replaced by new or existing equipment serving the same functional needs at the same facility or another facility under common control.

Notwithstanding the requirements of Rule 204, the Executive Officer shall notify the Facility Permit Holder 60 days prior to re-issuing the Facility Permit to reflect removal of the shutdown equipment from the Facility Permit.

Rule 2005

Rule 2005 sets forth requirements for new or modified equipment or processes at RECLAIM facilities. The purpose of the rule is to ensure that the RECLAIM program is equivalent to the federal and state NSR program requirements. Rule 2005 provides three separate requirements to meet the NSR programmatic equivalency:

1) Sources causing emission increases must be equipped with Best Available Control Technology (BACT),

2) Modeling must be used to demonstrate that operation of the source will not result in a significant increase in the air quality concentration of nitrogen dioxide (NO_2) if the facility total emissions exceed its 1994 starting allocations plus non-tradable credits, and

3) The facility must hold sufficient RTCs to offset emission increases for one year prior to commencement of operation and at the beginning of every compliance year thereafter.

These requirements are triggered in cases where a facility incurs an emission increase as defined under Rule 2005(d) – Emission Increase. The evaluation of emission increases under this paragraph is defined on a device-by-device basis at the maximum potential to emit. Any time a new NOx- (or SOx)-emitting RECLAIM device is installed, it triggers the credit holding requirements because it does not have any prior emissions, even in cases where the new device is replacing an older, dirtier device.

Among these requirements, the credit holding requirement ensures that the facility has adequate credits to offset emission increases year-by-year. It does not directly require emission decreases. On the other hand, all RECLAIM facilities are required to reconcile their Allocations to their emissions (i.e. hold enough RTCs to cover their emissions) by the end of each quarter and each compliance year pursuant to Rule 2004 – Requirements. Therefore, under RECLAIM, all facilities are required to have credits to offset all RECLAIM emissions regardless if they are subject to the requirements of Rule 2005.

The amendments made in June 3, 2011 required an existing RECLAIM facility to hold adequate RTCs for the first year of operation prior to commencement of operation of a new or modified source, but will not require the facility to hold RTCs at the commencement of subsequent compliance years, provided that the facility emission level remains below its starting Allocations plus non-tradable credits.

The offset requirements for new RECLAIM facilities remained unchanged. Thus a new facility will have to continue to hold adequate RTCs equal to the amount of emission increases at the beginning of each compliance year. Any unused RTCs cannot be sold until the end of the compliance year, or the applicable quarters if the facility has permit conditions to cap its emissions during each quarter, thus allowing sale of unused RTCs at the end of the quarter.

To help in remedying this holding requirement for new ~~electrical~~ electricity generating facilities that cannot change their allowable NOx emissions in their Facility Permit, staff is proposing a Regional NSR Holing Account in Rule 2002. Proposed changes in Rule 2005 would assure that the Regional NSR Holing Account would be used the for the purpose of complying with the NSR requirements.

Other Administrative Amendments

Besides the changes described in Rule 2002 and 2005 above, staff also proposes administrative amendments to Regulation XX to clarify the rule language and to ensure effective and consistent implementation of the RECLAIM program.

Rule 2002(b) - 5-Year Limitation on Amending Annual Emission Reports

Rule 2002 – Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx) specifies the procedures for quantifying RECLAIM allocations for facilities in the original (1994) RECLAIM universe, facilities electing to enter the program, and facilities included into the program because they experienced actual NOx or SOx emissions of four tons or more in a year. Allocations are quantified by multiplying throughput levels (*e.g.*, quantity of fuel consumed or of material processed) documented in peak year Annual Emission Reports (AERs), by emission factors specified in Rule 2002. However, if the emission factors used in preparing the peak year AER reports are lower than those in Rule 2002, then the lower factors are to be used for quantifying allocations.

Some facilities entering the RECLAIM program have sought to amend their past AERs, which dated as far back as 1989, in ways that increase the initial SOx and/or NOx allocations quantified for them pursuant to Rule 2002. The longer the time elapsed between the reporting period and submittal of the correction the more problematic the process of validating the proposed corrections and their supporting documentation becomes. In fact, such validation has been infeasible in some cases. Therefore, staff is proposing to add paragraph (b)(5) to Rule 2002 specifying that the Executive Officer will not consider any AER data submitted five years beyond the original due date when calculating a facility's allocation. This language would provide clarity to RECLAIM facilities and potential RECLAIM facilities regarding what AR submittals and/or revisions may be considered in determining their allocations, as well as relieve the costs, both financial and in terms of staff resources, associated with review and validation of AER submittals made long after the reporting periods for which they are submitted.

Rule 2002 (Table 4) – Minor Typographical Edit

Rule 2002's Table 4 – RECLAIM SOx Tier III Emission Standards includes a row for Diesel Combustion, which includes a BARCT Emission Standard of "15 ppmv as required under Rule 431.2." However, the standard in Rule 431.2 is actually "15 ppm by weight" rather than 15 ppmv (*i.e.*, 15 ppm by volume). The staff proposal would correct the Table 4 entry to "15 ppm by weight as required under Rule 431.2," consistent with the definition of Low Sulfur Diesel at Rule 431.2(b)(5).

Rules 2011 and 2012 - Delayed RATA Tests due to Extenuating Circumstances

Rules 2011 – Requirements for Monitoring, Reporting, and Recordkeeping for Oxides of Sulfur (SOx) Emissions and 2012 – Requirements for Monitoring, Reporting, and Recordkeeping for Oxides of Nitrogen (NOx) Emissions set forth monitoring, reporting, and recordkeeping requirements for sources of SOx and NOx at RECLAIM facilities. The accompanying Appendices A to these rules, Rule 2011 – Protocol for Monitoring, Reporting, and Recordkeeping for Oxides of Sulfur (SOx) Emissions and Rule 2012 – Protocol for Monitoring, Reporting, and Recordkeeping for Oxides of Nitrogen (NOx) Emissions, outline in greater detail the technical specifications required for monitoring, reporting, and recordkeeping for RECLAIM sources. Moreover, Attachment C, Subdivision B, Paragraph 2 of Appendix A of both these protocols, sets forth the timing and frequency of Semi-Annual Assessments in the form of Relative Accuracy Test Audits (RATAs) for RECLAIM Continuous Emission Monitoring Systems (CEMS). For instance, SOx and NOx equipment monitored by CEMS are required to perform RATAs on a semi-annual basis within six months of the end of the calendar quarter in which the CEMS last passed such a test. Such RATAs may be performed on an annual basis, provided that the relative accuracies of the SOx (NOx) pollutant concentration monitor, flow monitoring system, and the SOx (NOx) emission rate measurement system measured during the previous audit are 7.5% or less. These stringent testing requirements help ensure the accuracy of the CEMS in monitoring SOx and NOx emissions.

RATAs are conducted while the equipment is in operation. Equipment monitored by CEMS at some RECLAIM facilities, however, may experience extenuating circumstances that prevent them from conducting RATA tests in a timely manner. For instance, a major source may experience unforeseen equipment failure that renders it inoperable. Under such unforeseen events, the equipment cannot be made operational to conduct a RATA.

Additionally, facilities under contract with the California Independent System Operator (CalISO), as well as ~~electrical~~ electricity generating facilities owned and operated by municipalities, have experienced difficulties in meeting RATA deadlines because their equipment operates based on current energy demand and may not operate long enough (or at all) to conduct a RATA in the quarter in which the RATA is due. In contrast, most facilities typically require their major sources to be continually operational, used on a regular basis, and able to conduct a timely RATA for their equipment. In the event that their equipment is not in operation, the facility has the option of seeking a variance or filing an application for non-operational status to avoid violating the RATA requirement since sources permitted as non-operational are not required to conduct RATAs. However, ~~electrical~~ electricity generating facilities with equipment under contract with CalISO or owned and operated by municipalities often do not know when demand for electricity will result in generation equipment being required to operate until a day prior, creating scheduling difficulties in conducting RATAs and precluding the use of non-operational status. The inherent inconsistent operational nature of such equipment at electric generating facilities sometimes causes a need to postpone their RATAs.

Under current rule requirements, facilities having such extenuating circumstances seek variances for indeterminate amounts of time. The proposed amendments would, under specific conditions, allow RECLAIM Facility Permit Holders of equipment experiencing these extenuating circumstances to postpone RATAs. In the case of unforeseen equipment failure, Facility Permit Holders would have the option to postpone RATAs for this equipment to no more than 14 operating days after recommencing operation of the repaired equipment. Concerns were expressed that 14 operating days may not be sufficient in cases of sequential failures of the same equipment. However, the proposed 14 operating day RATA postponement for unforeseen equipment failure would apply separately for each unrelated, independent event. As such, if equipment operating under the 14 day RATA postponement provision should experience an unrelated failure prior to successfully completing a RATA, the 14 day clock would restart. On the other hand, if the same failure should recur in a similar situation, the 14 day clock would continue running and would not be reset. In the case of ~~electrical~~ electricity generating facilities under contractual obligation with CalISO to have equipment available or owned and operated by municipalities that did not operate long enough to conduct a RATA during the quarter in which it is due, the semi-annual or annual assessment could be postponed to the next calendar quarter provided the follow criteria are met:

- The RATA was scheduled for the first 45 days of the calendar quarter in which it is due, but the equipment's operating schedule prevents completion of the RATA; and

- A passing Cylinder Gas Audit is conducted during the calendar quarter in which the RATA is due.

Paragraph 2, Subdivision B, Attachment C, of Appendix A to both Rule 2011 and Rule 2012 establishes both the timeline and the frequency for Semi-Annual Assessments to be performed for equipment monitored by CEMS. The purpose of these stringent testing requirements is to ensure the accuracy of the CEMS in monitoring SOx and NOx emissions. These Semi-Annual Assessments obligate facility permit holders to conduct RATAs within six months of the end of the calendar quarter in which the CEMS was last tested. Alternatively, such RATAs may be performed on an annual basis, provided that the relative accuracies of the SOx (NOx) pollutant concentration monitor, flow monitoring system, and the SOx (NOx) emission rate measurement systems are all 7.5% or less. Furthermore, for CEMS on any stack or duct through which no emissions have passed in two or more successive quarters, the semi-annual assessments may be delayed until no later than 14 operating days after emissions pass through the stack/duct. Some RECLAIM facilities that have had to disconnect their equipment due to failures and remove it off-site for repair have requested to have their RATA due dates extended. Other RECLAIM facilities, specifically ~~electrical~~ electricity generating facilities that either have contractual agreements with CalISO to have their equipment available but not necessarily operating or are owned and operated by municipalities, have requested to delay their RATA testing until they have sufficient operating hours to conduct a RATA. Staff proposes to revise Attachment C. B.2. of Appendix A in both Rules 2011 and 2012 by adding subparagraphs (c) and (d), to allow RATA postponements due to these extenuating circumstances. For facilities that have major sources that are physically unable to operate to conduct a RATA, postponement of the RATA due date to within 14 unit operating days from the first re-firing of the major source is proposed to be allowed only if the following requirements are met:

- All fuel feed lines to the major source are either disconnected or opened and flanges are placed at both ends of the disconnected or opened lines, and

- The fuel meter(s) for the disconnected or opened fuel feed lines are maintained and operated and associated fuel records showing no fuel flow are maintained on site.

There were concerns from operators that for some units, disconnecting the fuel feed lines was not feasible. Alternatively, an operator can open the fuel strainers to accomplish the same goal. That is, with the strainers open it would be possible for enforcement staff to get visual confirmation that no fuel is flowing to the units. For any hour that fuel flow records are not available to verify no fuel flow, SOx (NOx) emissions would be required to be calculated using the maximum valid hourly emissions from the last 30 days of operation. Additionally, prior to equipment restart the Facility Permit Holder would be required to:

- provide written notification to the District no later than 72 hours prior to starting up the major source;
- start the CEMS no later than 24 hours prior to the start-up of the major source; and
- conduct and pass a Cylinder Gas Analysis (CGA) prior to the start-up of the major source.

CEMS emissions data after the re-start of operations would only be considered valid if the Facility Permit Holder passes the CGA test. Otherwise, for a non-passing CGA, the CEMS data would be considered invalid until the semi-annual or annual assessment is performed and passed. For such invalid CEMS emissions data, SOx (NOx) emissions would be calculated using the maximum valid hourly emissions from the last 30 days of operation, commencing with the hour of startup and continuing through the hour prior to performing and passing the semi-annual or annual assessment.

For ~~electrical~~ electricity generating facilities either having contractual agreements with CalISO to have their major source available but not necessarily operating, yet not having sufficient hours to conduct RATA testing or owned and operated by a municipality, amended rule language is being proposed to allow the postponement of the semi-annual or annual assessment to the next calendar quarter, provided that the facility demonstrates:

- the semi-annual or annual assessment was scheduled to be performed during the first 45 days of the calendar quarter in which the assessment is due but the assessment was not completed due to lack of adequate operational time, and
- a Cylinder Gas Audit (CGA) is conducted and passed within the calendar quarter when the assessment is due.

Rules 2011 and 2012 - Typographical Edits

The staff proposal would, if adopted, also make the following typographical clarifications and corrections:

- Under Rules 2011 and 2012 Appendix A, Attachment C B.2.b the word "unit" would be added to offer clarity regarding the time period for RATAs that are conducted on equipment for which no emissions have passed through any stack or duct in two or more successive quarters;

- The rule language "Proposed" and "Draft" found in Rule 2011 Appendix A, Attachment C B.2.e., which inadvertently had been left in the previous amended rules, would now be deleted;

- Rule language found in subparagraph (e) of Rule 2012 Appendix A, Attachment C B.2, referencing "Chapter 2, Subdivision B, Paragraph 10, Chapter 2, Subdivision B, Paragraph 11, and Chapter 2, Subdivision B, Paragraph 12" would be replaced with "Chapter 2, Subdivision B, Paragraphs 10, 11, 12, and 18", to clarify relative accuracy requirements for fuel flow measuring devices; and

- Rule language found in subparagraph (e) of Rule 2011 Appendix A, Attachment C B.2 referencing "Chapter 2, Subdivision B, Paragraphs 10, 11, and 12…" would be replaced with "Chapter 2, Subdivision B, Paragraphs 10, 11, 12, and 13…" to clarify the relative accuracy requirements for analyzers.

Proposed Amended Rules 2011, Appendix A, Attachment E and 2012, Appendix A, Attachment F – *Clarification of "Standard Gas Conditions"*

Standard Gas Conditions is defined in Rule 2011, Appendix A, Attachment E and Rule 2012, Appendix A, Attachment F as "a temperature of 68 ºF and one atmosphere of pressure." Rule 102 – Definition of Terms, on the other hand, defines standard conditions for SCAQMD purpose of SCAQMD purposes other than RECLAIM as "a gas temperature of 60 ºF and a gas pressure of [1 atmosphere]." Similarly, the natural gas industry uses standard conditions of 60 ºF and one atmosphere. Many gas meters, including those used by natural gas utilities for billing purposes, automatically correct their readings to 60 ºF and one atmosphere. As such, many RECLAIM facility operators need to convert their meter readings from the 60 ºF and one atmosphere standard to the 68 ºF and one atmosphere standard. While this conversion is quite simple (multiplication by a constant factor of 1.015), it sometimes causes confusion for facility operators, particularly for those with facilities where some, but not all, of the gas meters are corrected to 60 ºF and others are uncorrected. It also makes the correction slightly more complicated for facilities with uncorrected meters simply because standard tables are readily available for converting from actual conditions to the 60 ºF standard but not to the 68 ºF standard. The proposed amendments to Rule 2011, Appendix A, Attachment E and 2012 Appendix A, Attachment F would resolve this situation by giving each facility the operator the option to either the 60 ºF standard or the 68 ºF standard provided one or the other is used consistently throughout the facility for RECLAIM purposes.

Appendix Y – RTC Holdings as of September 22, 2015

ID	Name	Current IYB RTC Holding (tons)	Current IYB RTC Holding (tons per day)

Appendix Z – Comment Letters Received and Responses to Comments

The Public Workshop for RECLAIM was held on July 22, 2015. Comment letters received on and after that date are responded to below. Over the three year rule development process, many other letters, emails, and verbal comments have been received. These comments helped the rule proposal evolve, and staff appreciates all the stakeholder input.

More recent comment letters have been numbered and individual comments within each letter have been bracketed and numbered. Following each comment letter is staff's responses to the individual comments.

Comment Letter #1	WSPA's letter dated August 21, 2015, Phillips66 letter dated August 21, 2015

In addition to the letters above, the following comment letters were received from July 22 to August 10, 2015. The comments from these letters and staff responses are summarized in this Appendix, followed by an attachment that includes these comment letters.

Comment Letter #2	Norton Engineering letter dated August 10, 2015
Comment Letter #3	Norton Engineering letter dated September 4, 2015
Comment Letter #4	Industry Coalition letter dated August 21, 2015
Comment Letter #5	Latham & Watkins letter dated August 20, 2015
Comment Letter #6	Yorke Engineering, LLC letter dated August 21, 2015
Comment Letter #7	Charles F. Timms, Jr. August 21, 2015
Comment Letter #8	SCEC letter dated August 26, 2015

SUBJECT: WSPA COMMENTS ON PRELIMINARY DRAFT STAFF REPORT (PDSR) FOR NOX RECLAIM AMENDMENTS DATED JULY 21, 2015

Dear Dr. Fine:

1-1

The Western States Petroleum Association (WSPA) is a non-profit trade association representing twenty-five companies that explore for, produce, refine, transport and market petroleum, petroleum products, natural gas and other energy supplies in California, Arizona, Nevada, Oregon, and Washington. WSPA-member companies operate petroleum refineries and other facilities in the South Coast Air Basin that are within the purview of the Regional Clean Air Incentives Market (RECLAIM) program.

WSPA and the Industry RECLAIM Coalition (of which we are a member) have submitted several comment letters during this rulemaking process to request changes to the District Staff's proposal that we believe are necessary to preserve a healthy and successful RECLAIM program for all RECLAIM participants, as well as to satisfy the 2012 AQMP commitments to the State Implementation Plan (SIP) and USEPA. We have not yet received written responses to these comments. Nevertheless, we appreciate the opportunity to provide this letter to reiterate our previous concerns, and to discuss new issues arising from the PDSR.

Below are the highlights of our major concerns. More detailed comments are included in Attachment 1, attached hereto and incorporated herein by reference.

I. Shave Methodology and Arbitrary Removal of Unused RECLAIM Trading Credits (RTCs)

The District's Remaining Emissions method for calculation of RTC reductions conflicts with the CMB-01 Phase 1 and Phase 2 Control Measures as approved under the 2012 AQMP. The District's Remaining Emissions method would remove nearly all Unused RTCs from the RECLAIM market even though CMB-01 Phase 1 had explicitly considered and rejected such a reduction, instead determining that a 2 tpd reduction of Unused RTCs was more appropriate.[1] Additionally, the Incremental BARCT method proposed by the Industry RECLAIM Coalition is more consistent with Control Measure CMB-01 Phase 2 as approved under the 2012 AQMP because this method removes only those RTCs directly attributable to technology advancement (i.e., BARCT).[2]

Further, the proposed Compliance Margin of 10% may be inadequate to meet the market's historical need for Unused RTCs. Unused RTCs may be needed for several reasons, including
1-2 facility-level compliance margins, which vary depending on facility size and/or risk tolerance; RTC holding requirements imposed under Rule 2005; and market liquidity, to name a few. These Unused RTCs have historically averaged in the 15-30% range (approximately 5 to 9 tpd), with the sole exception being the RTC market crisis during the 2000 compliance year. The AQMD Staff's proposal, which includes only a 10% compliance margin, appears to be inadequate for satisfying this market requirement. Hence, WSPA recommends that Staff adopt the Incremental BARCT method as their preferred proposal.

While the proposed, limited RTC adjustment account may help certain Power Sector facilities subject to Rule 2005 New Source Review (NSR) RTC holding limit requirements, it does not resolve the holding requirements applicable to many current and future non-power facilities. It is recommended that any RTC adjustment account be accessible to all RECLAIM participants subject to the Rule 2005 NSR RTC holding requirement. WSPA also recommends that Staff provide technical justification to support the quantity of RTCs set aside to fund any such adjustment account. Finally, WSPA recommends that USEPA approval of the NSR set aside concept be obtained in writing prior to adoption of the rule amendment.

II. Shave Application and Implementation Schedule

Any NOx RECLAIM shave should be applied in an equally distributed "across-the-board" manner consistent with RECLAIM founding principles[3] and the precedent set under the 2005 NOx RECLAIM shave. In addition, the proposed schedule should be consistent with the 2012 AQMP commitment to the State Implementation Plan (SIP) which was 2 tpd in the first year; anything larger may not allow sufficient time for industry to implement emission control projects necessitated by the rulemaking.[4] Since RECLAIM is tied to BARCT (as discussed in more detail below), the lack of sufficient lead time means that the proposed shave goes beyond

[1] SCAQMD, 2012 AQMP. Page 4-9 states: "The control measure will seek further reductions of 2 tpd of NOx allocations if triggered." Appendix A, page IV-A-13 presents rationale for that conclusion.
[2] SCAQMD, 2012 AQMP. Page 4-26 states: "This phase of control is to implement periodic BARCT evaluation as required under the state law." Appendix A, page IV-A-60 presents more detailed discussion for the measure.
[3] SCAQMD, Staff Report for Proposed Amended Regulation XX – RECLAIM, January 2005, Executive Summary.
[4] WSPA-SCAQMD letter, July 14, 2015.

BARCT and that RECLAIM will not achieve equivalent or greater reductions than BARCT at equivalent or lesser cost. Therefore, the shave implementation schedule should be "back-loaded"
1-3 to accommodate a longer, more realistic project implementation period with at least 2 of the proposed 4 tpd (currently being proposed for 2016) being moved to 2019 or later. We are not recommending additional annual increments at this time, since the final shave amount has not been finalized.

III. Useful Life of Control Equipment

The proposed Useful Life of 25 years is inappropriate because AQMD rulemaking is far more frequent, with the prior major NOx RECLAIM rulemaking occurring only 10 years ago. Use of a 25 year assumption makes the rule costs appear lower than they actually are by diluting the
1-4 significant capital costs of required projects over a much longer time table than is likely to occur. The Staff analysis should be revised to reflect the 10-year Useful Life assumption, which is more consistent with recent SCAQMD rulemaking schedules and is also consistent with the Useful Life assumption typically used by CARB and other major Air Districts.

IV. BARCT Analysis

There is a statutory requirement that RECLAIM achieve equivalent or greater emission reductions than command and control at equivalent or lesser cost.

Command and Control Regulation Would Require BARCT of the Refining Sources Subject to RECLAIM: The District is required to adopt rules and regulations implementing the AQMP.[5] Among other things, these rules and regulations must require BARCT for existing sources.[6] In rulemaking addressing existing sources outside of RECLAIM, SCAQMD is mandated to require BARCT. Because of the mandate to require BARCT on all existing sources, it is fair to say that current command and control regulations and future measures adopted as part of the plan would at least be equivalent to BARCT. In the absence of a market-based mechanism (cap-and-trade program) such as RECLAIM, SCAQMD would adopt a rule requiring source-specific BARCT for each of the sources covered under RECLAIM.

1-5

The Proposed Shave Appears to Include an Additional 5.21 Tons per Day Beyond BARCT: The proposal set forth by the District indicates that the proposed BARCT would result in a reduction of 8.79 tpd of NOx from 2011 emissions at 2000/2005 BARCT. As described above, RECLAIM must achieve emission reductions equivalent to or greater than traditional command and control, or BARCT. Thus, a NOx shave equivalent to BARCT (which the District proposes at 8.79 tpd) would be the level for comparison with the Health and Safety Code provision stating that equivalent or greater reductions would be achieved at "equivalent or less cost compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the District's plan for attainment." Yet, SCAQMD does not seek merely its determined BARCT equivalency level of 8.79 tpd; it seeks 14 tpd of NOx reductions and has not demonstrated that such reductions will be achieved at equivalent or lower cost than

[5] Health & Saf. Code § 40460.
[6] Health & Saf. Code § 40440.

BARCT. The additional 5.21 tpd reduction goes above and beyond BARCT. Such a severe reduction is not essential to compliance with the statute.

SCAQMD Needs to Demonstrate that Achieving This Additional 5.21 Tons per Day Would Be Less Costly than Achieving BARCT on a Source-by-Source Basis in the District: The Health and Safety Code requires RECLAIM to achieve at least equivalent reductions as traditional command and control at an equivalent or lesser cost.[7] While the draft staff report does provide a cost accounting for BARCT, that accounting (which we believe to be understated) only covers 8.79 tons of the 14 ton per day shave. The draft staff report does not even mention, let alone provide detailed discussion of, the costs associated with the additional 5.21 tons per day being required by the proposed rule. Because the Legislature has required RECLAIM to impose costs less than or equal to command and control regulation (i.e., BARCT), and BARCT only makes up a portion of the proposed shave, the remaining reductions which are in excess of BARCT will cost more than BARCT. The costs related solely to BARCT are substantial with refinery costs over $900 million.[8] Costs associated with the additional 5.21 tpd reduction will only increase that figure in a substantial manner. The District must include the cost figures for the additional shave amount and justify imposing these reductions under the statutory standard of achieving command and control levels at equivalent or lower costs. It is simply not reasonable to exclude such a relevant factor from consideration.

V. NEC Study

1-6 The BARCT analysis for Refinery Sector categories should be revised to explicitly consider the findings presented in Norton Engineering Consultants' (NEC) BARCT Feasibility and Analysis Review.[9] NEC is a third-party expert hired to confirm the Staff's technical analysis in support of this rulemaking. Following the issuance of the PDSR, however, NEC responded to SCAQMD in an August 10, 2015 letter (see Attachment 2) to "clarify the most glaring misstatements/misunderstandings of the information [NEC] provided to the District." By selectively dismissing the third-party expert's findings, without resolution of the technical issues in dispute, Staff has compromised the process and the results of that process. It is unacceptable to arbitrarily reduce the overall shave by 0.85 tpd to resolve the differences in technical assumptions. For example, if the Staff disregards the conclusion from the NEC's third-party expert report, nearly 40 operating units would be impacted by this analysis error.[10] Furthermore, any adjustment that may be justified on a technical basis should be applied to the sector where the actual BARCT reduction occurs and not to the total shave reduction (i.e., Staff's proposed adjustment of 0.85 tpd should be applied to the Refinery Sector's BARCT reduction).

While WSPA understands that BARCT should represent a level of performance that is technically feasible and cost-effective for most units on a retrofit basis in a given source category, the District's assumptions regarding the feasibility of achieving the BARCT levels are

[7] Health & Saf. Code § 39616(c)(7).
[8] SCAQMD, *Preliminary Draft Staff Report, Proposed Amendments to Regulation XX Regional Clean Air Incentives Market (RECLAIM) NOx RECLAIM* (Draft NOx RECLAIM Staff Report), p. 23. (July 21, 2015)
[9] Norton Engineering Consultants (NEC), SCAQMD NOx RECLAIM – BARCT Feasibility and Analysis Review, Non-Confidential Final Report No. 14-045-4, 26 November 2014.
[10] SCAQMD, Preliminary Analysis – Refinery Boilers/Heaters, July 2014 (posted on AQMD website October 2014).

not supported by evidence that the units in question can achieve 2 ppm NOx. In fact, the data provided by Staff (Appendix B of the PDSR) indicates that only 4 of the 76 installed SCRs in the boiler and heater category are currently performing below 2 ppm. This alone suggests that the proposed BARCT is not representative. Even more, in a confidential WSPA refinery survey,[11] conducted by a third party contractor, only 2 of the 4 are retrofits. This does not represent the necessary proportion of the units in this source category.

The draft staff report proposes 2015 BARCT levels of 2 ppmv of NOx for FCCUs, refinery heaters and boilers greater than 40 mmbtu/hr, gas turbines, and sulfur recovery unit tail gas
1-7 incinerators. While the District justifies these levels based on an assumption that all refinery equipment can reach such levels, the draft staff report says otherwise. With respect to refinery heaters and boilers, very few of the existing refinery heaters and boilers already equipped with SCR are able to meet 2 ppmv of NOx. In fact, as stated in the draft staff report, of the 212 refinery boilers and heaters classified as major and large NOx sources, 14 heaters using refinery fuel gas have achieved 1.6-3.5 ppmv NOx, two boilers using natural gas have achieved 2-5 ppmv NOx, and a crude heater using refinery fuel gas achieved 3-8 ppmv NOx. Apart from some unknown percentage of the 14 process heaters, none of these sources already employing the control technology on which the BARCT level is based (SCR) have shown an ability to reduce emissions below 2 ppmv NOx. Accordingly, the District has not shown that a BARCT level of 2 ppmv NOx is achievable over the broad spectrum of refinery heaters and boilers subject to the proposed amendments. Therefore, 5 ppm is a more appropriate endpoint for refinery boilers/heaters.

The same is true with respect to FCCUs. The District proposes a 2015 BARCT level of 2 ppm NOx based on the ability of one FCCU achieving the proposed level. As explained by the District's consultant, of the three FCCUs currently operating with SCRs, only one of them achieves less than 2 ppmv NOx.[12] Again, achievability in one unit does not guarantee similar performance in other units, particularly units that have been operating under different conditions for many years. Each refinery has unique circumstances such as equipment type, age, and
1-8 configuration that factor into its ability to achieve the proposed emission levels. Thus, what may be achievable for one piece of equipment may not be for another. Further, while there may be controls available with the ability to achieve the proposed level of performance, such control may come at a cost that is unreasonable. The District has not shown that the proposed levels can be achieved across the board in a cost effective manner. As a result, and to be consistent with the statutory obligations, the District needs to reconsider and revise the proposed BARCT levels to ensure that they are achievable by a more representative percentage of the sources subject thereto.

VI. Costs and Cost Effectiveness

Exclusion of the NEC cost estimates results in an inappropriate minimization of the estimated Refinery Sector costs presented in the PDSR. It also inflates the presented emission reductions estimate for the Refinery Sector. The BARCT analysis should be revised to explicitly reflect the

[11] WSPA/ERM confidential survey of WSPA members concerning refinery heaters/boilers, March 2015.
[12] Norton Engineering, *Comments on Preliminary Draft Staff Report Proposed Amendments to Regulation XX Regional Clean Air Incentives Market (RECLAIM) NOx RECLAIM-SCRs for FCCUs Document No. 14-045-7* (August 10, 2015).

NEC cost estimates for Refinery Sector categories. Additionally, use of the Discounted Cash Flow (DCF) method along with interest rate and useful life assumptions make estimated costs for this rulemaking appear less expensive than they would be under the Levelized Cash Flow (LCF) method used by CARB and most other major Air Districts. WSPA believes that the LCF method is a better representation of cost effectiveness than the DCF method and recommends it be used. The same cost effectiveness threshold should be used for both DCF and LCF methods. Staff has used a higher cost threshold for LCF in the past than they used for DCF, so that the differences between the two methods are diluted.

1-9 The proposed $50,000 cost effectiveness threshold is greater than the AQMD's DCF cost effectiveness threshold for Command-and-Control sources in South Coast. Under the 2012 AQMP, the approved cost threshold for NOx control measures was $22,500 per ton,[13] and AQMD's current Best Available Control Technology (BACT) guidance document presents a cost effectiveness threshold that is only $19,100 per ton.[14] Also, the Health & Safety Code requires that market-based program costs be "equivalent or less compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the district's plan for attainment" and "the program will not result in disproportionate impacts, measured on an aggregate basis, on those stationary sources included in the program compared to other permitted stationary sources in the district's plan for attainment." [H&SC 39616(c)(1) and (7)]. Staff has not demonstrated that these legal obligations are satisfied. Therefore, WSPA recommends that the PDSR analysis be revised with the cost effectiveness threshold not greater than $22,500 (i.e., the cost effectiveness threshold used in the 2012 AQMP).

Further, the draft staff report understates the actual costs associated with meeting the proposed BARCT levels. As the District has done in past rulemakings, it hired NEC to provide reviews and recommendations on the analysis developed by SCAQMD as it relates to the technical feasibility of the control options as well as the cost effectiveness of each option. After gathering information from onsite visits to six of the refineries, NEC provided the District with a comprehensive evaluation of costs of each control option, the size and space needed for the equipment, and the time needed to install the control technologies. The District, however, chose to use different cost estimation approaches, opting to selectively disregard its own consultant's evaluation. This information was site specific and should be considered more credible than the
1-10 District's generic evaluation of costs. It is a hallmark of reasoned decision-making that an agency use the most accurate available information.

Apart from WSPA's concern relating to the dismissal of NEC's evaluation, the District's estimates do not include all of the costs that are required to be considered, and therefore vastly understate the cost impacts of the BARCT proposed. It appears that installation, design, and engineering costs have not been included properly. Moreover, it is critical to recognize that each refinery is unique such that BARCT levels achievable and cost effective at one refinery may not be at another. Plant configuration, equipment type, equipment age, length of time the SCR must remain in service and consistently achieving emission reduction targets between maintenance opportunities (most FCCUs, heaters, and boilers operate for years at a time, 24 hours per day and

[13] SCAQMD, 2012 AQMP, December 2012, pages 4-43.
[14] SCAQMD, BACT Guidelines, Part C: Policy and Procedures for Non-Major Polluting Facilities, 2006.

7 days per week), and composition of fuel, are a few of the factors in play with determining the costs associated with achieving the proposed levels. For example, some refinery configurations such as processes that utilize dual stacks, may require more than one SCR, and thus greater expenditures (i.e., double), to achieve the proposed level. It does not appear that such a scenario was considered by the District in developing its cost effectiveness determinations.

Accordingly, WSPA believes that the District's cost effectiveness calculations significantly understate the costs associated with achieving the proposed BARCT levels. We believe that even the Norton analysis underestimates actual costs. WSPA is currently developing additional information based on detailed engineering assessments that more accurately represent the costs associated with the proposed BARCT. We will submit this information to the record as it becomes available.

VII. Disproportionate Impacts

Under Health and Safety Code Section 39616(c)(7), the District must show that RECLAIM facilities are not being disproportionately impacted by participating in the program.[15] The draft staff report, noting the emission projections described in the 2012 AQMP, indicates that RECLAIM sources make up 37 percent of the projected NOx emissions for 2023 from stationary sources.[16] Table 2.1 of the draft staff report indicates that non-RECLAIM sources, including waste disposal and miscellaneous processes, will account for 46 tons per day of the annual average NOx emissions for the 2023 base year while RECLAIM sources (pre-shave) will account for 27 tons per day.[17]

In its proposal, the District is seeking substantial reductions from RECLAIM sources, the
1-11 majority of which come from the nine refineries in the Basin. Nonetheless, there is nothing in
the draft staff report or other proposal document that indicates what reductions will be required for non-RECLAIM facilities. In fact, there is no evidence presented that would lead the Board to make a finding that RECLAIM facilities are not taking the brunt of the load when it comes to requiring emission reductions. The District has failed to provide "appropriate information" to "substantiate" a finding of no disproportionate impact.

Indeed, for the Board to make such a finding, there must be evidence indicating that non-RECLAIM facilities are, on an aggregate basis, required to reduce their NOx emissions at the levels required by their RECLAIM counterparts (at least proportionately). Non-RECLAIM facilities represent the majority of the stationary NOx emissions, yet SCAQMD appears to be seeking *no* reductions from such sources. Barring appropriate information showing that non-RECLAIM sources are required to reduce emissions equivalent to what is proposed by these amendments, the Board cannot make the required findings and as a result, the proposed amendments violate the District's statutory mandate.

---

[17] *Id.*

VIII. Energy Efficiency Projects

1-12 Staff suggests that there are NOx emission co-benefits available from Refinery Sector sources due to energy efficiency projects that are in addition to the projected emission reductions under this rule. This is essentially an erroneous assumption due to the fact that the AQMD is relying on information that was submitted under the California AB32 Energy Efficiency and Co-Benefits regulation and most of the projects that were presented by Refinery Sector facilities in those 2011 vintage reports were already completed. As such, those emissions benefits were already reflected in the 2011 baseline year emissions presented in the PDSR. AQMD Staff acknowledges as much in PDSR Table 3.2. As such, these co-benefit reductions should not be presented or characterized as a potential additional benefit.

IX. Socioeconomic Impacts

1-13 Under Health and Safety Code Section 40728.5, the District is required to perform an analysis of the socioeconomic impacts of the proposed regulation. This assessment is important because it lays out the range of probable economic impacts to the regulated industries as well as the impact on the economy of the region as a whole. Unfortunately, the socioeconomic impacts analysis is not available at this time. WSPA believes that reviewing the analysis is important to its ability to meaningfully comment on these proposed regulatory changes. Accordingly, WSPA may change or supplement its comments on review of the analysis when it is released.

Thank you for considering the comments addressed in this letter. We look forward to continuing to work with you and your Staff on this important rulemaking. WSPA reserves the right to file additional comments or other materials as this rulemaking progresses.

Sincerely,

Suzanne E. Bernicle

ATTACHMENT 1

ADDITIONAL COMMENTS ON PRELIMINARY DRAFT STAFF REPORT (PDSR) FOR NO_X RECLAIM AMENDMENTS

	Page/Section	WSPA Comment
1-14	Page 2, Current Emissions and RTC Holdings.	AQMD should use 2012 compliance year emissions as the baseline year for "current emissions" for all industrial sectors. WSPA understands the rationale presented by AQMD for use of 2012 data to characterize baseline Power Sector emissions. However, non-Power RECLAIM facilities were also exhibiting lower output levels in 2011 due to the recession that started in 2007. This is shown in attached Figure 1. Looking at certain key industrial sectors yields a similar conclusion. On a sectoral level, publicly reported economic data (see Figure 2A and Figure 2B) shows that economic output and emissions for the cement and textile manufacturing sectors in AQMD were also still recovering from recessionary low points in 2011. For these reasons, WSPA recommends that AQMD revise the Staff Report to use 2012 compliance year emissions as the baseline emissions year for all industrial sectors.
1-15	Page 3: Table EX-1, Summary of Proposed BARCT (May 2015).	Table EX-1 presents data for the Refinery Sector which fails to reflect changes necessitated by the findings of the third-party expert hired to confirm the AQMD Staff's Refinery Sector technical analysis for this rulemaking. The Staff's BARCT analysis for the Refinery Sector categories should be revised to explicitly consider the findings presented in Norton Engineering Consultants' (NEC) BARCT Feasibility and Analysis Review.[1] The third-party experts were hired to confirm the AQMD Staff's technical analysis in support of this rulemaking. By selectively dismissing the third-party refinery sector expert's findings without resolution of the technical issues in dispute, AQMD Staff have compromised the rulemaking process. We also note that NEC has raised a significant number of technical issues with the conclusions presented in the PSDR for the Refinery Sector categories.[2] WSPA strongly suggests that these technical issues be resolved before further presentation of emissions reductions attributable to the proposed BARCT analysis.
1-16	Page 3. Last paragraph, 3rd sentence. Resolution of Uncertainties	WSPA recommends this section be re-written after the requested and required changes to the Staff's BARCT analysis have been completed. The subject paragraph suggests that Staff has "accounted for uncertainties that arose in the BARCT analysis…." We disagree. There continues to be a significant number of unresolved issues which result in uncertainty in the Staff analysis presented in the PDSR. This includes, but is not limited to the Staff's decision to selectively ignore the findings of the agreed upon third-party expert for the Refinery Sector.

[1] Norton Engineering Consultants (NEC), SCAQMD NOx RECLAIM - BARCT Feasibility and Analysis Review, Non-Confidential Final Report No. 14-045-4, 26 November 2014.

[2] James Norton, NEC, letter to Dr. Philip Fine, SCAQMD, Comments on Preliminary Draft Staff Report Proposed Amendments to Regulation XX Regional Clean Air Incentives Market (RECLAIM) NOx RECLAIM – SCRs for FCCUs Document No. 14-045-7, 10 August 2015.

1-17	Page 3. Last paragraph, 3rd sentence. Proposed Adjustment Account	The proposed "Adjustment Account" should be accessible by all RECLAIM facilities subjected to the Rule 2005 NSR RTC holding requirement. Furthermore, AQMD Staff should provide a technical rationale to support the quantity of RTCs set aside to fund any such adjustment account. The PDSR suggests the RTC demand caused by Rule 2005 RTC holding requirements are addressed by the proposed creation of an RTC Adjustment Account for power plants. However, the RTC holding requirements imposed under Rule 2005 are also applicable to many non-Power Sector facilities under RECLAIM New Source Review. The Staff's current proposal does nothing to address the RTC demand associated with these non-Power Sector facilities. This should be resolved.
	Page 3. Last paragraph, 3rd sentence. Proposed Adjustment Account	AQMD Staff should provide a regulatory discussion detailing how this proposed Adjustment Account would be managed, and how RTCs in the account would be treated with respect the to the State Implementation Plan (SIP).
1-18	Page 3. Last paragraph, 5th sentence. Compliance Margin	WSPA recommends this section be re-written to eliminate potential misstatements concerning the level of "unused RTCs" that might be available under the Staff's proposed shave. The Staff's "Remaining Emissions" approach as presented in the PDSR limits the overall "Compliance Margin" for RECLAIM facilities to 10% of projected 2023 emissions (i.e., not 23%). The Staff's Remaining Emissions estimate excludes some RECLAIM market sectors (i.e., cement) which had reduced emissions in 2011 due to the major recession from which certain sectors were still recovering. Staff has made an adjustment to account for that omission, but this paragraph then suggests that such adjustment is part of the overall market's Compliance Margin. That is incorrect.
1-19	Page 4: 1st full paragraph. Application of Shave	The proposed NOx RECLAIM shave should be applied in an equally distributed, "Across the Board" manner consistent with RECLAIM founding principles and the precedent set under the 2005 NOx RECLAIM shave. RECLAIM is a market-based program which was designed to use "the power of the marketplace"[3] to reduce air emissions from stationary sources. This approach was expressly intended not to impose "command-and-control" requirements on specific facilities or specific equipment therein. Rather, RECLAIM was intended to provide Southern California businesses with greater flexibility and a financial incentive to reduce air pollution at least equal to what traditional command-and-control rules would have required. This program has been very successful in reducing NOx emissions with RECLAIM facilities having reduced their overall actual emissions well in excess of the program's current target under Regulation XX.

3 SCAQMD RECLAIM website, http://www.aqmd.gov/home/programs/business/business-detail?title=reclaim.

		The District has previously considered and rejected targeted shaves as noted in the excerpts below: • Oct 1993, RECLAIM Program Summary: "Throughout the development of RECLAIM, the District evaluated several design options that would have treated some industries differently than others……After evaluating advantages and disadvantages, the District adopted a program that treats all sources consistently for equity and fairness." • 2005 Staff Report, Appendix E: "The Staff proposal is taking the "across-the-board" reduction of NOx RTC holdings approach by looking at the total reductions possible based on BARCT determinations and reducing allocations for all RTC holders by the same percentage…This approach, from a market design standpoint and based on the overall conceptual design of the RECLAIM program to achieve programmatic BARCT, is the most equitable…" The Staff proposal presented in the PDSR is inconsistent with the founding principles of the RECLAIM program that stressed the importance of a market-based program, as well as the precedent established by the SCAQMD in previous NOx regulatory reductions in 1999 and 2005. An equally distributed "across-the board" treatment of all sources, as originally designed and implemented since the program's inception in 1994, is critical to the continued success of the RECLAIM program.
1-20	Page 4: 1st full paragraph, 3rd sentence. Small Facilities	This sentence states "The remaining 210 facilities that hold 10% of the 26.5 tpd RTC are not proposed to be shaved because there was no new BARCT for the types of equipment and operation at these facilities." This statement is factually incorrect and should be corrected. AQMD Staff opted not to review BARCT for these facilities under this RECLAIM rulemaking. Additionally, AQMD and other California air districts have previously made BARCT determinations that would apply to the equipment and operations at those smaller emitting facilities (e.g., boilers, heaters, etc.) were they not under RECLAIM.[4]
1-21	Page 4: 2nd and 3rd full paragraphs. Implementation Schedule	The proposed Implementation Schedule should be revised to shave not more than 2 tons per day (tpd) from the program in the first year. This is consistent with Governing Board's direction under Control Measure CMB-01 Phase 1. Additionally, the overall schedule should be longer than the proposed seven (7) years to ensure RECLAIM facilities have sufficient time to comply. 2012 Air Quality Management Plan (AQMP) Control Measure CMB-01) Phase 1 was approved by the Governing Board on the basis that 2 tpd would be removed from RECLAIM in the event of the $PM_{2.5}$ contingency measure being triggered.[5] The proposed schedule should be consistent with that 2 tpd State Implementation Plan (SIP) commitment; anything

4 See SCAQMD Regulation XI for examples.
5 SCAQMD, 2012 AQMP. Page 4-9 states: "The control measure will seek further reductions of 2 tpd of NOx allocations if triggered." Appendix A, page IV-A-13 presents rationale for that conclusion.

		larger may not allow sufficient time for industry to implement emission control projects necessitated by the rulemaking. Also, the proposed schedule for full implementation by 2022 may be insufficient to achieve the proposed level of NOx emission reductions from RECLAIM facilities. Refinery Sector sources may need 8 years or more to fully engineer, permit, construct and operationalize all the projects needed to comply with the proposed rulemaking.[6]
1-22	Page 6: Table EX-2, Summary of Public Process.	To provide ample opportunity for stakeholder review and comment, AQMD Staff should revise this schedule to provide the public with a realistic schedule for this rulemaking that includes the CEQA Program Environmental Assessment (PEA) and the Socioeconomic Analysis.
1-23	Page 19: Co-Benefits of Energy Efficiency Projects.	This section should be completely removed from the PDSR or significantly revised to correct factual mischaracterizations. The information submitted by refineries to the California Air Resources Board in 2011 under the AB32 Energy Efficiency and Co-Benefits regulation reflected projects that mostly had been completed by 2011. Thus, those co-benefits were already reflected in the 2011 baseline year emissions presented in the PDSR and cannot be characterized as additional or creditable. Staff have acknowledged as much in PDSR Table 3.2.
1-24	Page 29 CEQA Alternatives	The size of the shave approved in the 2012 AQMP should be included in the list of CEQA alternatives.
1-25	Chapter 4: Costs and Cost Effectiveness. Cost Thresholds	The cost effectiveness threshold for this rulemaking should not be greater than $22,500 (i.e., the cost effectiveness threshold used in the 2012 AQMP) and the BARCT analysis presented in the PDSR should be revised accordingly. The $50,000 cost effectiveness threshold proposed by AQMD Staff is greater than the AQMD's DCF cost effectiveness threshold for Command-and-Control sources in South Coast. Under the 2012 AQMP, the approved cost threshold for NOx control measures was $22,500 per ton. As an additional data point, AQMD's current Best Available Control Technology (BACT) guidance document presents a DCF cost effectiveness threshold of only $19,100 per ton. Health & Safety Code (H&SC) §39616(c) requires that market-based program costs will be "equivalent or less compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the district's plan for attainment" and also requires "the program will not result in disproportionate impacts, measured on an aggregate basis, on those stationary sources included in the program compared to other permitted stationary sources in the district's plan for attainment."[7] The AQMD Staff analysis presented in the PDSR has not demonstrated that these obligations are satisfied.
	Chapter 4: Costs and Cost Effectiveness.	A 10-year "Useful Life" assumption is more appropriate given actual rulemaking timetables; the BARCT analysis presented in the PDSR should be accordingly revised to use a 10-year Useful Life assumption.

[6] Stillwater Associates LLC, RECLAIM Analysis for WSPA, July 2015.
[7] Health & Safety Code §39616(c)(1) and (7).

1-26	Useful Life Assumption	The AQMD Staff's proposed 25-year Useful Life is inappropriate because AQMD rulemaking occurs on a far more frequent recurrence. The last major NOx RECLAIM rulemaking was only 10-years ago. Use of a 25-year assumption makes the rule costs appear lower than actual by diluting the significant capital costs of required projects over a much longer time table than is likely to occur. The AQMD Staff analysis should be revised to reflect the 10-year Useful Life assumption which is more consistent with recent AQMD rulemaking schedules and is also consistent with the Useful Life assumption typically used by CARB and other major Air Districts.
1-27	Chapter 4: Costs and Cost Effectiveness. DCF Method	The BARCT analysis presented in the PDSR should be revised to utilize the Levelized Cash Flow (LCF) methodology used by CARB and other major air districts. Use of the DCF method, in combination with the proposed interest rate and Useful Life assumptions serves to distort the estimated costs for this AQMD rule by making them appear less expensive than they would be using the Levelized Cash Flow (LCF) method employed by CARB and other major Air Districts. The same threshold should be used for both DCF and LCF.
1-28	Chapter 5: RTC Reductions, Remaining Emissions Remaining Emissions Method	The AQMD Staff's "Remaining Emissions" method conflicts with Control Measure CMB-1 Phase 1 as approved under the 2012 AQMP and should be replaced with the Incremental BARCT method proposed by the Industry RECLAIM Coalition. The Remaining Emissions method presented in the PDSR conflicts with Control Measure CMB-1 Phase 1 because it would remove nearly all Unused RTCs (i.e., "surplus") from RECLAIM. CMB-01 Phase 1 explicitly considered and rejected such a reduction; instead arguing that a 2 tpd of reduction for Unused RTCs was more appropriate due to concerns that baseline RECLAIM emissions might reflect the economic downturn.[8] As noted above, many Southern California industry sectors covered by RECLAIM were in fact still under a recessionary hangover in 2011 so such concerns were valid. Furthermore, the "Incremental BARCT" method is more consistent with Control Measure CMB-1 Phase 2 approved under the 2012 AQMP[9] because the method would only remove RTCs in an amount attributable to technology advancement (i.e., BARCT). AQMD Staff's own analysis demonstrates that less than 9 tpd of proposed RTC reductions are attributable to the 2015 BARCT analysis. Yet the Staff proposal proposes to shave 14 tpd. Removing RTCs beyond what is supported by technology advancement may subject facilities in the RECLAIM program to disproportionate impacts, measured on an aggregate basis, compared to other permitted stationary sources in the District's plan for attainment. It may also subject

[8] SCAQMD, 2012 AQMP. Page 4-9 states: "The control measure will seek further reductions of 2 tpd of NOx allocations if triggered." Appendix A, page IV-A-13 presents rationale for that conclusion.

[9] SCAQMD, 2012 AQMP. Page 4-26 states: "This phase of control is to implement periodic BARCT evaluation as required under the state law." Appendix A, page IV-A-60 presents more detailed discussion for the measure.

	RECLAIM facilities to greater costs compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the District's plan for attainment. Either of these outcomes would conflict with H&SC 39616(c). AQMD has not demonstrated that the Staff proposal successfully meets these obligations. Further, under Section 40727, the Legislature has established that regulations must meet the requirements of necessity, authority, clarity, consistency, non-duplication, and reference. The necessity requirement ensures in part that unnecessary costs are not imposed on the economy of California. Accordingly, the District needs to establish that the shave is no more stringent than what is "necessary." Necessity "means that a need exists for the regulation, or for its amendment or repeal, as demonstrated by the record of the rulemaking authority."[10] Through the 2012 AQMP, SCAQMD has described that a need exists for a reduction in NOx emissions. The ceiling of that need was five tons per day. The magnitude of the current shave proposal goes above and beyond what is necessary to meet the requirements of the AQMP or any other statutory or regulatory obligation that SCAQMD faces

1-29	Chapter 5: RTC Reductions, Remaining Emissions Compliance Margin	The proposed Compliance Margin of 10% appears inadequate to meet the market's historical need for Unused RTCs and should be revised to the 20-30% range. The RECLAIM market has exhibited "Unused RTCs" since program inception. This may be for several reasons including facility compliance margins which range in size depending on facility size and/or risk tolerance, RTC holding requirements imposed under Rule 2005, or market trading to name few. These Unused RTCs have historically averaged in the 15-30% range (5 to 9 tpd) with the sole exception being the market crisis during the 2000 compliance year.[11] The AQMD Staff's proposal (with only 10% compliance margin) may be inadequate for satisfying this market requirement. Excessive shaving of Unused RTCs could result in a market which is unable to accommodate the economic activity levels projected in the Staff's analysis. Furthermore, removal of all Unused RTCs would directly conflict with Control Measure CMB-01 Phase 1 as authorized by the Governing Board.
1-30	Chapter 5: RTC Reductions, Remaining Emissions Table 5.1 – Remaining Emissions for Refinery Sector (May 2015)	The BARCT analysis for the Refinery Sector categories should be revised to explicitly consider the findings presented in Norton Engineering Consultants' (NEC) BARCT Feasibility and Analysis Review, and Table 5.1 should be accordingly revised. As noted in the PDSR, the Staff analysis fails to account for the technical recommendations from NEC, the third-party Refinery Sector expert hired by the AQMD. NEC's findings have material impacts on the resulting BARCT determinations for certain Refinery Sector categories. Once corrected, the projected "2023 Remaining Emissions at 2015 BARCT" for the Refinery Sector will increase, and the "2023 Emission Reductions Beyond 2000/2005 BARCT" will decrease. These technical corrections are critical to a fair application of the proposed shave.

10 Health & Saf. Code § 40727.
11 SCAQMD, Annual RECLAIM Audit Report for 2013 Compliance Year, 6 March 2015. See Table 3-2.

	Appendix A - Refinery Fluid Catalytic Cracking Units (FCCUs) Page 53. Incremental Costs and Cost Effectiveness Cost Effectiveness Calculations	The cost effectiveness analysis presented for FCCUs in Appendix A does not consider the 2000/2005 BARCT emissions or cost baselines. This conflicts with the methodology outlined in Chapter 4. The Staff BARCT analysis should be accordingly revised based on the incremental cost effectiveness approach outlined in Chapter 4. Staff proposes that the cost effectiveness of 2015 BARCT is to be calculated based on the incremental cost of progressing from 2000/2005 BARCT to the proposed 2015 BARCT level, divided by the incremental emissions benefit related to the progression from 2000/2005 BARCT to the proposed 2015 BARCT level (i.e., "2023 Emission Reductions Beyond 2000/2005 BARCT"). For some reason, it was not applied in this manner for the FCCUs. We request that this oversight be corrected.
1-31	Appendix A - Refinery Fluid Catalytic Cracking Units (FCCUs) Page 53. Incremental Costs and Cost Effectiveness Consideration of Third-Party Expert's Recommendations on Cost	The Staff's BARCT analysis for the Refinery FCCUs category should be revised to explicitly consider the findings presented in Norton Engineering Consultants' (NEC) BARCT Feasibility and Analysis Review.[12] The third-party experts were hired to confirm the AQMD Staff's technical analysis in support of this rulemaking. By selectively dismissing the third-party refinery sector expert's findings, without resolution of the technical issues in dispute, AQMD Staff have compromised the rulemaking process. We also note that NEC has raised a significant number of technical issues with the conclusions presented in the PSDR for the Refinery FCCUs which have reportedly been discussed with Staff and were reiterated in NEC's letter dated 10 August 2015.[13] Norton's comments are attached hereto and incorporated herein by reference. These technical issues are significant and should be resolved before any further characterization of emissions reductions attributable to proposed BARCT under the Staff's analysis.
1-32	Appendix B – Refinery Boilers and Process Heaters Page 60, Achieved-In-Practice NOx Levels for Boilers and Heaters Proposed BARCT	WSPA requests further technical demonstration to support the proposed BARCT level for refinery heaters and boilers; the proposed BARCT level does not appear to represent an achievable level of performance for most refinery heaters/boilers operating on refinery fuel gas. According to the AQMD's figures, fewer than 10% of the heater/boiler units already equipped with SCR technology are able to achieve the proposed BARCT level. This does not suggest the performance level can be broadly achieved with add-on emissions controls. If this level of performance effectively demands basic equipment replacement, the AQMD's BARCT analysis should identify and quantify costs for that demand. WSPA also requests clarification on the number of refinery heaters and boilers reported to that have "very low emissions levels." AQMD Staff have provided conflicting counts to stakeholders, and those counts conflict

[12] Norton Engineering Consultants (NEC), SCAQMD NOx RECLAIM - BARCT Feasibility and Analysis Review, Non-Confidential Final Report No. 14-045-4, 26 November 2014.

[13] James Norton, NEC, letter to Dr. Philip Fine, SCAQMD, Comments on Preliminary Draft Staff Report Proposed Amendments to Regulation XX Regional Clean Air Incentives Market (RECLAIM) NOx RECLAIM – SCRs for FCCUs Document No. 14-045-7, 10 August 2015.

		with information provided to WSPA directly by WSPA member refineries.[14] The PDSR reports fourteen refinery heaters in the AQMD as using refinery fuel gas and achieving NOx concentrations "between 1.6 and 3.5 ppmv" (corrected to 3% O2) using Selective Catalytic Reduction (SCR) technology. AQMD Staff also report that two boilers have achieved NOx emissions between 2 and 5 ppmv using LoTOx scrubbers and natural gas. We understand that AQMD's analysis is based on data collected from Southern California refineries under a 2013 survey.[15] AQMD had previously reported to the RECLAIM Working Group that, based on that same survey, only nine refinery heaters/boilers were achieving below 5 ppmv. WSPA requests clarification on how this count of units with "very low emissions levels" could have changed. Lastly, AQMD should not categorize units between performing "between 1.6 and 3.5 ppmv" as a single group consistent with the proposed BARCT. 3.5 ppmv does not equal 2 ppmv, and some units which achieve 3.5 ppmv may be unable to meet 2 ppmv even with add-on controls. We would suggest this group supports a BARCT determination of 3.5 ppmv; not 2 ppmv.
1-33	Appendix B – Refinery Boilers and Process Heaters Page 60, Achieved-In-Practice NOx Levels for Boilers and Heaters Cost Basis for BARCT and Consideration of Third-Party Expert's Recommendations on Cost	The Staff's BARCT analysis for the Refinery heaters and boilers should be revised to explicitly consider the findings presented in Norton Engineering Consultants' (NEC) BARCT Feasibility and Analysis Review, and any subsequent comments from NEC.[16] The third-party experts were hired to confirm the AQMD Staff's technical analysis in support of this rulemaking. By selectively dismissing the third-party refinery sector expert's findings without resolution of the technical issues in dispute, AQMD Staff have compromised the rulemaking process. The AQMD Staff's analysis suggests that the proposed BARCT level of 2 ppmv can be achieved with less equipment (e.g., 1 layer of catalyst) and less cost than suggested by the third-party Refinery expect; a firm that engineers such equipment as its primary business. Counter to the AQMD Staff's assertion that NEC was simply wrong on its design basis is the fact (reported by AQMD)[17] that fewer than 10% of the existing Refinery heaters/boilers with SCR technology are able to meet 2 ppmv. This result includes both new and retrofit installations and suggests that the proposed 2 ppmv NOx performance level may not be as easily achieved as suggested by Staff. Given the material impact of these technical issues on the BARCT analysis, they should be resolved before any further characterization of emissions reductions attributable to proposed BARCT under the Staff's analysis. Specifically, we request that the BARCT analysis presented in Appendix B be revised to consider the cost estimates presented by NEC.
	Appendix B – Refinery	The BARCT cost effectiveness analysis presented in this table suggests

[14] WSPA/ERM confidential survey of WSPA members concerning refinery heaters/boilers, Mar 2015.
[15] SCAQMD, Preliminary Draft Staff Report (PDSR) for Proposed Amendments to NOx RECLAIM, 21 July 2015.
[16] Norton Engineering Consultants (NEC), SCAQMD NOx RECLAIM - BARCT Feasibility and Analysis Review, Non-Confidential Final Report No. 14-045-4, 26 November 2014.
[17] SCAQMD, NOX RECLAIM Working Group Meeting, 19 September 2013.

1-34	Boilers and Process Heaters Table B.11 - Details of Cost Estimates for Boilers and Heaters (March 2015)	AQMD Staff have selectively applied the methodology outlined in Chapter 4. This is specifically a problem for select heaters which are reportedly already meeting proposed BARCT. In these instances, Staff has claimed emissions reductions relative to the 2000/2005 BARCT level without assigning any programmatic costs for those reductions. This is inconsistent with the programmatic approach outlined in Chapter 4, under which cost effectiveness of 2015 BARCT is to be calculated based on the incremental cost of progressing from a 2000/2005 BARCT level to the proposed 2015 BARCT level, divided by the incremental emissions benefit related to the progression from 2000/2005 BARCT to the proposed 2015 BARCT level (i.e., "2023 Emission Reductions Beyond 2000/2005 BARCT"). WSPA does not believe it appropriate for Staff to selectively "pick and choose" when use the prescribed programmatic approach. The Staff BARCT analysis should be revised accordingly to be fully consistent with the incremental cost effectiveness approach outlined in Chapter 4.
1-35	Appendix D - Coke Calciner Staff's Recommendation	WSPA appreciates that AQMD Staff accepted NEC's recommended BARCT level of 10 ppmv and has incorporated it into the BARCT analysis for this source category.
1-36	Appendix E - Sulfur Recovery Units/Tail Gas Incinerators Page 110. Costs and Cost Effectiveness Design Basis for BARCT and Consideration of Third-Party Expert's Recommendations	The Staff's BARCT analysis for the Refinery Sulfur Recovery Units/Tail Gas Incinerators (SRU/TG Incinerators) category should be revised to explicitly consider the findings presented in Norton Engineering Consultants' (NEC) BARCT Feasibility and Analysis Review.[18] The third-party experts were hired to confirm the AQMD Staff's technical analysis in support of this rulemaking. As with other categories, the AQMD Staff's analysis suggests that the proposed BARCT level of 2 ppmv can be achieved for SRU/TG Incinerators with less equipment (e.g., fewer layers of catalyst) and less cost than suggested by the third-party Refinery expert; a firm that engineers such equipment as its primary business. By selectively dismissing the third-party refinery sector expert's findings without resolution of the technical issues in dispute, AQMD Staff have compromised the rulemaking process. Given the impact of these technical issues on the projected emissions and costs for this category, these issues should be resolved before any further characterization of emissions reductions attributable to proposed BARCT under the Staff's analysis. Specifically, we request that the BARCT analysis presented in Appendix E be revised to consider the cost estimates presented by NEC. Tables E.1 and E.2 should include NOx concentration levels.
1-37	Appendix K – Co-Benefits of Energy Efficiency Projects	This appendix should be completely removed from the PDSR or significantly revised to correct factual mischaracterizations.

[18] Norton Engineering Consultants (NEC), SCAQMD NOx RECLAIM - BARCT Feasibility and Analysis Review, Non-Confidential Final Report No. 14-045-4, 26 November 2014.

	The information submitted by refineries to the California Air Resources Board in 2011 under the AB32 Energy Efficiency and Co-Benefits Regulation reflected projects that had mostly been completed by 2011. Thus, those co-benefits were already reflected in the 2011 baseline year emissions presented in the PDSR and cannot be characterized as additional or creditable. Staff have acknowledged as much in Table K.1 and also PDSR Table 3.2.

1-38

Part III – RTC Reduction Approaches Appendix U – Staff's Proposal and CEQA Alternatives	The proposed NOx RECLAIM shave should be applied in an equally distributed, "Across the Board" manner consistent with RECLAIM founding principles and the precedent set under the 2005 NOx RECLAIM shave. RECLAIM is a market-based program which was designed to use "the power of the marketplace"[19] to reduce air emissions from stationary sources. This approach was expressly intended not to impose "command-and-control" requirements on specific facilities or specific equipment therein. Rather, RECLAIM was intended to provide Southern California businesses with greater flexibility and a financial incentive to reduce air pollution at least equal to what traditional command-and-control rules would have required. This program has been very successful in reducing NOx emissions with RECLAIM facilities having reduced their overall actual emissions well in excess of the program's current target under Regulation XX. The District has previously considered and rejected targeted shaves as noted in the excerpts below: • Oct 1993, RECLAIM Program Summary: "Throughout the development of RECLAIM, the District evaluated several design options that would have treated some industries differently than others……After evaluating advantages and disadvantages, the District adopted a program that treats all sources consistently for equity and fairness." • 2005 Staff Report, Appendix E: "The Staff proposal is taking the "across-the-board" reduction of NOx RTC holdings approach by looking at the total reductions possible based on BARCT determinations and reducing allocations for all RTC holders by the same percentage…This approach, from a market design standpoint and based on the overall conceptual design of the RECLAIM program to achieve programmatic BARCT, is the most equitable…" The Staff proposal presented in the PDSR is inconsistent with the founding principles of the RECLAIM program that stressed the importance of a market-based program, as well as the precedent established by the SCAQMD in previous NOx regulatory reductions in 1999 and 2005. An equally distributed "across-the board" treatment of all sources, as originally designed and implemented since the program's inception in

[19] SCAQMD RECLAIM website, http://www.aqmd.gov/home/programs/business/business-detail?title=reclaim.

	1994, is critical to the continued success of the RECLAIM program.

Responses to Letter #1

Response 1-1 Previous WSPA Comment Letters

Please see staff's responses to previous WSPA and the Industry Coalition's letter and comments attached to the Draft Socioeconomic Staff Report.

Response 1-2 Shave Methodology and Arbitrary Removal of Unused RTCs

Staff disagrees with the commenter's assessment in several areas.

Intent of Control Measure CMB-01 and RTC Reductions

It is important to understand that the Basin is currently classified as a "severe" non-attainment area for PM2.5 and "extreme" non-attainment for ozone. Based on recent data, the Basin did not meet the PM2.5 ambient air quality standards by the original attainment date of 2014 or the revised attainment date of 2015. Thus, staff is obligated to find all technological feasible and cost-effective control technologies to help the Basin achieve maximum emission reductions and attain the PM2.5 and ozone ambient air quality standards as expeditiously as possible. Control Measure CMB-01 is a control measure in the 2012 AQMP that called for a total NOx reduction of 3-5 tpd in 2 phases: 2-3 tpd in Phase I with implementation date in 2014 (already overdue) and 1-2 tpd in Phase II with implementation date in 2020.[7, 8] Staff committed to submit 3 tpd, the lower end of the range, to satisfy the SIP commitment. The intent of the Control Measure CBM-01 was not to limit the reduction to 3-5 tpd: [9]

> *"It should be noted that since there are substantial NOx reductions needed by 2023, if additional reductions are feasible and cost effective, they will be evaluated during rulemaking."*

The control measure also states that the District is required to monitor advances in BARCT, and if BARCT advances, the District is required to periodically re-assess the overall facility caps, and reduce the RTC holdings to applicable equivalent command & control BARCT levels.

---

[7] The implementation dates are shown in Tables 4-2 and 4-4 of the 2012 AQMP

[8] The 2 tpd in the statement that WSPA cited "The control measure will seek further reductions of 2 tpd NOx allocations if triggered" on page 4-9 of the 2012 AQMP refers to the additional 2 tpd in Phase 2.

[9] Page IV-A-60, Appendix IVA of the 2012 AQMP

Staff has identified and evaluated all feasible and cost-effective BARCT to achieve 14 tpd RTC reduction as proposed in the PDSR. As stated in Control Measure CMB-01, the Control Measure did not limit the reduction to 3-5 tpd. There is no language in control measure CMB-01 that explicitly considered and rejected removing more than 2 tpd of unused RTCs.

Regarding the implementation schedule for the 14 tpd RTC reduction, in the 5 years from 2009-2013, the unused RTCs in the NOx RECLAIM program ranged from 5 to 8 tpd, [10] thus staff is proposing a 4 tpd RTC reduction in 2016. Additional reduction from implementation of BARCT will take 2 - 4 years for procurement, engineering, planning, and construction, therefore staff is proposing that the remaining shave of 10 tpd take place over 5 years between 2018 and 2022.

Methodology for BARCT Reductions & Removal of Unused RTCs

On contrary with the commenter's assessment, Control Measure CMB-01 from the 2012 AQMP does not prescribe how the shave should be calculated and thus it is not in conflict with the shave methodology. The proposed shave in the RECLAIM program is estimated based on remaining emissions. This proposed method is consistent with past practice in the 2005 and 2010 RECLAIM amendments.

To calculate the shave, staff first estimated the remaining emissions at BARCT levels projected to the compliance year 2023 including economic growth and 10% compliance margin. The shave was calculated as the difference between the current RTC holdings and the remaining emissions projected to 2023. Staff also reduced the shave by 0.85 tpd to account for uncertainties and provide some additional compliance margin. The total shave proposes removal of RTCs necessary to attain BARCT levels of emissions, including removing some unused surplus RTCs in the market.

Shave = Current RTC Holdings – (2023 Remaining Emissions + Uncertainty)
= RTCs attributable to difference between 2000/2005 & 2015 BARCT + Portion of Unused RTCs
= 26.5 – (11.67 + 0.85) = 8.8 + 5.2 = 14 tpd

WSPA has suggested staff remove only the RTCs directly attributable to technology advancement (8.77 tpd) but not the unused RTCs. The unused RTCs however create a dampening effect on RTC prices that allows RECLAIM facilities to purchase RTCs in lieu of implementing BARCT. For example, in 2009-2013, there were about 5 – 8 tpd surplus RTCs in the market and the average RTC prices were in a range of $1,162 – $5,491 per ton compared to the average cost-effectiveness

[10] Table 1.1 of the Preliminary Draft Staff Report

of control range $8,300 - $13,000 per ton.[11, 12] Thus, the facilities opted to purchase low cost abundant surplus RTCs to reconcile their emissions at the end of the compliance year in lieu of installing control to reduce "real" emissions. For example, the refineries did not install any SCRs in responses to the 2005 NOx RECLAIM amendment even though staff had estimated about 51 SCRs would be installed by 2011. Removing surplus RTCs is therefore critically important to ensure the effectiveness of the RECLAIM program and meet state law requirements to require the use of BARCT for existing sources.

WSPA has suggested staff estimate the shave based the projected actual emissions but not the current RTC holdings.[13] However, removing 8.77 tpd from current RTC holdings will not be enough to ensure that the RECLAIM universe emits at an emission level that represents the maximum degree of reductions achievable as required by H&SC 40406. Staff analysis has shown that the RECLAIM universe can achieve a level of 12.5 tpd remaining emissions. To reduce RTCs from the current 26.5 tpd to reach the target of 12.5 tpd requires a "shave" of 14 tpd. A smaller shave would be met by simply giving up unused RTCs, not producing any significant actual emission reductions.

Compliance Margin

RECLAIM facilities typically hold extra RTCs in their account to ensure that they will have enough RTCs to reconcile their emissions at the end of the compliance year.[14] Plant operation and emissions may fluctuate. CEMS may be offline and facilities must use missing data procedures to calculate emissions which may be higher than actual emissions. Also, facilities may underestimate their actual emissions and need to hold a stream of RTCs to account for adjustments after audit. In previous RECLAIM amendments, staff provided 10% compliance margin to help the facilities deal with these uncertainties. Staff did the same in this amendment allowing a 10% compliance margin but actual unused RTCs may be even higher. As illustrated below, this level of compliance margin will result in 23% unused RTCs above the remaining emissions. Staff believes this will adequately meet the market's need for unused RTCs.

---

[11] Discrete RTC prices shown in Figure 1.2 of the PDSR: $1,162 - $5,491 per ton for 2005-2012.

[12] Cost effectiveness for individual source categories: $11,000 - $17,000 per ton for refinery boilers/heaters >110 mmbtu/hr and FCCUs, $9,000 - $10,000 per ton for industrial boilers, $4,000 - $11,000 per ton for metal melting/heat treating and miscellaneous combustion (page 3 of the Board Letter for the 2005 NOx RECLAIM Amendment, Agenda No. 25, January 7, 2005). Overall program average cost effectiveness: $8,300 - $13,000 per ton (page 8 of the Board Letter for the 2005 NOx RECLAIM Amendment, Agenda No. 25, January 7, 2005).

[13] Industrial Coalitions' Approach: Shave = Projected 2011 Emissions @ 2005 BARCT – Projected 2023 Emissions @2015 BARCT = 8.77 tpd. Staff's Approach = RTC Holdings – 2023 Remaining Emissions – Adjustment = 14 tpd

[14] Page 54 the Staff Report of the 2005 NOx RECLAIM Amendment.

Remaining RTCs after shave = 26.5 tpd – 14 tpd = 12.5 tpd
Remaining emissions = 2.71 tpd (refinery) + 7.47 tpd (non-refinery) = 10.18 tpd
Surplus RTCs = 12.5 tpd – 10.18 tpd = 2.3 tpd
% Unused RTCs = 2.3 tpd / 10.18 tpd = 23% above remaining emissions

The compliance margin is not expected to meet the RTC holding requirements imposed under Rule 2005. Instead, staff has created a Regional NSR Holding Account to help facilities in the power sector subject to Rule 2005 NSR requirements. This Account will be taken from the 14 tpd shave and not from the post-shave unused RTCs. Staff has discussed this issue with the U.S. EPA to seek their approval on the concept and receive feedback on whether or not this concept can be applied to all RECLAIM facilities.

Staff believes the compliance margin is not needed to create market liquidity. It is envisioned that the facilities would install control equipment to reduce emissions to the BARCT levels as required by state law and would create surplus RTCs to trade and keep the market liquid.

Response 1-3 Shave Application and Implementation Schedule

At the inception of the RECLAIM program in 1993, the compliance year 2000 allocations were estimated for each facility in RECLAIM based on the methodology described in Rule 2002(d), and the compliance year 2003 allocations were estimated based on the methodology described in Rule 2002(e). There was no “across-the-board” uniform percentage shave.

In the 2005 NOx RECLAIM amendment, a uniform percentage shave (22.5%) was applied “across-the-board” because the BARCT identified at that time was applicable to “across-the-board” facilities (e.g. low NOx burners for ovens, kilns, furnaces.)

The shave for the SOx RECLAIM in 2010 was not distributed “across-the-board” because 1) the BARCT identified was applicable to only 11 major facilities,[15] and 2) the non-uniform characteristics of the market made it inequitable to distribute the shave to all facilities.[16] To ensure that the 11 major facilities would install BARCT equivalent to command-and-control and to keep other facilities in the market, the 2011 SOx shave was applied only to investors and one-third of the facilities in the SOx RECLAIM universe.

It should be noted that the methods used to establish the 1993, 2005 or 2010 shaves did not establish founding principles and precedence on how the shave must be distributed. How the shave

[15] The 11 major facilities included six refineries, a coke calciner, two sulfuric acid plants, a cement plant, and a glass plant.

[16] The 11 major facilities hold 87% of RTCs and contributed more than 94% of emissions. The remaining 21 facilities hold 6% of RTCs and contributed 6% of emissions.

should be distributed in each rule amendment is affected by the BARCT identified, the distribution of RTCs in the market, and staff's analysis on how best to implement BARCT.

For the proposed rule amendment, staff identified the new BARCT applicable for 20 major facilities (9 refineries and 11 non-refineries) and recommended shaving 56 facilities that hold 90% of the NOx RTCs and contributed 86% of the emissions. Staff proposed not to shave the remaining 219 facilities that hold only 10% of the NOx RTCs to keep them in the market.

Regarding the different shave percentages for the refinery sector and the non-refinery sector, staff estimated that by implementing BARCT the refinery and non-refinery sector could reduce 6.00 tpd and 2.77 tpd, respectively. Therefore, staff proposed shaving the RTC holdings from the refinery sector at a higher rate than the non-refinery sector weighted by the emission reductions that could be achieved. Staff proposed to shave the refinery sector by 66% and the non-refinery sector by 47%. The non-uniform shave is to ensure that the facilities subject to BARCT would install BARCT. After a shave of 22.5% "across-the-board" in 2005, the refineries opted to buy unused RTCs and not install any SCRs to reduce NOx emissions even though staff had estimated it was feasible and cost-effective for the refineries to install 51 SCRs by 2011.

In this case, if the percent shave were set at the same amount "across-the-board", facilities that do not have available BARCT, or where BARCT technology does not achieve the uniform 53% reduction, would have to purchase more RTCs from the refineries that can achieve 66% reduction. This would result in a redistribution of wealth from the non-refinery sectors to refineries. While this occurs to some extent under the staff proposal, the effect would be greatly increased.

For CEQA and socioeconomic analyses, staff considered five alternative approaches to allocate the RTC reductions. All five alternatives have "across-the-board" shave. The challenge of the RECLAIM program is to find the most appropriate shave distribution to protect the environment, attain the NAAQS, satisfy state and federal CAA requirements and AQMP commitments, and at the same time, allow for economic growth, provide equity, and safeguards for the functioning of the RECLAIM program.

With respect to the implementation time, because the implementation date for 2 tpd reductions in Phase 1 was due in 2014 and there are 5-8 tpd surplus RTCs in the market, staff believes that at a minimum 2 tpd reduction or up to 4 tpd reduction should be removed from the market no later than 2016, not "back-loaded" to 2019 as the commenter suggested. As explained in Response 1-2, the removal of unused RTCs is expected to raise the RTC prices and stimulate the implementation of control equipment. It is urgent to implement the control equipment and reduce actual emissions as expeditiously as possible to meet the NAAQS for PM2.5 and ozone.

Staff has planned for a sufficient lead time of approximately 2-3 years for the procurement, planning and engineering of BARCT. Except for the retrofits of Refinery 1's gas turbines scheduled in 2018, staff currently estimated that other retrofits would occur in 2019-2022 consistent with the commenter's recommendation. Staff has estimated that Refinery 1's gas turbines would be retrofitted in 2018 because the units have turnaround scheduled annually. This estimated schedule is used in the socioeconomic analysis with an assumption that the unused RTCs will be removed from the market early.

Response 1-4 Useful Life of Control Equipment

In the cost analysis for the proposed NOx RECLAIM amendment, staff has used a 25-year useful life for SCRs, LoTOx/scrubbers, and UltraCat applications. The commenter suggested that staff should have used a 10-year life since rule amendment is likely to occur in a 10-year interval (e.g. previous NOx RECLAIM amendment in 2005) and thus a 25-year life assumption makes the rule costs appear lower that they actually are by diluting the significant capital costs of required projects over a much longer time table than is likely to occur.

Staff used a 25-year life to be consistent with the following facts: [17]

1) The actual profile of SCRs in the SCAQMD: 27% of the refinery combustion equipment in the Basin has SCRs installed more than 25 years ago, and 63% of the refinery combustion equipment has SCRs installed more than 20 years ago. These units are still in operation and thus support the assumption of a 25-year useful life in the cost analysis.

2) Other air districts' staff has used similar assumption for control equipment life in their cost analysis: a) Some SCRs for refinery heaters in the Bay Area were installed in 1984 and thus the Bay Area air district staff uses a 20-year useful life in rule development. b) The SCRs in the Santa Barbara air district were installed in 1980-1990's and are still in good operating conditions, and thus the Santa Barbara air district staff supports a 25-year useful life of control device. c) Staff found several BACT analyses for the air districts in Florida that used 20- or 25-year useful life for SCRs.

3) The EPA OAQPS Costs Guidelines use a 20-year life for control equipment such as SCRs in their cost analysis.

4) Air pollution control manufacturers that staff contacted indicated that 20- or 25-year life is a reasonable assumption for control device such as SCRs, scrubbers, or LoTOx applications.

[17] Presented at the April 29, 2015 Working Group Meeting.

The commenter is concerned that a future RECLAIM amendment may require removal of equipment installed to meet the 2015 shave, so that the actual useful life is less than 25 years. This hypothetical has not been borne out by past experience. Even though the RECLAIM amendment was revised in 2005 and staff had estimated that the refineries would have to install 51 SCRs for refinery boilers/heaters by 2011, only 4 of these boilers/heaters were retrofitted with SCRs in responses to the EPA consent degrees or order of abatement. None of the SCRs were installed in responses to the 2005 BARCT assessment. Staff 2015 BARCT analysis did not identify any control equipment that would need to be removed in order to comply with the 2015 BARCT.

Furthermore, BARCT requirements were not revised in 2005 for refinery gas turbines, refinery SRU/TGTUs, refinery boilers/heaters >40 – 110 mmbtu/hr, glass melting furnaces, cement kilns and ICEs, thus the time interval between the BARCT assessments for these units is actually 22 years counting from the inception of the RECLAIM program in 1993. Adding several years allowed for planning, engineering, permitting, construction, and procurement of control equipment, the total time interval between installations of control equipment would be about 25 years.

The commenter implied that CARB may use a 10-year life for control devices. SCRs or scrubbers for major stationary sources are more durable than catalytic filters for mobile sources. CARB may use a 10-year life in their cost analysis for mobile source rules; however staff has consistently used a longer life when applicable in the cost analysis for major stationary sources: 1) a 25-year life was used in the cost analysis for electrostatic precipitators to control particulate emissions from FCCUs in Rule 1105.1; 2) a 20-year life was used for domes for refinery storage tanks in Rule 1178; 3) a 25-year life was used for SCRs in the 2005 NOx RECLAIM amendment; 4) a 25-year life was used for scrubbers in the 2010 SOx RECLAIM amendment; and 5) a 20- to 25-year life was used in Rule 1111. For other rules and regulations such as Rule 1146.1 and Rule 1147 that addressed low NOx burners, staff may use less than 25-year life depending on the type of control equipment and stationary sources. Finally, the commenter's concern can be addressed in any future RECLAIM amendment. In the event that the Board amends the rules in the near future to render obsolete any control equipment added, staff would add those stranded costs to the cost of that future amendment or consider a longer compliance schedule to maximize the useful life of the control equipment as much as possible.

Response 1-5 BARCT Analysis

In its comment letter electronically delivered on August 21, 2015, the Western States Petroleum Association (WSPA) claimed that "[…] RECLAIM must achieve emission reductions equivalent to or greater than traditional command and control, or BARCT. Thus, a NOx shave equivalent to BARCT (which the District proposes at 8.77 tpd) would be the level for comparison with the Health and Safety Code provision stating that equivalent or greater reductions would be achieved at `equivalent or less cost compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the District's plan for attainment.' Yet, SCAQMD does not seek merely its determined BARCT equivalency level of 8.77 tpd; it seeks 14 tpd of NOx reductions and has not demonstrated that such reductions will be achieved at equivalent or lower cost than BARCT. The additional 5.21 tpd reduction goes above and beyond BARCT. […]"

1) **Removing 8.77 tpd of NOx RTCs would not result in the BARCT-equivalent level of actual NOx emission reductions:** BARCT requires *actual* emission reductions. The 2015 BARCT analysis demonstrated that there would be an actual NOx emission reduction of 8.77 tpd from the 2011-2012 activity levels at 2015 BARCT compared to the same activity levels at 2005 BARCT. This represents 8.77 tpd reductions in actual emissions. If the overall NOx RTC holdings had closely matched the total amount of actual NOx emissions from the NOx universe, the removal of 8.77 tpd of NOx RTCs would likely induce an equivalent amount of actual NOx emission reductions. However, over the past five years, actual NOx emissions from RECLAIM facilities fell below the overall NOx RTC holdings by 21-30%, resulting in approximately 5.45-8.41 tpd of unused NOx RTCs (unused for compliance purposes). Therefore, the removal of 8.77 tpd of NOx RTCs would first eliminate some, if not all, of these unused NOx RTCs from the market and only thereafter result in actual emissions reductions. Therefore, total emission reductions would be less than the BARCT-equivalent level of actual NOx emission reductions. The problem of excess unused RTCs is illustrated by the fact that the 2005 NOx shave did not achieve 2005 BARCT levels for the RECLAIM universe. The 7.7 tpd of NOx shave adopted in the 2005 RECLAIM amendments was phased in over the period of 2007-2011; however, only about 4 tpd of actual NOx emission reductions occurred between 2006 (the year before the 2005 shave began) and 2012 (the year after the 2005 shave was fully phased in). Almost two-thirds of the actual emission reductions resulted from facility shutdowns, not installation of controls or other changes at RECLAIM facilities. Therefore, as long as there are persistently unused RTCs available in the market, the RTC shave would need to be larger than the tons of emission reductions calculated for the BARCT analysis to induce an equivalent level of actual emission reductions. The proposed phased-in shave of 14 tpd is anticipated to be able to induce sufficient emission reductions by 2023 so that the expected total NOx emissions from the RECLAIM universe in 2023 would be consistent with the projected NOx emissions in 2023 at the 2015 BARCT levels. (Please see the Staff Report for the shave methodology.)

   In summary, staff disagrees with WSPA's comment that the proposed phased-in shave of 14 tpd would go "above and beyond BARCT."

2) **Installation of pollution control equipment is just one of the compliance options and the estimated control installation costs may not be fully incurred to achieve the BARCT-equivalent level of actual NOx emission reductions:** Unlike the traditional command-and-control regulations that typically requires the installation of pollution control equipment on all

emission sources, a RECLAIM facility has the flexibility of using RTCs to offset its facility-wide emissions and is expected to do so whenever it is the least costly option. Since the 1970s, economic research has demonstrated, both theoretically and empirically, that the compliance flexibility offered by such cap-and-trade programs generates cost-savings (e.g., Tietenberg 1990; Chan et al. 2012).[18]

The major source of the cost-savings under any cap-and-trade program is the differential in each market participant's ability to cost effectively reduce emissions. For a facility that can more cost-effectively reduce emissions, it benefits from the sale of surplus emission credits to offset pollution control installation costs; whereas for a facility that finds actual emission reductions too costly, it buys emission credits to account for the emission reductions that can be more cost-effectively achieved elsewhere. Therefore, emission credit prices in a well-functioning market must lie in between the upper and lower bounds of cost per ton of emission reductions among all market participants. If there is a large oversupply of emission credits and the market price ends up too low, there will be little incentive for facilities to implement any actual emission reductions.

A RECLAIM facility is expected to retrofit an emission source only when it meets both of the following conditions: first, it does not hold sufficient RTCs to offset facility-wide emissions at the end of the compliance period; second, the cost of control installation per ton of emission reduction is lower than the expected average RTC price over the life of the control equipment. Even if a facility finds it more cost-effective to install pollution control equipment, it still would not incur the full cost of control installation if control installation results in surplus RTCs that the facility eventually sells to offset the control installation cost. In comparison, command-and-control regulations would require, under all circumstances, that this same facility install the control equipment and incur the full cost of control installation. As a result, total costs to install controls under RECLAIM will always be equal to or less than under command and control. Under command and control, each facility must install the required controls, whereas under RECLAIM, the highest cost option is where each facility installs BARCT controls, because the total actual costs may be lower if a facility identifies any other more cost-effective alternative to remain in compliance.

3) **California Health & Safety Code §39616 applies, if at all, to the entire RECLAIM program since adoption, and not to a single shave:** The WSPA comment letter interpreted

[18] Tietenberg, Thomas H. 1990. "Economic Instruments for Environmental Regulation." *Oxford Review of Economic Policy*. 6 (1): 17-33. Chan, Gabriel, Robert Stavins, Robert Stowe, and Richard Sweeney. 2012. "The SO2 Allowance Trading System and the Clean Air Act Amendments of 1990: Reflections on Twenty Years of Policy Innovation." Cambridge, Mass.: Harvard Environmental Economics Program.

that H&SC §39616 applies to the adoption of RECLAIM and also separately to each of the subsequent amendments. Staff disagrees with this interpretation. H&SC §39616 (c) specifies that: "In adopting rules and regulations to implement a market-based incentive program, a district board shall, at the time that the rules and regulations are adopted, make express findings." One of those findings pursuant to H&SC §39616 (c)(1) is that emission reduction benefits and the costs of the program shall be compared with those of "current command and control regulations and future air quality measures that would otherwise have been adopted as part of the district's plan for attainment." H&SC §39616 (c) does not refer to "amendments". Nevertheless, assuming that the finding needed to continue to be made upon amendment of the rules, it makes sense to make that finding with respect to the entirety of the RECLAIM program since its adoption because the statute repeatedly refers to "the program" in specifying findings that need to be made. Thus, the structure of H&SC §39616 is directed to the program as a whole, which includes the entirety of the program since its adoption. With the exception of the 2000-2001 period when the California energy crisis took place, the historical discrete NOx RTC prices ($5,500 or lower per ton) have consistently been at the lower end of or below the cost-effectiveness range of pollution controls. As a result, many RECLAIM facilities have accrued substantial cost-savings over the years by being able to delay or forego the installation of pollution control equipment that would have been required at different points in time by command-and-control regulations. And even if the H&SC §39616 (c)(1) finding needs to be made for this proposed shave alone, the proposed shave is expected to only reduce the future stream of this cost-savings. Even so, a reduced cost-saving is still a cost-savings compared to command-and-control regulations. Thus, this amendment will clearly not cost more than the projected cost of command and control.

Staff acknowledges that, for a portion of the smaller emitters that have no cost-effective controls identified so far, they may have been affected by past RTC price spikes and could potentially be impacted by any future price fluctuations, either due to their RTC holdings or their limited financial capacity to hedge against price volatilities. However, their potential losses would be at the same time economic gains for the RTC sellers; therefore, the resulting net cost, if any, is expected to be zero or negligible to the entire RECLAIM program, particularly compared with the program's cost savings. While individual facilities may experience different costs and savings, H&SC §39616 applies to the RECLAIM universe as a whole.

It is misleading to separate the proposed NOx RTC shave into 8.77 tpd and 5.21 tpd and to argue that the 5.21 tpd shave of excess unused RTCs goes beyond BARCT, because BARCT is defined as the maximum degree of emissions reductions achievable (H&SC § 40406), and a shave of 14 tpd from current RTC levels of 26.51 tpd is necessary to attain the 12.51 tpd (26.51 tpd – 14 tpd = 12.51 tpd) of remaining NOx emissions in 2023, which staff analysis shows can be achieved with 2015 BARCT, after making allowances for growth, a compliance margin, and uncertainties that arose in the BARCT analysis. As a result, the 14 tpd shave does not go beyond BARCT. For the same reason, it is a distorted assertion that the estimated full control installation cost of $0.62-1.09 billion should be attributed to 8.77 tpd of NOx RTC shave only, with additional costs allegedly attributable to shaving the 5.21 tons of excess unused RTCs. This cost was estimated for *actual* NOx emission reductions of 8.77 tpd under command-and-control regulations, and it serves as the most conservative (i.e., maximum) estimate of the overall compliance cost for the proposed NOx shave of 14 tpd that will be needed to achieve the BARCT-equivalent level of NOx emission reductions. As noted above, costs to RTC buyers are offset by gains to RTC sellers so that this factor does not increase costs to the RECLAIM universe. The claim that costs should include the "value" of shaved RTCs is addressed below.

In the 2005 RECLAIM amendments, some stakeholders commented that the shaved RTCs would result in real, significant financial cost to companies and should be recognized as a cost. However, staff disagreed at the time RECLAIM was first adopted and still disagrees today. Staff has never considered the "cost" of the shaved RTC's to be recognized as a "cost" for determining equivalency with command and control. At the outset of RECLAIM, RTCs were allocated to RECLAIM facilities free of charge, yet they now have value to the facilities as a commodity that can be bought and sold. While RTCs have value, they are not a property right. The proposed amendments to RECLAIM will reduce the number of RTCs. Since there was no cost associated with allocated RTCs for a facility, there should be no financial loss to the RECLAIM universe as the SCAQMD retires them. Any additional purchase of RTCs executed by a facility is made in lieu of emission control. The choice between the RTC purchase and emission control is solely a business decision that is made to generate an expected stream of cost-savings afforded only by the RECLAIM program and not available under command-and-control. Therefore, any RTC investment loss should not be considered as a compliance cost to be compared to the compliance cost under command-and-control regulations. Moreover, this loss may be offset by any potential increase in RTC price due to a decreased RTC supply, which would subsequently raise the market value of a facility's remaining RTC holdings. Finally, any loss of "value" of shaved RTCs cannot be compared to command and control, because in that case, there are no RTCs and thus no similar "value" was ever created.

4) **Many unused RTCs are the result of shutdown selloffs, which have caused undue delay of BARCT-equivalent level of actual NOx emission reductions:** According to staff analysis of the RECLAIM transaction records, many of the unused RTCs were sold, as Infinite-Year-Blocks (IYBs), to operating RECLAIM facilities by some of the now-closed facilities prior to facility closure. These excess RTCs have been artificially depressing RTC prices and have induced RECLAIM facilities to delay the installation of cost-effective controls. A case in point is the 2005 NOx RECLAIM amendments. Despite 7.7 tpd of NOx RTC shave being implemented over the period of 2007-2011, only 4 tpd of actual NOx emission reductions had occurred by the end of the 2012 Compliance Year. Some of the 4 tpd of actual reductions came

from operational changes at refineries, which chose to run gas turbines instead of higher-emitting boilers at various points in time. However, just less than two thirds of the 4 tpd actual reductions were due to facility shut-downs and not measures taken to reduce actual emissions by facilities in the program. In 2005, the shave amount was partially based on the BARCT analysis that included the installation of 51 SCR units at refineries. However, not one has been installed due to the RECLAIM program. (Four SCR units were installed only due to orders for abatement.) While that choice did not violate RECLAIM, it resulted in facilities not achieving the level of emissions they would have achieved had they applied BARCT. As a result, there is a need to ensure that the currently proposed shave is sufficient to induce emission reductions equivalent to 2015 BARCT levels, accounting for growth to 2023.

The original intent of RECLAIM, or any cap-and-trade program, is for all participating facilities to benefit from the differential in each operating facility's ability to cost effectively reduce emissions. It is not to shift a closed facility's prior pollution credits to any facility still in operation and cause undue delay of BARCT-equivalent level of actual NOx emission reductions. (Under command-and-control, any pollution credits from a shut-down facility would at least be discounted by BACT.) As a result, staff proposes this level of BARCT-based shave to substantially reduce the amount of unused RTC credits in the market in order to better ensure the timely implementation of BARCT as required under state law.

Response 1-6 NEC Study

Staff disagrees with the commenter's suggestion that the BARCT cost analysis for the refinery sector needs to be revised to explicitly consider the findings presented by the Norton Engineering Consultants (NEC). First of all staff and NEC both obtained the same average cost effectiveness for refineries. Table 6.1.6 summarized the differences in staff's and NEC's findings in each category of sources:

Total difference in emission reductions: 6.00 tpd (staff) – 5.67 tpd (NEC) = 0.33 tpd
Total difference in PWVs: $629 million (staff) - $562 million (NEC) = $67 million
No difference in average cost-effectiveness for refineries = $11 K per ton (NEC and staff).

Secondly, staff has reduced the proposed shave by 0.85 tpd to more than account for the difference in 0.35 tpd shown above and provide additional compliance margin. The cost-effectiveness value of $11 K per ton estimated by both NEC and staff is lower than the estimated $16 K per ton for the Control Measure CMB-01 in the 2012 AQMP. [19]

The difference between the two analyses occurs in the category of boilers/heaters. Staff's estimates resulted in 0.33 tpd more emission reductions because 35 more heaters that were considered cost-effective compared to NEC's estimates because NEC and staff used different cost

[19] Page IV-A-58, Appendix IV-A, and Table 6-4 of 2012 AQMP.

data to estimate cost. Staff believes its proposal was reasonable since its approach utilized information in the facility permits, information provided by the refineries through the Survey, and information provided by several prominent manufacturers of control devices for each specific category of sources. NEC used a verbal quote for one FCCU SCR to derive the costs for FCCUs, boilers/heaters and SRU/TG applications. The SCR catalysts for FCCU are not the same as the catalysts for boilers/heaters and SRU/TG applications. Nevertheless, staff added 0.8 tpd to the remaining emissions (i.e. reduced the shave by 0.8 tpd) to allow for this difference. Further explanations are provided in Response 1-6 for FCCUs and Response 1-7 for boilers/heaters.

Table Z.1-6 – Differences in Staff's and NEC's Findings

Category	Proposed BARCT	Emission Reductions	Cost Effective Units	PWVs	Incremental Cost Effectiveness DCF (note 1)	Conclusion
Boilers and Heaters with SCRs	No difference 2 ppm	Staff = 0.94 tpd NEC = 0.61tpd Diff. = 0.33 tpd	Staff = 83 units NEC = 48 units Diff. = 35 units	Staff = $242M NEC = $162M	Staff = $28K/ton NEC = $29K/ton	0.85 tpd shave reductions (note 2)
FCCUs with SCRs	No difference 2 ppmv	No difference 0.43 tpd	No difference 5 FCCUs (note 3)	Staff = $152M NEC = $211M (note 3)	Staff = $18K/ton NEC = $25K/ton	No difference
SRU/TGTUs with SCRs	No difference 2 ppmv	No difference 0.32	No difference 9 SRU/TGTUs	Staff = $83M NEC = $96M	Staff = $28K/ton NEC = $33K/ton	No difference
Gas Turbines with SCRs	No difference 2 ppmv	No difference 4.14 tpd	No difference 11 gas turbines	Staff = $98M NEC = $53M	Staff = $3K/ton NEC = $1K/ton	No difference
Coke Calciner with LoTOx	No difference 10 ppmv	No difference 0.17 tpd	No difference 1 coke calciner	Staff =$54M NEC =$39.5M	Staff = $35K/ton NEC = $25K/ton	No difference
Total		**Staff = 6.00 tpd NEC = 5.67 tpd**	**Diff. = 35 heaters**	**Staff = $629M NEC = $562M**	**Staff = $11K/ton NEC = $11K/ton**	**0.85 tpd shave reductions (note 2)**

Note: 1) Ratio LCF/DCF = 1.6, e.g. $1K/ton DCF = $1.6K/ton LCF. 2) Staff provided 0.85 tpd reductions in shave to account for uncertainties in cost analysis assumptions for boilers/heaters and additional compliance margin. 3) Refinery 4 FCCU is scheduled to be shut-down in 2017-2018 which would result in lowering the costs estimated for this category.

As shown in this table, except for boilers/heaters, the same equipment was identified as cost-effective regardless of whether NEC costs or staff estimated costs were used, so there is no difference in calculated BARCT emission reductions. In the socioeconomic report, staff used the high end of the total costs.

Response 1-7 NEC Study for Boilers/Heaters

WSPA ~~sasserts~~asserts that because only a few boilers and heaters are currently equipped with SCR are currently meeting 2 ppmv NOx, this level cannot be BARCT.

NOx Feasible Level

First, it is important to note that staff is obligated to find technology that can reduce maximum amount of pollution to help the basin achieve the ozone and PM2.5 standards and meet the requirement sated in H&SC §40406:

> "… *an emission limitation that is based on the maximum degree of reduction achievable, taking into account environmental, energy, & economic impacts by each class or category of source*."

The two criteria required to be considered for BARCT are 1) technologically feasible and 2) cost-effective. The feasible and cost-effective control technology must be considered BARCT even if they are not yet operational in the District. In this case, WSPA admits that some units are currently achieving 2 ppmv which is strong evidence that this level is achievable. Staff is not required to focus only on achieved-in-practice and fully commercialized control technology (i.e. technology that is either being offered commercially by vendors or is in commercial demonstration or licensing)[20]. Staff can use a control technology that has been previously installed and operated successfully at a similar type of source, or has potential for application to the source (i.e. has been successfully applied to similar sources with similar gas stream characteristics). For boilers/heaters category, staff included the analysis for SCRs as well as Great Southern Flameless and ClearSign as shown in Appendix B of the PDRS.

Contrary to the commenter's understanding, the H&SC does not specify any threshold on the number of units that must be proven achieved-in-practice for a control technology to be considered feasible. [21]As an example, in the 2010 SOx RECLAIM amendment, staff assessed and determined that a level of 10 ppmv SOx was feasible and cost-effective for a sulfuric acid plant using wet gas scrubber technology even though there was no sulfuric acid plant that had yet achieved this level. The sulfuric acid plant installed a wet gas scrubber in 2011 after the rule was amended, source-tested the unit, and demonstrated that the unit met a level much less than 10 ppmv.

Regarding the count of boilers/heaters, based on information received from the refinery Survey, 14 heaters using refinery fuel gas were reported to achieve 1.6 - 3.5 ppmv NOx with SCRs (Table B.3 of Appendix B). Four of the 14 heaters were reported to achieve 1.6 ppmv NOx. The heaters' maximum ratings are 88, 125, 177, and 199 mmbtu/hr. Based on information in the permit applications, three heaters were first installed in 1970, the fourth heater and the SCR were installed

---

[20] American Coatings Assoc. v. SCAQMD, 54 CAL. 4TH 446 (2013)

[21] American Coatings Assoc. v. SCAQMD, 54 CAL. 4TH 446 (2013)

in 1994. In 2004, all four heaters were modified to increase the overall heaters' capacities, and thus all 4 heaters were subject to a permit limit of 5 ppmv NOx. It should be noted that the SCR has been in operation for 21 years and still achieves a level below 2 ppmv NOx. Thus, it is reasonable for staff to consider 2 ppmv as a feasible BARCT level.

It seems that the WSPA/ERM's confidential survey in March 2015 reported different information than the information in the permits. It indicated that only 2 of the 4 heaters were retrofits and the remaining 2 heaters were new.

As stated above, besides SCRs, staff has also identified other control technologies that can potentially achieve 2 ppmv NOx level such as Great Southern Flameless, ClearSign, and LoTOx. A crude heater manufactured by Great Southern Flameless installed at the Coffeyville refinery in Kansas achieved 3-8 ppmv NOx without the use of SCR. Two boilers using natural gas equipped with LoTOx achieved 2-5 ppmv. ClearSign has recently signed a contract with Tesoro to retrofit a heater at Tesoro refinery and hopefully this project can be proven to achieve 2 ppmv NOx without the use of SCR. Great Southern Flameless, ClearSign, and several prominent SCR manufacturers provided staff the estimated costs of control equipment that can be designed to achieve 2 ppmv NOx.

Response 1-8 FCCUs

WSPA contents that staff should not set a BARCT level of 2 ppmv NOx for FCCUs because only one FCCU is currently achieving this level. Staff is required to find technology that can potentially reduce maximum amount of pollution to meet the requirement stated in the H&SC §40406 and help the basin achieve the NAAQS for ozone and PM2.5. Although staff recognizes that there are differences among different refineries, both staff analysis and NEC's analysis identified 2 ppmv as achievable BARCT for FCCUs.

Staff has evaluated two potential control technologies for FCCUs, SCRs as well as scrubber/LoTOx and estimated the cost-effectiveness values for both technologies to ensure that the control technologies were cost-effective. The SCR and LoTOx/scrubbers manufacturers confirmed that 2 ppmv is feasible and provided cost information for the cost analysis.

Each refinery may have unique circumstances (e.g. equipment type, age) and different upstream configuration, however the downstream control equipment such as LoTOx/scrubber and SCR can be designed to achieve the 2 ppmv level as confirmed by the manufacturers and agreed by NEC.

There is precedent in identifying controls based on achievements by a single FCCU at the time the rule adoption. For example, in previous rule development in the SCAQMD, only one FCCU had achieved the BARCT level of Rule 1105.1 at the time the rule was developed.[22] Likewise, only one FCCU in the Basin had achieved the BARCT level of 5 ppmv SOx at time the rule was amended in 2010.

Regarding SCR costs, staff estimated a range of $152 million (no markups) to $163 million (with two layers of markups used by NEC). NEC estimated $211 million (with different feed rates.) NEC's estimates were about 40% higher than staff's estimates. The SCRs were cost-effective at 2 ppmv using either NEC's or staff's estimates. The cost effectiveness for FCCU SCRs has a range of $18K/ton - $25 K/ton.

Response 1-9 Costs and Cost Effectiveness Analysis

This comment asserts that staff's BARCT analysis should be changed because NEC estimated higher costs for certain equipment.

Cost Effectiveness for Refinery Sector

The costs and cost-effectiveness values for each individual class or category of sources are summarized in Table 6.1.6. The overall weighted average cost-effectiveness for the refinery sector based on NEC's and staff's estimates is $11 K per ton DCF ($18 K per ton LCF) with SCR technology, which is well below the thresholds that the commenter cited for the BACT Guidelines and the 2012 AQMP.

Since RECLAIM achieves its reductions in the aggregate rather than based on individual equipment, it is appropriate to look at cost-effectiveness in the aggregate using total program costs and total program reductions.

This comment also asserts that staff should have used the LCF methodology. Staff used a threshold level of $50,000 per ton DCF to exclude individual equipment from the BARCT analysis to be consistent with the SOx RECLAIM amendment in 2010. The cost-effectiveness values based on DCF and LCF methods are not directly comparable to each other: DCF discounts all future operation and maintenance costs to their present values whereas LCF amortizes the initial capital and installation costs over the equipment lifetime. This is why DCF values are always lower than LCF values for the exact same amount of estimated compliance cost. Due to this methodological difference, staff disagrees with the commenter's claim that the same cost effectiveness threshold should be used for both DCF and LCF methods. If the threshold for DCF was $50,000 per ton, the threshold for LCF should be about $80,000 per ton.

[22] Rule 1105.1 – Reduction of PM10 and Ammonia Emissions From Fluid Catalytic Cracking Units, Adopted November 7, 2003.

Cost Effectiveness Thresholds in BACT Guidelines

The commenter cited a threshold in the BACT Guidelines of $19,100 per ton NOx reduced. It should be noted that this threshold was estimated in the 2nd quarter of 2003 and should be adjusted to $28,000 per ton as of 2015 dollars. The threshold considers the difference in costs and emissions between a proposed BACT and an uncontrolled case. The commenter however should cite the threshold for “incremental” cost effectiveness which looks at the difference in costs and emissions between a proposed BACT and a less stringent control level. The threshold for “incremental” cost effectiveness is $57,200 per ton as of 2nd quarter 2003 and should be adjusted to $80,000 per ton as of 2015 dollars. This is a more appropriate comparison when looking at two possible incrementally different levels of control.

More important, these thresholds are for equipment located at non-major polluting facilities (also known as minor sources BACT, or MSBACT, in Part C of the BACT Guidelines). There are no thresholds for sources located at major polluting facilities such as the refineries, BACT/LAER is required without any cost consideration for sources located at major polluting facilities (Part A and B of the BACT Guidelines).

Cost Effectiveness for Entire Proposed RECLAIM Project (Refinery and Non-Refinery)

This comment further asserts that RECLAIM facilities may be being treated disproportionately compared to facilities under command-and-control by having higher cost effectiveness. First of all, it is necessary to look at the RECLAIM program as a whole since H&S Code 39616 (c)(7) refers to “disproportionate impacts measured on an aggregate basis” on sources in RECALIM. As shown below, the cost effectiveness for the entire RECLAIM project, including refinery and non-refinery, ranges from $7K - $12K per ton.

The PWVs for the entire NOx RECLAIM project as shown in Tables 4.3 and 4.4 (w/o cement kilns):

Low end: $565 million (refinery) + $163 million (non-refinery) = $728 million
High end: $923 million (refinery) + $176 million (non-refinery) = $1099 million

Total emission reductions: 6.00 (refinery) + 2.77 (non-refinery) = 8.8 tpd

The overall range of cost-effectiveness for the entire RECLAIM project:

Low end of range: 728,000,000/8.8/25/365 = $9,066 per ton
High end of range: 1,099,000,000/8.8/25/365 = $13,686 per ton

Table Z.1-9 Cost Effectiveness Comparison

	Cost Effectiveness ($/ton)
Proposed Amendment	9,066 – 13,686
Control Measure CMB-01	7,950 (Phase I) – 16,000 (Phase II) [23]
Threshold in BACT Guidelines for “Minor Sources”	80,000 [24]
2012 AQMP	22,500 [25]

As shown in Table Z.1-9, the cost-effectiveness for this proposed NOx RECLAIM amendment is less than the thresholds that the commenter cited for the BACT Guidelines and the 2012 AQMP. They are also within the average cost effectiveness estimated for Control Measure CMB-01 in the 2012 AQMP.

Moreover, the NOx cost-effectiveness threshold of $22,500 proposed in the 2012 AQMP was intended as a threshold above which tiered levels of analysis would be conducted. It was not intended as a threshold above which a control measure would automatically be excluded. Therefore, this threshold should not be used to determine whether proposed rules or amendments would be cost effective.

In conclusion, it is conservative in using a threshold of $50,000 per ton for “incremental” cost effectiveness to eliminate cost-ineffective individual scenarios.

Response 1-10 Costs and Cost Effectiveness Analysis

This comment asserts that NEC conducted a comprehensive evaluation of site-specific factors for each refinery, which staff did not appropriately consider. However, staff has maximized the use of site specific information provided by NEC on installation, design, engineering costs, space needed, plant configuration, equipment type, equipment age, length of time for SCR to operate and remain in service, and time needed for construction.

As explained in response 1-6, in only one case did NEC reach a different conclusion than staff regarding the appropriate BARCT (boilers/heaters). For that category, staff removed the emission reductions associated with equipment that was cost-effective under staff’s analysis but not under NEC’s analysis from the BARCT reductions (0.33 tpd. In fact, staff actually removed 0.8 tpd from the proposed shave.) The socioeconomic report gives appropriate consideration to the higher end of total BARCT costs.

[23] Table 6-3 and 6-4 of the 2012 AQMP, and page IV-A-13 and page IV-A-58, Appendix IV-A of the 2012 AQMP
[24] “Incremental” cost effectiveness on page 29 of the SCAQMD BACT Guidelines, dated July 2006, adjusted to 2005 dollars
[25] Cited by the commenter, page 4-43 of the 2012 AQMP, February 2013

This commenter further asserts that staff did not properly consider installation, design, and engineering costs and that what is cost effective at one refinery may not be at another. Again, NEC confirmed, after visiting the sites, that staff's proposed BARCT was appropriate for all cases except refinery boilers/heaters, described above. Staff looks forward to receiving the additional information WSPA states that it will submit.

Response 1-11 Disproportionate Impacts

This comment asserts that RECLAIM facilities may be disproportionately impacted because non-RECLAIM facilities represent the majority of stationary source NOx emissions yet the District does not appear to be seeking reductions from them. The commenter also argues that reductions from non-RECLAIM sources must be "proportionate".

It is incorrect to assert that staff is not seeking reductions from non-RECLAIM sources. Staff is seeking emission reductions for all sources, RECLAIM and non-RECLAIM, where feasible and cost-effective control technologies are available to help the basin achieve the ozone and PM2.5 ambient air quality standard as expeditiously as possible.

Even though RECLAIM sources collectively account for 27 tpd NOx emissions while non-RECLAIM sources such as residential fuel combustion, waste disposal, and miscellaneous processes together account for 46 tpd, RECLAIM is the fourth largest source of NOx emissions in the Basin and the top #1 emitting stationary source. There is no requirement to reduce NOx emissions from all sources at the same time. Nor is there any requirement that all sources must reduce emissions "proportionately", i.e. by the same percentage.

Instead the law requires the District to seek BARCT-level reductions from all existing sources. BARCT is not a fixed percentage such as 40% or 50% reductions. Instead, it is defined as the maximum level of reductions achievable for each class or category of sources. For example, some equipment may be already relatively low-emitting so the maximum achievable reductions may be a smaller percentage, and some equipment may not have a cost-effective option available that will achieve the same percentage reduction as the RECLAIM sources. As long as each category implements the maximum reductions achievable for that category, there is no disproportionate impact.

Staff has continually sought BARCT NOx emission reductions from all sources, large and small. Recent examples include Rules 1110.2 (engines), 1146, and 1146.1 (boilers, heaters, steam generators) and Rule 1147 (miscellaneous NOx sources). The District has regulated sources as small as residential water heaters (Rule 1121).

Furthermore, the control technologies that can reduce emissions from RECLAIM sources are commercially available and some are achieved-in-practice whereas the control technologies for many non-RECLAIM sources are being developed and not yet identified in the 2012 AQMP.

In addition, the RECLAIM program offers many other benefits to the RECLAIM facilities which show that these sources are not suffering disproportionate impacts on an aggregate basis.

— *Source-specific standards.* The non-RECLAIM facilities are subject to source-specific standards (e.g. concentration limit or mass emission limit) and every source (e.g. boiler or heater) at the non-RECLAIM facilities must be controlled to the same concentration limit or mass emission limit, and the source-specific command-and-control limit cannot be exceeded at all times whereas the RECLAIM facilities can operate their equipment with flexibility, they can purchase RTCs from other RECLAIM facilities to reconcile the emissions with the facility caps at the end of the compliance year in lieu of installing control;

— *BACT Discount.* The emissions from shutdown equipment at the non-RECLAIM facilities are required to be discounted to the BACT level before ERCs can be issued whereas the RECLAIM facilities can use or trade the RTCs associated with shutdown equipment without any BACT discount;

— *NSR Offset Factor.* The new or modifying non-RECLAIM facilities undergoing New Source Review (NSR) are required to offset any NOx or SOx emission increase by a factor of 1.2 to 1.0 ratio whereas the RECLAIM facilities are not subject to this offset. Instead, the RECLAIM facilities are required to hold sufficient RTCs based on their maximum potential to emit at a ratio of 1.0:1.0 at the beginning of each compliance year, and they can sell back the unused RTC offset holdings at the end of each compliance year.

— *Flexibility to Install Control.* The RECLAIM facilities have the flexibility to install the least cost controls first, and have the flexibility to use the program averaging and cross-cycle trading to balance their compliance option.

— *Trading.* In addition, the RECLAIM facilities receive monetary benefits from trading their RTCs (equivalent to "Potential-to-Emit") for the past 22-year life of the RECLAIM program to reduce the costs of compliance.

Because of the many benefits available in the RECLAIM program, staff believes that the RECLAIM facilities are not being disproportionately impacted by participating in the program.

Response 1-12 Energy Efficiency Projects

In responses to question #10 of the Survey Questionnaire,[26] the refineries sent to staff the CARB's report released in June 2013.[27] Note that the actual emissions and the RTC holdings have different "currencies". It is very likely that the 2011 emissions baseline already reflects the energy efficiency projects (i.e. 0.7 tpd co-benefit reductions were included in the baseline.) However, The RTC holdings ("Potential to Emit") were last adjusted in 2005, and at that time, the energy efficiency projects were not yet been completed, thus the RTC holdings ("Potential to Emit") have not yet been reduced to reflect the energy efficiency projects. However, staff did not reduce the shave by 0.7 tpd to reflect the co-benefit reductions of the energy efficiency projects because this was used to offset the increase between the 2011 and 2012 emissions baseline for the refinery sector. The information on energy efficiency projects as part of the responses to the refinery Survey should be included in the PDSR.

Response 1-13 Socioeconomic Impacts

Staff is working on the socioeconomic report and the report will be made available soon.

Response 1-14 2012 Compliance Year Emissions Baseline

Staff used the 2011 compliance year emissions as baseline because 2011 is the last year for implementation of the 2005 NOx RECLAIM amendment. Staff estimated the shave based on the remaining emissions projected to the 2023 compliance year. If the compliance year 2011 emissions were used, the growth factor from 2011-2023 will be used to project the emissions to 2023. If the compliance year 2012 emissions, the growth factor from 2012-2023 will be used to project the remaining emissions. Both methods should result in the same 2023 remaining emissions for RECLAIM facilities assuming that the growth factors are projected reasonably accurate to reflect the change in emissions. For the refinery sector, staff used a [WW3][m4]growth factor of 1.0 provided by the refineries since the inception of the RECLAIM program in 1993. The 2012 compliance year emissions are 0.6 tpd higher than the 2011 compliance year emissions, thus the 2023 remaining emissions would be 0.6 tpd higher for refinery sector. However, there are 0.6 tpd co-benefits associated with the energy efficiency projects that were not being taking out of the RTCs holdings in the 2015 NOx RECLAIM amendment which would wash out the effect of the change in baseline year.

[26] Appendix L of the PDSR
[27] Appendix K of the PDSR

Response 1-15 NEC's Cost Analysis

Refer to Responses 1-6, 1-7 and 1-10. On contrary to the commenter's remarks, staff strongly believes the approach used is consistent with the requirements in H&S Codes in evaluating and conducting a technical feasibility and cost-effectiveness analysis for the NOx RECLAIM project. Staff did not ignore NEC's findings. On the contrary, staff has maximized the use of NEC's site specific information on installation, engineering costs, space needed, plant configuration, equipment type, equipment age, length of time for SCR to operate and remain in service, and time needed for construction. Moreover, NEC reached the same conclusion as staff for BARCT for all refinery source categories except boilers/heaters. For that category, staff adjusted the BARCT goal by adding 0.8 tpd to the goal, which is more than enough to account for the emission reductions attributable to equipment that was not cost-effective under the NEC analysis.

Response 1-16 0.85 tpd for Uncertainties

Refer to Response 1-7. Staff believes that providing 0.8 tpd RTCs is sufficient to account for the uncertainties and differences in the analysis related to boilers/heaters which amount to only 0.33 tpd difference in emission reductions between staff's and NEC's analyses

Response 1-17 Regional NSR Holding Account for Non-Electric Generating Facilities

Staff has created a Regional NSR Holding Account to help facilities in the power sector subject to Rule 2005 NSR requirements. Staff has discussed this issue with the U.S. EPA to seek their approval on the concepts. Other facilities have more flexibility than Electric Generating Facilities to reduce their PTE and thus their required RTC holdings if their actual emissions are lower than their PTE.

Response 1-18 Compliance Margin

Refer to Response 1-2 for discussion on compliance margin. The cement plant was shutting down but staff still included 0.29 tpd for the remaining emissions of cement kilns and 0.1 tpd for the remaining emissions of other shutdown facilities. Since the cement plant and other shutdown facilities are not coming back in business, this amount of RTCs will serve as additional compliance margin to the entire NOx RECLAIM universe.

Response 1-19 Across-the-Board Shave

Refer to Responses 1-3.

Response 1-20 Emissions from 219 Facilities

Staff will revise the statement to state:

"The remaining 219 facilities that hold 10% of the 26.5 tpd RTC are not proposed to be shaved because there is was either no new BARCT for the types of equipment and operation at these facilities (e.g. these facilities do not have FCCUs, coke calciner), or limited amount of emission reductions that could be achieved (less than 0.1 tpd for ICEs and small boilers/heaters).

Response 1-21 Implementation Schedule

Staff believes that the amount of unused RTCs in the market can support 4 tpd early reductions in 2016, and extending one more year from 2022 to 2023 may not be necessary.

Response 1-22 Longer Public Participation

Staff has been conducted public meetings on the proposed NOx RECLAIM for almost 3 years, and staff is planning for a public hearing in November 2015. The CEQA and socioeconomic analyses would be released for public comments according to the requirements in the H&SC §40440.5.

Response 1-23 Energy Efficiency Projects

Refer to Response 1-12.

Response 1-24 CEQA Alternatives

The size of the shave to represent 3-5 tpd of Control Measure CMB-01 of the 2012 AQMP would be about 11% - 19%, between the "No Project" Alternative (0% shave for Alternative 4) and the "Industry Proposal" Alternative (33% shave for Alternative 3).

Response 1-25 Cost Analysis

Please refer to Responses 1-5, 1-9, and 1-10.

Response 1-26 Useful Life 25 Years
Refer to Response 1-4.

Response 1-27 DCF versus LCF Cost Effectiveness

Refer to Response 1-9.

Response 1-28 Reductions and Remaining Emissions

Refer to Response 1-2 for the response addressing remaining emissions, Control Measure CMB-01, shave methodology, and the necessity to seek for more than 5 tpd reductions as estimated in Control Measure CMB-01. Refer to Response 1-11 for the response addressing disproportionate impacts. Refer to Responses 1-5 for the response addressing H&S Code 39616 requirements.

Response 1-29 Compliance Margin

Refer to Response 1-2. In addition, WSPA's comment admits that the program has functioned on as little as 15% compliance margin, and has not shown any need for the much longer amount of excess RTCs allowed by the industry's proposal.

Response 1-30 Remaining Emissions for Refinery Sector

Refer to Responses 1-6 and 1-7. NEC identified the same BARCT for all refinery categories except boilers/heaters. Staff provided 0.8 tpd reductions in shave to account for comments received from stakeholders regarding uncertainties in the BARCT analysis and thus provide additional compliance margin. Staff is required to show incremental cost effectiveness for the entire category of source and not for individual equipment. Thus, incremental emission reductions = 0.43 tpd (incremental emissions from 2005 BARCT) and incremental PWVs = $152 - $391 million for the FCCU category.

Response 1-31 Appendix A - FCCUs

Refer to Response 1-6.

Response 1-32 Appendix B – 2 ppmv Level for Boilers/Heaters

Refer to Response 1-7. The count of boilers/heaters presented at the September 19, 2013 Working Group Meeting (9 heaters having NOx emissions between 1.6 – 5 ppmv) was updated at a later date. The updated list in the PDSR showed 14 heaters with NOx emissions between 1.6 – 3.5 ppmv. Furthermore, the level of 2 ppmv not 3.5 ppmv should be considered as BARCT since it is "*…an emission limitation that is based on the maximum degree of reduction achievable, taking into account environmental, energy & economic impacts by each class or category of source*".

Response 1-33 Appendix B – NEC's Analysis for Boilers/Heaters

Refer to Response 1-7. Several heaters have already achieved this level presenting strong evidence that it is achievable. The difference in emission reductions between the two estimates was only 0.35 tpd and staff provided 0.85 tpd reductions in RTC shave to account for uncertainties in the assumptions of the cost analysis and additional compliance margin.

Response 1-34 Appendix B – Cost Analysis for Boilers/Heaters

Staff does not understand the comment. The "programmatic" overall average cost effectiveness for boilers/heaters category is $27,529 ton NOx reduced as shown in Table B.11, page 77 and Table 4.3. Refer to Table 6.1-6 for comparison between NEC's and staff's estimates. Also, refer to Response 1-7.

Response 1-35 Appendix D – Coke Calciner

This comment supports staff recommended BARCT for this category. No response is needed.

Response 1-36 Appendix E – SRU/TGs Applications

NEC's cost analysis does not alter the BARCT conclusion for SRU/TG applications. There were no differences in emission reductions between the two estimates. NEC's estimates of costs were 16% higher than staff's estimates. SCRs were cost-effective with NEC's and staff's estimates of costs. See Table 6.1-6.

Response 1-37 Appendix K – Energy Efficiency Projects
Refer to Response 1-12

Response 1-38 Shave Approach
Refer to Response 1-3.

Comment Letter #2 – NEC's Letter Dated August 10, 2015

Comment 2-1 FCCU SCR Costs

NEC stated that they agreed that 2 ppmvd (3% O_2) NOx emissions is a justifiable emission level for SCR applications to FCCUs, Fired Heaters, Boilers, Gas Turbines and TGU/SRUs, with caveats….. NEC believed that it is possible to achieve these levels, but to guarantee long term reliable performance (refineries typically operate 24/7 for periods of 4 to 6 years) it is prudent and quite possibly necessary to design future SCRs to increase residence time, improve NH_3 distribution, improve overall flue gas flow distribution, add catalyst, etc. SCAQMD staff agrees with this concept but NEC and staff have strong disagreement as to how much change from current SCR designs will be required to achieve the sought after NOx reductions not only on day one but at the end of year one and year five and beyond.

Response 2-1

Staff concurs that there may need to be a change from current SCR designs in order to achieve the 2 ppmv. As presented in the Preliminary Draft Staff Report (PDSR), the SCR profile for the refinery FCCU SCRs currently installed relies on 2-layers of catalyst. The NEC model is scaled to operate using 3-catalyst layers. This merely reflects a difference in engineering approach. NEC is arguing that the third bed is needed for reliability, however Refinery 1 has operated their FCCU SCR with two beds of catalysts and achieved less than 2 ppmv NOx since 2003 and several manufacturers provided costs based on SCR applications using a 2-layer catalyst bed that meet the proposed 2 ppmv BARCT emissions level, thus staff believes that 2 layers of catalysts are sufficient. The NEC model is not based on or proposed for a specific SCR application, but instead provides a configuration that will achieve the same reductions. The resulting technical specifications between the two approaches are different, whereby the SCR box size, catalyst volume, and layer configuration, among other aspects of installation, account for the difference in cost estimates. However, the potential additional cost to enhance SCR designs does not impact the total proposed reduction in RTC holdings.

Comment 2-2 Basis for Catalyst Addition and Velocity Reductions vs Vendor Budget Quotes

All FCCU SCR catalyst beds are in the range of 3 - 4' deep, all are prone to plugging by catalyst and/or ABS and all have limitations on allowable pressure drop, so superficial velocity is a good basis for comparison between units. The district has three operating FCCU SCRs. All units have two catalyst beds and operate at superficial gas velocities in the range of 8 to 13 ft/sec. Two of the three units, operating at superficial velocities of 12 and 13 ft/sec do not achieve emissions of 2 vppm @ 3% O_2. The other unit, highlighted in the draft report, achieves less than 2 vppm @ 3% O_2 operating at a superficial velocity of 7.7 ft/sec. The "good" unit is operating with inlet NOx levels which are 50% of design or lower and at lower than design flue gas flows. There are several ways to bring the two "non-performing" units into compliance with the revised standard, each with different costs and different overall performance impacts. NEC was not commissioned to do an evaluation of individual units and propose improvement options, but rather to make an assessment of what it would take, cost wise, to reliably achieve the 2 ppmv limit for grass roots SCR installations. Based on the experience of operating units in the district, and our direct experience with FCCU units for other clients (due to confidentiality agreements we cannot divulge client identities and specific locations) reliably achieving 2 vppm NOx emissions in an FCCU over a five year run will require the addition of catalyst and will be designed for superficial velocities of 10 ft/sec or less. Considering that SCR catalyst vendors have not developed and guaranteed a specific SCR design for 2 ppmvd @ 3% O_2 NEC feels that it is prudent to assume that a third bed of catalyst (SCR or ASC) and cross section designed to achieve a maximum superficial velocity of 10 ft/sec is sufficient to characterize the most likely cost of a SCR unit capable of achieving 2 ppmvd in a typical refinery FCCU environment. The impact of the increased cross sectional area and the addition of a third bed of catalyst on the cost of an SCR installation has been overstated by district staff as a 284% increase in catalyst volume over manufacturer's estimates. The increase over manufacturer's budget estimates/proposals is actually 92%, one half of staff's reported delta.

Response 2-2

Staff understands the reasoning behind NEC's methodology in determining the impact of the increased cross sectional area and the addition of a third bed of catalyst on the cost of an SCR installation. A review of Item 1 on page 121 of the PDSR indicated that the "total catalyst volume" was incorrectly stated and should have read "total SCR volume." and was followed by an incorrect projected catalyst volume and space velocity. It is important to note that the NEC reports did not directly state the height of the catalyst layer within each SCR layer but referred to the SCR layer as 11 ft. Correspondence with NECs staff indicated that the catalyst layer height would be less than 55% of the SCR layer height and subsequent conversations with NEC projected the catalyst layer height within the range specified above. The uncertainty in the catalyst layer height may have contributed to the incorrect calculation of catalyst volume presented in the PDSR assessment in Appendix F. We concur that the increase over manufacturer's budget estimates/proposals is approximately 92 percent and the next version of the staff report will corrected.

Comment 2-3 Staff's SCR Design Comparison Did Not Accurately Reflect NEC's "Typical" FCCU SCR Design

Staff used an incorrect basis for comparing NEC's typical FCCU SCR with district units in Table F.3. A revised comparison, using data from Refineries 1, 5 and 6 is shown below.

Table 1 (F. 3 Showing NEC Typical SCR)
Performance Information of Existing SCRs

	Refinery 1	Refinery 5	Refinery 6	NEC Typical
FCC Feed Rate, kBPD	95	71	84	55
SCR Inlet Flue Gas Flow, ACFS	6,585	5,525	9,685	3,848
SCR Manufacturer	1	3	2	--
No. Catalyst Layers	2	2	2	3
Catalyst Volume, ft^3	6,200	2,975(1)	6,200(5)	4,600
Design Inlet NOx, ppmv	133(2)/40-80(3)	150	35	45
Design Outlet NOx, ppmvd	--	17	6	2
NOx Measured, ppmvd	<2	15-17	5.6 – 6.4	1.5 (Est.)
Superficial Gas Velocity, fps	7.4	13.3	11.6	10.0
Space Velocity, 1/hr	3,823(6)	6,686(4)	5,624(5)	3,011
Removal Efficiency	95 - 97%(3)	89%	83%	97%

Notes:

1. Staff incorrectly stated catalyst volume as 2,391 ft3 in Table F.3. 2,975 ft3 catalyst volume confirmed by NEC with Refinery 5 and via review of SCR data provided by Refinery 5 to SCAQMD.
2. Design value reported as 155 ppmv @ 0% O2. Value presented in table is corrected to 3% O2.
3. Measured outlet NOx value of <2 ppmv corresponds to operation of unit with inlet NOx in the range indicated. Removal efficiency based on range of actual operation.
4. Staff reports space velocity value of 2,974/hr in table F.3.
5. Confidential data provided by SCAQMD staff is insufficient to calculate the catalyst volume for this unit without making the following assumption on the depth of a catalyst module which we assume to be 45". Staff used ½ of this value in Table F.3 corresponding to catalyst bed depth (catalyst element height) of 22.5". Recommend staff confirm catalyst volume with Refinery 6.
6. Confidential data on unit design and performance, provided by SCAQMD staff, used to calculate inlet volumetric flow and space velocity. Values differ from staff's entries in Table F.3.

Response 2-3

Staff has looked over the values presented in the abovementioned revised comparison. It is difficult to confirm several of the values presented in this table and the notes. It is also important to note that the PDSR did not include the NEC model (proposed to achieve a 2ppmv emissions limit) in F.3. Staff referred to the 3-catalyst layer NEC approach that was presented in the Non-Confidential Final Report. The NEC data were encumbered in the Confidential Reports as a model for scaling FCCU SCR specifications and costs to the appropriate FCCU application. Furthermore, it should be noted that staff did not estimate the catalyst volumes or space velocities for Refinery 1, 6 or 5 as NEC stated in the footnotes of Table 1 above. The numbers included in the PDSR were either reported by the refineries through the Survey or documented in the permit applications. Staff confirmed with Refinery 6 on the FCCU SCR catalyst volume and Refinery 6 reported the catalyst volume was not 6,200 cubic feet as estimated by NEC in Table 1 above.

In addition, it is important to note that staff's analysis in the PDSR relied on the manufacturers' cost data provided to staff which did not project based on any specific superficial gas velocity or space velocity. The manufacturers provided costs based on a profile of the SCR currently used at Refinery 1 that rely on 2 layers of catalysts to meet 2 ppmv BARCT level. The bottom line is that NEC's added cost based on a design including 3 layers of catalysts would not affect the overall conclusion on the cost-effectiveness of the FCCU SCRs and would not impact the total proposed reduction in RTC holdings.

Comment 2-4 NEC's "Typical" FCCU SCR Design

In their review, staff is suggesting that NEC's typical SCR is overdesigned and as a result overpriced. Staff's comparisons suggest an overdesign factor of as much as 284%. We do not agree with this assessment. As can be seen in Table 1 (shown in Comment 2-3) , NEC's typical SCR should be able to achieve 97% NOx reduction by virtue of the addition of catalyst at higher gas velocities than the SCR operating at Refinery 1. The typical SCR design provides an approximate 21% margin in space velocity over the Refinery 1 SCR design primarily due to the addition of a third catalyst bed. The addition of a third bed has inherent performance advantages in that it provides for partial redistribution of unreacted NH_3 and NOx versus further cross sectional area additions. If it is determined that the incremental cost of specially fabricated catalyst modules (shorter depth) is low, some further optimization may be possible to reduce SCR cost. It is worth noting that the ~21% catalyst margin will have a 12% overall TIC and PWV cost impact.

Response 2-4

In reexamining our evaluation, staff agrees that your typical SCR is not overpriced. Staff also understands the reasoning for your selection of a third catalyst bed, and as previously discussed, the PDSR erred in catalyst volume calculation. However, even with a 3rd catalyst bed the change in overall cost-effectiveness would not impact the total programmatic shave. Staff will continue to utilize our approach in deriving the costs based on the manufacturers' information and Refinery 1's profile of 2 layers of catalysts to meet 2 ppmv BARCT level.

Comment 2-5 Mark-up factor 1.35

The following paragraphs provide background for NEC's use of a 35% conditioning factor for vendor equipment quotes at early stages of projects. These concepts were discussed with SCAQMD staff during reviews of our report and in subsequent follow-up phone conversations and e-mails. Due to the extensive discussion around this topic we are mystified by staff's characterization of this "bid conditioning factor" as, and here I paraphrase, 'an undefined and therefore invalid cost increase'.

Obtaining budgetary quotations from vendors for their equipment is part of the process of developing cost estimates for any project. At the early stages of projects, or when general information is sought, vendors are not provided comprehensive design basis information and therefore do not have a complete picture of the operating envelope for their proposed equipment. In these instances, some vendors will use costs from recent projects and "factor" them to the provided process conditions, other vendors may develop estimates based on equipment designed specifically to meet the provided process conditions. In either eventuality, the vendor is providing a quality estimate with reasonable accuracy (about +/- 10%) for the specified process conditions, without providing a performance guarantee and without review of the specific codes and standards applicable to refinery installations.

As project definition improves the process basis becomes fixed, equipment sizes become more reliable, performance guarantees are finalized, and vendor quote accuracy improves. Industry experience shows that at the early stages of a project, basis uncertainty alone, necessitates the addition of a 15 – 25% conditioning factor to a vendor's budget quote, in addition to other bid conditioning factors, to account for the difference seen between early equipment bids and final, full definition, performance guaranteed, equipment bids based on a definitive project basis.

Refineries are built to a more rigorous set of standards than typical air pollution control equipment which makes projects in the refining sector slightly more expensive than typical industrial projects. Standards which will have an impact on either the SCR design, the structural support design, location of equipment, internal and external maintenance access, etc., are likely to increase Direct SCR M&L costs. At this stage of project definition a factor of 10% is added to a vendor's equipment bid to account for the cost of meeting local plant standards.

The 1.35 "mark-up" or bid conditioning factor used in NEC's cost work-up for all SCR projects (FCCU, Heaters/Boilers, etc.) is not an arbitrary factor used to inflate costs, as implied in Appendix F, but is actually the low end of a time tested and proven means to determine the actual cost of a piece of equipment after full project definition is complete, including application of local industry standards to the design of the equipment, performance guarantees are offered and firm pricing for equipment components is provided by the vendor.

Response 2-5

Staff appreciates the in-depth background information of the bid conditioning factor, and regret the inclusion of language characterizing the use of the factor as "invalid". The PDSR approach relies on the EPA model defined in Appendix A with a 50% contingency factor added to the cost estimate. However, staff recognizes NEC's expertise in evaluating costs to place equipment in operation, but we will continue to utilize our approach in deriving the costs and will present your derived results for comparison. Staff derived the SCR costs for Refinery 5, 6 and 7 based on

Refinery 1 actual costs, thus the bid conditioning is not applicable here. For Refinery 4 and 9, the SCR costs were based on the costs provided by several prominent manufacturers and since SCR is a mature technology, staff feels that a 50% contingency factor is sufficient. Even if the bid conditioning factor was used, staff's estimates would be $163 million for 5 SCRs at Refinery 5, 6, 7, 4 and 9 (Appendix F) compared to $211 million as estimated by NEC. The bottom line is that NEC's estimates of $211 million would not affect the overall conclusion on the cost-effectiveness of the FCCU SCRs and would not impact the total the total programmatic shave.

Comment 2-6 75% increase in labor to the costs of the SCR

Another cost factor discussed with SCAQMD staff, and apparently dismissed as a simple adder to make costs appear high, is the cost of actually installing the equipment supplied by the SCR vendor in the plant. The vendor does not do construction and does not quote the cost of field assembly in their quote which only covers fabrication and supply of the equipment, in this case the SCR catalyst, support frames, ammonia injection grid and the carbon steel box.

The labor cost factor used in NEC's development of project costs is applied to the SCR vendor's factored estimate to account for the labor required to install the manufacturer's equipment at the site, transportation, taxes, tie-ins, insulation, access, structural steel, etc. Installation labor for equipment can range from a low of about 30% of the equipment cost to as much as 200% of direct equipment cost depending on the complexity of the equipment, the material it is made of and other equipment specific factors. In general, low cost equipment manufactured of low cost materials have higher installation percentages than highly complex equipment made of high cost materials. As a reference point, "Applied Cost Engineering", Clark F. D. and Lorenzoni A. B.; Marcel Decker Inc., 1978, uses a factor of 2.2 times direct material costs to estimate the direct M&L cost of a fired heater installation, a factor of 3.0 times direct material costs to estimate the direct M&L cost of a pump installation and a factor of 2.9 to estimate the direct M&L cost of a distillation tower. Due to the simplicity of the SCR equipment and its use of low cost materials we have used an installation labor cost factor of 0.75 (75%) to account for physical installation of the SCR, structural steel, fit-up of ducting, connection of piping, foundations, excavation, instrumentation, insulation, equipment storage, etc. This factor does not account for any costs associated with: demolition of existing equipment, modification of existing equipment, labor inefficiencies attributed to working in an operating plant, relocation and/or modification to underground utilities, piping, piping supports, ammonia storage facilities, control system additions, instrumentation wiring, conduit, power wiring, area paving, area lighting, area utilities, safety facilities, soot blowers, etc.. The cost of these items is rolled up into the overall TIC factor applied to escalate SCR M&L costs to a total project cost.

Response 2-6

As with the bid conditioning factor, staff concurs that the NEC approach which adds a 75% labor cost factor is a valid alternate assessment of the projected project costs. As previously mentioned we will present the information that you used in your assessment but we will continue to utilize our approach in deriving the costs. The PDSR approach relies on the EPA model with a 50% contingency factor added to the cost estimate. The EPA model did not have the 75% labor cost factor. Since the SCR technology is commercially available for more than two decades, staff did not feel that a 75% increase in labor is a necessity. However, as shown in Table F.5, Appendix F, even if the 75% labor cost factor was included, staff's estimates would be $163 million for 5 SCRs at Refinery 5, 6, 7, 4 and 9 compared to $211 million estimated by NEC. The bottom line is that NEC's estimates of $211 million do not affect the overall conclusion on the cost-effectiveness of the FCCUs and do not impact the total the total programmatic shave.

Comment 2-7

SCAQMD staff disputes NEC's use of a TIC factor of 4.5 to convert direct M&L costs for the SCR into TIC for the SCR PROJECT. This factor is a reasonable estimate for project items not specifically identified in the direct M&L costs (indirect costs, engineering and owner's costs, labor productivity, ancillary equipment and systems, revamp items, duct work, area paving, lighting, utilities, safety systems, control system connections and programming, instrumentation, soot blowers, etc.) As a point of reference, the TIC factor used by NEC, in this analysis, is 90% of the average TIC factor of 4.9 used to estimate SOx control costs in NEC's SOx RECLAIM report.

Response 2-7

Staff appreciates NEC's position on the TIC factor and agree with the reasonableness behind its selection. After the NEC Non-Confidential Report was posted for review, staff met with refinery personnel and their consultants who provided examples of SCR equipment purchases and installations at out-of-state refineries. Their data supported a 4.0-4.5 factor for PWV evaluation. Appendix A of the PDSR uses the 4.5 factor as an upper bound of cost estimation for the FCCU SCR PWV and cost analysis (i.e. $163 million for SCRs with 2 layers of catalysts). Staff reevaluated the EPA methodology in conjunction with a 50% contingency factor (i.e. $152 million for SCRs with 2 layers of catalysts). Regardless, use of both methodologies provides a range of expected costs.

Comment 2-8

SCAQMD staff is correct in pointing out that NEC used incorrect design capacities in developing the FCCU SCR costs shown in section 1.2 of NEC's non-confidential report (14-045-4, November 26, 2014). NEC back calculated expected FCCU rates from flue gas flow rate data provided by AQMD staff to obtain estimated FCCU sizes. The following table presents a revision to the report table based on corrected FCCU sizes as indicated by district staff. Also included in the table is an update to the cost of a Grass Roots SCR for Refinery 6 based on a comparison of flue gas rates to the SCR versus the typical (base case) SCR. Revised NEC estimates provided in Table 2 do not include any reduction to NEC's original cost estimate model.

Response 2-8

Staff thanks NEC for back calculating the expected FCCU rates from the correct design capacities. However, staff cannot verify some of the assumption in footnote 1 that NEC used for Refinery 6 and thus we continue to present the $211 million that NEC estimated. The bottom line is that NEC's estimates of $211 million do not affect the overall conclusion on the cost-effectiveness of the FCCUs and do not impact the total the total programmatic shave.

Comment 2-9

Staff provided a review of NEC's cost estimates based on a comparison to the cost provided for Refinery 1's SCR to demonstrate that NEC's estimating method is overly conservative. In this comparison staff claims that NEC's cost tool over predicts the cost of this installation by $11M (27%). The difficulty in comparing a specific project to a generalized curve is that the project has a specific scope which in most cases is different than the assumed scope of the "typical" project. This is the case for the SCR installation at Refinery 1 which, according to Refinery 1 personnel, did not include the cost for waste heat boiler modifications. Subtracting this component from the TIC for a typical FCCU SCR installation and recalculating PWV yields a cost of $45.45M which is 10.8% higher than staff's cost work-up on this project of $41M, not the 26% difference indicated in Appendix F. Staff had the WHB cost information NEC used in our estimates, we do not understand why they did not make the PWV comparison on the same basis.

Response 2-9

The PDSR estimation of Refinery 1's PWV was based on data provided by refinery staff. Staff took the data reported by Refinery 1 as the total project cost for the SCR system including all peripheral equipment.

Comment 2-10

Staff also provided a review of NEC's cost estimates based on staff's assessment of differences between the data provided by an SCR vendor to staff and NEC for an installation at Refinery 9. In staff's evaluation of the data provided by the vendor they incorrectly calculate the total catalyst volume to be 3,100 ft^3 vs the actual vendor proposal which provided only 2,400 ft^3. Staff also incorrectly calculates NEC's estimated catalyst volume at 12,697 ft^3 vs an actual value of 4,600 ft^3 (1.92 x vendor proposal, see previous discussion on catalyst volumes and specification of a third bed).

Response 2-10

With regard to your second comment first, staff agrees that the catalyst volume was incorrectly presented in the PDSR. The 12,697 ft3 actually represents the total SCR volume. As presented in the PDSR, the manufacturer's recommendation for the Refinery 9 catalyst volume was 3,300 ft3. A review of the data provided by the SCR manufactures will be conducted to conform to proposed specifications and correct any misrepresentations in the PDSR.

Comment 2-11

NEC provides a few comments on SCAQMD staff's determination of PWVs for FCCU SCRs.

1. In using the costs provided for Refinery 1's SCR staff is assuming that all district SCRs can be installed without any impact on upstream equipment and that installation of the SCR can be executed in an open, non congested area. Refinery 1's SCR was installed prior to the installation of a large ESP, which occurred around 2006. If the SCR was to be installed today, or at any time after installation of the large ESP, costs would be higher due to productivity debits associated with working in a congested area and quite possibly even higher due to the need to move or modify some equipment to make the installation possible. In the most extreme case the SCR and ducting may have to be field erected from small fabricated assemblies due to access constraints.

2. Staff used a 0.7 power factor to scale the costs for Refinery 1's SCR project to different sizes. Costs for FCCU regenerator flue gas systems scale more accurately when a figure of around 0.6 is used. The effect of using a larger scale factor is a greater reduction in project costs for all projects with the differences getting proportionately greater the further one gets from the base case unit size. In essence using the 0.7 factor instead of 0.6, in this particular evaluation, will decrease costs for all units and will disproportionately decrease the cost of smaller units.

3. In using vendor budget quotes for SCRs, staff needs to add erection labor to the vendor quote. There is no indication that this is done in staff's analysis.

4. Staff does not condition the vendor's quotes to account for operational conditions, including unit upsets, and other project unknowns which will have direct bearing on SCR design details, performance and costs. An allowance must also be made for the accuracy inherent in vendor's budget quotations, which does not appear anywhere.

5. The PWVs provided for Refinery 7 and Refinery 9 are $27M and $19M respectively. There is an apparent inconsistency in these numbers as the stated capacity for each of these units is 55 kBPD. Units of the same capacity should have PWVs close to one another not differing by 42%. Staff should check these numbers and ensure that the SCR project scope differences between these two units can explain the large difference in cost.

Response 2-11

Again, staff appreciates and respect NEC's opinion with regards to our technical assessment of the FCCU costs. Staff notes areas of agreement and issues to be resolved.

1. Refinery 1 provided staff with comprehensive cost data for its FCCU SCR. As such, we used this model to estimate PWV and associated costs for other FCCUs where applicable. Your comments are correct in asserting the uniqueness of Refinery 1's situation, in particular the relative date of installation of an ESP to the FCCU. We realize that there are uncertainties in the cost estimate due to such considerations and have added a 50% contingency to our estimated costs. .

2. The PDSR based its scaling using a 0.7 factor established in practice and in the literature. The costs of $211 million estimated with the use of a 0.6 factor do not impact to the cost effectiveness calculation.

3. Staff concurs that the erection labor is a part of the installation costs included in the 4.5 factor

4. As previously stated, the PDSR cost estimates for the FCCUs included a 50% contingency factor to account for vendor cost estimation variability.

5. The PWVs for Refinery 7 and Refinery 9 were estimated using two different approaches. Refinery 7's PWV was estimated based on Refinery 1 actual cost data while Refinery 9's PWV was estimated based on the cost data submitted by the manufacturers. Originally, in 2013-2014 time frame, the manufacturers did not provide cost data for Refinery 7, 5 or 6 since these FCCUs already have SCRs or wet gas scrubbers. In Table F.5 of the PDSR, staff provided 2 different approaches to estimate the costs for Refinery 7 and Refinery 9. Using the manufacturer's cost data with 2 layers of catalysts and no markups, the PWVs for Refinery 7 and 9 would be $20 million. Using the manufacturer's cost data with 2 layers of catalysts and two levels of markups as recommended by NEC, the PWVs for Refinery 7 and 9 would be $31 million.

Comment Letter #3 – NORTON Engineering – September 4, 2015

General Comments

In its opening paragraph NEC is quoted "We stated, quite clearly, in the final report and in subsequent discussions with staff, that we agree that 2 ppmvd (3% O_2) NOx emissions is a justifiable emission level for SCR applications to FCCUs, Fired Heaters, Boilers, Gas Turbines and TGU/SRUs, with caveats. While a few existing units can meet this guideline under current operating conditions, many more, similarly designed units have not demonstrated similar low emissions capabilities. With the exception of Gas Turbine installations (which have an equivalent emission level of 6 ppmv @ 3% O_2) most low emission SCRs in service today, being built today and even those being designed today carry manufacturer's guarantees to meet a NOx limit of 5 vppm @ 3% O_2. In spite of the limited number of units (other than gas turbines) operating at or below 2 vppm NOx, we believe that it is possible to achieve these levels, but to guarantee long term reliable performance (refineries typically operate 24/7 for periods of 4 to 6 years) it is prudent and quite possibly necessary to design future SCRs to increase residence time, improve NH_3 distribution, improve overall flue gas flow distribution, add catalyst, etc. SCAQMD staff agrees with this concept but we have strong disagreement as to how much change from current SCR designs will be required to achieve the sought after NOx reductions not only on day one but at the end of year one and year five and beyond."

NEC also commented on the general approach to creating cost curves to determine an effective cost curve to represent the PWV vs the maximum boiler/heater firing rate. Their analysis highlighted the paucity of SCR data and questioned the linear approach taken by staff. They commented that their power law curve better captured the relationship (within error bounds) when applied to specific Basin refinery SCR cases. They expressed that their cost curve better represented smaller heaters (<100mmbtu/hr heat release).

Response to General Comments

Staff recognized the issue and has directly quoted the NEC disclaimer from in the Non-Confidential Report in Appendix B of the DSR to help define the primary difference in the control equipment specifications proposed by staff and NEC.

With regard to the cost curve development and application, staff's analysis expanded beyond a solely SCR application to include control equipment including Great Southern Flameless Heaters, ClearSign Duplex technology for burners, as well as Electrodynamic Combustion Control technology. The staff analysis assessed the five sets of data to develop a set of representative PWVs to firing rates. Staff acknowledged in the DSR that cost curves developed by staff and NEC for higher firing rates converged and that the main difference was at firing rates less than 200 mmbtu. The differences between the cost curves generated by the varying control equipment design assumptions lead to the uncertainty reflected in the number of boilers and heaters deemed cost effective. The uncertainty as defined by the difference in emissions reduced 0.33 tpd for the category has been accounted for in the 0.85 tpd adjustment to the shave.

Comment 3-1 Scope of NEC's Review

NEC indicated that staff agreed with NEC that any dilution of NEC's effort to evaluate other alternative technologies than SCRs would not be desirable.

Response 3-1

Staff agrees that during an in-person conversation with Mr. Norton, the general understanding was for NEC to focus on SCRs as the primary control methodology. Regardless, staff sent to NEC information related to all control technologies discussed in Appendix A to Appendix E including technical studies, technical analyses, data that the refineries submitted as a result of the Survey, data that staff received from the manufacturers, facility drawings, facility permits, and manufacturers' contacts for NEC to review. In an email, staff also introduced NEC to all of the manufacturers that staff contacted.

Comment 3-2 Using FCC SCR Costs Increased Heater & Boiler SCR Cost Estimates

NEC explained the reasons that NEC elected to use FCCU SCR as the basis for its analysis for heater and boiler SCR. They cited uncertainty in vendor's response to their inquiries for additional data. They favorably compared a Basin refinery heater that achieved 1.6 ppmv to their FCCU SCR design and increase the costs to reflect installation of duct fan, new CEMS and ammonia storage tank.

Response 3-2

Staff agreed with NEC that the catalysts for FCCUs are not the same as the catalysts for boilers and heaters. Several prominent manufacturers indicated that a high dust application such as FCCU require a catalyst flow passage (or pitch) of about 7 mm. The refinery boiler and heater is a low dust application, and the catalyst pitch for this application is about 3 mm. The SCR for a refinery boiler and heater is generally compact and contains 1 layer of catalysts. The FCCU SCR contains 2 to 4 layers of catalysts, 2 or more filled with catalysts and 1 possible spare. The FCCU SCR has a large box area designed to fit additional equipment such as soot blower. Staff contends that NEC recommendation of 3 layers of catalysts for a FCCU SCR and 4 layers of catalysts for a boiler and heater SCR designed at 10 feet per second is different than a design provided by several prominent SCR manufacturers.

The SCAQMD facility permit database contains information on the catalyst volumes of the SCRs currently in operation in the District. The table below shows the catalyst volumes for several SCRs at the refineries, the rating for the boilers/heaters in mmbtu/hr, and the NOx emissions in ppmv that the refineries reported through the Survey. On average, the catalyst volume for the boiler and heater SCRs achieving 2 - 7 ppmv NOx is about 0.96 cubic feet of catalysts per mmbtu/hr based on the information in the facility permit database. The manufacturers indicated that the amount of catalysts needed to achieve 2 ppmv NOx is about 293 cubic feet for a 300 mmbtu/hr heater, and 92 cubic feet for 100 mmbtu/hr heater, or on average 0.96 cubic feet per mmbtu/hr. Staff estimated about 1.2 cubic feet per mmbtu/hr.

Table Z. 1 – Comparison of Information for Boiler and Heater SCR

Process Data	**NOx Emissions from Survey (ppmv)**	**Heaters/Boilers' Rating from Facility Permit Database (mmbtu/hr)**	**Catalyst Volume from Facility Permit Database (cubic feet)**
SCR for 4 catalytic reformer heaters	1.64	589	537
SCR for a hydrotreating heater	2.26	78	92
SCR for 3 coker heaters	2.71	528	623
SCR for a crude distillation heater	2.7	83	62
SCR for a hydrogen plant heater	2.7	653	691
SCR for 3 hydrotreating heaters	2.67	63	92
SCR for a crude heater	3.31	85	96
SCR for a crude heater	5	300	120
SCR for a boiler	5.39	245	225
SCR for 3 crude distillation heaters	5.69	849	810
Average catalyst volume using information from facility permit database (cubic feet per mmbtu/hr)			0.96
Catalyst volume provided by manufacturers for 2 ppmv SCRs (cubic feet per mmbtu/hr))			0.96
Catalyst volume estimated by Staff (cubic feet per mmbtu/hr)			1.2
Catalyst volume provided by NEC (cubic feet per mmbtu/hr)			17

Comment 3-3 NEC TIC Factor of 4.5 vs. Staff TIC Factor of 3.8

NEC explained the reasons that NEC elected to use a factor of 4.5 and the need to adjust vendor costs to include ancillary equipment such as ducting, fans, CEMS.

Response 3-3

Staff agreed with NEC and the refineries to use a factor of 4.5 and adjusted vendor costs to include ancillary equipment such as ducting, fans, CEMS. Staff revised the estimates prior to the release of the PDSR. The revised estimates resulted in slightly lower incremental emission reductions at a nominal increase in cost.

Comment 3-4 Basis for SCR Catalyst Increase and Velocity Reductions vs Vendor Budget Quotes

NEC indicated that staff analysis was based on only one SCR achieving 1.6 ppmv. This SCR has 1 layer of catalysts, however the heaters were fired at 65% capacity. NEC indicated that the vendor information provided by AQMD staff indicated that doubling a vendor catalyst volumes would be needed to ensure reliable operation in excess of five years, thus the minimum number of layers of catalysts needed would be 1 layer x 2 / 0.65 = 3 layers. NEC recommended 4 layers to ensure long term compliance while burning variable composition of refinery fuel gas. NEC also recommended 10 feet per second instead of 12 feet per second velocity as recommended by the manufacturers.

Response 3-4

Several prominent manufacturers indicated that one layer of catalysts is sufficient for a heater and boiler (or a gas turbine, or a SRU/TGTU incinerator) firing with refinery fuel gas. The SCR is typically designed at full rated capacity of the heater and boiler to sustain an operation between 3-year to 5-year turnaround period. The manufacturers indicated that even though the refinery fuel gas may contain some components (e.g. sulfur) that may poison the SCR catalysts, they have not yet seen a significant impact on catalyst poisoning in refinery fuel gas applications. The manufacturers indicated that a well-designed and maintained SCR system with good ammonia distribution system can meet 2 ppmv NOx.

Comment 3-5 Cost of New CEMS vs Upgrade and Ammonia Tank

NEC indicated that they did not have any data on the status/condition of existing CEMS. NEC proposed the cost of a new CEMS at an approximate cost of $1 million. NEC indicated that they used ~~used~~ a common 11,000 gallons ammonia tank for all sizes of heaters and boilers in their proposals.

Response 3-5

The cost of $1 million for CEMS is not consistent with the information submitted in CEMS applications. Staff understand the reason for a common 11,000 gallons ammonia tank and included the costs for ammonia tanks as recommended by NEC in the revised estimates prior to the release of the PDSR. This adjustment results in nominal change in costs.

Comment 3-6 High Catalyst Replacement Costs Skewed NEC PWVs High

NEC indicated that NEC agreed with staff that replacement costs of the 4-layer SCR catalyst system would skew NEC PWV higher and NEC corrected their estimates.

Response 3-6

Staff concurs.

Comment 3-7 NEC's estimates are higher than staff's "conservative" PWVs

The SCR listed in PDSR Table G.8 is shared between four heaters. The combined total rated capacity of the four heaters is 589 mmbtu/hr. NEC indicated that staff should have used $43.2 million as an estimate for a shared SCR of a 589 mmbtu/hr heater compared with $38.5 million to the total costs of the four individual SCRs that staff estimated. NEC estimated that 4 individual SCR units installed to meet the 589 mmbtu rating would require $99 M.

Response 3-7

Staff agrees that the common stack-shared SCR application is more appropriate and less costly that individual units being installed. NEC also noted that the difference in costs estimated by staff and their engineers was less than 12 percent.

Comment Letter #4 - RECLAIM Industry Coalition, August 21, 2015

Comment 4-1 Shave amount and timing

A shave of 4 tons per day in 2016 does not allow any time for facilities to develop and implement emission reduction measures. The Coalition believes that the shave amount for the period 2016-2017 should be no more than 2 tons per day, and that there is no reason that all two tons have to be shaved in 2016.

Response 4-1

With respect to the implementation time, because the implementation date for 2 tpd reductions in Control Measure CMB-01 Phase 1 was past due in 2014 and there are 5-8 tpd surplus RTCs in the market, staff believes that at a minimum 2 tpd reduction or up to 4 tpd reduction should be removed from the market no later than 2016-2017. Staff disagrees that this proposal does not allow adequate time for implementation because there are sufficient unused RTCs in the market to allow a 4 ton shave in 2016-2017 without requiring controls to be installed in those years. The removal of unused RTCs would raise the RTC prices and stimulate the implementation of control equipment. It is urgent to implement the control equipment and reduce actual emissions as expeditiously as possible to meet the NAAQS for PM2.5 and ozone.

Comment 4-2 Shave amount and timing

There is no commitment in the AQMP to make a 4-ton per day shave in 2016. The AQMP contemplated a 2-3 ton per day reduction in Phase I and another 1-2 tons per day in Phase II. With respect to the total amount of the shave, the Coalition continues to believe that shaving a total of 14 tons per day of RTCs from the RECLAIM market in order to achieve the 8.79 tons per day reductions the District seeks to obtain as a BARCT adjustment is neither necessary nor justified

Response 4-2
Please see Response 1-2.

Comment 4-3 Cost effectiveness

The Coalition continues to believe that a 25 year useful life assumption (used consistently for all equipment in this proposed rulemaking) is not appropriate for all equipment.

Response 4-3
Please see Response 1-4.

Comment 4-4 Cost effectiveness

District staff minimizes control costs by using a cost-effectiveness calculation that is not used by the California Air Resources Board and most other major California air districts (i.e. LCF Method). Additionally, the use of a $50,000 per ton figure (i.e. based on DCF method) as the cost threshold is more than twice the $22,500 per ton threshold (i.e. based on LCF method) applied to command-and-control regulated sources.

Response 4-4
Please see Response 1-9.

Comment 4-5 Cost effectiveness

We also note that Norton Engineering (the third party independent contractor retained by the District to review and assess the District staff's cost effectiveness determinations) has raised questions regarding the District staff's cost effectiveness determinations and its dismissal of Norton Engineering's analyses when those analyses showed higher costs than the District staff's evaluation showed.

Response 4-5
Please see Responses 1-6.

Comment 4-6 Need for the "gap"

Our analysis has shown that even if the District staff concluded that NO BARCT improvements had been made between 2005 and today, the staff's methodology would result in 6 tons per day of NOx RTCs being removed from the program. RTCs being removed under the District's methodology would include those needed for 1) NSR Holding Requirements, 2) Electric Grid Reliability and Implementation of AQMP Attainment Strategies (i.e., large scale electrification to replace current combustion processes), 3) Post-2023 Growth, 4) Investor Holdings, 5) Shutdowns and 6) ERC Conversions. The Regional NSR Holding Account is to be used for both NSR Holdings and to cover actual emissions in certain cases which raises the question of whether it is large enough. The shave of 14 tpd is too large and runs the risk of repeating the program "meltdown" of 2000-2001 during the power crisis when insufficient RTCs were available.

Response 4-6

Staff agrees with the commenter that using the staff's methodology (Figure EX-1), if there were no new 2015 BARCT, the RTC shave would be:

Allocations – (2011 emissions at 2005 BARCT x 1.1 for 10% compliance margin) = 26.5 – (1.1 x 18.3) = 6.4 tpd

This shows that the 2005 shave was not large enough to remove the unused RTCs (or the "gap") to the level that can stimulate the installation of actual control devices. Thus, in the past 10 years since 2005, there was only 4 SCRs installed at the refineries even though staff had estimated that it was feasible and cost effective for the refineries to install 51 SCRs by 2011.

Staff methodology in estimating the remaining emissions in 2023 does include the impact of growth to 2023 and the possibility of returning operation for shutdown facilities and new electric generating facilities. Staff may need to revisit the NOx RECLAIM post 2023 to incorporate advancement in control technology, but it is not appropriate to include post-2023 growth in the 2023 target as this will result in an artificially high target. Staff also creates a separate Regional NSR Holding Account to address the NSR holding requirements for new power producing facilities and is in the process of discussing with EPA to seek its approval. Moreover, the NSR Holding requirement and the use for power emergencies are not additive. Since the facility NSR Holding requirement is its maximum potential to emit, actual emissions will always be smaller and will be covered by the same RTCs used for the NSR Holding requirement. Investor holdings and ERC conversions are subject to shave consistent with the previous 2005 and 2010 RECLAIM amendments. Staff has accounted for electric reliability by allowing "nontradable/nonusable" RTCs to become usable by power producers if a grid reliability emergency is declared. Staff has accounted for increase electrification through the growth factor which assumes increased use of renewables. Note that ERCs of non-RECLAIM facilities do not hold their values to eternity, they are often recalled and reduced per Regulation XIII. Rule 2002 (f)(1) contains a safety valve to provide a stability for the RECLAIM market and ensure that when RTCs are not sufficiently available (i.e. the 12-month rolling average RTC price exceeds $~~15,000~~22,500 per ton), staff can convert the non-tradable/non-usable RTCs to tradable/usable RTCs upon the concurrence of the Governing Board.

Comment 4-7 Energy efficiency projects

The Coalition strongly opposes any effort to further reduce RTC allocations due to "energy efficiency projects" that have or would reduce NOx emissions. Any reduction in NOx emissions not strictly required by BARCT should be encouraged and the benefits of making those reductions retained by the facility operator making them.

Response 4-7

Staff did not consider further reduce RTC allocations due to energy efficiency projects at this time. However, it should be noted that the energy efficiency projects resulted in 0.7 tpd concurrent reductions of NOx completed in 2011, and the RTC allocations adjusted in 2005 have not yet been reduced to account for these reductions.

Comment Letter #5 – Latham & Watkins, August 20, 2015

Comment 5-1 March 20, 2015 freeze date for shave estimation

The first time Harbor Cogeneration Company (HCC) was made aware of the freeze date of March 20, 2015 for shave estimation was just prior to the public workshop on July 22, 2015. However, staff proposal to establish a retroactive baseline date without prior advance notice constitutes an unprecedented ex post facto action that unfairly disadvantages entities that have made good faith trades after March 20. Two examples were provided and the commenter suggested the District propose the date of rule amendment as the freeze date for shave estimation.

Response 5-1

Staff has revised the proposal and notified the stakeholders regarding the proposed new freeze date of September 22, 2015. Staff cannot practically make the freeze date for shave estimation the date of rule amendment because the rule language and calculation of shave must be completed for public review and comment prior to the Governing Board hearing for rule adoption. Staff disagrees that setting the freeze date prior to rule adoption is an "ex post facto" regulation. The prohibition on "ex post facto" laws or regulations applies to making conduct criminal that was not criminal when it occurred, or increasing the criminal penalty [in re Lomax, 66 Cal. App 4th 639 (1998)]. In contrast, ordinary civil law may be made retroactive, but it must be expressly so stated in the language, or state statute, or clear form extrinsic evidence [Myers v Philip Morris Companies, Inc., 28 Cal 4th 828 (2002)].

Comment Letter #6 – Yorke Engineering, LLC., August 21, 2015

Comment 6-1 New Emission Factors for Rule 219 Exempt Equipment

We support the District's August 19th proposal for new provisions in Rule 2012 Chapter 4 to allow equipment certified by either U.S. EPA, CARB, or SCAQMD to use an emission factor other than the default factor of 130 lb/mmscf to report NOx emissions.

Response 6-1

An August 19th presentation by staff acknowledged the issue and mentioned a possible path forward relying on source tests rather than the default factor. Based on feedback form stakeholders, the concept did not seem to achieve the goals of the request, and thus, staff is not proposing an alternative to the default factors at this time.

Comment 6-2 Source Test for Rule 219 Equipment

The District's August 19th proposal for certified Rule 219 exempt equipment indicates source tests may be required to verify lower emissions. We request that no source test shall be required for certified equipment.

Response 6-2

Source testing is the preferred method of verifying the certified emissions for these units. The RECLAIM program offers the flexibility of a market program, but also has stricter standards for emission reporting than many command and control regulations. Based on feedback from stakeholders, the concept did not seem to achieve the goals of the request, and thus, staff is not proposing an alternative to the default factors at this time.

Comment 6-3 RTU Reporting

The current requirements are specified in 2012 Appendix A, Chapter 7 – Remote Terminal Unit (RTU) Electronic Reporting. This section of the rule requires facilities to use dial-up modem technology to transmit a text string that must be very specifically formatted. We have wasted hours of time working with this antiquated system which is still required by the regulation. We urgently request that the District update their electronic reporting system to allow more modern and easy to use technology.

Response 6-3

We agree that the electronic reporting system needs to be updated. This upgrade, however, would be very resource intensive for SCAQMD staff and the affected operators and is outside the scope of this rule making. The RTU electronic reporting system will be upgraded and the corresponding rulemaking will occur at that time.

Letter # 7 - Charles F. Timms, Jr. August 21, 2015

Comment 7-1 Electric Generating Facilities Need Quicker Access to Non-tradable/Non-usable RTCs

Based on the experience of power plants during the energy crisis of 2000-2001, this cumbersome, two-step process for releasing these RTCs to cover annual emissions appears to be too slow to avoid skyrocketing spot prices or an outright shortage of RTCs for power plants to either cover annual emissions or demonstrate resource adequacy. We understand that the Los Angeles Department of Water and Power will be presenting a more detailed description of how the two-step process for releasing RTCs during the energy crisis of 2000-2001 did not avoid high prices and shortages of RTCs at that time.

The Cities therefore suggest that a provision be added allowing power plants to request that some or all of this pool of non-tradable, non-usable RTCs be converted to usable but non-tradable RTCs, in exchange for a fee of $7.50 per pound. Once converted, the RTCs could be used to cover annual emissions or meet resource adequacy needs for the year in which the request is made, but they could not be traded. In addition, the power plant also would not be allowed to trade any of its own RTC allocation for the year in which the request to convert is made.

The fee serves two purposes. First, it gives power plants the incentive to rely on the RTC market if the spot price remains below $7.50 per pound. As long as the spot price of RTCs remains below that level, power plants will not have an economic incentive to make a request to convert. Instead, they will rely on the RTC market to acquire additional needed RTCs. But if the spot price rises above $7.50 per pound, then they will have an incentive to make a request, if they deem it prudent to do so. Of course, power plants would be free to wait for the slower two-step process to unfold regarding the 12-month rolling average price, and obtain additional unrestricted RTCs without a fee, if they deem that to be the more prudent course.

The fee also serves the purpose of providing the District with funds to achieve additional NOx reductions from other sources, including mobile sources, for which cost-effective reductions cannot otherwise be obtained.

Response 7-1

SCAQMD staff has taken your comments into consideration and has proposed a mechanism for accessing non-tradable/non-usable credits and also credits in the Regional NSR Holding Account with associated triggers. For the first year of the shave, the entire non-tradable/non-usable portion of a facility may be accessed if the rolling 12-month RTC price exceeds $~~15,000~~22,500/ton. Those credits would become usable and tradable. The non-tradable/non-usable credits would also be accessed if the Governor of California declares a State of Emergency, but would be usable/non-tradable. Staff is not proposing a fee for access to the Regional NSR Holding Account due to comments received at Working Group and other meetings from many other electric generating facilities that a fee should not be imposed for using these credits.

The commenter also expresses that the non-tradable/non-usable RTCs not be removed from the facility permits after the end of the shave as these credits will be greatly needed then. Staff has established the Regional NSR Holding Account such that the non-tradable credits for newer ~~electrical~~ electricity generation facilities that would normally go to the SIP after one year for each year of the shave would now go in the Regional account every year of the shave beginning in 2017. So when the shave is complete, the shaved portion would be available to meet NSR purposes for these facilities and also provide relief in the event of a power crisis. A regional hold account offers more flexibility than if each facility held the amount reduced for their facility. For example, if there is a power emergency, not every facility will need to run. One or more facilities may be non-operational, and it is conceivable that not all facilities will be called on to the same extent to operate during an emergency.

Comment 7-2

As mentioned earlier, the staff proposal contains an "Adjustment Account" enabling post-1993 power plants to meet the NSR holding requirement on a programmatic basis. We understand that staff estimates that 1 to 1 ½ tons of RTCs will be needed for this account [see Draft Staff Report at p. 33]. We suggest that the RTCs in this account also be made available to affected facilities to cover their annual emissions, in exchange for a fee of $7.50 per pound. There does not appear to be any impediment to allowing the RTCs involved to serve both purposes.

As in the case of a request to convert non-tradable, non-usable RTCs to usable but non-tradable RTCs, the fee serves the dual purpose of giving power plants the incentive to rely on the RTC market if the spot price remains below $7.50 per pound, and also providing the District with funds to achieve additional NOx reductions from other sources for which cost-effective reductions cannot otherwise be obtained.

This use of the "Adjustment Account" could be viewed as an alternative to the suggested provision regarding the non-tradable, non-usable RTCs discussed above.

Attachment 2 to this letter contains an example of rule language that might be used to allow RTCs in the "Adjustment Account" to both meet the NSR holding requirement and be available to cover annual emissions.

Response 7-2

As stated in the previous response, access to the Regional NSR Holding Account would be for credits that could cover NSR holding requirements for newer ~~electrical~~ electricity generating facilities, as well as covering annual emissions for all ~~electrical~~ electricity generating facilities in the event of a power crisis.

Comment 7-3

Two suggestions on the provisions related to the RATA testing:

> First, the due date for performing the RATA should be 30 days, rather than 14 days, from the re-firing of the major source. The additional time is needed in some circumstances to perform tests on the source to ensure reliable and safe operation. [See PAR 2012, Appendix A, Attachment C, Section (B)(2)(c)]
>
> Second, the proposed requirement to disconnect and flange the fuel feed lines is unnecessary and costly. The proposed requirement is unnecessary because the fuel meters are required to be maintained, associated fuel records are required to be kept, and stack emissions are continuously monitored and recorded. So there are multiple sources of data to rely on to verify that the source is not operating. The proposed requirement is costly and time consuming because significant manpower and equipment would be needed to meet it. There also may be health and safety risks if asbestos-containing materials are encountered in the work. The Cities therefore suggest that this requirement be deleted. [See PAR 2012, Appendix A, Attachment C, Section (B)(2)(c)]

Response 7-3

Staff believes that the due date of 14 operating days from re-firing of a major source is sufficient for performing a RATA. The operating days do not have to be consecutive days so the total calendar days since the re-firing could be longer.

The proposed amendment for requiring the disconnection and flanging of fuel feed lines to demonstrate non-operation is necessary because this is the only reliable way to ensure that SCAQMD compliance staff can visibly confirm non-operation and no fuel flow. This prevents possible circumvention for other existing methods of demonstrating non-operation such as stack emission monitoring and recordkeeping.

Comment 7-4

a. **Provisions Involving the Non-tradable, Non-usable Adjustment Factor**

i. The staff proposal should be clarified to provide that the 12-month rolling average RTC price that may trigger release of the non-tradable, non-usable RTCs is the "weighted" average. [PAR 2002(f)(1)(E)]

ii. The staff proposal speaks of determining the 12-month rolling average RTC price for all trades in the "current compliance year." It is not clear how this language would apply to a 12-month rolling average price when the 12 months in question straddle two adjacent compliance years. [PAR 2002(f)(1)(E)]

iii. In PAR 2002(f)(1)(F), the correct cross-reference appears to be to PAR 2002(f)(1)(E), not PAR 2002(f)(1)(F).

Response 7-4

The comment discusses the provisions regarding the non-tradable, non-usable adjustment factors. The commenter states that 12-month rolling average should be a weighted average. Staff calculates the rolling 12-month average by totaling the dollar sum of all the sales and dividing by the total sum of all the pounds (or tons). This price is reported monthly to the stationary source committee. The commenter also questions how the 12-month rolling average is determined for all trades in the current compliance year when there are two cycles that overlap. Staff calculates the 12-month rolling average for all trades including cross-cycle transactions, but not including RTC transactions reported at no price or RTC swap transactions. The commenter also pointed out a rule reference error in PAR 2002 (f)(1)(F). Staff has corrected the reference.

Comment 7-5

b. **Provisions Involving the "Adjustment Account"**

i. The staff proposal includes a provision allowing access to "Adjustment Account" RTCs for the purpose of compliance with annual emissions during a State of Emergency as declared by the Governor. [see PAR 2002(f)(5)] This provision raises several questions:

(1) How is the account to be funded for this purpose, and with what quantity of RTCs? As we indicated earlier, we understand that staff estimates that 1 to 1 ½

tons will be needed to meet the NSR holding requirement. Will additional amounts be added to fund the account to allow compliance with annual emissions?

(2) Why is access to RTCs limited to a State of Emergency declared by the Governor, as opposed to a State of Emergency declared by a local government official, such as a Mayor?

(3) We understand that in response to questions raised at the Working Group meeting on August 19, District staff indicated that RTCs in this account can be used both to meet the NSR holding requirement and to cover annual emissions. If our understanding is correct, then the rule language needs to be clarified.

(4) It may not be appropriate for the Executive Officer to have unfettered discretion to determine the amount and distribution of RTCs. By making these determinations, he would in effect decide which power plants generate electricity during a State of Emergency. Such decisions may be beyond his authority and expertise. It is important, moreover, that every power plant have access to the RTCs it needs to meet its operating requirements.

Response 7-5

The comment discusses the provisions involving the Regional NSR Holding Account (previously called the Regional NSR Holding Account). The commenter asks how the account will be funded and whether additional funds will be needed to allow compliance with annual emissions. The Regional NSR Account will be funded up to the amount that is shaved from those electric generating facilities that have multi-year NSR holding requirements each year of the shave. As stated in Response 7-1, for the first year of the shave the entire non-tradable/non-usable portion of a facility may be accessed if the rolling 12-month RTC price exceeds $~~15,000~~22,500/ton. Those credits would become usable and tradable. The non-tradable/non-usable credits would also be available for offsetting emissions if the Governor of California declares a State of Emergency related to power generation or grid stability, but would be usable/non-tradable. For NSR holding purposes, newer ~~electrical~~ electricity generation facilities can access both their non-tradable/non-usable RTCs and the Regional NSR Holding Account RTCs.

The commenter also asks why the State of Emergency declaration can only be made by the Governor and not by a local government official. Staff believes that a major power crisis would warrant this type of declaration and not just an elevation in power demand. Staff understands that there are other factors to consider, such as the increase in the electrification in the transportation sector that may cause the demand to rise. Combined with the lesser amount of RTCs available as a result of the shave and higher resultant RTC prices, power-producing facilities may need some relief to gain access to more RTCs. Staff feels that the safety valves in the proposed amendment would address these concerns. Nonetheless, staff proposes to add resolution language to monitor the power-producing sector for trends in power consumption and associated NOx emissions as electricity demand potentially increases.

The commenter also states that the rule language needs to be clarified to detail that the Regional NSR Holding Account would accommodate NSR requirements and annual emissions in the event of a power crisis. Staff has made these clarifications in the rule language and staff report.

The commenter lastly states that it may not be appropriate for the Executive Officer to determine the amount and distribution of RTCs and thereby make the determination of which electric generating facilities would generate electricity during a State of Emergency. Each individual electric generating facility subject to the shave would also have access to its non-tradable/non-usable account if the 12-month rolling average RTC price threshold trigger is reached, or if a State of Emergency is declared. The credits in the Regional NSR Holding Account would also be made available to all electric generating facilities under a State of Emergency. If the State of Emergency is prolonged, the proposed amendments now provide for a report to the Governing Board after any power crisis trigger such that a plan for distribution of RTCs and possible program adjustments can be made before the supply of emergency RTCs is exhausted.

Comment Letter # 8 – SCEC Dated August 26, 2015

Comment 8-1

Responsiveness of Mitigating Actions. The Cities are concerned that rolling average RTC price may trail too far behind sudden RTC price increases and the requirement to obtain Governing Board authorization to convert the holdings to tradable and useable credits may not be suitably responsive to our needs as municipal utilities. In other words, the Cities' need for certainty and swift access to RTCs may be jeopardized and we will be forced to participate in a market with escalating costs and limited RTC availability until the point that the $15,000 threshold is reached. By the time the SCAQMD responses are implemented, it will be too late to undo the damage to the utilities and local communities.

Response 8-1

The comment states that if access to additional credits can be realized in a faster timeframe for unforeseen situations where emergency power generation may be necessary. The staff proposal has safety valves through which additional credits can be accessed, including the immediate access in the event of a power crisis. We understand that there may be some situations where the need to additional credits may arise more rapidly than, for example, a gradual upward trend in power generation. A facility would still have time to reconcile emissions at the end of a compliance quarter and compliance year, which include a reconciliation period.

Comment 8-2

Request for Flexibility in Accessing Non-~~tradeable~~tradable / Non-useable Holdings. The Cities are supportive of the proposals to expand access to credits (at either no costs or $7.50 per pound which is equivalent to $15,000 per ton) and believe that they would be beneficial to the utilities and the RECLAIM program in general. By providing access to these credits in advance of a market upset, the District would provide municipal utilities the certainty needed to meet our mission at a reasonable cost and the limited access of utilities to their non-tradable credits may actually prevent market upsets that would trigger the widespread release of non-tradable/non-useable credits to all RECLAIM operators. Finally, if utilities are assessed a fee for their use of the non-tradable/non-usable credits in advance of the 12-month price trigger being reached, the proceeds would be available to the District to facilitate voluntary NOx emission reductions

Response 8-2

The comment expresses support for the accessibility to non-tradable credits in the event of a market upset. SCAQMD staff has provided safety valves to provide access to the non-tradable/non-usable account and to the Regional NSR Holding Account in the event of the 12-month rolling average threshold price trigger being reached or in a State of Emergency. Other stakeholders do not believe there should be a cost to access such credits. Please see response 7-1.

Comment 8-3

Sunset of Non-tradable/Non-usable Holdings. The Cities understand that SCAQMD proposes to discontinue the non-tradable/non-useable holdings in the year 2022. Given the uncertainty presented by increased integration of renewable resources and regional electrification, the Cities ask SCAQMD to provide for continued utilization of the non-tradable / non-useable holdings, at least for municipal utilities.

Response 8-3

The comment requests that the non-tradable/non-usable holdings to be provided in perpetuity to municipal utilities. The staff proposal intends to submit the non-tradable portion of the shave into the SIP, and if they were held indefinitely and could potentially be accessed, they would never be available for SIP emission reductions. However, for new electric generating facilities subject to multi-year NSR holding requirements, the shaved portions of holdings will go into the Regional NSR Holding Account. This account will hold the RTCs for NSR purposes in perpetuity and will provide relief to these facilities, while setting aside some RTCs for future uncertainty in the electricity market. Staff intends to include a resolution to closely monitor the impacts of potentially increased electricity demand and renewable penetration on NOX emissions, and will propose RECLAIM program adjustments to the Governing Board if needed.

Comment 8-4

Regional NSR Holding Account, Compatibility of Dual Purposes. The Cities appreciate that SCAQMD is proposing alternatives that would ease the NSR holding requirement burden and also provide additional RTCs in the event of an emergency. However, it is not clear that both purposes can be simultaneously served, given the amount of RTCs that SCAQMD proposed to allocate to the account. The Cities ask that SCAQMD clarify how the account can be available for emergency use by all ~~electrical~~ electricity generating facilities, without jeopardizing the ability of new facilities to make the NSR holding demonstration.

Response 8-4:

The commenter has concerns with how the Regional NSR Holding Account will be able to support the NSR requirements for facilities if the account is accessed by all electric generating facilities in a State of Emergency. The proposed rule language clarifies how the NSR Regional Holding Account would be implemented, and that it would be available to all ~~electrical~~ electricity generating facilities under a State of Emergency. There is no issue with using such RTCs for dual purposes. The NSR holding requirements cease after the compliance period ends, and if they are not used to offset actual emissions, the credits become available for other purposes. This is the situation as it exists today as RTCs can be sold after the compliance period ends.

Comment 8-5

Additional entities or authorities should be allowed to declare the presence of an energy emergency at both a regional and local level. Many emergencies requiring local power generation may exist within the boundaries of a city and state or regional authorities may not be able to investigate and make the necessary declaration quickly. Local authorities, such as a City Manager or Mayor, should also be allowed to make a declaration that would allow for the release of RTCs from the Regional NSR Holding Account.

Response 8-5

The commenter asks why the State of Emergency declaration can only be made by the Governor and not by a local government official. Staff believes that a major power crisis would warrant this type of declaration and that local emergencies can be handled within the framework of the RECLAIM program, such as purchasing credits in the market to reconcile these emissions. If there is a necessity for credits, such an exceedance of the 12-month rolling average RTC price threshold trigger, then the non-tradable credits could be made available. See Response 7-5.

Comment 8-6

It is unclear how access to RTCs would be granted or how competing applicants would be prioritized by SCAQMD to receive RTCs. SCAQMD must further define its role in the process of granting access to the Regional NSR Holding Account if the Cities are to be assured that credits are available not only for the NSR holding demonstration, but also for easy access in case of an emergency.

Response 8-6

The comment requests for further definition as to how the Regional NSR Account credits will be prioritized for distribution. If the Governor declares a power emergency, the current year non-tradable/non-usable RTCs held by electric generating facilities can be used to offset emissions after exhausting their own usable RTCs, unless they sold any part of their RTC holdings for the subject compliance year. If an eligible facility has exhausted their non-tradable/non-usable RTCs, it may apply for use of the accumulated RTCs in the Regional NSR account. The supply of emergency annual RTCs will be sufficient to handle a short term crisis. If the crisis is prolonged such that the demand for emergency RTCs is greater than the supply, there will be time to return to the Governing Board to make program adjustments. The staff proposal includes provisions to report to the Governing Board and proposes a plan for RTC distribution and other program adjustments when the State of Emergency access is triggered.

Comment 8-7

The Cities ask SCAQMD to clarify how the Regional NSR Holding Account would affect the way in which new power producing facilities would manage the remaining RTCs listed in their facility permits, with respect to the Rule 2005 (f) holding requirement. Ideally, provisions to accommodate the holding requirement would also allow facility operators to sell the remaining unused RTCs listed in their permit in advance of compliance year closure. We also ask SCAQMD to give consideration to the same discretionary use of the Regional NSR Holding Account by municipal utilities that is proposed within this letter for the non-tradable/non-useable holdings.

Response 8-7

The comment requests for further clarity on how the Regional NSR Account will affect how the RTCs are reflected on the facility permits. Amounts of NSR holdings going into the Regional account year by year is listed in Rule 2002 for each facility. On the facility RECLAIM permits, Section B would still contain the usable/tradable and non-usable/non-tradable amounts, but the permit condition will refer to Rule 2002.

The commenter also request the same use of the credits from the Regional NSR account to the non-tradable/non-usable holdings. For newer electric generating facilities, the non-tradable/non-usable holdings and the holdings in the Regional account are essentially drawn from the same pool of credits. For every portion of the shave designated as non-tradable/non-usable, the RTCs will go into the Regional account the following year, instead of being submitted into the SIP. Facilities would have access to the Regional account portion for offsetting annual emissions if a State of Emergency is declared. The non-tradable credit portion for newer facilities would not be available for sale, however.

Comment Letter # 9 – Eco Services Letter Dated August 28, 2015

Comment 9-1

Eco Services does not support a program that leaves no reasonable means of complying. We support revisions to the RECLAIM program that rely on implementation of feasible and cost-effective controls. Sources that can implement BARCT can and should do so as a first step towards additional reductions. We strongly urge the SCAQMD to consider this approach which will result in a reduction of NOx emissions based on cost-effective controls which will not cripple the RECLAIM trading program and leave smaller emitters no real cost-effective option for compliance. If the SCAQMD pursues the across the board shave, it will effectively be imposing cost-effective requirements on the BARCT sources but not considering cost-effectiveness at all for non-BARCT sources. Eco Services believes that is inequitable and inappropriate.

If the SCAQMD does pursue an across the board NOx shave, Eco Services recommends that the changes to RECLAIM include some type of measure to limit the costs of NOx credits in addition to the current $15,000 per ton annualized average cost, particularly for small emitters. An equitable rule should provide the regulated community with a cost-effective means of complying. We request that the SCAQMD somehow provide a ceiling on the financial impact it will have on RECLAIM participants in terms of cost-effectiveness. BARCT sources will be subjected to cost-effective controls. Similarly, the financial impact to non-BARCT sources should also be based on cost-effectiveness.

It is our understanding that Non-Tradable/Non-Useable allocations will be issued to emitters, and that these “safety valve” allocations can be used as compliance instrument when the average cost of annual NOx RTC exceeds $15,000 per ton (or $7.50 per pound). However, we believe that the time for cost averaging should be significantly shortened to prevent the repeat of situation similar to year 2000 when the value of annual NOx RTC went far above the $7.50 per pound threshold. Also, additional safe guards should be considered to prevent non-compliance for non-BARCT sources if the NOx RECLAIM market fails such that no NOx RTCs are available to be purchased.

Response 9-1

The comment expresses concerns about the effect of the shave on a facility, such as Eco Services that does not have equipment subject to BARCT. Staff appreciates your comment and acknowledge all your efforts in reducing SOx emissions with the installation of the wet gas scrubber at your facility. We believe that if BARCT reductions are achieved in 2022, there should still be a comparable margin in the market between the allocation cap and the actual emissions as there is today. The current market has about a 28% margin, while in 2022 the market should have about a 23% margin if BARCT controls are installed. The implementation schedule is over several years, so the full magnitude of the shave would occur gradually. As the allocation cap decreases, the price of RTC is expected to rise. Despite this, there is a safety valve that would allow for more RTCs to be accessed in the event that the 12-month rolling average threshold price trigger is reached. The commenter also has concerns of the financial impact to facilities facing a similar situation. Please refer to the socioeconomic report. The commenter also makes reference to a prior comment letter submitted on April 27, 2015 which refers to the price of purchasing credits based on the current market value. We acknowledge that at the current price of credits of around $100 per pound, the cost of purchasing credits after the shave to offset annual emissions would be in the neighborhood of $2.6 million for your facility. Your facility is included as part of the shave because it is among the top 90% of RTC holders and the RECLAIM program will have some structural buyers.

Comment Letter #10 – Charles Timms, Jr. Letter Dated September 17, 2015

Comment 10 - 1

We have identified some additional rule language that would need to be amended to facilitate our proposal that power plants be provided with quicker access to non-tradable/non-usable NOx RTCs, and/or access to RTCs in the Adjustment Account, if needed to cover annual emissions. This additional language will ensure that the relevant RTCs are only credited to the SIP on a year-by-year basis to the extent they are not needed for power plant compliance purposes. See Attachment 1 to this letter.

In addition, the Cities support the proposal of the Los Angeles Department of Water and Power to expand the emergency provisions in the staff proposal to allow power plants to access RTCs in the Adjustment Account if an energy emergency alert is declared by the relevant electrical "Reliability Coordinator." See Attachment 2 for proposed rule language.

Proposed Amended Rule 2002(f)(1)(J) shall be amended to read as follows:

"The NOx RTC adjustment factors for compliance years 20019 through 2021 shall not be submitted for inclusion into the State Implementation Plan until the adjustments have been in effect for one full compliance year. The 2022 NOx RTC adjustment factors shall not be submitted for inclusion in the State Implementation Plan until 12-months after the adjustments have been in effect for one full compliance year. At the end of each compliance year reconciliation period from 2022 and each year thereafter, the Power Producing Facility shall surrender unused non-tradable RTCs to the District for inclusion into the State Implementation Plan."

Proposed Amended Rule 2002(f)(5) shall be amended to read as follows:

"During a State of Emergency as declared by the Governor or an Energy Emergency Alert as declared by the Reliability Coordinator, the Executive Officer will allow Power Producing Facilities access to Adjustment Account RTCs for the purpose of compliance with the annual emissions. ~~These available RTCs will be limited to those that are in excess of those specified for use in paragraph (f)(4).~~ The amount and distribution of the RTCs will be determined by the ~~Executive Officer~~ Power Producing Facilities based on the ~~impact that~~ amount of energy they produce during the State of Emergency ~~has on the RECLAIM program~~ or the Energy Emergency Alert."

'Reliability Coordinator' means the entity that is the highest level of authority who is responsible for the reliable operation of the Bulk Electric System as defined in the North American Electric Reliability Corporation Glossary."

Response 10-1

The commenter has suggested that additional rule language be added to ensure that unused RTCs for emissions compliance from electric generating facilities are submitted into the SIP on a year-by-year basis. The proposed rule language establishes the mechanism by which the non-tradable and Regional NSR accounts are handled. The non-tradable account is the yearly shaved amount of RTCs. The rule language states that after one full compliance year the credits will be submitted into the SIP. For the first year of the shave, the non-tradable account can be accessed if the 12-month rolling average threshold price trigger is reached or if there is a State of Emergency. For electric generating facilities with continual NSR requirements, the non-tradable balance can be used for NSR holding purposes, and subsequently will become the portion that will fund the Regional NSR account for the same purpose. However, the RTCs may be used for compliance with annual emissions and will become usable if the price trigger is reached or a State of Emergency is declared. Existing electric generating facilities will also have access to their non-tradable/non-usable RTCs in a State of Emergency, as well as the Regional NSR Holding Account. If the non-tradable account is accessed, the following year's permit will be adjusted accordingly.

The commenter also provided some suggested rule language that echoes the same comments from the previous comment letter regarding the designation of a State of Emergency by someone other than the Governor. As stated in the response to comment 7-5, the safety valves that are proposed by staff are sufficient to ensure that there will be available credits in the event of either a shortage of credits or a major power crisis as declared by the Governor. Staff does not support allowing the Reliability Coordinator to dictate access to the Regional NSR account because an "alert" is not a true State of Emergency requiring extraordinary measures.

Comment Letter #11 – Southern California Edison No Date

Comment 11-1

The shave should drive sources towards BARCT

The shave, as proposed, would constitute a 53% reduction in the total number of RTCs in the market. 67% would be taken from the refinery sector while 47% would be taken from the non-refinery sector, including electric generation facilities. While this would be better than an outright across-the-board shave, it still would trigger costs for the electric generation sector that would have no commensurate impact on reducing air emissions. The electric generation facilities are already at Best Available Control Technology (BACT) with no existing opportunity to reduce emissions (other than curtailing operation, which is not feasible for electric generation facilities since electric demand will dictate operating times). While there is recognition there will have to be some reduction of RTCs from electric generation facilities, the shave should cause facilities not currently at BARCT to install better controls. With the proposed percentages, the costs will disproportionally impact facilities that are already at BACT and result in a subsidization by those at BACT of facilities not yet utilizing the best controls.

Response 11-1

The commenter states that there will be cost impacts to electricity generating facilities when there is no reduction in emissions from these sources. While we recognize that most of the equipment used by the electric generation sector is at BARCT or BACT, the proposed shave affects the top 90% of RTC holders and is necessary to obtain the highest amount of feasible reductions to meet SCAQMD's attainment goals. Note that most electricity generating facilities hold a significantly more RTCs than their actual emissions, and that staff is proposing resolution language to monitor trends in electricity demand and propose program adjustments if necessary. The staff proposal has several safety valves that can address certain issues that are specific to the ~~electrical~~ electricity generating sector, such as relief from yearly NSR holding requirements.

Comment 11-2

The proposed shave amount on the Electric Generation Facilities in effect caps the amount of fuel we can use

As stated above, SCE's electric generation facilities are already at BACT or BARCT, with no currently feasible opportunity, from a control standpoint, to reduce emissions further. With no advancements in control technology, the only way to further reduce emissions is by curtailing operation (i.e. limiting fuel usage). Thus, if no credits were available for purchase on the open market, which is a possibility given the proposed size of the shave, the only way to stay in compliance would be by reducing fuel usage.

It should also be noted that under the California Health & Safety Code for market-based programs [§39616(c)], a program must not result in disproportionate impacts to stationary sources in the program as compared to other permitted stationary sources not in the program. A typical permitted source not in the RECLAIM program is subject to rule-based command and control regulations. Were SCE's facilities not in the RECLAIM program, command and control regulations would require BACT concentration limits with no further limits on operation or fuel use, unless such further limits were agreed to for PTE or CEQA limit purposes. However, because the facilities are in RECLAIM, not only are they subject to BACT, but also to the holding requirement and the potential surrender of RTCs. The result is that if there aren't enough RTCs in the market, this proposed shave would effectively cap fuel use. By setting a concentration limit as well as a fuel use limit, this proposed shave would go beyond command and control regulations.

Response 11-2

The commenter states concerns with a potential shortage of credits as a result of the shave. As stated in the previous response, there are safety valves in the current rule and also in the rule proposal that would prevent this condition from occurring. For example, existing electric generating facilities would have access to non-tradable credits in the event that the 12-month rolling average threshold price trigger is reached or if a State of Emergency is declared. New electric generating facilities (in RECLAIM after October 15, 1993), would have access to a Regional NSR Holding Account to relieve them of NSR holdings requirements that often require holding excess credits at the potential to emit level, even though the actual emissions are far below this level. In addition, in the event of a power emergency, all electric generating facilities would have access to the Regional NSR account for credits used to offset these emissions during an emergency.

Comment 11-3

The amount of the shave could have impacts on grid reliability during emergency situations.

The current proposal contemplates what amounts to a 53% shave in the existing RTC market. While action must be taken to reduce current NOx emissions, this action must not result in a situation where generating facilities are unable to operate during emergency situations. The electric grid is a complex, interrelated system. All components work together to generate and ultimately distribute electric power to end users. If, for example, a major transmission line were to go down, there would be an immediate need for local, dispatchable generation to begin operating. If these facilities don't have sufficient RTCs to operate in these circumstances, the system would be faced with energy resources that could not be operated under SCAQMD rules, which would result in load curtailment. Because of the complexity of the system, there is no bright line that can be drawn. The District must therefore exercise caution and not bring about a market that is incapable of responding to emergency situations.

Response 11-3

The comment states that access to additional credits should be realized in a faster timeframe for unforeseen situations where emergency power generation may be necessary. Non tradable/non-usable RTCs are proposed to be accessed immediately if a State of Emergency is declared. Please refer to the response to Comment 11-2. Despite this, a facility would still have some time to reconcile all of its emissions at the end of a compliance year quarter, plus the reconciliation period.

Comment 11-4

Changes to the RATA testing requirements are supported

Thank you for meeting previously with SCE and DWP on this matter and recognizing that there was a legitimate need to change the rule language regarding postponement of RATAs. In the past, SCE has experienced multiple incidents where equipment has failed in the quarter in which a RATA was due, and found that the District's options for RATA postponement were impractical. With no reasonable alternative to postpone testing, and in order to avoid enforcement, the facilities were forced to petition the SCAQMD Hearing Board for variances. SCE believes the proposed language addresses this issue and now provides a legitimate alternative for RATA postponement without variance relief.

While we fully support the option presented, we are requesting an increase of the 14 unit operating day extension to 30 unit operating days. The main concern is with SCE's Pebbly Beach Generating Station on Catalina Island. Due to its remote location, weather related delays of transportation options to the island, and the high work load schedule of our source testing firm, it can be difficult to organize a RATA test in a short timeframe. The testing firm must separately schedule a time to barge its equipment out to the island, and if power demand on the island were high, the engines may need to run as soon as possible when they return to service, which could impact the test protocol This is especially true for the cleaner engines, as they must operate more frequently in order to comply with facility-wide emission limits. If the source testing firm could not schedule a visit to the island and the engines had to operate to support the power demand, 14 operating days might not be enough time to complete an appropriate RATA. As an alternative, if staff is not open to extending the 14 unit operating day window, SCE suggests having an equivalent operating hour limit. This could give the facility more time to schedule a test without increasing the overall operating time of the unit. Whether there are 14 days or 30 days to complete a RATA, a facility has plenty of incentive to complete the RATA as soon as possible so as to minimize the use of missing data procedures. We ask that the District consider this extension. But other than this amendment, we fully support the rule language as presented by the District and we appreciate the work done by staff to address this issue.

Response 11-4

The comment requests additional time for the extension of postponed RATA testing from 14 operating days to 30 operating days. The operating days do not have to be consecutive days so the total calendar days since the re-firing could be longer than 14 consecutive days.

Comment 11-5

SCE Supports the adjustment account for compliance with Rule 2005 Subdivision (f).
Existing USEPA interpretation of the NSR requirements hold that a facility in RECLAIM must obtain sufficient RTCs at the beginning of the calendar year to cover the total potential to emit (PTE) for the year notwithstanding that most facilities do not operate at or near their PTE. This results in a substantial procurement of RTCs that are necessarily bought at a time they are most expensive, but if not used are then sold off when they are of little value. Further, there is no environmental benefit created by what is, in effect, an over-procurement of credits. SCE supports the proposal by the District to create an adjustment account that would cover this RTC requirement. It would eliminate the costly procurement of RTCs beyond what is really needed to cover actual emissions and, quite simply, it makes sense. We urge the District to continue to seek EPA concurrence with this proposal.

Response 11-5

The comment expresses the support for the establishment of the Regional NSR Holding Account. We appreciate your support for these provisions affecting newer electric generating facilities with burdensome NSR holding requirements.

Comment Letter #12 – GE Capital & Inland Empire Energy Center Letter Dated September 22, 2015

Comment 12-1

Inland Empire Energy Center, LLC, a wholly-owned subsidiary of General Electric (GE), is the permit holder for the Inland Empire Energy Center (IEEC). GE purchased all NOx RTCs required for the IEEC instead of having them purchased by IEEC, LLC. The GE RTC account is, and always has been, 100% dedicated to the IEEC. Thus GE's NOx RRTC account should be designated as an Electric Generating Facility (non-refinery) account for purposes of the allocation shave. We therefore request that the GE RTC account be correctly categorized as an Electric Generating Facility (non-refinery) account in Table 8. Currently, GE is categorized as an "investor".

Response 12-1

The comment requests for the Investor account that is associated with Inland Empire Energy Center only to be categorized as an electric generating facility subject to the shave for the non-refinery sector. SCAQMD staff has reviewed the information you submitted and we agree that the investor account is associated with this electric generating facility only. The updated list of facilities will reflect the categorization of the investor account as a facility among the electric generating facilities affected by the shave. Table 8 of Rule 2002 will also be updated to reflect this change.

Comment Letter #13

Comment 13-1 The Shave for the Program Should be a Minimum of 14.85 tpd

We do not agree with the decision to reduce the total shave amount by 0.85 tpd, from the required 14.85 tpd to 14 tpd. California's Health & Safety Code is abundantly clear that trading programs must "result in an equivalent or greater reduction in emissions at equivalent or less cost compared with current command and control regulations. . . ." Cal. Health & Safety Code §39616. In reviewing the materials produced through this rulemaking, the Best Available Retrofit Control ("BARCT") assessments show that a BARCT-equivalent program would result in 14.85 tpd fewer emissions. Accordingly, to comply with Health & Safety Code section 39616, the shave for the RECLAIM program must also be at least 14.85 tpd. We also suggest shaving even more from the program given the large size of the "black box" that must be reduced to meet ozone standards.

Response 13-1

SCAQMD staff understands the commenter's request for as many reductions as possible to be able to meet the attainment goals of the region. The reason that the overall RTC reduction is 14 tons per day and not more is to account for some BARCT uncertainties that arose in the refinery boiler and heater category. Staff and the consultant hired to do an independent BARCT assessment had some reasonable, but different engineering and cost assumptions which resulted in an adjustment to the staff proposal to account for this uncertainty.

Comment 13-2 The Implementation Schedule is Weak

We are deeply concerned that the schedule for implementation for the shave is too protracted. *See* Slide 4 of the Staff Presentation. Given recent difficulties in meeting various air quality standards, including the 1997 and 2006 standards for fine particle pollution ("PM2.5"), it would be prudent to move up some of the latter year reductions. In fact, we suggest amending the schedule to the following to ensure reductions on the front end in time for compliance with
Standards: 2016: 5tpd, 2018: 3 tpd, 2019: 3 tpd, 2020: 2 tpd, 2021: 1.85 tpd.

Response 13-2
Staff agrees with front loading some of the RTC reductions and has proposed a 4 ton per day reduction in 2016. The implementation schedule serves two purposes. The first is to address the SIP commitments to EPA regarding the contingency measure for 2016. The second is to ensure facilities have adequate time to install controls if that is how they choose to comply.

Comment 13-3 The District Should Not Establish a NSR Set Aside

Health Advocates do not support the implementation of a District-operated set-aside for New Source Review ("NSR") holdings. There is no basis for the District to undertake this task. In fact, this provision exists to ensure the program does not erode air quality progress in the region. We think this is a necessary safeguard, and we have not heard a compelling reason why the District should take on this duty. Industries have complied with this provision for decades, and it makes sense to continue to place this duty on industry.

Response 13-3

The commenter disagrees with the staff proposal to offer the Regional NSR Holding Account for ~~electrical~~ electricity generating facilities. The staff proposal aims to reduce the total allocation of the RECLAIM universe by over 53%. This is a very substantial reduction, much more so than the 22.5% reduction that resulted from the 2005 amendments to RECLAIM. ~~Electrical~~ Electricity generating facilities are in a unique situation in that they are all at either BARCT or BACT. In addition, the newer electric generating facilities have to meet the NSR holding requirements every year at the potential to emit level, even though the actual emissions are far below this level. While the staff proposal will shave those electric generating facilities among the top 90% of RTC holders by 49%, the Regional Account would provide some relief from their NSR holding obligations and help to maintain a functioning market in the event of a power emergency. This Regional Account would account for a small fraction of the overall proposed RTC reduction, which is designed to achieve BARCT-equivalent levels of emissions across the program.

Comment 13-4 The California Environmental Quality Act Analysis Should Examine a Command and Control Alternative

It is important that the Governing Board and the public receive full information on the environmental landscape of this action. In particular, through the California Environmental Quality Act (“CEQA”) process, an assessment of a Command and Control alternative will be important to understand how quickly desperately needed reductions could be implemented in the South Coast under a regulatory program requiring implementation of readily available technologies, many of which have not been installed at the largest NOx emitters in the South Coast. Under the currently proposed approach, clean up would be protracted for many years as the shave is implemented. A Command and Control Alternative would achieve reductions sooner than this compliance schedule.

Response 13-4

The commenter requests that a command and control alternative should be evaluated by CEQA. The purpose of the RECLAIM program is to allow emission reductions equivalent or greater to command and control at an equivalent or less cost. The BARCT analysis analyzed the technologies available to effect emission reductions that are cost effective and that are in compliance with the California Health and Safety Code. The actual control technologies to meet BARCT would be the same under command and control as assumed in the Project in the CEQA document, so the environmental impacts would be the same.

Comment 13-5

The claims of industry lobbyists that the IYB credits are appropriately priced are not true. In fact, like the short term credits, these credits are exceptionally low. Even with a more than doubling of the IYB prices in 2014 compared to 2013, these credits are only 18% of the $609,187 cost established by the District pursuant to section 39616(f) of the California Health & Safety Code, which is set to ensure credit prices do not go too high. That the failure of these IYB credits to even approach 1/5 of the District's ceiling for credit costs just bolsters the excessive number of credits in the NOx RECLAIM system. Overall, the evidence conclusively suggests that the credits are not priced correctly to push for pollution reductions at a level commensurate with what command and control would achieve, which is borne out in the District's BARCT assessments.

Response 13-5
Comment noted.

Comment 13-6 The Shave Approach Must Ensure Reductions from Refineries and Electric Generating Facilities.

The evidence presented by the District in this rulemaking indicates that refineries have used the NOx RECLAIM system as a shield from actually installing pollution control equipment like Selective Catalytic Reduction ("SCR"). Given this past behavior, we suggest that the best path forward is that refineries be taken out of the NOx RECLAIM program and be required to install pollution control equipment.

Response 13-6

The comment states that refineries should be removed from the RECLAIM program to force the installation of control equipment. As stated in the previous comment, the staff proposal is for a 53% overall RTC reduction from the RECLAIM universe. The refinery sector would experience a 66% RTC reduction. Staff believes that there is a sufficient impetus in the staff proposal to effect cost effective control technology installations at these facilities.

Comment Letter #14 Arnie Smith Email Dated August 11, 2015

Comment 14-1

At this point, we are probably one to two months away from having finalized NOx RECLAIM rules. Then, we are only another two months from the beginning of the first compliance year. There will be inadequate time for project development with any results in 2016/2017 - even for simpler scopes like burner replacements in existing heaters or catalyst upgrades in existing SCRs. But, new scrubbers or new SCRs would not be able to provide any mitigation benefit until 2018/2019.

The ongoing SOx RECLAIM Program had a gap of 26 months from the end of rule-making to the beginning of compliance - which would allow for some mitigation to be realized in the first compliance year. A three year gap would have insured an even stronger result.

A three year gap between rule-making and the first compliance year for NOx RECLAIM would have provided a better start for a real NOx reduction.

Response 14-1

The commenter expresses his concern that the proposed implementation schedule for the shave would provide inadequate time for projects to be completed and provided a reference to a document from the Association for the Advancement of Cost Estimating (AACE) that many engineering, procurement, and construction (EPC) firms use for designing their projects. The commenter uses the reference to illustrate that it takes many months of lead time and up to two to three years for emission reduction projects to be installed. Staff understands that there is a lead time associated with any construction project, but believes that the initial 4 ton per day reduction in 2016 would be satisfied by removing unused RTCs while still being able to provide the market with sufficient credits until further reductions in the allocation cap are realized. There is currently about a 28% margin from the allocation cap and the actual emissions. With a 4 ton per day reduction, it is anticipated that there would still be sufficient credits in the market to cover actual emissions. By 2018 when the next portion of the shave will be effective, several smaller projects would likely be installed, so when 2019 is reached, those larger projects that the commenter has referred to would be in place and would result in emissions under the allocation cap.

Comment Letter #15 Karl Lany Email Dated August 20, 2015

Comment 15-1

Thanks for taking the steps you have to accommodate Rule 219 boiler technology into the proposed RECLAIM amendments. After giving the concept more consideration, I continue to question the proposed requirement that such boilers be subject to testing requirements in order to qualify for RECLAIM reporting factors that reflects certification standards.

The entire SCAQMD program for certified diesel engines rests upon certification standards and excludes any emissions testing. It makes sense that the benefits of certification (exclusion from unnecessary emissions tests) that are extended to process unit diesel engines in RECLAIM would also be extended to permit exempt natural gas boilers that are subjected to a similar certification program.

I sincerely hope that SCAQMD reconsiders its proposed testing requirements for Rule 219 boilers in RECLAIM and instead provides a more practical solution that reflects the legitimacy of its boiler certification program.

Response 15-1

The commenter requests a reconsideration of the source testing requirements of small, unpermitted boilers in the staff proposal for usage of a lower emission factor for reporting Rule 219 equipment emissions. See Response 6-2.

Comment Letter #16 George Piantka Email Dated August 14, 2015

Comment 16-1

In Rule 2005, will there be proposed language to address annual holding limit requirements for a facility like Walnut Creek?

Response 16-1

The comment asks for proposed language for the affected facility. Staff is proposing to list the actual NSR holdings going into the Regional account year by year in Rule 2002 for those affected facilities. On the facility RECLAIM permits, Section B would still contain the usable/tradable and non-usable/non-tradable amounts, but the Regional account holdings will refer to the Rule 2002 as part of the permit conditions.

Comment 16-2

The financial impact to a new facility like Walnut Creek is different than an existing RECLAIM facility or new plant at an existing RECLAIM facility. In satisfying NSR (unlike a legacy RECLAIM facility), IYB Cycle 1 and 2 RTCs were purchased from the market. Demonstration that we satisfied the RTCs for annual NOx PTE was not only necessary for the Permit to Construct and annual Permit to Operate but also for the financing of the WCEP. We would now represent that the asset has lost the equivalent of 47% of its NOx IYB RTCs at the current rate of say $115/lb-yr and address the means to which we can demonstrate our continued holding and/or access to these RTC for the lenders. While not obvious, the financial implications are different than a facility that has relied on an existing RECLAIM account or the ability to reconcile its emissions for the respective year. It is the difference between losing the unrealized value of IYB RTCs in a legacy RECLAIM account versus the purchase, shave and possible replacement of them at the new market condition (or from the Regional NSR Holding Account?) to meet its PTE. This is one of the reasons why we believe WCEP should be exempt from the shave.

Response 16-2

The comment expresses concerns with the shave and its effect on a new facility that will continue to have NSR holding requirements every year. Staff acknowledges this situation for new electric generating facilities and the proposal includes provisions that would provide some relief for the NSR holding requirements with the establishment of the Regional NSR Holding Account.

Comment Letter #17 Chuck Casey Email Dated September 24, 2015

Comment 17-1

The list as provided in table U.1 needs to be audited with a full explanation of who is included or excluded and the reason for each. The NOx shave percentage adjusted for non-refinery RTC holders' weighted reduction, currently 47%, would require adjustment if the list changes.

Response 17-1

The commenter requests for a clarification on which electric generating facilities are part of the proposal for the shave and if cogeneration facilities are to be considered electric generating facilities for inclusion in the shave. SCAQMD staff has taken your comments into consideration and acknowledges that all electric generating facilities were included into the shave, even those under the 90% RTC Holders cutoff so that those with NSR holding obligations would be able to use the Regional NSR Holding Account. Upon further consideration, staff has removed those electric generating facilities that are under the 90% cutoff for RTC holders from the list of facilities for the shave.

Comment Letter #18 Los Angeles Department of Water and Power Dated August 14, 2015

Comment 18-1

The commenter feels that since its facilities are already at BARCT/BACT, cannot reduce power production to meet demand if there are no credits available, and could face a potential increase in NOx emissions due to transportation electrification, the current rule language for the conversion of non-tradable/non-usable RTCs to non-tradable/usable is inequitable and costly. LADWP recommends an alternative approach applicable to ~~electrical~~ electricity generating facilities such that the non-tradable/non-usable RTCs continue to be deemed non-tradable, but *usable* for compliance *without* the price threshold trigger.

Response 18-1

SCAQMD staff has taken these comments into consideration and has proposed a mechanism for accessing non-tradable/non-usable credits and also credits in the Regional NSR Holding Account with associated triggers. For the first year of the shave, the entire non-tradable/non-usable portion of a facility may be accessed if the rolling 12-month RTC price exceeds $22,500/ton. Those credits would become usable and tradable. The non-tradable/non-usable credits and the Regional NSR holding Account could also be accessed if the Governor of California declares a State of Emergency related to electricity demand or power stability in the Basin, but would be usable/non-tradable. Over time, the amount of RTCs in the Regional NSR Holding Account increases, and staff is not proposing a charge for use of these credits in the event of a power generating emergency declared by the Governor.

Staff is considering additional provisions for a faster responding price trigger to access the non-tradable/non-usable RTCs. Staff is also developing Governing Board adoption resolution language to direct staff to track the effects of increased electrification of transportation and penetration of renewable power sources on the electricity market, and report to the Stationary Source Committee annually with recommendations for program adjustments, if necessary.

These market safeguards will ensure that ~~electrical~~ electricity generating facilities have access to credits in the event of a power emergency without the curtailment of power, while also providing an alternative for these facilities to no longer participate in a market program. Staff is proposing rule language that would allow ~~electrical~~ electricity generating facilities whose equipment is at BACT or BARCT to opt out of the RECLAIM program. This would subject ~~electrical~~ electricity generating facilities to Command and Control rules.

Comment 18-2

LAWDP recommends that the 2022 NOx RTCs for power producing facilities not be submitted for inclusion into the State Implementation Plan in order to serve native load customers and anticipate future increased electrical demand.

Response 18-2

The commenter provides recommended alternative rule language for Proposed Rule 2002 (f)(1)(J) to not require RTCs reduced from ~~electrical~~ electricity generating facilities to be submitted into the SIP. The proposed rule language establishes the mechanism by which the non-tradable and Regional NSR accounts are handled. The non-tradable account is the yearly shaved amount of

RTCs. The rule language states that after one full compliance year the credits will be submitted into the SIP. For the first year of the shave, the non-tradable account can be accessed if the 12-month rolling average threshold price trigger is reached or if there is a State of Emergency. Existing power plants will also have access to their non-tradable/non-usable RTCs in a State of Emergency, as well as the credits in the Regional NSR Holding Account for subsequent years of the shave. Staff believes these safeguards would provide ~~electrical~~ electricity generating facilities with RTCs to meet their demand needs. In addition, staff is proposing to add language to the adoption Resolution directing staff to track the effects of increased electrification of transportation and penetration of renewable power sources on the electricity market, and report to the Stationary Source Committee annually with recommendations for program adjustments, if necessary. The RTCs in the Regional Holding Account will not be submitted in the SIP, and thus, if needed and with future rule amendments, could potentially be used to offset NOx emissions due to increased demand for electricity over the long term. Staff feels that this approach will provide the necessary program safeguards in lieu of not submitting the RTCs resulting from the 2022 NOx adjustment factors for ~~electrical~~ electricity generating facilities into the State Implementation Plan. Otherwise, the potential emission reductions represented by these RTCs could never be used for demonstrating attainment of the ozone or PM2.5 NAAQS, even though they may not be needed to offset actual emissions.

Comment 18-3

~~Electrical~~ Electricity generating facilities' ability to access RTCs in the Regional NSR Holding Account (formerly Adjustment Account) for the purposes of compliance is constrained due to the State of Emergency declaration. The rule language suggests that the RTCs in this account are limited after NSR requirements are met. This introduces great uncertainty whether there will be sufficient RTCs in this account. There are instances when LADWP must have its generating units available for operation in a short time frame to adjust to renewable production volatility. A "Reliability Coordinator" should have the authority to declare the State of Emergency and determine the distribution of RTCs. In addition, the staff report should explicitly state that the Regional NSR Holding Account RTCs would not be submitted to the State Implementation Plan.

Response 18-3

The comment expresses concerns on how the Regional NSR Holding account would function for ~~electrical~~ electricity generating facilities during a State of Emergency. The proposed rule language provides the mechanism by which access to these RTCs are given. Under a State of Emergency declaration, the current compliance year non-tradable/non-usable NOx RTCs may be used to offset emissions after exhausting the tradable/usable RTCs. If a facility has exhausted its non-tradable/usable RTCs, it may apply for the use of RTCs in the Regional NSR Holding Account. The facility requesting RTCs from the Regional account would submit a written request to the Executive Officer specifying the amount of RTCs needed. The Executive Officer will determine the amount and distribution of the RTCs from the Regional account based on certain criteria specified in the proposed amended rule. If there are not enough RTCs for all the power plants requesting relief, the RTCs will be distributed proportionately. These RTCs would be non-tradable, but usable to offset emissions, and thus not be submitted into the SIP.

The commenter also states that it may not be appropriate for the Executive Officer to determine the amount and distribution of RTCs and thereby make the determination of which power plants would generate electricity during a State of Emergency. Given the quarterly reconciliation period, staff believes there will be sufficient time and available RTCs for the Executive Officer to make findings and distribute RTCs to facilities soon after a short term power crisis. If the crisis is prolonged, there will be time to propose program adjustments and/or rule amendments to the Governing Board.

Staff believes that a major power crisis would warrant a State of Emergency declaration and not just an elevation in power demand. Staff understands that there are other factors to consider, such as the increase in the electrification in the transportation sector that may cause the demand to rise, as the commenter stated. Combined with the lesser amount of RTCs available as a result of the shave and higher resultant RTC prices, ~~electrical~~ electricity generating facilities may need some relief to gain access to more RTCs. Staff feels that the safety valves in the proposed amendment would address these concerns. Nonetheless, staff proposes to add resolution language to monitor the power-producing sector for trends in power consumption and associated NOx emissions as electricity demand potentially increases. If the State of Emergency is prolonged, the proposed amendments provide for a report to the Governing Board after any power crisis trigger such that a plan for distribution of RTCs and possible program adjustments can be made before the supply of emergency RTCs is exhausted.

The comment lastly states that the staff report should explicitly state that the RTCs in the Regional NSR Holding Account will not be submitted to the SIP. Both the rule language and the draft staff report state that these RTCs will not be submitted to the SIP.

Comment 18-4
LADWP recommends that the description "Gas Turbines" under the Nitrogen Oxides Basic Equipment column be amended to read "Refinery Gas Turbines" to distinguish that the Power Producing Facility gas turbines are not subject to BARCT in this rule amendment process.

Response 18-4
The commenter requests an amendment to the equipment description for gas turbines in Table 6 of proposed amended rule 2002. As part of the BARCT analysis, gas turbines in both the refinery and non-refinery sectors were analyzed for BARCT. In particular, there are some gas turbines in the non-refinery sector which produce power that are subject to BARCT. Thus, the description in Table 6 is broader than "Refinery Gas Turbines." The turbines at the ~~electrical~~ electricity generating facilities that the commenter refers to are not subject to BARCT because most of the units already operate at BACT, and this distinction is made in Appendix Q of the draft staff report that contains the BARCT analysis. Note that the amount of the reductions calculated for the proposed shave did not include any of the units that were already at or below the BARCT level.

Comment 18-5
The 14 operating day window for conducting a postponed RATA is insufficient. LADWP also requests that the clarification in the preliminary draft staff report that states that the proposed 14 operating day RATA postponement would apply separately for each unrelated, independent event also be placed in the rule language.

Response 18-5

The commenter had experienced multiple sequential failures to a unit which prompted the comment. Staff agrees that each unrelated independent event that rendered a major source incapable of operating separately qualifies for a postponement under this provision. Staff has revised the proposed rule to make this explicit. The commenter verbally expressed that this change satisfactorily addresses the concern regarding the length of time for conducting a RATA after the source is returned to service.

Comment 18-6
LADWP suggests that the semi-annual or annual assessment be allowed to be delayed even if the RATA was scheduled during the second 45 days of the calendar quarter in which the assessment was due, instead of being scheduled during the first 45 days of the calendar quarter as the current rule proposes.

Response 18-6
The operations of ~~electrical~~ electricity generating facilities are highly dependent on demand. RATA testing should be scheduled at the first opportunity available. Due to the unpredictability of electric demand, the schedule for operations is subject to change and actual operations that allow for RATA testing may not occur throughout an entire quarter. In those circumstances, the facility operator has exercised reasonable diligence in attempting to comply with RATA requirements, but failed to due to circumstances beyond its reasonable control. Therefore, the exemption is only offered in these cases. It is unreasonable to allow delay in conducting RATA if a facility operator decided to wait until the last part of the quarter to try and schedule a RATA. Staff explained this viewpoint to the commenter who has verbally accepted the reasoning.

Comment 18-7
The proposed requirement to disconnect and flange the fuel feed lines when a unit is physically incapable of operation and maintain operational fuel meters introduces health and safety issues, compromises structural integrity of the pipelines and would be costly at steam generating units scheduled to be replaced.

Response 18-7
SCAQMD staff discussed this issue with the commenter and agreed to incorporate language similar to the suggested language. The revised language did not make it into the version that was released October 6, 2015 but will be incorporated into the proposed amended rule that will be considered by the Governing Board.

Comment 18-8
LADWP presents a completely different alternative regulatory approach for consideration, which involves a credit mechanism by which ~~electrical~~ electricity generating facilities would have access to RTCs to support native load and transportation electrification. Two white papers are attached that detail this alternative approach and crediting mechanism, in addition to suggested resolution language addressing increased transportation electrification. Tradable RTCs would serve to address native load, and non-tradable RTCs would be allocated to cover increased generation due to mandatory and non-mandatory electrification measures. The tradable RTCs would not be adjusted, while the non-tradable RTCs would be adjusted to reflect the actual increased demand.

The SIP crediting mechanism is based on a similar approach that EPA has developed to incorporate energy efficiency and renewable energy strategies into SIP attainment strategies, which involves a quantification of NOx emission reductions that would be achieved from basin-wide electrification and a quantification of NOx emission increases from ~~electrical~~ electricity generating facilities to support this electrification.

Response 18-8

The commenter has presented an alternative approach, with supporting enclosures, which would address the increase in transportation electrification and the associated increase in electrical demand and NOx emissions. The framework of this mechanism, in part, involves the consideration of control measures for attainment strategies as part of the State Implementation Plan. The approach of the commenter's strategy is outside the scope of this rule making for RECLAIM. As detailed in the previous responses to this comment letter, the staff proposal outlines market safeguards that will help to address any possible market upset due to a shortage of credits, high RTC prices, and the potential increase in electrification basin-wide. The objective of the proposed project is to fulfill the obligation of 2012 AQMP control measure CMB-01, which is a reduction of RTCs from the NOx RECLAIM market based on a BARCT analysis. Under the staff proposal, if every unit subject to BARCT would install controls, there would still be a sufficient margin of credits available, comparable to the margin that exists today between the allocation cap and actual emissions. To attempt to quantify the anticipated increase in electrical demand due to the electrification of the transportation sector today would be speculative. The staff proposal has provided additional safeguards, such as the threshold price trigger for access to non-tradable RTCs and access to the Regional NSR Holding Account in the event of a major power emergency. The commenter's suggested resolution language has been noted and resolution language will be prepared that directs staff to monitor the power-producing sector for trends in power consumption and associated NOx emissions as electricity demand potentially increases.

.

Comment Letter #19 Shell Energy North America (US), L.P. Letter Dated August 6, 2015

Comment 19-1

To meet the proposed amendments, the facility would need to make significant modifications to the SCR, CO catalyst, and to the exhaust modules housing the catalyst, far exceeding typical cost benefit ratios. The alternative emissions reduction choice would be to replace the combustor on the gas turbine, also cost prohibitive. There is no further cost effective NOx reduction technology for this facility. The only way that that such facilities can comply with the current proposed rule is to purchase additional NOx RTCs. This represents a significant expense for generating facilities especially considering the current market conditions in California, including the recent decommissioning of San Onofre Nuclear Generating Station. We request that SCAQMD consider that peaking generation facilities with lower capacity factor built to BACT should not be obligated under the proposed rule to make further emissions reductions, and allow the emissions offsets previously procured for the unit to meet current and future SCAQMD requirements.

Response 19-1

The comment requests that the facility in question should not be required to make further emission reductions and allow the use of NSR offset credits to meet current and future SCAQMD requirements. The staff proposal includes facilities that hold credits that are in the top 90% of all the RTC holders in the NOx RECLAIM universe. Since this facility is among those facilities in the top 90%, it would be subject to a shave of 49%. A peaking facility such as the one the commenter is referring to is in a similar situation as other ~~electrical~~ electricity generating facilities that are subject to NSR requirements, have emissions that are far below what they need to hold for NSR purposes, and have RTC holdings that significantly exceed their actual emissions. It is for this specific purpose that the Regional NSR Holding Account was created to assist in facilities meeting their NSR obligation without going to the market to purchase credits. As explained in the proposed rule language and in other responses to comments, a newer ~~electrical~~ electricity generating facility subject to NSR holding requirements would have the shaved credits put into the Regional account, and the exact quantities are listed for each of the affected facilities in Table 9 of Rule 2002 for every year of the shave. It is not expected that such facilities install further controls since most the equipment is already either at BARCT or BACT. The proposed rule has safeguards that can make non-tradable credits and Regional NSR Holding Account credits available under certain specific conditions in the event of an unstable market or in a major power emergency. Staff is also proposing rule language that would allow ~~electrical~~ electricity generating facilities whose equipment is at BACT or BARCT to opt out of the RECLAIM program. This would subject ~~electrical~~ electricity generating facilities to Command and Control rules.

Comment 19-2

We believe that the Date of Amendment (the date that RTC holdings will be adjusted (should be set closer to or upon the actual date when the final Rule is published. Additionally, it is not clear how the March 20, 2015 date was established and does not address how NOx RTCs that were transferred between March 20, 2015 and the date of implementation of the Proposed Rule will be treated. We request that the SCAQMD act prospectively; the NOx RTC holdings should be the quantity as of the date of the implementation of the Proposed Rule.

Response 19-2

The commenter requests that the freeze date of the RTC holdings be changed to the date of the rule implementation. Staff has revised the proposal and notified the stakeholders regarding the proposed new freeze date of September 22, 2015. Staff cannot practically make the freeze date for shave estimation the date of rule adoption because the rule language and calculation of shave must be completed for public review and comment prior to the Governing Board hearing for rule adoption. Note that the March date was retained for determining which facilities were in the top 90%, but the freeze date was changed due to stakeholder input.

Comment 19-3

Additional information and clarification is needed regarding the Proposed Regional NSR Holding Account for Generators PAR 2000 (f) (4).

Response 19-3

The commenter requests additional clarity and information regarding the Regional NSR Holding Account for newer ~~electrical~~ electricity generating facilities subject to NSR holding requirements. The proposed rule language has been revised to provide clarity as to how the Regional account will be funded and accessed. Table 9 in Rule 2002 contains the list of affected facilities with NSR holdings with a yearly balance of RTCs that will go into the account. Further discussion regarding the proposed amendments is contained in Appendix X of the draft staff report.

PREFACE

This document constitutes the Final Program Environmental Assessment (PEA) for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM). A Notice of Preparation/Initial Study (NOP/IS) was released for a 57-day public review and comment period from December 5, 2014 to January 30, 2015 which identified the environmental topics of aesthetics; air quality and greenhouse gas emissions; energy; hydrology and water quality; hazards and hazardous materials; solid and hazardous waste; and, transportation and traffic, as potentially being significantly adversely affected by the project. Eight comment letters were received from the public regarding the preliminary analysis in the NOP/IS. The comment letters received relative to the NOP/IS and responses to individual comments are included in Appendix G of this document.

The Draft PEA was released for a 53-day public review and comment period from August 14, 2015 to October 6, 2015 which identified the topics of topics of air quality and GHGs, hydrology (water demand), and, hazards and hazardous materials (due to ammonia transportation) as exceeding the SCAQMD's significance thresholds associated with implementing the proposed project. Eight comment letters were received from the public regarding the analysis in the Draft PEA. The comment letters received relative to the Draft PEA and responses to individual comments are included in Appendix I of this document.

In addition, subsequent to release of the Draft PEA, modifications were made to the proposed project and some of the revisions were made in response to verbal and written comments received. To facilitate identification, modifications to the document are included as underlined text and text removed from the document is indicated by ~~strikethrough~~. To avoid confusion, minor formatting changes are not shown in underline or strikethrough mode.

Staff has reviewed the modifications to the proposed project and concluded that none of the revisions constitute: 1) significant new information; 2) a substantial increase in the severity of an environmental impact; or, 3) provide new information of substantial importance relative to the draft document. In addition, revisions to the proposed project in response to verbal or written comments would not create new, avoidable significant effects. As a result, these revisions do not require recirculation of the document pursuant to CEQA Guidelines §15073.5 and §15088.5. Therefore, this document now constitutes the Final PEA for the proposed project.

Chapter 1 – Executive Summary

1.0 Introduction 1-1
1.1 California Environmental Quality Act 1-2
1.2 Previous CEQA Documentation for Regulation XX 1-5
1.3 Intended Uses of this Document 1-13
1.4 Areas of Controversy 1-13
1.5 Executive Summary 1-16

Chapter 2 - Project Description

2.0 Project Location 2-1
2.1 Project Background 2-1
2.2 Project Objectives 2-4
2.3 Project Description 2-5
2.4 Technology Overview 2-12

Chapter 3 – Existing Setting

3.0 Introduction 3.0-1
3.1 Aesthetics
3.1.1 Regulatory Setting 3.1-1
3.1.2 Environmental Setting 3.1-2
3.2 Air Quality and Greenhouse Gases
3.2.1 Criteria Air Pollutants and Identification of Health Effects .. 3.2-1
3.2.2 Non-Criteria Pollutants 3.2-23
3.3 Energy
3.3.1 Regulatory Setting 3.3-1
3.3.2 Energy Trends in General (Statewide) 3.3-7
3.3.3 Alternative Clean Transportation Fuels 3.3-11
3.3.4 Renewable Energy 3.3-17
3.3.5 Consumptive Uses 3.3-24
3.4 Hazards and Hazardous Materials
3.4.1 Hazardous Materials Regulations 3.4-1
3.4.2 Emergency Response to Hazardous Materials and Waste Incidents 3.4-18
3.4.3 Hazardous Materials Incidents 3.4-18
3.4.4 Hazards Associated with Air Pollution Control and Alternative Fuels 3.4-20
3.5 Hydrology and Water Quality
3.5.1 Regulatory Background 3.5-1
3.5.2 Hydrology 3.5-6

3.5.3 Water Demand and Forecasts 3.5-13
3.5.4 Water Supply 3.5-20
3.5.5 Water Conservation 3.5-29
3.5.6 Water Quality...3.5-31
3.5.7 Wastewater Treatment 3.5-33
3.6 Solid and Hazardous Waste
3.6.1 Regulatory Background 3.6-1
3.6.2 Solid Waste Management 3.6-6
3.6.3 Hazardous Waste Management...3.6-13
3.7 Transportation and Traffic
3.7.1 Transportation Regulatory Framework................................ 3.7-1
3.7.2 Existing Traffic Setting.. 3.7-5

Chapter 4 – Environmental Impacts

4.0 Potential Environmental Impacts and Mitigation Measures........... 4.0-1
4.1 Aesthetics
4.1.1 Introduction... 4.1-1
4.1.2 Significance Criteria 4.1-1
4.1.3 Potential Aesthetics Impacts and Mitigation Measures......... 4.1-1
4.1.4 Cumulative Aesthetic Impacts 4.1-5
4.1.5 Cumulative Mitigation Measures... 4.1-5
4.2 Air Quality and Greenhouse Gases
4.2.1 Introduction... 4.2-1
4.2.2 Significance Criteria 4.2-2
4.2.3 Potential Air Quality Impacts and Mitigation Measures 4.2-2
4.2.4 Cumulative Air Quality Impacts..4.2-26
4.2.5 Cumulative Mitigation Measures...4.2-27
4.2.6 Potential Greenhouse Gas Impacts 4.2-29
4.2.7 Greenhouse Gas Mitigation Measures 4.2-33
4.3 Energy
4.3.1 Introduction... 4.3-1
4.3.2 Significance Criteria 4.3-2
4.3.3 Potential Energy Impacts and Mitigation Measures.............. 4.3-2
4.3.4 Cumulative Energy Impacts..4.3-14
4.3.5 Cumulative Mitigation Measures...4.3-14
4.4 Hazards and Hazardous Materials

CHAPTER 1

EXECUTIVE SUMMARY

Introduction

California Environmental Quality Act

Previous CEQA Documentation For Regulation XX

Intended Uses of this Document

Areas of Controversy

Executive Summary

1.0 INTRODUCTION

The California Legislature created the South Coast Air Quality Management District (SCAQMD) in 1977[1] as the agency responsible for developing and enforcing air pollution control rules and regulations in the South Coast Air Basin (Basin) and portions of the Salton Sea Air Basin and Mojave Desert Air Basin referred to herein as the District. By statute, the SCAQMD is required to adopt an air quality management plan (AQMP) demonstrating compliance with all federal and state ambient air quality standards for the District[2]. Furthermore, the SCAQMD must adopt rules and regulations that carry out the AQMP[3]. The Final 2012 AQMP concluded that reductions in emissions of particulate matter (PM), oxides of sulfur (SOx), oxides of nitrogen (NOx), and volatile organic compounds (VOC) are necessary to attain the state and national ambient air quality standards for ozone, and particulate matter with an aerodynamic diameter of 2.5 microns or less (PM2.5). Ozone, a criteria pollutant which has been shown to adversely affect human health, is formed when VOCs react with NOx in the atmosphere. VOCs, NOx, SOx (especially sulfur dioxide) and ammonia also contribute to the formation of PM10 and PM2.5.

The Basin is designated by the United States Environmental Protection Agency (EPA) as a non-attainment area for PM2.5 emissions because the federal PM2.5 standards have been exceeded. For this reason, the SCAQMD is required to evaluate all feasible control measures in order to reduce direct PM2.5 emissions, as well as PM2.5 precursors, such as NOx and SOx. The Final 2012 AQMP sets forth a comprehensive program for the Basin to comply with the federal 24-hour PM2.5 air quality standard, satisfy the planning requirements of the federal Clean Air Act, and provide an update to the Basin's commitments towards meeting the federal 8-hour ozone standard. In particular, the Final 2012 AQMP contains a multi-pollutant control strategy to achieve attainment with the federal 24-hour PM2.5 air quality standard with direct PM2.5 and NOx reductions identified as the two most effective tools in reaching attainment with the PM2.5 standard. The 2012 AQMP also serves to satisfy the recent requirements promulgated by the EPA for a new attainment demonstration of the revoked 1-hour ozone standard, as well as to provide additional measures to partially fulfill long-term reduction obligations under the 2007 8-hour Ozone State Implementation Plan (SIP).

As part of this ongoing PM2.5 reduction effort, SCAQMD staff is proposing amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM) to achieve additional NOx emission reductions to address best available retrofit control technology (BARCT) requirements and to modify the RECLAIM trading credit (RTC) "shaving" methodology. The primary focus of the proposed project is to bring the NOx RECLAIM program up-to-date with the latest BARCT requirements while achieving the proposed NOx emission reductions in the 2012 AQMP Control Measure #CMB-01: Further NOx Reductions from RECLAIM (e.g., at least three to five tons per day by 2023). In addition, the proposed project is designed to implement both the Phase I and Phase II reduction commitments described in #CMB-01.

Control measure CMB-01 included an initial estimate of two to three tons per day of NOx emission reductions. However, further analysis of the actual BARCT NOx emission control opportunities for the various equipment/process categories demonstrated that the proposed project could achieve 14 tons per day of NOx emission reductions by 2023 which is much higher

1 The Lewis-Presley Air Quality Management Act, 1976 Cal. Stats., ch 324 (codified at Health and Safety Code, §§40400-40540).
2 Health and Safety Code, §40460 (a).
3 Health and Safety Code, §40440 (a).

than estimates provided in the 2012 AQMP. Higher NOx emission reductions will further assist in attaining the national ambient air quality standards evaluated in the 2012 AQMP.

The proposed project will apply to the following types of equipment/source categories in the NOx RECLAIM program: 1) fluid catalytic cracking units (FCCUs); 2) refinery boilers and heaters; 3) refinery gas turbines; 4) sulfur recovery units – tail gas treatment units (SRU/TGUs); 5) non-refinery/non-power plant gas turbines; 6) non-refinery sodium silicate furnaces; 7) non-refinery/non-power plant internal combustion engines (ICEs); 8) container glass melting furnaces; 9) coke calcining; 10) Portland cement kilns; and, 11) metal heat treating furnaces. Additional amendments are proposed to establish procedures and criteria for reducing NOx RECLAIM RTCs and NOx RTC adjustment factors for year 2016 and later. Other minor changes are proposed for clarity and consistency throughout the proposed amended regulation.

The overall NOx emission reductions of 14 tons per day are expected to be achieved incrementally from 2016 to 2022. In particular, the proposed project is estimated to reduce RTCs by four tons per day of NOx emissions or more starting in 2016 and continuing with an additional reduction of two tons per day of NOx for years 2018 through 2022. Despite this projected direct environmental benefit to air quality, the Notice of Preparation (NOP) and Initial Study (IS), prepared pursuant to the California Environmental Quality Act (CEQA), identified the following environmental topics as areas that may be adversely affected by the proposed project: aesthetics; air quality and greenhouse gas emissions; energy; hazards and hazardous materials; hydrology and water quality; solid and hazardous waste; and, transportation and traffic. This ~~Draft~~ Final Program Environmental Assessment (PEA) has been prepared to analyze further whether the potential impacts to these environmental topics are significant.

1.1 CALIFORNIA ENVIRONMENTAL QUALITY ACT

The California Environmental Quality Act (CEQA), California Public Resources Code §21000 *et seq.*, requires environmental impacts of proposed projects to be evaluated and feasible methods to reduce, avoid or eliminate significant adverse impacts of these projects to be identified and implemented. The lead agency is the "public agency that has the principal responsibility for carrying out or approving a project that may have a significant effect upon the environment" (Public Resources Code §21067). Since the SCAQMD has the primary responsibility for supervising or approving the entire project as a whole, it is the most appropriate public agency to act as lead agency (CEQA Guidelines[4] §15051 (b)).

CEQA requires that all potential adverse environmental impacts of proposed projects be evaluated and that methods to reduce or avoid identified significant adverse environmental impacts of these projects be implemented if feasible. The purpose of the CEQA process is to inform the lead agency, responsible agencies, decision makers and the general public of potential adverse environmental impacts that could result from implementing the proposed project and to identify feasible mitigation measures or alternatives, when an impact is significant.

Public Resources Code §21080.5 allows public agencies with regulatory programs to prepare a plan or other written documents in lieu of an environmental impact report once the Secretary of the Resources Agency has certified the regulatory program. The SCAQMD's regulatory program was certified by the Secretary of Resources Agency on March 1, 1989, and has been adopted as

[4] The CEQA Guidelines are codified at Title 14 California Code of Regulations, §15000 et seq.

SCAQMD Rule 110 – Rule Adoption Procedures to Assure Protection and Enhancement of the Environment.

CEQA includes provisions for the preparation of program CEQA documents in connection with issuance of rules, regulations, plans, or other general criteria to govern the conduct of a continuing program, including adoptions of broad policy programs as distinguished from those prepared for specific types of projects such as land use projects, for example (CEQA Guidelines §15168). A program CEQA document also allows consideration of broad policy alternatives and program-wide mitigation measures at a time when an agency has greater flexibility to deal with basic problems of cumulative impacts (CEQA Guidelines §15168 (b)(4)). Lastly, a program CEQA document also plays an important role in establishing a structure within which CEQA review of future related actions can effectively be conducted. This concept of covering broad policies in a program CEQA document and incorporating the information contained therein by reference into subsequent CEQA documents for specific projects is known as "tiering" (CEQA Guidelines §15152).

A program CEQA document, by design, provides the basis for future environmental analyses and will allow future project-specific CEQA documents, if necessary, to focus solely on the new effects or detailed environmental issues not previously considered. If an agency finds that no new effects could occur, or no new mitigation measures would be required, the agency can approve the activity as being within the scope of the project covered by the program CEQA document and no new environmental document would be required (CEQA Guidelines §15168 (c)(2)).

The proposed amendments to Regulation XX are considered a "project" as defined by CEQA. The proposed project will reduce NOx emission and will provide an overall environmental benefit to air quality. However, SCAQMD's review of the proposed amendments also shows that implementation of the proposed project may also have a significant adverse effect on the environment.

In addition, because the proposed amendments to Regulation XX and their subsequent implementation: 1) are connected to the issuance of rules, regulations, plans, or other general criteria to govern the conduct of a continuing program (CEQA Guidelines §15168 (a)(3)); and, 2) contain a series of actions that can be characterized as one large project and the series of actions are related as individual activities that would be carried out under the same authorizing regulatory authority and having similar environmental effects which can be mitigated in similar ways (CEQA Guidelines §15168 (a)(4)), the type of CEQA document appropriate for the proposed project is a Program Environmental Assessment (PEA). The PEA is a substitute CEQA document, prepared in lieu of a program environmental impact report (EIR) (CEQA Guidelines §15252), pursuant to the SCAQMD's Certified Regulatory Program (CEQA Guidelines §15251 (l); codified in SCAQMD Rule 110). The PEA is also a public disclosure document intended to: 1) provide the lead agency, responsible agencies, decision makers and the general public with information on the environmental impacts of the proposed project; and, 2) be used as a tool by decision makers to facilitate decision making on the proposed project.

The first step of preparing a Draft PEA is to prepare a Notice of Preparation (NOP) with an Initial Study (IS) that includes an Environmental Checklist and project description. The Environmental Checklist provides a standard evaluation tool to identify a project's adverse environmental impacts. The NOP/IS is also intended to provide information about the proposed project to other public agencies and interested parties prior to the release of the Draft PEA.

On December 5, 2014, the SCAQMD, as Lead Agency for the proposed project, released a NOP/IS for the proposed project for a 57-day public review and comment period which ended on January 30, 2015. Since the proposed project may have statewide, regional or areawide significance, a CEQA scoping meeting is required and was held for the proposed project pursuant to Public Resources Code §21083.9 (a)(2) on January 8, 2015~~4~~. The evaluation in the NOP/IS identified the topics of aesthetics; air quality and greenhouse gas emissions; energy; hazards and hazardous materials; hydrology and water quality; solid and hazardous waste; and, transportation and traffic, as potentially being adversely affected by the proposed project.

During the NOP/IS public comment period, the SCAQMD received eight comment letters relative to the CEQA analysis. These letters and their responses can be found in Appendix G of this document. In addition, Appendix H of this ~~Draft~~ PEA summarizes the comments received at the CEQA Scoping Meeting held on January 8, 2015 and the responses to the comments.

The Draft PEA was released for a 53-day public review and comment period from August 14, 2015 to October 6, 2015. In accordance with CEQA Guidelines §15064 and §15168, SCAQMD has prepared this ~~Draft~~ Final PEA to evaluate the potentially significant adverse impact topics that were identified in the NOP/IS (e.g., aesthetics; air quality and greenhouse gas emissions; energy; hazards and hazardous materials; hydrology and water quality; solid and hazardous waste; and, transportation and traffic) for the proposed project. This ~~Draft~~ Final PEA further analyzes whether or not the potential adverse impacts to these environmental topic areas are significant. The ~~Draft~~ Final PEA concluded that only the topics of air quality and GHGs, hydrology (water demand), and, hazards and hazardous materials (due to ammonia transportation) would have significant adverse impacts.

Eight ~~Any~~ comment~~s~~ letters were received during the public comment period on the analysis presented in the~~is~~ Draft PEA. Responses to these comment letters have been prepared. The comment letters along with the responses are ~~will be responded to and~~ included in Appendix I of this~~e~~ Final PEA. Subsequent to release of the Draft PEA, modifications were made to the proposed project and some of the revisions were made in response to verbal and written comments received. Staff has reviewed the modifications to the proposed project and concluded that none of the modifications constitute: 1) significant new information; 2) a substantial increase in the severity of an environmental impact; or, 3) provide new information of substantial importance relative to the draft document. In addition, revisions to the proposed project in response to verbal or written comments would not create new, avoidable significant effects. As a result, these revisions do not require recirculation of the document pursuant to CEQA Guidelines §15073.5 and §15088.5.

Thus, this Final PEA, prepared pursuant to CEQA Guidelines §15132, identifies air quality and GHGs, hydrology (water demand), and, hazards and hazardous materials (due to ammonia transportation) as areas that may be adversely affected by the proposed project. Prior to making a decision on the adoption of the proposed amendments to Regulation XX, the SCAQMD Governing Board must review and certify the Final PEA as providing adequate information on the potential adverse environmental impacts that may occur as a result of adopting the proposed amendments to Regulation XX.

1.2 PREVIOUS CEQA DOCUMENTATION FOR REGULATION XX

This ~~Draft~~ Final PEA is a comprehensive environmental document that analyzes potential environmental impacts from the proposed amendments to Regulation XX. SCAQMD rules, as ongoing regulatory programs, have the potential to be revised over time due to a variety of factors (e.g., regulatory decisions by other agencies, new data, and lack of progress in advancing the effectiveness of control technologies to comply with requirements in technology forcing rules, etc.). Several previous environmental analyses have been prepared to analyze past amendments to the rules that comprise Regulation XX. The following paragraphs summarize these previously prepared CEQA documents and are included for informational purposes only. The current ~~Draft~~ Final PEA focuses on the currently proposed amendments to Regulation XX and does not rely on these previously prepared CEQA documents. The following documents can be obtained by submitting a Public Records Act request to the SCAQMD's Public Records Unit. In addition, a link for downloading files from the SCAQMD's website is provided for those CEQA documents prepared after January 1, 2000. The following is a summary of the contents of these documents, in reverse chronological order.

Notice of Exemption From CEQA for Proposed Amended Rule 2005 – New Source Review For RECLAIM; June 2011: The amendments to Rule 2005 – New Source Review For RECLAIM, changed the RECLAIM Trading Credit (RTC) hold requirement for an existing RECLAIM facility, provided its emission level stays below the level of its starting Allocations plus non-tradable credits. The amendment requires an existing RECLAIM facility to hold adequate RTCs for the first year of operation prior to commencement of operation of a new or modified source, but does not require the facility to hold RTCs at the commencement of subsequent compliance years, provided that the facility emission level remains below its starting Allocations plus non-tradable credits. The offset requirements for new RECLAIM facilities remained unchanged. The SCAQMD concluded that the amendments to Rule 2005 would not have an effect on emissions and that there was no possibility that the project would have the potential to have a significant adverse effect on the environment. In addition, the SCAQMD concluded that the amendments were categorically exempt because they were considered actions to protect or enhance the environment pursuant to CEQA Guidelines §15308 – Action by Regulatory Agencies for the Protection of the Environment. Therefore, pursuant to CEQA Guidelines §15061 (b)(3) - Review for Exemption, the project was determined to be exempt from CEQA and a Notice of Exemption was prepared. This document can also be obtained by visiting the following website at: http://www.aqmd.gov/docs/default-source/ceqa/notices/notices-of-exemption/2011/2005noegeneral.pdf?sfvrsn=2

Final Program Environmental Assessment (PEA) for proposed amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM); November 2010 (SCAQMD Number 06182009BAR / SCH Number 2009061088): A Draft PEA was prepared for amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM), Rule 2002 – Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx), were adopted to would reduce the allowable SOx emission limits based on current Best Available Retrofit Control Technology (BARCT) for the following industrial equipment and processes: 1) petroleum coke calciners; 2) cement kilns; 3) coal-fired boiler (cogeneration); 4) container glass melting furnace; 5) diesel combustion; 6) fluid catalytic cracking units; 7) refinery boilers/heaters; 8) sulfur recovery units/tail gas treatment units; and, 9) sulfuric acid manufacturing. Additional amendments were made that established procedures and criteria for reducing RECLAIM Trading Credits (RTCs) and RTC adjustment factors for year 2013 and later. The Draft PEA was released for a 45-day public review period from August 18, 2010 to October 1, 2010. The Draft PEA identified the topics of air quality and hydrology (water demand) as the only areas that may be significantly adversely affected by the project. After circulation of the Draft PEA, a Final PEA was prepared and certified by the SCAQMD Governing Board on November 5, 2010. This document can be obtained by visiting the following website at: http://www.aqmd.gov/docs/default-source/ceqa/documents/aqmd-projects/2010/final-program-environmental-assessment-for-proposed-amended-regulation-xx.pdf?sfvrsn=4

Notice of Exemption From CEQA for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM); April 2007: The amendments to Regulation XX – RECLAIM were administrative in nature and focused on the following rules: Rule 2004 – Requirements; Rule 2007 – Trading Requirements; and Rule 2010 – Administrative Remedies and Sanctions. The amendments to Rule 2004 provided an exemption from submitting Quarterly Certification Emission Reports for facilities that do not have any NOx or SOx emitting equipment located on site. The amendments to Rule 2007 clarified the trading requirements for foreign entities that are not residing or licensed to conduct business in California, and clarified reporting requirements for parties entering into a forward contract or a contingent right contract. Amendments to Rule 2010 specified liability for allocation violations when changes of ownership occur. Other minor administrative changes were included that improved the clarity of these rules. The SCAQMD concluded that the amendments would not have an effect on emissions and that there was no possibility that the project would have the potential to have a significant adverse effect on the environment. Therefore, pursuant to CEQA Guidelines §15061(b)(3) - Review for Exemption, the project was determined to be exempt from CEQA and a Notice of Exemption was prepared. This document can also be obtained by visiting the following website at: http://www.aqmd.gov/docs/default-source/ceqa/notices/notices-of-exemption/2007/noe-proposed-amended-regulation-xx-rules-2004-2007-2010.pdf?sfvrsn=2

Notice of Exemption From CEQA for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM); May 2005: The amendments to Regulation XX – RECLAIM were administrative in nature and focused on the following rules and protocols: Rule 2000 – General; Rule 2001 – Applicability; Rule 2005 – New Source Review for RECLAIM; Rule 2007 – Trading Requirements; Protocol for Rule 2011 – Requirements for Monitoring, Reporting, and Recordkeeping for Oxides of Sulfur (SOx) Emissions; and Protocol for Rule 2012 – Requirements for Monitoring, Reporting, and Recordkeeping for NOx Emissions. Amendments to Rule 2000 and Protocols for Rules 2011 and 2012 were proposed for consistency with the new source requirements for non-RECLAIM sources and for clarification that mobile source emissions are part of the total RECLAIM pollutants emitted from a facility. Amendments to Rule 2005 clarified that emissions from affected sources shall include mobile source emissions and to include an alternative quarterly holding period for RTCs for offsetting emissions from a new source. Amendments to Rule 2007 reinstated the trading provision that would allow power producers to transfer NOx RECLAIM Trading Credits among facilities under common ownership which was inadvertently omitted during the January 7, 2005 amendments to Rule 2007. The SCAQMD concluded that the amendments would not have an effect on emissions and that there was no possibility that the proposed project would have the potential to have a significant adverse effect on the environment. Therefore, pursuant to

CEQA Guidelines §15061(b)(3) - Review for Exemption, the project was determined to be exempt from CEQA and a Notice of Exemption was prepared. This document can also be obtained by visiting the following website at: http://www.aqmd.gov/home/library/public-information/noe-archive/noe---year-2005

Final Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM); December 2004 (SCAQMD No. 031104BAR): A Draft Environmental Assessment (EA) for amendments to Regulation XX (Rule 2001 – Applicability; Rule 2002 – Allocations for NOx and SOx; Rule 2007 – Trading Requirements; Rule 2009 – Compliance Plans for Power Producing Facilities; Rule 2010 – Administrative Remedies and Sanctions; Rule 2011 – Requirements for Monitoring, Reporting, and Recordkeeping for SOx Emissions; and, Appendix A – Protocol for SOx; and, Rule 2012 – Requirements for Monitoring, Reporting, and Recordkeeping for NOx Emissions; and, Appendix A – Protocol for NOx) was released for a 45-day public review period from October 22, 2004 to December 7, 2004. The amendments implemented control measure CMB-10 in the 2003 AQMP and addressed BARCT requirements to achieve additional NOx emission reductions. The Draft EA identified the topic of air quality as the only area that may be significantly adversely affected by the project. After circulation of the Draft EA, a Final EA was prepared and certified by the SCAQMD Governing Board on January 7, 2005. This document can be obtained by visiting the following website at: http://www.aqmd.gov/home/library/documents-support-material/lead-agency-scaqmd-projects/aqmd-projects---year-2005

Notice of Exemption From CEQA for Proposed Amended Rule 2007 – Trading Requirements; September 2004: The purpose of the amendments to Rule 2007 was to address CARB concerns regarding the reintroduction of power plants to the RECLAIM trading market. The proposal contained a provision that delayed the date when the trading restrictions would be lifted until such time that other RECLAIM rule amendments (scheduled for January 2005) were adopted that would decrease allocations to implement the 2003 AQMP Control Measure CMB-10 and to reflect BARCT in accordance with Health and Safety Code (HSC) §40440. The air quality objective was to ensure that BARCT adjustments are made to facility allocations prior to removal of power plant trading restrictions. The SCAQMD concluded that the amendments would not have an effect on emissions and that there was no possibility that the project would have the potential to have a significant adverse effect on the environment. Therefore, pursuant to CEQA Guidelines §15061 (b)(3) - Review for Exemption, the project was determined to be exempt from CEQA and a Notice of Exemption was prepared. This document can also be obtained by visiting the following website at: http://www.aqmd.gov/home/library/public-information/noe-archive/noe---year-2004

Notice of Exemption From CEQA for Proposed Amended Rule 2015 – Backstop Provisions; June 2004: The purpose of the amendments to Rule 2015 was to address the USEPA's conditional approval of Regulation XX – RECLAIM, as amended May 11, 2001. The USEPA determined that the accounting procedures for and mitigations of excess emissions that occur during a breakdown in the current version of the RECLAIM program needed to be modified because these provisions conflict with USEPA's 1999 'Excess Emissions Policy' and §110 and Part D of the federal Clean Air Act (CAA). Specifically, the amendments to Rule 2015: 1) required the SCAQMD to monitor excess emissions occurring during breakdowns that are not covered by facility RTCs, and to compare that amount to the quantity of available, unused RTCs each year for the entire RECLAIM program; and, 2) required offsets for excess unmitigated breakdown emissions. The SCAQMD concluded that the amendments would not have an effect on emissions and that there was no possibility that the project would have the potential to have a significant adverse effect on the environment. Therefore, pursuant to CEQA Guidelines §15061 (b)(3) - Review for Exemption, the project was determined to be exempt from CEQA and a Notice of Exemption was prepared. This document can also be obtained by visiting the following website at: http://www.aqmd.gov/home/library/public-information/noe-archive/noe---year-2004

Addendum to May 2001 Final Environmental Assessment for Proposed Amended Rule 2007 – Trading Requirements; Proposed Amended Rule 2011 – Requirements for Monitoring, Reporting, and Recordkeeping for SOx Emissions; and, Proposed Amended Rule 2012 – Requirements for Monitoring, Reporting, and Recordkeeping for NOx Emissions; October 14, 2003 (SCAQMD No. 101403BAR): The amendments to Rule 2007 required the power producers to re-enter the RECLAIM trading market. Specifically, the power producing facilities were brought back into the RECLAIM trading market and allowed to use RTCs to reconcile emissions, and to sell or transfer RTCs below the original allocation after compliance year 2003. The amendments to Rules 2011 and 2012 clarified that the 90-day recertification period for Continuous Emission Monitoring Systems (CEMS) applies when a new CEMS or a component of an existing CEMS is added to an existing or modified major RECLAIM source. An Addendum to the May 2001 Final EA for the amendments to Regulation XX (Rules 2007, 2011, and 2012) was prepared. The SCAQMD determined that an Addendum to the May 2001 Final EA was the appropriate document to prepare because none of the conditions described in CEQA Guidelines §15162 were triggered since the amendments did not contain new information of substantial importance and would not create any new significant adverse impacts or substantially increase the severity of the previously identified significant environmental effects in the original project. Further, the SCAQMD concluded that the amendments would not change the environmental analysis or conclusions in the previously certified May 2001 Final EA. Pursuant to CEQA Guidelines §15164 (c), it was not necessary to circulate the Addendum for public review. The Addendum to the May 2001 Final EA was certified by the SCAQMD Governing Board on December 5, 2003. This document can also be obtained by visiting the following website at: http://www.aqmd.gov/home/library/documents-support-material/lead-agency-scaqmd-projects/aqmd-projects---year-2003

Final Environmental Assessment for Proposed New and Amended Rules, Regulation XX – RECLAIM; Rule 1631 – Pilot Credit Generation Program for Marine Vessels; Rule 1632 – Pilot Credit Generation Program for Hotelling Operations; Rule 1633 – Pilot Credit Generation Program for Truck/Trailer Refrigeration Units; and Rule 2507 – Pilot Credit Generation Program for Agricultural Pumps; May 2001 (SCAQMD No. 010201JDN): An integrated group of new and amended rules were adopted to help ensure compliance with emission allocations contemplated during initial RECLAIM program design while reducing impacts of California's electricity crisis on the RECLAIM market. The project included proposed new and amended RECLAIM rules and four voluntary mobile and area source NOx pilot credit generation rules. The project components were designed to work together to lower and stabilize RTC prices by increasing supply, reducing demand, and increasing RTC trading information availability and accuracy. A Draft EA for the amendments to Regulation XX plus proposed Rules 1631, 1632, 1633 and 2507 (which established pilot NOx credit generation rules as a means of creating additional NOx RTCs) was released for a 30-day public review period from March 27, 2001 to April 25, 2001. The analysis showed that there were potential adverse environmental effects that may result from implementing the amendments (primarily removing power producers from the trading market). The Draft EA identified "air quality" and "hazards and hazardous materials" as the only areas that may be significantly adversely affected by the project. After circulation of the Draft EA, a Final EA was prepared and certified by the SCAQMD Governing Board on May 11, 2001. This document can be obtained by visiting the following website at: http://www.aqmd.gov/home/library/documents-support-material/lead-agency-scaqmd-projects/aqmd-projects---year-2001/fea-for-proposed-new-and-amended-regulation-xx

Final Environmental Assessment for Proposed Amended Rules 1303 – Requirements, 2005 – New Source Review for RECLAIM, 1302 - Definitions and 1309.1 - Priority Reserve; April 9, 2001 (SCAQMD No. 021401MK): The amendments to Rules 1303 and 2005 revised the modeling standard for sources locating in an attainment sub-region of the district so that any proposed new emissions plus the measured background could not create a violation of any applicable ambient air quality standard. In sub-regions designated as nonattainment areas for specified criteria pollutants, the modeling criteria remained the same, but emissions from new or modified sources were not allowed to exceed the allowable change in concentration thresholds as set forth in Rule 1303, Table A-2. The amendments to Rule 1309.1 allowed temporary access to the SCAQMD's Priority Reserve PM10 account for new electric generating facilities (EGF) for applications deemed complete between 2001 and 2003, provided that all the other requirements were met and the appropriate mitigation fee was paid. The Draft EA was released for a 30-day public review and comment period from February 14, 2001 to March 15, 2001. The Draft EA concluded that the project would not have any significant or potentially significant effects on the environment. After circulation of the Draft EA, a Final EA was prepared and certified by the SCAQMD Governing Board on April 20, 2001. This document can be obtained by visiting the following website at: http://www.aqmd.gov/home/library/documents-support-material/lead-agency-scaqmd-projects/aqmd-projects---year-2001

Notice of Exemption From CEQA for Proposed Amended Rule 2011 – Requirements for Monitoring, Reporting, and Recordkeeping for Oxides of Sulfur (SOx) Emissions; and, Proposed Amended Rule 2012 – Requirements for Monitoring, Reporting, and Recordkeeping for Oxides of Nitrogen (NOx) Emissions; March 2001: Because the substantive components of the project involved the addition of an alternative recordkeeping option, the SCAQMD concluded that the amendments would not have an effect on emissions and that there was no possibility that the project would have the potential to have a significant adverse effect on the environment. Therefore, pursuant to CEQA Guidelines §15061 (b)(3) - Review for Exemption, the project was determined to be exempt from CEQA and a Notice of Exemption was prepared. This document can also be obtained by visiting the following website at: http://www.aqmd.gov/home/library/public-information/noe-archive/noe---year-2001

Final Environmental Assessment for Proposed Amended Rules 1302 – Definitions, 1303 – Requirements, 1306 – Emissions Calculations, 2000 – General; and BACT Guidelines; August 23, 2000 (SCAQMD No. 33100JDN): The amendments bifurcated the New Source Review (NSR) control technology requirements into Lowest Achievable

Emission Rate (LAER) for federal major polluting facilities and Minor Source Best Available Control Technology (MSBACT) for all others. Unlike federal LAER, state law allows the cost of the control equipment to be taken into consideration when making a BACT determination. All major polluting facilities, as defined in the federal CAA, would continue to be required to employ LAER for a new or relocated source and any emission increase from a modified source. All other facilities would be required to employ MSBACT. The amendments applied to both RECLAIM and non-RECLAIM sources. Additionally, the amendments allowed relocations of non-major polluting facilities that meet certain conditions, including no emission increases upon relocation and for two years thereafter, to maintain the existing control level from the prior location instead of requiring the installation of new BACT controls. The Draft EA was released for a 30-day public review and comment period from July 11, 2000 to August 9, 2000. The Draft EA concluded that the project would not have any significant or potentially significant effects on the environment. After circulation of the Draft EA, a Final EA was prepared and certified by the SCAQMD Governing Board on October 20, 2000. This document can be obtained by visiting the following website at: http://www.aqmd.gov/home/library/documents-support-material/lead-agency-scaqmd-projects/aqmd-projects---year-2000

Notice of Exemption for Proposed Amended Rule 2005 - New Source Review for RECLAIM, Rule 2011 - Requirements for Monitoring, Reporting, and Recordkeeping for SOx Emissions, and Rule 2012 - Requirements for Monitoring, Reporting, and Recordkeeping for NOx Emissions; April 1999: The amendments included clarifications to New Source Review requirements for change of operator and modifications to new facilities. For major sources, the amendments clarified monitoring requirements and added calculation methods for cases currently not addressed. For large sources, the amendments added monitoring and calculations methods for cases currently not addressed and clarified source testing requirements. For process units, the amendments established concentration limits for determining emissions and added guidelines for category specific emission rates. The amendments also corrected rule references, extended deadlines for monthly emissions reporting, and added clarifying language to enhance enforcement and consistency. The amendments were necessary to clarify rule requirements and improve enforceability. The amendments also increased flexibility for RECLAIM facilities. The SCAQMD concluded that the amendments would not have an effect on emissions and that there was no possibility that the project would have the potential to have a significant adverse effect on the environment. Therefore, pursuant to CEQA Guidelines §15061 (b)(3) - Review for Exemption, the project was determined to be exempt from CEQA and a Notice of Exemption was prepared.

Notice of Exemption for Proposed Amended Rule 2000 - General, Rule 2011 - Requirements for Monitoring, Reporting and Recordkeeping for SOx Emissions and Rule 2012 - Requirements for Monitoring, Reporting, and Recordkeeping for NOx Emissions; April 1997: The amendments clarified the rule requirements for emissions from contractors' equipment at RECLAIM facilities by: 1) adding a definition for contractor; 2) specifying that emissions from contractors' equipment should be accounted for by the RECLAIM facility in the same manner as emissions from rental equipment, with the exception of specific processes that do not contribute to a facility’s manufacturing process; and, 3) excluding emissions from certain contractors' equipment at a Super Compliant facility. The SCAQMD concluded that the amendments would not have an effect on emissions and that there was no possibility that the project would have the potential to have a significant adverse effect on the environment. Therefore, pursuant to CEQA Guidelines §15061 (b)(3) - Review for Exemption, the project was determined to be exempt from CEQA and a Notice of Exemption was prepared.

Notice of Exemption for Proposed Amended Rule 2000 - General, Rule 2001 - Applicability, Rule 2002 - Allocations for NOx and SOx, Rule 2005 - New Source Review for RECLAIM, Rule 2011 - Requirements for Monitoring, Reporting and Recordkeeping for SOx Emissions, Rule 2012 - Requirements for Monitoring, Reporting, and Recordkeeping for NOx Emissions and Rule 2015 - Backstop Provisions; February 1997: The amendments modified requirements for non-operating and infrequently-operated major sources, exemption provisions, emission factors, and certain monitoring, reporting, and recordkeeping (MRR) requirements. The SCAQMD concluded that the amendments would not have an effect on emissions and that there was no possibility that the project would have the potential to have a significant adverse effect on the environment. Therefore, pursuant to CEQA Guidelines §15061 (b)(3) - Review for Exemption, the project was determined to be exempt from CEQA and a Notice of Exemption was prepared.

Final Supplemental Environmental Assessment for Proposed Amended Rule 2002 - Allocations for NOx and SOx, Rule 2004 - Requirements, Rule 2005 - New Source Review for RECLAIM, Rule 2011 - Requirements for Monitoring, Reporting, and Recordkeeping for SOx Emissions, Rule 2012 - Requirements for Monitoring, Reporting, and Recordkeeping for NOx Emissions, and Rule 2015 - Backstop Provisions; June 1996: The amendments clarified rule requirements and improved monitoring, reporting, and recordkeeping flexibility for RECLAIM facilities. The amendments provided: 1) procedures consistent with Rule 430 - Breakdown Provisions; 2) procedures for reporting equipment breakdowns affecting RECLAIM pollutants; 3) more accurate emission factors; 4) clarifications of RTC allocations after year 2010; 5) consolidated requirements for reports on RECLAIM issues; 6) clarified requirements for Super Compliance facilities; 7) a period of time for CEMS repairs; 8) clarifications of monitoring, reporting, recordkeeping, and other requirements; and, 9) an alternative to the NOx ending emission factor for cement kilns based on a demonstration plan. Pursuant to CEQA, the SCAQMD prepared a Draft Supplemental Environmental Assessment (SEA) for the amendments to Regulation XX - RECLAIM. The Draft SEA was a supplement to the October 1993 Final EA for Regulation XX (SCAQMD No. 930524SS) and was circulated for a 45-day public review and comment period that ended May 10, 1996. The Final SEA was certified by the SCAQMD Governing Board on July 12, 1996.

Notice of Exemption for Proposed Amended Rule 1303 - Requirements (New Source Review) and Rule 2005 - New Source Review for RECLAIM; May 1996: The amendments incorporated protection of visibility for Federal Class I areas into Regulations XIII and XX. Protection of visibility for Federal Class I areas and notification of Federal Land Managers are requirements of federal law. The SCAQMD determined that the amendments were exempt from CEQA pursuant to CEQA Guidelines §15308 - Action by Regulatory Agencies for the Protection of the Environment, since the activity was covered by this Class 8 exemption for actions to assure the maintenance, restoration, enhancement, or protection of the environment. Therefore, pursuant to CEQA Guidelines §15061 (b)(3) - Review for Exemption, the project was determined to be exempt from CEQA and a Notice of Exemption was prepared.

Final Supplemental Environmental Assessment for Proposed Amended Regulation XX – RECLAIM; December 1995: The Final Supplemental EA for Regulation XX addressed the potential air quality, energy and risk of upset impacts associated with the exemption of two facilities from the RECLAIM program, State Implementation Plan (SIP) approvability issues and the allocation revision for one facility participating in the program. Air quality was the only environmental area determined to be adversely impacted from the amendments. The air quality impacts resulted from removing two facilities from the RECLAIM program and the loss of anticipated NOx emission reductions from the allocation revisions. A Statement of Findings and Overriding Considerations were prepared for the project.

Notice of Exemption for Proposed Amended Rule 2011 - Requirements for Monitoring, Reporting and Recordkeeping for SOx Emissions, and Rule 2012 - Requirements for Monitoring, Reporting, and Recordkeeping for NOx Emissions; September 1995: The SCAQMD concluded that the amendments would not have an effect on emissions and that there was no possibility that the project would have the potential to have a significant adverse effect on the environment. Therefore, pursuant to CEQA Guidelines §15061 (b)(3) - Review for Exemption, the project was determined to be exempt from CEQA and a Notice of Exemption was prepared.

Final Supplemental Environmental Assessment for Proposed Amended Rule 2002 - Allocations for NOx and SOx; March 1995: The Final EA for Rule 2002 addressed the potential air quality and energy impacts from adjusting the years 2000 and 2003 Allocations for the petroleum coke calcining industry. Air quality was the only area determined to be adversely impacted from the amendments due to the loss of future emission reductions. A Statement of Finding and Overriding Considerations was prepared for the amendments.

Final Environmental Assessment for the Proposed Adoption of Regulation XX - RECLAIM; October 1993: A Draft EA for the proposed NOx and SOx RECLAIM program, comprised of three volumes: Volume I - Development Report and Proposed Rules, Volume II - Supporting Documentation and Volume III - Socioeconomic and Environmental Assessments, was released for a 30-day public review and comment period on May 24, 1993. In response to comments received regarding the Draft EA, some components of the proposed project were modified. Subsequently, a Revised Draft EA was prepared and re-circulated for an additional public review and comment period of 45 days on July 22, 1993 The SCAQMD concluded that the changes in the Revised Draft EA did not alter the significance determination for any environmental impact areas analyzed in the May 1993 version of the Draft EA. After circulation of the Revised Draft EA, a Final EA was prepared and certified by the SCAQMD Governing Board at its hearing in October 1993.

Notice of Preparation/Initial Study of Draft Environmental Assessment for the Proposed Adoption of Regulation XX - RECLAIM; October 1992: The NOP/IS of a Draft EA for the proposed adoption of the NOx and SOx RECLAIM program was released for a 30-day public review and comment period on October 23, 1992. The NOP/IS identified “air quality,” “energy,” and “hazards and hazardous materials” as the key areas that may be adversely affected by the proposed project.

1.3 INTENDED USES OF THIS DOCUMENT

In general, a CEQA document is an informational document that informs a public agency's decision-makers and the public generally of potentially significant adverse environmental effects of a project, identifies possible ways to avoid or minimize the significant effects, and describes reasonable alternatives to the project (CEQA Guidelines §15121). A public agency's decision-makers must consider the information in a CEQA document prior to making a decision on the project. Accordingly, this ~~Draft~~ Final PEA is intended to: a) provide the lead agency, responsible agencies, decision makers and the general public with information on the environmental effects of the proposed project; and, b) be used as a tool by the SCAQMD Governing Board to facilitate decision making on the proposed project.

Additionally, CEQA Guidelines §15124 (d)(1) requires a public agency to identify the following specific types of intended uses of a CEQA document:

1. A list of the agencies that are expected to use the PEA in their decision-making;
2. A list of permits and other approvals required to implement the project; and,
3. A list of related environmental review and consultation requirements required by federal, state, or local laws, regulations, or policies.

There are no permits or other approvals required to implement the project. Moreover, the project is not subject to any other related environmental review or consultation requirements.

However, if an affected facility chooses to install new equipment or modify existing equipment, then SCAQMD permits, as well as other agency permits or other approvals depending on the physical changes being proposed, may also be required. To the extent that local public agencies, such as cities, county planning commissions, et cetera, are responsible for making land use and planning decisions related to projects proposed as a result of implementing the proposed project, they could possibly rely on this PEA during their decision-making process. Similarly, other single purpose public agencies approving projects at facilities complying with the proposed project may rely on this PEA. If the applicable lead agency finds that no new effects could occur, or no new mitigation measures would be required, the lead agency can approve the activity as being within the scope of the project covered by the PEA and no new environmental document would be required (CEQA Guidelines §15168 (c)(2)). If there are proposed activities that would have effects that were not examined in the PEA, then depending on the types of activities proposed by the affected facility and where the project is located, the appropriate lead agency would need to prepare an additional CEQA document to analyze the additional effects.

1.4 AREAS OF CONTROVERSY

CEQA Guidelines §15123 (b)(2) requires a public agency to identify the areas of controversy in the CEQA document, including issues raised by agencies and the public. Over the course of developing the proposed project, the predominant concerns expressed by representatives of industry and environmental groups, either in public meetings or in written comments, regarding the proposed project are highlighted in Table 1-1.

Table 1-1
Areas of Controversy

	Area of Controversy	Topics Raised by the Public	SCAQMD Evaluation
1.	Amount of proposed NOx shave and availability of RTCs	Industry representatives expressed concern that reducing the available NOx RTCs by the proposed amount would have severe impacts on the NOx RECLAIM program because there will not be enough NOx RTCs in the market.	The staff analysis shows that after the proposed shave is imposed, there will be sufficient NOx RTCs available to maintain trading within the NOx RECLAIM program given foreseeable opportunities for emissions reductions. Furthermore, the proposed NOx shave provides for a compliance margin and the NOx program includes provisions for adjustments if the price of RTCs exceeds certain thresholds.
2.	Equity of proposed NOx shave	NOx reductions should be based on facility-specific and technology-specific data, or, as others have commented, should be applied evenly across the all facilities. Many facilities cannot reduce NOx further. Other facilities do not have equipment subject to BARCT.	The proposed shave is based on source categories for which additional NOx reductions can be achieved in a cost-effective manner. It recognizes 219 ~~210~~ facilities hold 10 percent of the 26.5 tpd of the available NOx RTCs, and that for these facilities, no NOx RTC shave is proposed because either no new BARCT (not cost effective and/or infeasible) was identified, or gains in emission reductions would be negligible, for the types of equipment and source categories.
3.	Results of the BARCT analysis	The SCAQMD's consultant's report assessing the staff BARCT analysis recommended alternate engineering assumptions in certain areas.	While staff believes the engineering assumptions in the staff BARCT analysis are appropriate, the difference in BARCT reductions attributable to the alternate engineering assumptions suggested by the consultant is relatively small. To account for this difference and to provide a compliance margin, staff is proposing a shave of 14 tpd, reduced from the initial BARCT result of 14.79 ~~14.85~~ tpd.

Table 1-1 (continued)
Areas of Controversy

	Area of Controversy	Topics Raised by the Public	SCAQMD Evaluation
4.	Equivalency with command-and-control	The NOx RTC shave BARCT reductions of 8.77 ~~8.79~~ should be applied to the total RTC holdings rather than to the actual emissions in order to maintain the viability of the market	The total shave amount of 14 tpd is applied to total RTCs holdings. Consistent with previous RECLAIM rule amendments, the California Health & Safety Code, and the purpose of the program, BARCT implementation seeks to reduce actual emissions rather than RTC holdings. This approach will result in approximately 8.77 ~~8.79~~ tons per day of BARCT reductions of actual NOx emissions attributable to installing and operating additional controls. Otherwise, actual emissions reductions of only about two tpd over the next seven years would be achieved.
5.	2012 AQMP Commitment in the State Implementation Plan (SIP)	The control measure CMB-01 in the 2012 AQMP committed only three to five tpd NOx emission reductions but this rule development is seeking a higher amount of NOx reductions beyond what was committed in the SIP.	The staff proposal is the result of a much more rigorous and in-depth analysis as compared to the analysis that supported control measure CMB-01. For a market-based incentive program, SCAQMD staff is required by the California Health and Safety Code to conduct periodic BARCT reassessments and demonstrate equivalency with command-and-control rules which would otherwise be developed as a result of BARCT reassessment. CMB-01 anticipated this BARCT assessment but could not predict the results of the assessment, and therefore made commitments for a more modest reduction. This staff proposal recommends a reasonably available 14 tpd of NOx RTC reductions, based on BARCT, as required by state law, and which are needed to help the Basin achieve the PM2.5 standards by 2019 and 2025 and the ozone standards by 2024 and 2032.

Table 1-1 (concluded)
Areas of Controversy

	Area of Controversy	Topics Raised by the Public	SCAQMD Evaluation
6.	Availability of RTCs for future power plant needs	There may not be enough available RTCs after the shave for power producers to provide a reliable supply of electricity over the short-term (e.g., during high demand events such as a heat wave) and over the long-term (e.g., increased use in electricity needed to power electric vehicles).	The staff proposal would establish a separate Regional NSR Holding ~~adjustment~~ A~~a~~ccount to hold RTCs for electricity generating facilities (EGFs) ~~power plants~~ to meet their NSR holding obligations. Many newer peaking plants are required to hold RTCs at the potential to emit level each year even though their actual emissions are far below this level. The holding ~~adjustment~~ account would relieve EGFs ~~power producing facilities~~ from the obligation of holding RTCs in order to meet the NSR holding requirements of Rule 2005. RTCs would still be required for the purpose of reconciling annual emissions. Furthermore, if the demand for power results in a severe shortage that would lead to the state Governor declaring a state of emergency, an EGF ~~power producing facility~~ would be able to access the holding ~~adjustment~~ account for non-tradable credits to offset annual emissions.

Pursuant to CEQA Guidelines §15131 (a), "Economic or social effects of a project shall not be treated as significant effects on the environment." CEQA Guidelines §15131 (b) states further, "Economic or social effects of a project may be used to determine the significance of physical changes caused by the project." Physical changes caused by the proposed project have been evaluated in Chapter 4 of this PEA. No direct or indirect physical changes resulting from economic or social effects have been identified as a result of implementing the proposed project.

Of the topics discussed to address the concerns raised relative to CEQA and the secondary impacts that would be associated with implementing the proposed project, to date, no other controversial issues were raised as a part of developing the proposed project.

1.5 EXECUTIVE SUMMARY

CEQA Guidelines §15123 requires a CEQA document to include a brief summary of the proposed actions and their consequences. In addition, areas of controversy including issues raised by the public must also be included in the executive summary (see preceding discussion). This ~~Draft~~ Final PEA consists of the following chapters: Chapter 1 – Executive Summary;

Chapter 2 – Project Description; Chapter 3 – Existing Setting, Chapter 4 – Potential Environmental Impacts and Mitigation Measures; Chapter 5 – Project Alternatives; Chapter 6 - Other CEQA Topics and various appendices. The following subsections briefly summarize the contents of each chapter.

Summary of Chapter 1 – Executive Summary

Chapter 1 includes a discussion of the legislative authority that allows the SCAQMD to amend and adopt air pollution control rules, identifies general CEQA requirements and the intended uses of this CEQA document, and summarizes the remaining chapters that comprise this ~~Draft~~ Final PEA.

Summary of Chapter 2 - Project Description

To comply with the requirements in HSC §§40440~~ and 39616~~[5], SCAQMD staff conducted a BARCT assessment of the NOx RECLAIM program which resulted in adjusting BARCT levels for both equipment and source categories in the refinery and non-refinery sectors. For the refinery sector, a new level of BARCT is proposed for FCCUs, refinery boilers/heaters rated great than 40 mmBTU/hr, refinery gas turbines, coke calciners, and SRU/TGUs. For the non-refinery sector, a new BARCT level is proposed for container glass melting furnaces, cement kilns, sodium silicate furnaces, metal heat treating furnaces rated great than 150 mmBTU/hr, gas turbines and ICEs not located on the outer continental shelf (OCS). No new BARCT is proposed for 30 electricity generating facilities (EGFs)~~power plants~~. Overall, a total of 14 tpd of NOx RTC reductions from the current 2015 RTC holdings of 26.5 tpd is proposed to be implemented over a seven-year period from 2016 to 2022.

For the 275 facilities that are in the NOx RECLAIM program, the 14 tpd of NOx RTC reductions will be reduced from the allocations of 56 ~~65~~ facilities plus the investors that, together, hold 90 percent of the NOx RTC holdings. Investors are included in the refinery sector and treated as one facility. For the remaining 219 ~~210~~ facilities that hold 10 percent of the 26.5 tpd of the NOx RTCs, no NOx RTC shave is proposed because no new BARCT (not cost effective and/or infeasible) was identified for the types of equipment and source categories at these facilities. By following this approach, the shave is distributed as follows:

- ~~67~~66% shave for 9 refineries and investors (treated as one facility)
- ~~47~~49% shave for 21 ~~30 power plants~~ EGFs
- ~~47~~49% shave for 26 non-major facilities
- 0% shave for 219 ~~210~~ remaining facilities

In addition, the overall NOx RTC reductions of 14 tpd are expected to be achieved incrementally from 2016 to 2022, according to the following implementation schedule:

- 2016 – 4 tons per day
- 2018 – 2 tons per day
- 2019 – 2 tons per day
- 2020 – 2 tons per day

[5] The reference to Health and Safety Code §39616 has been deleted because it does not require a BARCT analysis. The RECLAIM program proposed here satisfies the findings set forth in Health and Safety Code §39616, although it is not legally required to do so.

- 2021 – 2 tons per day
- 2022 – 2 tons per day

To incorporate the proposed NOx RTC shave and implementation schedule, amendments to the NOx RECLAIM regulation are proposed to establish procedures and criteria for reducing NOx RECLAIM RTCs and NOx RTC adjustment factors for year 2016. The proposed amendments contain the following key elements:

- Amend Rule 2001 – Applicability, to allow the owner or operator of an EGF to opt out of the NOx RECLAIM program.
- Amend Rule 2002 - Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx), to establish procedures and criteria for reducing NOx RTCs and NOx RTC adjustment factors for year 2016 and later.
- Amend Rule 2002 to add new BARCT emission factors ending in 2021 for an assortment of equipment/process categories.
- Amend Rule 2002 to change the maximum $15,000 per ton price trigger to $22,500 per ton (discrete credits, 12-month rolling average) and add a maximum trigger level of $35,000 per ton (discrete credits, 3-month rolling average).
- Amend Rule 2002 to allow new EGFs: 1) the use of the Regional NSR Holding Account for their New Source Review holding requirement; and, 2) access to this account during a Governor's declared state of emergency.
- Amend Rule 2002 to delete the provisions pertaining to RTC Reductions Exemptions.
- Amend Rule 2002 to add provisions to address the retirement of RTCs from complete facility closure or equipment shutdowns.
- Amend Rule 2005 – New Source Review for RECLAIM, to ~~clarify the criteria for how Adjustment~~ establish a Regional NSR Holding Account for EGF New Source Review holding requirements and set criteria for the use of those RTCs ~~are treated when conducting a New Source Review analysis for RECLAIM facilities~~ in the event the Governor declares a state of emergency for power generation.
- Amend Rule 2011 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping Oxides of Sulfur (SOx) Emissions (Attachment C – Quality Assurance and Quality Control Procedures) to allow RECLAIM Facility Permit Holders of equipment experiencing certain extenuating circumstances to postpone Relative Accuracy Test Audits (RATAs).
- Amend Rule 2012 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping Oxides of Nitrogen (NOx) Emissions (Attachment C – Quality Assurance and Quality Control Procedures) to allow RECLAIM Facility Permit Holders of equipment experiencing certain extenuating circumstances to postpone RATAs.
- Make administrative and other minor changes such as correcting typographical errors as well as clarifying and updating the rule and rule protocol language for consistency.

Other minor changes are proposed for clarity and consistency throughout the proposed amended regulation. Instructions for obtaining the latest version ~~A copy~~ of the proposed amended Rules (PAR) 2001, 2002 and 2005 can be found in Appendices A1, A2, and B, respectively, of this ~~Draft~~ Final PEA and instructions for obtaining the latest version ~~. A copy~~ of the proposed amended protocols for Rules 2011 and 2012 can be found in Appendices C and D, respectively.

Summary of Chapter 3 - Existing Setting
Pursuant to the CEQA Guidelines §15125, Chapter 3 – Existing Setting, includes descriptions of those environmental areas that could be adversely affected by the proposed project as identified in the NOP/IS (Appendix F). The following environmental areas identified in the NOP/IS that could potentially be adversely affected by implementing the proposed project are: aesthetics; air quality and greenhouse gas emissions; energy; hazards and hazardous materials; hydrology and water quality; solid and hazardous waste; and, transportation and traffic. As such, Chapter 3 contains subchapters devoted to describing the existing setting for each environmental topic area evaluated in the PEA.

Summary of Chapter 4 - Environmental Impacts
CEQA Guidelines §15126 (a) requires that a CEQA document shall identify and focus on the "significant environmental effects of the proposed project." Direct and indirect significant effects of the project on the environment shall be clearly identified and described, giving due consideration to both the short-term and long-term effects.

The NOP/IS identified and described those environmental topics where the proposed project could cause significant adverse environmental impacts (e.g., aesthetics; air quality and greenhouse gas emissions; energy; hazards and hazardous materials; hydrology and water quality; solid and hazardous waste; and, transportation and traffic). The type of emission reduction projects that may be undertaken to comply with the proposed project is the main focus of the analysis in this PEA. There are multiple source categories with multiple approaches to reducing NOx emissions. With so many possibilities or permutations of how operators of NOx RECLAIM facilities could achieve actual NOx reductions, there is no way to predict what each facility operator will do. For this reason, the proposed project analysis has been crafted to illustrate the worst-case effects of applying the various NOx control technologies along with demonstrating the flexibility that is provided by the RECLAIM program to facility operators when it comes to choosing the methods for reducing NOx emissions. The analysis focuses on the installation and operation of NOx control technologies for the various equipment types/source categories.

The following subsections briefly summarize the analysis of potential adverse environmental impacts from the implementation of the proposed project. Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs. Further, since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74. Thus, the analysis in this PEA for the refinery sector is conservative as it overestimates the potential adverse impacts for the following environmental topics.

Aesthetics
Physical modifications may result as part of implementing the proposed project and will vary depending on the equipment source category/process. The analysis in this CEQA document is based on the assumption that new air pollution control equipment is

expected to be installed and existing air pollution control equipment is expected to be modified as part of implementing the proposed project. Aesthetic impacts associated with the installation of new or the modification of existing NOx control, were identified in the NOP/IS to be potentially significant and, as such, are evaluated in this PEA.

Implementation of the proposed project is expected to result in construction activities at some or all of the affected facilities, which are complex industrial facilities. Due to the large size profiles of the affected equipment, the construction activities associated with installing control equipment are expected to require the use of heavy-duty construction equipment, such as cranes, which may temporarily change the skyline of the affected facilities, depending on where they are located within each facility's property. However, because each affected facility is located in a heavy industrial area, the construction equipment is not expected to be substantially discernable from what would be needed for routine operations and maintenance activities. For these reasons, the construction activities are expected to blend in with the existing industrial environment and thus, are not expected to affect the visual continuity of the surrounding areas.

In addition, for any installation of a WGS, operational aesthetic impacts resulting from a substantial visible steam (water vapor) plume that would emanate from the WGS stack were evaluated in this PEA. The analysis will show that if any WGS is installed as part of the proposed project at any of the affected facilities, the steam plume, though visible, is not expected to significantly adversely affect the visual continuity of the surrounding area of each affected facility because no scenic highways or corridors exist within the areas of the refineries, the coke calciner, the sulfuric acid plants and the glass melting plant. Further, the visual continuity of the surrounding area is not expected to be adversely impacted because each WGS, if constructed, will be built within the confines of industrial areas and would be visually consistent with the profiles of the existing affected facilities. Thus, even if each WGS could be visible, depending on the location within each property boundary, the aesthetic significance criteria would not be exceeded. For these reasons, less than significant aesthetics impacts during operation are expected from the proposed project.

Overall, the aesthetics impacts were determined to be less than significant during both construction and operation for the proposed project.

Air Quality and Greenhouse Gases

The proposed project is expected to result in a total of 14 tpd of NOx RTC reductions from the current RTC holdings of 26.5 tpd, to be implemented over a seven-year period from 2016 to 2022. For the 275 facilities that are in the NOx RECLAIM program, the 14 tpd of NOx RTC reductions will affect 56 ~~65~~ facilities plus the investors, who collectively hold 90 percent of the NOx RTC holdings. Investors are included in the refinery sector and treated as one facility. For the remaining 219 ~~210~~ facilities that hold 10 percent of the 26.5 tpd of the NOx RTCs, no NOx RTC shave is proposed because no new BARCT (not cost effective and/or infeasible) was identified for the types of equipment and source categories at these facilities. By following this approach, the shave of NOx RTC holdings is distributed as follows:

- 66 ~~67~~% shave for 9 refineries and investors (treated as one facility)
- 49 ~~47~~% shave for 21 electrical generating facilities (EGFs) ~~30 power plants~~

- 49 ~~47~~% shave for 26 non-major facilities
- 0% shave for 219 ~~210~~ remaining facilities

SCAQMD staff has conducted a BARCT analysis for all 275 facilities and of these, 21 out of 30 EGFs ~~power producing facilities~~ were shown to operate at current BARCT or BACT levels. For 224 non-power plant facilities plus 9 EGFs for a total of 233 facilities, either no new BARCT was identified or the installation of control equipment was determined to not be cost-effective. Further, only 35 ~~44~~ facilities are expected to comply with the proposed NOx RTC shave through the purchase of RTCs which will have no environmental impact. In addition, the sale and/or purchase of RTCs by investors (treated as one facility) will also have no environmental impact.

To reduce NOx from the remaining 21 facilities (e.g., 275 ~~–~~ – 21 EGFs (with shave) ~~30 power producers~~ - 224 non-power plant facilities – 9 EGFs (without shave) = 21) which are either major or large sources of NOx for which new BARCT has been identified, the BARCT analysis found that it would be both feasible and cost-effective for facility operators to install new control equipment or modify existing control equipment at 20 facilities with 11 facilities belonging to the non-refinery sector and 9 facilities belonging to the refinery sector.

As a result, operators of these 20 facilities may choose to modify existing equipment by retrofitting with air pollution control technologies in order to comply with the shave of NOx RTCs. The physical changes involved that may occur as a result of implementing the proposed project focus on the installation of new or the modification of existing control equipment on the following types of equipment and processes: 1) fluid catalytic cracking units; 2) refinery boilers and heaters; 3) refinery gas turbines; 4) sulfur recovery units – tail gas treatment units; 5) non-refinery/non-power plant gas turbines; 6) non-refinery sodium silicate furnaces; 7) non-refinery/non-power plant internal combustion engines; 8) container glass melting furnaces; 9) coke calcining; and, 10) metal heat treating furnaces. Table 1-2 summarizes the potential NOx control technologies that may be considered as part of implementing the proposed project.

Table 1-2
Potential NOx Control Devices Per Sector and Equipment/Source Category

Sector	Equipment/Source Category	Potential NOx Control Devices
Refinery	Fluid Catalytic Cracking Units (FCCUs)	SCR LoTOx™ with WGS LoTOx™ without WGS
Refinery	Refinery Process Heaters and Boilers	SCR
Refinery	Refinery Gas Turbines	SCR
Refinery	Sulfur Recovery Unit / Tail Gas Units (SRU/TGUs)	LoTOx™ with WGSs SCR
Refinery	Petroleum Coke Calciner	LoTOx™ with WGS UltraCat with DGS
Non-Refinery	Container Glass Melting Furnaces	SCR UltraCat with DGS
Non-Refinery	Sodium Silicate Furnaces	SCR UltraCat with DGS
Non-Refinery	Metal Heat Treating Furnaces	SCR
Non-Refinery	Internal Combustion Engines (Non-Refinery/Non-Power Plant)	SCR
Non-Refinery	Turbines (Non-Refinery/Non-Power Plant)	SCRs

Construction activities associated with installing or modifying existing air pollution control equipment are expected and have the potential to generate significant adverse air quality impacts for criteria pollutants. In addition, operational activities due to periodic truck trips such as the delivery of supplies to support the operations of the various control technologies and the removal of waste from the control processes for disposal or recycling are also expected and have the potential to generate significant adverse air quality impacts for NOx and greenhouse gases (GHGs).

With regard to GHG emissions, the proposed project involves combustion processes which could generate GHG emissions such as CO2, CH4, and N2O. However, the proposed project does not affect equipment or operations that have the potential to emit other GHGs such as SF6, HFCs or PFCs. Implementing the proposed project is expected to increase GHG emissions that exceed the SCAQMD's GHG significance threshold for industrial sources. In addition, implementing the proposed project is expected to generate significant adverse cumulative GHG air quality impacts.

Energy

Implementation of the proposed project is expected to increase the amount of energy needed to both construct and operate the new and modified air pollution control devices. During construction, increased use of diesel fuel and gasoline are expected from on- and off-road vehicle and equipment use. Operational activities of the new and modified air pollution control equipment are expected to result in an overall increase in electricity as well as an increased use of diesel fuel associated with supply delivery trips and waste removal trips as part of day-to-day operations. Despite the potential increases in energy use overall as part of implementing the proposed project, the increases are not expected to exceed the energy significance thresholds.

Hazards and Hazardous Materials

Implementation of the proposed project may alter the hazards and hazardous materials associated with the existing facilities affected by the proposed project. Air pollution control equipment and related devices are expected to be installed or modified at affected facilities such that their operations may increase the quantity of materials used in the control equipment, some of which are hazardous. For example, the proposed project could result in the increased use of hazardous materials such as ammonia and sodium hydroxide and non-hazardous materials such as soda ash and hydrated lime. Thus, the routine transport of hazardous materials, use, and disposal of hazardous materials may increase as a result of the proposed project. The hazards analysis focuses on the materials used that may be hazardous. The analysis concluded that the proposed project is expected to generate significant adverse hazards and hazardous materials impacts for ammonia deliveries and less than significant hazards and hazardous materials impacts for ammonia use and storage. For the substances other than ammonia that were identified as hazardous, the proposed project is expected to generate less than significant hazards and hazardous materials impacts.

Hydrology and Water Quality

Implementation of the proposed project may cause hydrology and water quality impacts associated with the existing facilities affected by the proposed project. Specifically, the installation of WGS technology involves an increased demand for water and an increased amount of wastewater discharge. None of the other NOx control technologies contemplated by the proposed project are expected to create hydrology and water quality impacts.

For water demand, there are three significance thresholds based on whether: 1) the total water demand of the proposed project is less than five million gallons per day; 2) the existing water supply has the capacity to meet the increased demands of the proposed project; and, 3) the potable water demand is less than 262,820 gallons per day. The analysis shows that the increased potential demand for total water that may result from implementing the proposed project either during construction or operation is not expected to exceed the significance threshold of five million gallons of total water demand per day.

The analysis shows a potential increase in water use of 353,724 gallons per day for all 20 facilities conducting hydrotesting activities on a peak day. The amount of water that may be needed to conduct hydrotesting on a peak day is greater than the SCAQMD's significance threshold of 262,820 gallons per day of potable water. Thus, the amount of potable water that may be used on a daily basis for hydrotesting activities post-construction but prior to operation is potentially significant.

The analysis also shows a potential increase in water use for facilities that utilize WGS technology would be a range, from 553,499 gallons per day to 558,978 ~~602,1854~~ gallons per day, which exceeds the SCAQMD's significance threshold of 262,820 gallons per day of potable water. Thus, the amount of potable water that may be used on a daily basis for operating NOx control equipment (e.g., WGSs) is also potentially significant.

Because the entire state of California is in the midst of a severe drought and because construction of WGS technology may not occur for at least another year or more, it was ~~is~~ not clear at the time of release of the Draft PEA if the local water suppliers would ~~will~~ have enough potable water to meet the increased demands to supply the WGSs in the future. Subsequently, SCAQMD staff has been able to verify that projected water deliveries of potable water and recycled water to the affected facilities sources will be able to supply the potential water demand needs of the proposed project. While the use of recycled water may be able to offset some of the potable water demands from the proposed project, not all of the facilities whose storage tanks need hydrotesting and whose operations are potential candidates for WGS technology, have current access to recycled water. For this reason, the analysis conservatively concludes that the amount of water that may be needed to hydrotest storage tanks and to operate WGS technology may create significant adverse hydrology (water demand) impacts.

Relative to water quality, the analysis will also show that implementing the proposed project may increase the amount of wastewater discharged from certain affected facilities. However, the potential increases will not cause a permit revision to any affected facility's wastewater permit and as such, will not exceed the wastewater significance threshold. For this reason, the wastewater impacts from the proposed project are expected to be less than significant.

Solid and Hazardous Waste

Construction activities associated with installing NOx control equipment such as demolition and site preparation/grading/excavating could generate solid waste as result of implementing the proposed project. However, the amount of debris generated during construction at 20 facilities would not be expected to exceed the designated capacity of local landfills. For this reason, the construction impacts of the proposed project on waste treatment/disposal facilities were concluded to be less than significant. Solid waste may also be generated from the operation of the new NOx air pollution control equipment at both the refinery and non-refinery facilities. Further, it is possible that some, if not all, of the 20 affected facilities will address any increase in waste through their existing waste minimization plans. For example, some of the affected facilities in both the refinery and non-refinery sectors currently have existing catalyst-based operations and the spent catalysts are either regenerated, reclaimed or recycled, in lieu of disposal, and this practice would be expected to continue. The overall impacts of the proposed project on waste treatment/disposal facilities due to solid waste that may be generated from both refinery and non-refinery facilities during construction and operation were concluded to be less than significant.

Transportation and Traffic

Implementation of the proposed project may cause adverse transportation and traffic impacts associated with the existing facilities affected by the proposed project. Specifically, construction-based traffic associated with the installation of NOx control technology is expected from construction workers, delivery trucks and haul trucks. During operation of the proposed project, regular deliveries and waste disposal activities are also expected to increase at each of the affected facilities. Despite the increases, the analysis shows that the transportation and traffic impacts, though adverse, are less than significant for the proposed project during both construction and operation.

Potential Environmental Impacts Found Not To Be Significant

The NOP/IS for the proposed project included an environmental checklist of approximately 17 environmental topics to be evaluated for potential adverse impacts from a proposed project. Review of the proposed project at the NOP/IS stage identified seven topics (e.g., aesthetics; air quality and greenhouse gas emissions; energy; hazards and hazardous materials; hydrology and water quality; solid and hazardous waste; and, transportation and traffic), for further review in the ~~Draft~~ Final PEA. Where the NOP/IS concluded that the project would have no significant direct or indirect adverse effects on the remaining environmental topics, of the comments received on the NOP/IS or at the public meetings, none of the comments changed this conclusion. The screening analysis concluded that the following environmental areas would not be significantly adversely affected by the proposed project:

- agriculture and forestry resources
- biological resources
- cultural resources
- geology and soils
- land use and planning
- mineral resources
- noise
- population and housing
- public services
- recreation

The NOP/IS for the proposed project was circulated for a 57-day review and comment period from December 5, 2014 to January 30, 2015. At the time the NOP/IS was circulated, the environmental checklist did not include tribal cultural resources as a topic to be evaluated under Cultural Resources as part of a CEQA document. However, the requirements of California Assembly Bill (AB 52) went into effect on July 1, 2015. AB 52 is promulgated in Public Resources Code §21080.3.1 (d) and requires a formal notification to all California Native American Tribes about lead agency projects that would require the preparation of a CEQA document. While the Office of Planning and Rule (OPR) has until July 1, 2016 to finalize the implementation guidance for this requirement, the SCAQMD is required to comply with AB 52 in the interim.

Subsequent to release of the NOP/IS, modifications were made to the environmental checklist (e.g., a new question was added), significance criteria, and discussion of Cultural Resources impacts in response to the requirements in AB 52 to consider the proposed project's potential effects on Cultural Native American Tribe resources. Although the NOP/IS did not include a preliminary analysis of tribal cultural resources, to make the analysis of environmental impacts consistent with the recent changes to the environmental checklist, a discussion of impacts from the proposed project relative to tribal cultural resources has been included in this subchapter of the ~~Draft~~ Final PEA. No significant impacts on tribal cultural resources were identified. Thus, even with the additional information pertaining to tribal cultural resources, the overall conclusion of "No Impact" for this topic area remains unchanged.

Other CEQA Topics

CEQA documents are required to address the potential for irreversible environmental changes, growth-inducing impacts and inconsistencies with regional plans. The analysis confirms that proposed project would not result in irreversible environmental changes or the irretrievable commitment of resources, foster economic or population growth or the construction of additional housing, or be inconsistent with regional plans.

Summary Chapter 5 - Alternatives

The proposed project and five alternatives to the proposed project are summarized in Table 1-3: Proposed Project (Shave Applied to 90 percent of RTC Holders – 56 ~~65~~ facilities), Alternative 1 (Across the Board), Alternative 2 (Most Stringent), Alternative 3 (Industry Approach), Alternative 4 (No Project), and, Alternative 5 (Weighted by BARCT Reduction Contribution for all facilities and investors). Pursuant to the requirements in CEQA Guidelines §15126.6 (b) to mitigate or avoid the significant effects that a project may have on the environment, a comparison of the potentially significant adverse impacts from each of the project alternatives for the individual rule components that comprise the proposed project is provided in Table 1-4. In addition to the topic of the topics of air quality and GHGs, the alternatives comparison in Table 1-4 addresses the topics of aesthetics, energy, hazards and hazardous materials, hydrology and water quality, solid and hazardous waste, and transportation and traffic. Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs. Further, since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74. Thus, the analysis in this PEA for the refinery sector is conservative as it overestimates the potential adverse environmental impacts for the proposed project as summarized in Table 1-4.

Aside from these topics, no other potentially significant adverse impacts were identified for the proposed project or any of the project alternatives. The proposed project is considered to provide the best balance between emission reductions and the adverse environmental impacts due to construction and operation activities while meeting the objectives of the project. Therefore, the proposed project is preferred over the project alternatives.

Project Background

Project Objectives

Project Description

Technology Overview

2.0 PROJECT LOCATION

The proposed amendments to Regulation XX would apply to equipment and processes operated at NOx RECLAIM facilities located throughout the entire SCAQMD jurisdiction. The SCAQMD has jurisdiction over an area of approximately 10,743 square miles, consisting of the four-county South Coast Air Basin (Basin) (Orange County and the non-desert portions of Los Angeles, Riverside and San Bernardino counties), and the Riverside County portions of the Salton Sea Air Basin (SSAB) and Mojave Desert Air Basin (MDAB). The Basin, which is a subarea of the SCAQMD's jurisdiction, is bounded by the Pacific Ocean to the west and the San Gabriel, San Bernardino, and San Jacinto mountains to the north and east. It includes all of Orange County and the non-desert portions of Los Angeles, Riverside, and San Bernardino counties. The Riverside County portion of the SSAB is bounded by the San Jacinto Mountains in the west and spans eastward up to the Palo Verde Valley. The federal nonattainment area (known as the Coachella Valley Planning Area) is a subregion of Riverside County and the SSAB that is bounded by the San Jacinto Mountains to the west and the eastern boundary of the Coachella Valley to the east (see Figure 2-1).

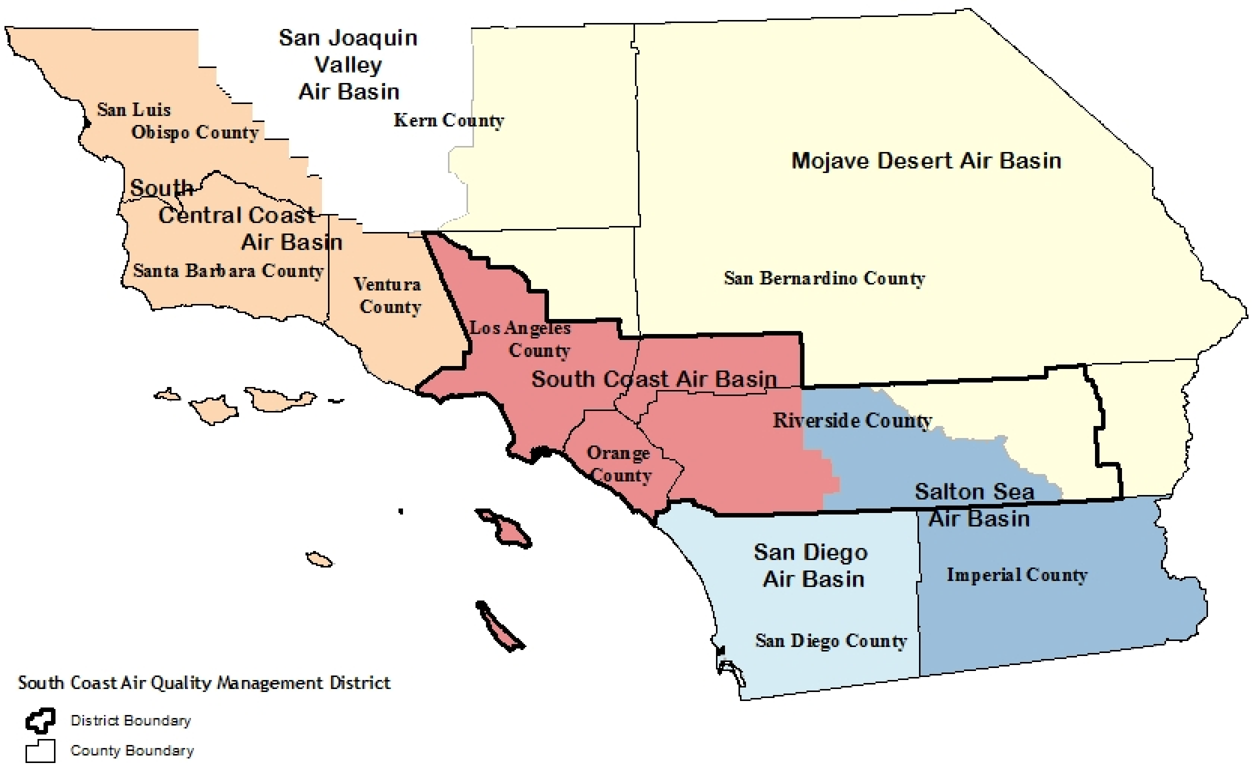

Figure 2-1: Southern California Air Basins

2.1 PROJECT BACKGROUND

On October 15, 1993, the SCAQMD Governing Board adopted Regulation XX, referred to herein as the RECLAIM program. Regulation XX is comprised of 15 rules which contain a declining market-based cap and trade mechanism to reduce NOx and SOx emissions from the largest stationary sources in the Basin and subsequently help meet air quality standards while providing facilities with the flexibility to seek the most cost-effective solution for achieving the required reductions. Instead of setting specific limits on each piece of equipment and each process that contributes to air pollution as is stipulated by traditional 'command-and-control' regulations, under the RECLAIM program each facility has a NOx and/or SOx annual emissions limit (allocation) and facility operators can decide what equipment, processes and materials they will use to reduce emissions to meet or go further below their annual emission limits. In lieu of reducing emissions, facility owners or operators may elect to use the trading market to purchase RTCs from other facilities that have reduced emissions below their annual target.

The portion of Regulation XX that focuses on reducing NOx emissions is referred to as "NOx RECLAIM" while the portion that focuses on reducing SOx emissions is referred to as "SOx RECLAIM." Regulation XX contains applicability requirements, NOx and SOx facility allocations, general requirements, as well as monitoring, reporting, and recordkeeping requirements for NOx and SOx sources located at RECLAIM facilities. The RECLAIM program started with 41 SOx facilities and 392 NOx facilities, but by the end of the 2005 compliance year, the program was populated with 33 SOx facilities and 304 NOx facilities. The population at the end of compliance year 2011 consists of 33 SOx facilities and 276 NOx facilities. The reduction in the number of facilities participating in the RECLAIM program since inception has been primarily due to facility shutdowns and/or consolidations. By the end of compliance year 2013, there were 275 facilities in the NOx RECLAIM universe.

Under the NOx RECLAIM program, the RECLAIM facilities were first issued annual allocations of NOx emissions (also known as facility caps) in 1993 and the facility cap reflected BARCT in effect at that time. RECLAIM facilities have the flexibility to install air pollution control equipment, change their operations, or purchase RECLAIM Trading Credits (RTCs). The NOx RECLAIM facilities are required to reconcile the actual facility emissions with the annual allocations. The annual allocations were designed to decline annually from 1993 until 2003 and remained constant after 2003, when the SCAQMD conducted a BARCT reassessment for NOx in 2005 and another for SOx in 2010, and subsequently reduced the facility annual allocations further.

To assure a more liquid market, as well as protect RECLAIM participants from price fluctuations that may be caused if all the RTCs expire at the same time, two trading cycles were established. Further, to balance emissions among the participating facilities in the RECLAIM program, the affected facilities were randomly divided into two cycles which vary by compliance year. That is, the Cycle 1 compliance year spans from January 1 to December 31 while the Cycle 2 compliance year spans from July 1 to June 30. A backstop level of $15,000 per ton was established to trigger program reevaluation.

Between compliance year 1994 and compliance year 1999, NOx emissions at RECLAIM facilities, in aggregate, were below the annual allocations, and the price of NOx RTCs remained relatively stable, ranging from $1,500 to $3,000 per ton. However, beginning June 2000, RECLAIM program participants experienced a sharp and sudden increase in NOx RTC prices for both 1999 and 2000 compliance years. This was mainly due to an increased demand for power generation due to the California energy situation and the delay of installing NOx control equipment by many power plant operators, which resulted in the power-generating industry purchasing a large quantity of RTCs and depleting the supply of available RTCs. The average price of NOx RTCs for compliance year 2000, traded in the year 2000 increased sharply to over $45,000 per ton compared to the average price of $4,284 per ton traded in 1999. Since the RTC price for NOx exceeded the backstop price of $15,000 per ton, an evaluation of the RECLAIM program was triggered.

The Governing Board, at its October 2000 meeting, directed staff to examine the issues affecting the high price of NOx RTCs and recommend actions to stabilize NOx RTC prices. Additionally, the Governing Board directed the Executive Officer to form an Advisory Committee to provide input to staff regarding possible approaches to stabilize NOx RTC prices. Fourteen power producing facilities, each with a generating capacity of 50 megawatts (MW) or greater, purchased 67 percent of the NOx RTCs that were traded during compliance year 2000, suggesting that the increased demand and high prices of NOx RTCs were primarily due to the power producers. However, the annual allocations for all the power producers only accounted for approximately 14 percent of total RECLAIM annual allocations for compliance year 2000. At the same time, the RECLAIM program reached the ‘cross-over point’ where emissions equal allocations because many RECLAIM facilities, relying on previously low RTC prices, did not determine that it was more cost-effective to begin installing controls until after the RTC prices had peaked.

In recognition of the inherent lag time between the ability of facility operators to actually install and operate new control equipment, the Governing Board concluded that immediate changes to the RECLAIM program were necessary and, at the January 19, 2001 Board Meeting, directed staff to form a working group to develop and propose amendments to the RECLAIM program. The goal of the proposed amendments was to implement realistic, effective solutions to reduce and stabilize the prices of NOx RTCs. In May 2001, Regulation XX was amended to place trading restrictions on power producing facilities with the caveat that they could fully rejoin the trading market in the 2004 compliance year, provided that the Governing Board determined prior to July 2003 that their re-entry would not result in any negative effect on the remainder of the RECLAIM facilities or on California’s energy security needs. In addition, the amendments also required the power plants to install BARCT and introduced credit generating rules. Lastly, a Mitigation Fee Program was established for the power plants to make up excess emissions through an option to pay a fee used by the SCAQMD to mitigate emissions through alternative means or programs.

Pursuant to these requirements, SCAQMD staff examined the energy security needs of California and the potential impacts on the RECLAIM market. The Governing Board determined that reentry of the power plants would not be expected to have a negative effect on California’s energy security needs or on other RECLAIM facilities. Overall, power plants equipped with BARCT have reduced their NOx emission rates by approximately 80 percent or more from previously uncontrolled levels.

Based on these emission levels, the 14 power producing facilities are anticipated to emit a total of 1,395 tons per year of NOx and their total annual allocations are 1,705 tons per year for each year from 2003 to 2010. Further, the RTC holdings for the compliance years 2003 through 2010 range from 1,550 to 2,330 tons per year of NOx. This represented a surplus in the NOx RTC holdings at the time ranging from 155 to 935 tons per year. When considering the data relative to the typical annual operational capacity of a power producing unit at below 30 percent, except for 2001 when in-Basin units operated at 35 percent capacity, on average it would take all units operating at a capacity of 55 percent to cause a shortage in NOx RTCs. Therefore, based on the projected excess RTCs and typical operating capacities, power producers were then considered likely to be sellers of NOx RTCs in the RECLAIM program. For these reasons, the Governing Board at the June 6, 2003 public hearing, made the finding that lifting the trading restrictions for power producers in the RECLAIM trading market would not have a negative effect on the remainder of the RECLAIM facilities or on California’s energy security needs. Subsequently, the Governing Board adopted proposed changes to RECLAIM Rules 2007, 2011, and 2012 at the December 5, 2003 public hearing which removed most of the trading restrictions on power producers. As a result, effective September 2004, the power producers were given unrestricted use of RTCs.

On January 7, 2005, amendments were made to the NOx RECLAIM program that resulted in a reduction of RTCs across the board by 7.7 tons per day, based on a BARCT evaluation. The RTCs were reduced from compliance years 2007 to 2011. The total RTCs in the NOx RECLAIM universe allocated in compliance year 2011 amounted to 26.5 tons per day. The audited emissions in compliance year 2011 were 20.01 tons per day, equating to 6.49 tons per day of excess holdings.

In accordance with the Health and Safety Code (HSC) ~~§~~§40440~~ and 39616~~[1], an additional BARCT assessment of the NOx RECLAIM program is once again required to: 1) assess the advancement in control technology; 2) to ensure that RECLAIM facilities achieve the same emission reductions that would have occurred under a command-and-control approach; 3) to ensure that emission reductions from the NOx RECLAIM program contribute towards achieving the federal National Ambient Air Quality Standards (NAAQS); and, 4) to assure that the participating facilities will continue to achieve emission reductions as expeditiously as possible to carry out the commitments in the 2012 AQMP. Except for power producing facilities, the proposed RTC shave reduction will be based on compliance year 2011 activity levels for all other affected facilities. The 2012 activity levels will be used for RTC reductions from power producing facilities because this activity level better represents this sector's energy consumption.

2.2 PROJECT OBJECTIVES

CEQA Guidelines §15124 (b) requires a statement of objectives to describe the underlying purpose of the proposed project. The purpose of the statement of objectives is to aid the lead agency in developing a reasonable range of alternatives to evaluate in the EIR (or equivalent CEQA document) and to aid the decision-makers in preparing a statement of findings and a statement of overriding considerations, if necessary. The objectives of the proposed project are to:

1) Comply with the requirements in Health and Safety Code (HSC) ~~§~~§40440 ~~and 39616~~[1] by conducting a BARCT assessment of the NOx RECLAIM program and reducing the amount of available NOx RTCs to reflect emission reductions equivalent to implementing available BARCT;
2) Modify the RTC "shaving" methodology to implement the emission reductions per the BARCT assessment;
3) Ensure that RECLAIM facilities, in aggregate, achieve the same emission reductions that would have occurred under a command-and-control approach;
4) Achieve the proposed NOx emission reduction commitments in the 2012 AQMP Control Measure #CMB-01: Further NOx Reductions from RECLAIM; and,
5) Achieve NOx emission reductions to assist in attaining the NAAQS.

[1] The reference to Health and Safety Code §39616 has been deleted because it does not require a BARCT analysis. The RECLAIM program proposed here satisfies the findings set forth in Health and Safety Code §39616, although it is not legally required to do so.

2.3 PROJECT DESCRIPTION

To comply with the requirements in HSC §§40440~~ and 39616~~[1], SCAQMD staff conducted a BARCT assessment of the NOx RECLAIM program which resulted in adjusting BARCT levels for both equipment and source categories in the refinery and non-refinery sectors. For the refinery sector, a new level of BARCT is proposed for FCCUs, refinery boilers/heaters rated great than 40 mmBTU/hr, refinery gas turbines, coke calciners, and SRU/TGUs. For the non-refinery sector, a new BARCT level is proposed for container glass melting furnaces, cement kilns, sodium silicate furnaces, metal heat treating furnaces rated great than 150 mmBTU/hr, gas turbines and ICEs not located on the outer continental shelf (OCS). No new BARCT is proposed for 30 EGFs~~power plants~~. Tables 2-1 and 2-2 summarize the proposed 2015 BARCT levels for the refinery and non-refinery sectors, respectively, along with the associated projected NOx emission reductions.

Table 2-1
Proposed 2015 BARCT Levels and Projected NOx Emission Reductions for Refinery Sector

Refinery Sector Equipment/Source Category	Proposed 2015 BARCT Level	Projected NOx Emission Reductions (tpd)
FCCUs	2 ppmv at 3% O2	0.43
Refinery Boilers and Heaters rated at >40 mmBTU/hr	2 ppmv or 0.002 lb/mmbtu	0.94 ~~0.96~~
Refinery Gas Turbines	2 ppm at 15% O2	4.14
Coke Calciner	10 ppmv at 3% O2	0.17
SRU/TGUs	2 ppmv at 3% O2 or 95% reduction	0.32
	TOTAL	**6.00 ~~6.02~~**

Note: tpd = tons per day

Table 2-2
Proposed 2015 BARCT Levels and Projected NOx Emission Reductions for Non-Refinery Sector

Non-Refinery Sector Equipment/Source Category	Proposed 2015 BARCT Level	Projected NOx Emission Reductions (tpd)
Container Glass Melting Furnaces	80% reduction	0.24
Sodium Silicate Furnace	80% reduction	0.09
Metal Heat Treating Furnaces >150 mmbtu/hr	9 ppmv at 3% O2	0.56
Gas Turbines (non-OCS)	2 ppmv at 15% O2	1.04
Internal Combustion Engines (non-OCS)	11 ppmv at 15% O2	0.84
Cement Kilns	0.5 lbs/ton	1.29*
	Total	**2.77**

Note: tpd = tons per day

* The 1.29 tpd of projected NOx emission reductions from cement kilns were not included in the total of 2.77 tpd projected NOx emission reductions for the non-refinery sector because the cement kilns that were originally operated at CPCC that would otherwise be subject to a BARCT reassessment were not in operation in 2011. However, because the cement kilns were the top source of NOx emissions in 2008, SCAQMD staff conducted a BARCT analysis for cement kilns and reduced the remaining emissions projected to the 2023 level for the cement facility to the BARCT level.

The total combined BARCT-equivalent emission reductions from the refinery and non-refinery sectors are 8.77 ~~8.79~~ tpd (6.00 ~~6.02~~ tpd for the refinery sector plus 2.77 tpd for the non-refinery sector.) To account for projected growth[2] amongst the sectors, the remaining emissions in 2023 at these proposed 2015 BARCT levels would be 10.23 ~~10.18~~ tpd (2.76 ~~2.71~~ tpd for the refinery sector plus 7.47 tpd for the non-refinery sector). In addition, a 10 percent compliance margin has been added to the remaining emissions to account for uncertainties that arose in the BARCT analysis and to account for facilities that have shut down operations. Finally, ~~an adjustment~~ a Regional NSR Holding A~~a~~ccount to hold RTCs for EGFs ~~power plants~~ to meet their NSR holding obligations is also proposed. Currently, there are 26.5 tpd of NOx RTC holdings. Overall, a total of 14 tpd of NOx RTC reductions from the current RTC holdings of 26.5 tpd is proposed[3]. To help the Basin achieve the PM2.5 standard by 2024 and the ozone standard by 2032, 14 tpd of NOx RTC reductions are proposed to be implemented over a seven-year period from 2016 to 2022.

For the 275 facilities that are in the NOx RECLAIM program, the 14 tpd of NOx RTC reductions will only affect 56 ~~65~~ facilities plus the investors that, together, hold 90 percent of the NOx RTC holdings. Investors are included in the refinery sector and treated as one facility. For the remaining 219 ~~210~~ facilities that hold 10 percent of the 26.5 tpd of the NOx RTCs, no NOx RTC shave is proposed because no new BARCT (not cost effective and/or infeasible) was identified for the types of equipment and source categories at these facilities. By following this approach, the shave is distributed as follows:

- 66~~67~~% shave for 9 refineries and investors (treated as one facility)
- 49~~47~~% shave for 21 ~~30 power plants~~ electricity generating facilities
- 49 ~~47~~% shave for 26 non-major facilities
- 0% shave for 219 ~~210~~ remaining facilities

In addition, the overall NOx RTC reductions of 14 tpd is expected to be achieved incrementally from 2016 to 2022, according to the following implementation schedule:

- 2016 – 4 tons per day
- 2018 – 2 tons per day
- 2019 – 2 tons per day
- 2020 – 2 tons per day
- 2021 – 2 tons per day
- 2022 – 2 tons per day

In particular, the proposed project is estimated to reduce four tons per day of NOx emissions starting in 2016 because the amount of unused RTCs in the NOX RECLAIM program over the past five years (e.g., from 2009 to 2013) ranged from five tpd to eight tpd, demonstrating that there is enough cushion to support reduction of four tpd in 2016. However, because it could take from two to four years for the affected facilities to plan, obtain permits, and install air pollution control equipment or modify existing equipment in response to the proposed project, the

---

[2] The growth factor assumptions are: 1) 1.0 for the refinery sector; 2) 0.89 for power plants; and 3) 1.1 for the non-refinery sector.

[3] RTC Reductions = RTC Holdings – Remaining Emissions in 2023 - Adjustments = 14 tpd

remaining shave of 10 tpd is scheduled to take place over the five-year period from 2018 to 2022.

To incorporate the proposed NOx RTC shave and implementation schedule, amendments to the NOx RECLAIM regulation are proposed to establish procedures and criteria for reducing NOx RECLAIM RTCs and NOx RTC adjustment factors for year 2016. The proposed amendments contain the following key elements:

- Amend Rule 2001 – Applicability, to allow the owner or operator of an EGF to opt out of the NOx RECLAIM program.
- Amend Rule 2002 - Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx), to establish procedures and criteria for reducing NOx RTCs and NOx RTC adjustment factors for year 2016 and later.
- Amend Rule 2002 to add new BARCT emission factors ending in 2021 for an assortment of equipment/process categories.
- Amend Rule 2002 to change the maximum $15,000 per ton price trigger to $22,500 per ton (discrete credits, 12-month rolling average) and add a maximum trigger level of $35,000 per ton (discrete credits, 3-month rolling average).
- Amend Rule 2002 to delete the provisions pertaining to RTC Reductions Exemptions.
- Amend Rule 2002 to add provisions to address the retirement of RTCs from complete facility closure or equipment shutdowns.
- Amend Rule 2002 to allow new EGFs~~power producers~~: 1) the use of the ~~Adjustment~~ Regional NSR Holding Account for their New Source Review holding requirement; and, 2) access to this account during a Governor's declared state of emergency.
- Amend Rule 2005 – New Source Review for RECLAIM, to establish a~~n~~ ~~Adjustment~~ Regional NSR Holding Account for EGF ~~power plant~~ New Source Review holding requirements and set criteria for the use of those RTCs in the event the Governor declares a state of emergency for power generation.
- Amend Rule 2011 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping Oxides of Sulfur (SOx) Emissions (Attachment C – Quality Assurance and Quality Control Procedures)
- Amend Rule 2012 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping Oxides of Nitrogen (NOx) Emissions (Attachment C – Quality Assurance and Quality Control Procedures)
- Make administrative and other minor changes such as correcting typographical errors as well as clarifying and updating the rule and rule protocol language for consistency.

Other minor changes are proposed for clarity and consistency throughout the proposed amended regulation. Instructions for obtaining the latest version ~~A copy~~ of PARs 2001, 2002 and 2005 can be found in Appendices A1, A2, and B, respectively of this ~~Draft~~ Final PEA. Instructions for obtaining the latest version ~~A copy~~ of the proposed amended protocols for Rules 2011 and 2012 can be found in Appendices C and D, respectively.

The following is a more detailed summary of the key proposed amendments to the affected rules and protocols that comprise Regulation XX.

PAR 2001

Exit from RECLAIM – subdivision (g)

- Add paragraph (g)(1) to provide an electricity generating facility (EGF) the option of exiting from the NOx RECLAIM program. This opting out of NOx RECLAIM would be contingent upon the submittal of a plan application subject to plan fees specified in Rule 306 and the criteria specified in this paragraph.
- Add subparagraph (g)(2)(A) to specify permit conditions relative to opting out of NOx RECLAIM for new and existing EGFs (see clauses (g)(2)(A)(i) and (g)(2)(A)(ii), respectively).
- Add subparagraph (g)(2)(B) to ensure that an EGF operator will not exceed its respective BACT or BARCT levels of emissions or any existing permit condition limiting NOx emission that is lower than BACT or BARCT as of the date of the opt-out plan submittal.
- Add subparagraph (g)(2)(C) to limit total facility emissions to the amount of RTCs held as of September 22, 2015 in the same proportion as its share of the EGF's emissions during the three completed compliance years prior to the date of opt-out plan submittal.
- Add subparagraph (g)(2)(D) to limit emissions from each NOx source to the amount of RTCs required to be held for that source pursuant to Rule 2005 as of the date of the opt-out plan submittal, applicable to EGFs for which all permits were issued on or after January 1, 1994.
- Add subparagraph (g)(2)(E) to clarify that subdivision (j) – Rule Applicability, would not apply to the EGF for any equipment installed or modified after the date of approval of the opt-out plan, and for existing equipment at the earliest practicable date but no later than three years after the date of the approved opt-out plan.
- Add subparagraph (g)(2)(F) to require an EGF operator to continue to comply with the requirements of Rule 2012 – Requirements for Monitoring, Reporting, and Recordkeeping for Oxides of Nitrogen (NOx) Emissions and its associated protocols unless the Executive Officer has approved an alternative monitoring and recordkeeping plan which is sufficient to determine compliance with all applicable rules.
- Add subparagraph (g)(2)(G) to clarify for EGFs that are not subject to Regulation XXX – Title V Permits that the EGF's permit must be re-designated as an "opt-out facility permit" and shall remain in effect, subject to annual renewal, unless expired, revoked, or modified pursuant to applicable rules. The EGF operator must continue to pay RECLAIM permit fees pursuant to Rule 301 (l).
- Add paragraph (g)(3) to provide criteria for the Executive Officer to approve or disapprove the opt-out plan.
- Revise paragraph (g)(4) to remove an approved EGF from the list of facilities not allowed to be removed from NOx RECLAIM.

Exemptions – subdivision (i)

- Add subparagraphs (i)(1)(K) and (i)(2)(O) joining approved EGFs to the list facilities exempt from NOx RECLAIM.

PAR 2002

RECLAIM Allocations – subdivision (b)

- Clarify in new paragraph (b)(5) that emission data submitted pursuant to Rule 301 paragraph (l)(10) shall not be considered in determining facility Allocation if new or amended data is submitted more than five years after the original due date.

Annual Allocations for NOx and SOX and Adjustments to RTC Holdings – subdivision (f)

- Delete the Non-tradable/Non-usable NOx RTC Adjustment Factor column ~~Change compliance year "2011 and after" to "2011 to 2015" for the existing NOx RTC adjustment factors~~ in subparagraph (f)(1)(A).
- Add new RTC adjustment factors to subparagraphs (f)(1)(B) and (f)(1)(C) for tradable/usable and non-tradable/non-usable NOx RTCs for facilities listed in Tables 7 and 8, respectively, in order to achieve projected NOx emission reductions from NOx RTC holders beginning in compliance year 2016 and later.
- Clarify in new subparagraph (f)(1)(D) that RTCs which are designated as non-tradeable/non-usable shall be held, but not used or traded.
- Add new subparagraph (f)(1)(E) staff to establish a 3-month averaging period to be used for the price threshold value in subparagraph (f)(1)(I).
- Add new subparagraph (f)(1)(F) to establish procedures for submitting the Non-tradable/Non-usable NOx RTCs as part of the State Implementation Plan commitment.
- Add new subparagraph (f)(1)(G) to establish procedures for transferring the amount of NOx RTCs holdings listed in Table 9 of Rule 2002 to the Regional NSR Holding account.
- Add new subparagraph (f)(1)(H) to allow the EGFs identified in Table 9 to use a combination of their Tradable/Usable and Non-tradable/Non-usable RTCs and the amount for each facility listed in Table 9 (i.e., the RTCs in the Regional NSR Holding account).
- Revise subparagraph (f)(1)(I) to add a RTC price threshold of $35,000 per ton (discrete year credits) based on a 3-month averaging period and to change the price threshold from $15,000 to $22,500 per ton (discrete year credits) for the 12-month averaging period.
- Add new subparagraph (f)(1)(J) to establish a minimum price threshold of $200,000 per ton (infinite year block) based on the 12-month rolling average. For the purpose of Rule 2002, infinite year block refers to trades involving blocks of RTCs with a specified start year and continuing into the future for ten or more years.
- Revise subparagraph (f)(1)(K) to require a report to the Board if the price thresholds are exceeded (subparagraph (f)(1)(I)) or fall below (subparagraph (f)(1)(J)) that includes a commitment and schedule for conducting a more rigorous control technology implementation, emission reduction, cost-effectiveness, market analysis, and socioeconomic impact assessment of the RECLAIM program. This report to the Board will be made at a public hearing at the earliest possible regularly scheduled Board Meeting, but no more than 90 days from the determination.

- Revise subparagraph (f)(1)(L) to include the NOx RTC adjustment factors for compliance years 2016, and 2018 through 2022 in the State Implementation Plan.
- Revise subparagraph (f)(1)(M) to c~~C~~larify procedures for determining NOx RTC Allocation for facilities entering the RECLAIM program after the date of adoption~~January 7, 2005 in subparagraph (f)(1)(K) to reflect the new RTC adjustment factors added to subparagraphs (f)(1)(B) and (f)(1)(C)~~.
- Revise paragraph (f)(4) to add new procedures for converting Non-tradable/Non-usable RTCs and the Regional NSR Holding Account during a State of Emergency declared by the Governor related to electricity demand or power grid stability within the SCAQMD jurisdictional boundaries.
- Revise paragraph (f)(5) to require the Executive Officer to report to the Governing Board within 60 days of the end of the quarter in which the State of Emergency was declared by the Governor related to electricity demand or power grid stability within the SCAQMD jurisdictional boundaries.
- ~~Add new allowance in paragraph (f)(4) for all power producing facilities that have received SCAQMD Permits to Construct on or after October 15, 1993 to have access to an Adjustment Account in order to comply with the new source review holding requirements in subdivision (f) of Rule 2005.~~
- ~~Add criteria in paragraph (f)(5) for all power producing facilities to have access to an Adjustment Account RTCs during a State of Emergency as declared by the Governor. The amount and distribution of the RTCs will be determined by the SCAQMD's Executive Officer and will take into account the impact that the State of Emergency has on the RECLAIM program.~~

RTC Reduction Exemption – subdivision (i)

- Staff is proposing to replace this subdivision in its entirety with a new subdivision on Facility and Equipment Shutdowns.
- ~~Clarify paragraph (i)(1) that the RTC reduction exemption does not include RTC holdings for compliance year 2016 and thereafter.~~
- ~~Clarify subparagraph (i)(1)(B) that the application for an RTC reduction exemption needs to demonstrate that the reported emissions for Compliance Year 2013 are not from equipment listed in existing Table 3 or new Table 6 and that the achieved emission rates are less than the emission factors listed in existing Table 3 or new Table 6, whichever is lower.~~
- ~~Clarify subparagraphs (i)(1)(C) and (i)(2)(C) that the application for an RTC reduction exemption needs to demonstrate that the RTCs for Compliance Year 2016 have never been transferred or sold by the facility.~~
- ~~Clarify clause (i)(1)(D)(i) to allow the exclusion of control costs for any equipment listed in existing Table 3 or new Table 6.~~
- ~~Clarify paragraph (i)(3) that an application for an RTC reduction exemption shall be submitted no later than six months after the adoption of the proposed project.~~

- ~~Clarify paragraph (i)(8) to require a facility qualifying for an exemption to include emissions from equipment listed in existing Table 3 or new Table 6 in its Annual Permit Emission Program (APEP) report.~~

Facility and Equipment Shutdowns – subdivision (i)

- Add new paragraph (i)(1) to require the highest ranking official of any facility selling any infinite year block (IYB) RTCs to provide the Executive Officer a written statement that there is no intention to shut down the facility. For the purpose of this rule, IYB refer to trades involving blocks of RTCs with a specified start year and continuing into the future for ten or more years. This requirement would go into effect on the adoption date of the amendment.
- Add new paragraph (i)(2) to define the criteria for a permanently shut down facility.
- Add new paragraph (i)(3) to specify the amount of NOx RTCs that would be required to be surrendered as part of the facility shutdown.
- Add new paragraph (i)(4) to exempt equipment from being counted against facility shutdowns if the equipment's operational capacity is replaced by new or existing equipment serving the same functional needs at the same facility or another facility under common control.

RECLAIM NOx 2021 Ending Emission Factors – new Table 6

- Add new BARCT emission factors up to the year 2021 for certain boilers and heaters, cement kilns, FCCUs, gas turbines, container glass melting furnaces, permitted ICEs, metal heat treating furnaces, petroleum coke calciners, sodium silicate furnaces, and SRU/TGUs.

List of NOx RECLAIM Facilities Referenced in Subparagraph (f)(1)(B) – new Table 7

- Add new table which identifies the specific facilities (e.g., major refineries and coke calciner) that will be subject to the NOx RTC holdings adjustment factors in subparagraph (f)(1)(B).

List of NOx RECLAIM Facilities Referenced in Subparagraph (f)(1)(C) – new Table 8

- Add new table which identifies the specific facilities that will be subject to the NOx RTC holdings adjustment factors in subparagraph (f)(1)(C).

List of NOx RECLAIM Facilities for the Regional NSR Holding Account with Balances (in lbs) – new Table 9

- Add new table which identifies the specific facilities that will access the Regional NSR Holding Account. This table is referenced in subparagraphs (f)(1)(G) and (f)(1)(H).

PAR 2005

Requirements for New or Relocated RECLAIM Facilities – Subdivision (b)

- Amend subparagraph (b)(2)(A) to clarify the Facility Permit approval criteria in that a facility demonstrating that they hold sufficient RTCs will also need to demonstrate that they hold sufficient RTCs accessed from the Regional NSR Holding ~~Adjustment~~ Account per subparagraphs (f)(1)(G) and (f)(1)(H) ~~(f)(4)~~ of Rule 2002.

Offsets – Subdivision (f)

- Amend paragraphs (f)(2) and (f)(3) by excluding Regional NSR Holding ~~Adjustment~~ Account RTCs from the selling limitations that currently applies to unused RTCs.

Rule 2011 Appendix A (SOx Protocol for Rule 2011)

Attachment C - Quality Assurance and Quality Control Procedures

- Add new procedures and criteria for postponing the due date of semi-annual or annual assessments of a major source.
- Add new procedures and criteria for postponing the due date of semi-annual or annual assessments of an electricity ~~electrical~~ generating facility (EGF).

Rule 2012 Appendix A (NOx Protocol for Rule 2012)

Attachment C - Quality Assurance and Quality Control Procedures

- Add new procedures and criteria for postponing the due date of semi-annual or annual assessments of a major source.
- Add new procedures and criteria for postponing the due date of semi-annual or annual assessments of an electricity ~~electrical~~ generating facility (EGF).

2.4 TECHNOLOGY OVERVIEW

NOx Emission Sources

The NOx RECLAIM program currently consists of 275 facilities as of the 2013 compliance year. SCAQMD staff conducted a BARCT analysis for these 275 facilities. Of these, 21 EGFs ~~30 power producing facilities~~ where shown to operate at current BARCT or BACT levels. For 219 ~~224~~ facilities, either no new BARCT was identified or the installation of control equipment was determined to not be cost-effective and/or infeasible. Further, only 35 ~~44~~ facilities are expected to comply with the proposed NOx RTC shave through the purchase of RTCs which will have no environmental impact. In addition, the sale and/or purchase of RTCs by investors (treated as one facility) will also have no environmental impact.

SCAQMD staff conducted an analysis of the potential feasibility and cost-effectiveness of adding controls to reduce NOx from the remaining 21 facilities (e.g., 275 - 21 EGFs (with shave) ~~30 power producers~~ - 224 non-power plant facilities – 9 EGFs (without shave) = 21) which are either major or large sources of NOx for which new BARCT has been identified. Further, 19 of the 21 facilities are also among the top NOx RTC holders.

The BARCT analysis further found that it would be both feasible and cost-effective for facility operators to install new control equipment or modify existing control equipment in response to the proposed NOx RTC shave for facilities which operate with current SCAQMD permits. Of the 21 facilities, 12 facilities belong to the non-refinery sector and 9 facilities belong to the refinery sector. These facilities are identified as follows:

<u>Nine Facilities in the Refinery Sector:</u>

- Six refineries owned by five companies operate FCCUs, refinery boilers and heaters, refinery gas turbines, and SRU/TGUs: Tesoro (two locations: Wilmington and Carson); Phillips 66 (two locations: Wilmington and Carson); Chevron; ExxonMobil; and, Ultramar (also referred to as Valero)
- One sulfur plant: Tesoro (Wilmington location)
- One coke calciner plant: Tesoro (Wilmington location)

Of the above-listed facilities, six refineries operate one FCCU each, one SRU/TGU each, and a multitude of refinery process heaters and boilers and refinery gas turbines. The quantity of major and large source NOx emissions from the refineries comprises approximately 54 percent of the total NOx emitted from the universe of RECLAIM facilities in compliance year 2011.

<u>12 Facilities in the Non-Refinery Sector:</u>

- One container glass manufacturing plant: Owens-Brockway Glass Container Inc.
- One sodium silicate manufacturing plant: PQ Corporation
- One steel plant operating two metal heat treating furnaces rated greater than > 150 million British Thermal Units per hr (mmBTU/hr): California Steel
- Seven facilities operating gas turbines: Southern California Gas Company, SDGE, THUMS Long Beach, Wheelabrator Norwalk Energy, LA City Department of Airports, Tin Inc., and Berry Petroleum
- Three facilities operating IC Engines: SDGE and Southern California Gas Company (two facilities)
- One facility operating Portland cement kilns: CPCC

The major and large sources belonging to non-refineries among the top NOx emitting facilities that were analyzed for BARCT emitted 18 percent of the RECLAIM universe's total emissions inventory in compliance year 2011.

It is important to note that CPCC is no longer operating their Portland cement kilns with current SCAQMD permits. Because CPCC's operators hold NOx RTCs, the BARCT analysis can be applied to this facility by shaving their NOx RTCs holdings. However, because the affected equipment is not operational, the installation of BARCT control equipment would not be expected.

In conclusion, the proposed project may result in the installation of new or the modification of existing NOx emission control equipment for 20 of these industrial equipment and processes (e.g., 9 facilities from the refinery sector and 11 facilities from the non-refinery sector) and Portland cement kilns are excluded from this assumption for reasons that are further explained in the Portland Cement Kiln discussion under the Non-Refinery / Non-Power Plant Category section later in this chapter.

<u>Combustion Equipment</u>

Combustion is a high temperature chemical reaction resulting from burning a gas, liquid, or solid fuel (e.g., natural gas, diesel, fuel oil, gasoline, propane, and coal) in the presence of air (oxygen and nitrogen) to produce: 1) heat energy; and, 2) water vapor or steam. An ideal combustion reaction is when the entire amount of fuel needed is completely combusted in the presence of air so that only carbon dioxide (CO2) and water are produced as by-products. However, since fuel contains other components such as nitrogen and sulfur plus the amount of air mixed with the fuel can vary, in practice, the combustion of fuel is not a "perfect" reaction. As such, uncombusted fuel plus smog-forming by-products such as NOx, SOx, carbon monoxide (CO), and soot (solid carbon) can be discharged into the atmosphere.

Of the total NOx emissions that can be generated, there are two types of NOx formed during combustion: 1) thermal NOx; and, 2) fuel NOx. Thermal NOx is produced from the reaction between the nitrogen and oxygen in the combustion air at high temperatures while fuel NOx is formed from a reaction between the nitrogen already present in the fuel and the available oxygen in the combustion air. As the source of nitrogen in fuel is more prevalent in oil and coal, and is negligible in natural gas, the amount of fuel NOx generated is dependent on fuel type. For example, with oil that contains significant amounts of fuel-bound nitrogen, fuel NOx can account for up to 50 percent of the total NOx emissions generated. In another example, only 10 percent of NOx emissions from FCCUs are thermal NOx while the remaining 90 percent of NOx is generated from fuel by combusting petroleum coke. Though boilers, process heaters, petroleum coke calciners, FCCUs, gas turbines, and other miscellaneous equipment have varying purposes in commercial, industrial, and utility applications, at a minimum, they all generate thermal NOx as a combustion by-product. The following provides a brief description of the various types of existing combustion equipment that may be affected by the proposed amendments to Regulation XX and subsequently retrofitted with NOx control equipment.

REFINERY CATEGORY

<u>Refinery Process Heaters and Boilers</u>

Refinery process heaters and boilers are used extensively throughout various processes in refinery operations such as distillation, hydrotreating, fluid catalytic cracking, alkylation, reforming, and delayed coking.

A process heater is a type of combustion equipment that burns liquid, gaseous, or solid fossil fuel for the purpose of transferring heat from combustion gases to heat water or process streams. Process heaters are not kilns or ovens used for drying, curing, baking, cooking, calcining, or vitrifying; or any unfired waste heat recovery heater that is used to recover sensible heat from the exhaust of any combustion equipment.

A typical boiler, also referred to as a steam generator, is a steel or cast-iron pressure vessel equipped with burners that combust liquid, gas, or solid fossil fuel to produce steam or hot water. Boilers are classified according to the amount of energy output in millions of British Thermal Units per hour (mmBTU/hr), the type of fuel burned (natural gas, diesel, fuel oil, etc.), operating steam pressure in pounds per square inch (psi), and heat transfer media. In addition, boilers are further defined by the type of burners used and air pollution control techniques. The burner is where the fuel and combustion air are introduced, mixed, and then combusted.

There are a total of 212 boilers and heaters classified as major and large NOx sources at the refineries (23 boilers and 189 heaters). Collectively, the 212 boilers and heaters emitted approximately 7.39 tons per day in 2011.

Refinery process heaters and boilers are primarily fueled by refinery gas, one of several products generated at the refinery. In addition, most of the refinery process heaters and boilers are designed to also operate on natural gas, but liquid or solid fuels are rarely used. The combustion of fuel generates NOx, primarily "thermal" NOx with small contribution from "fuel" NOx and "prompt" NOx.

For the purpose of the analysis in this PEA, controlling NOx emissions from refinery boilers and process heaters is assumed to be accomplished with selective catalytic reduction (SCR) technology. While low NOx burners may be effective at reducing NOx emissions, SCRs were analyzed because SCR technology has been demonstrated to have more adverse construction and operational impacts than low NOx burners. Thus, by analyzing SCRs in lieu of low NOx burners, the analysis in this PEA applies the most conservative assumptions to represent a "worst-case" scenario. For a full description of this control technology, see the NOx Control Technologies section.

<u>Refinery Gas Turbines</u>

Gas turbines are used in refineries to produce both electricity and steam. Refinery gas turbines are typically combined cycle units that use two work cycles from the same shaft operation. Refinery gas turbines also have an additional element of heat recovery from its exhaust gases to produce more power by way of a steam generator. Gas turbines can operate on both gaseous and liquid fuels. Gaseous fuels include natural gas, process gas, and refinery gas. Liquid fuels typically include diesel. The units in this category are cogenerating units that recover the useful energy from heat recovery for producing process steam. There are a total of 21 gas turbines/duct burners classified as major NOx sources at the refineries in the SCAQMD. Collectively, the 21 gas turbines/duct burners emitted about 1.33 tons per day of NOx in 2011.

Frame gas turbines are exclusively used for power generation and continuous base load operation ranging up to 250 MW with simple-cycle efficiencies of approximately 40 percent and combined-cycle efficiencies of 60 percent. The existing gas turbines operating at the refineries are rated from seven MW to 83 MW. Most of the refinery gas turbines are operated with duct burners, heat recovery steam generator (HRSG), SCR, and CO catalysts. Figure 2-2 shows a typical layout of a combined cycle utility gas turbine with a duct burner, HRSG, and control system.

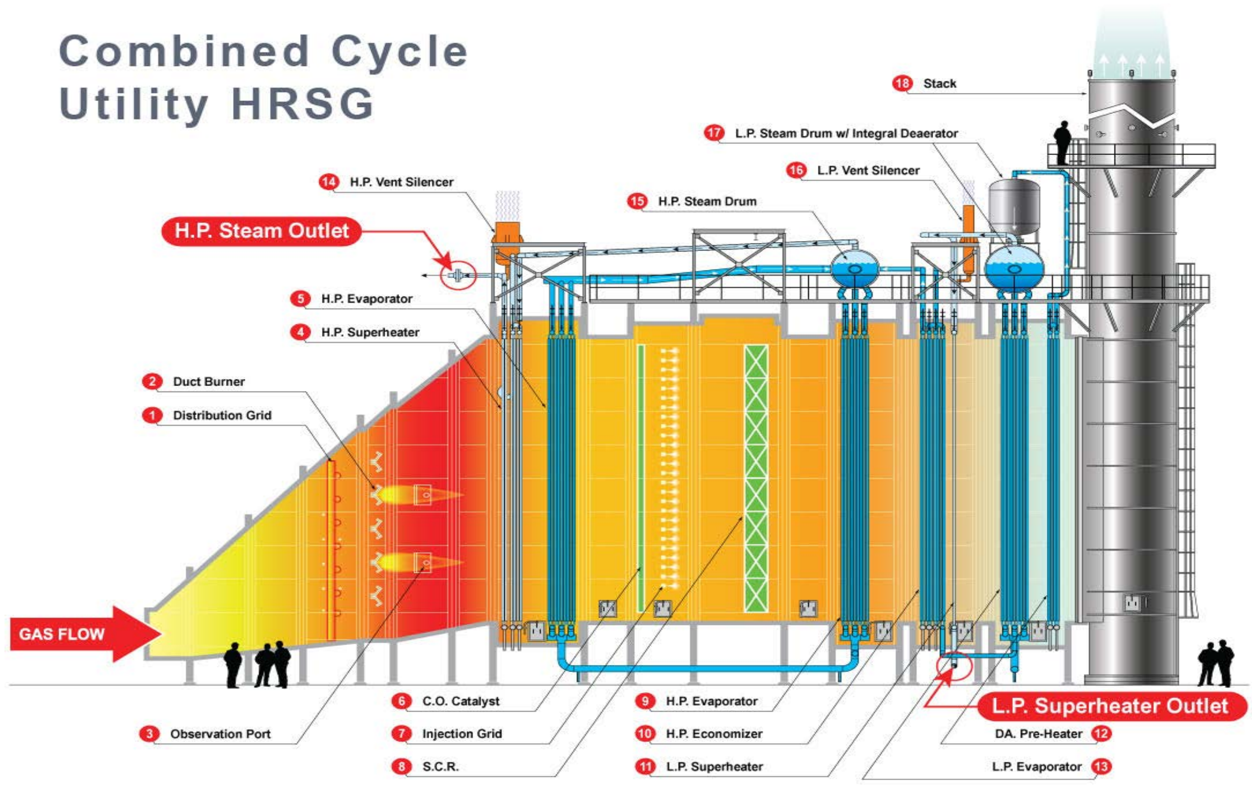

Figure 2-2: Gas Turbine with Duct Burner

For the purpose of the analysis in this PEA, controlling NOx emissions from refinery gas turbines is assumed to be accomplished with SCR technology. For a full description of this control technology, see the NOx Control Technologies section.

Sulfur Recovery Units and Tail Gas Units (SRU/TGUs)

Refinery SRU/TGTUs, including their incinerators, are classified as major sources of both NOx and SOx emissions. Because sulfur is a naturally occurring and undesirable component of crude oil, refineries employ a sulfur recovery system to maximize sulfur removal. A typical sulfur removal or recovery system will include a sulfur recovery unit (e.g., Claus unit) followed by a tail gas treatment unit (e.g., amine treating) for maximum removal of hydrogen sulfide (H_2S). A Claus unit consists of a reactor, catalytic converters and condensers. Two chemical reactions occur in a Claus unit. The first reaction occurs in the reactor, where a portion of H_2S reacts with air to form sulfur dioxide (SO_2) followed by a second reaction in the catalytic converters where SO_2 reacts with H_2S to form liquid elemental sulfur. Side reactions producing carbonyl sulfide (COS) and carbon disulfide (CS_2) can also occur. These side reactions are problematic for Claus plant operators because COS and CS_2 cannot be easily converted to elemental sulfur and carbon dioxide. Liquid sulfur is recovered after the final condenser. The combination of two converters with two condensers in series will generally remove as much as 95 percent of the sulfur from the incoming acid gas. To increase removal efficiency, some newer sulfur recovery units may be designed with three to four sets of converters and condensers.

To recover the remaining sulfur compounds after the final pass through the last condenser, the gas is sent to a tail gas treatment process such as a SCOT or Wellman-Lord treatment process. For example, the SCOT tail gas treatment is a process where the tail gas is sent to a catalytic reactor and the sulfur compounds in the tail gas are converted to H_2S. The H_2S is absorbed by a solution of amine or diethanol amine (DEA) in the H_2S absorber, steam-stripped from the absorbent solution in the H_2S stripper, concentrated, and recycled to the front end of the sulfur recovery unit. This approach typically increases the overall sulfur recovery efficiency of the Claus unit to 99.8 percent or higher. However, the fresh acid gas feed rate to the sulfur recovery unit is reduced by the amount of recycled stream, which reduces the capacity of the sulfur recovery unit. The residual H_2S in the treated gas from the absorber is typically vented to a thermal oxidizer where it is oxidized to sulfur dioxide (SO_2) before venting to the atmosphere.

The Wellman-Lord tail gas treatment process is when the sulfur compounds in the tail gas are first incinerated to oxidize to SO_2. After the incinerator, the tail gas enters a SO_2 absorber, where the SO_2 is absorbed in a sodium sulfite (Na_2SO_3) solution to form sodium bisulfite ($NaHSO_3$) and sodium pyrosulfate ($Na_2S_2O_5$). The absorbent rich in SO_2 is then stripped, and the SO_2 is recycled back to the beginning of the Claus unit. The residual sulfur compounds in the treated tail gas from the SO_2 absorber is then vented to a thermal (or catalytic) oxidizer (incinerator) where the residual H_2S in the tail gas is oxidized to SO_2 before venting to the atmosphere. NOx is a by-product of operating the incinerator.

The type of NOx control option to be utilized in response to this portion of the proposed project is assumed to be LoTOx™ technology with a WGS. For a full description of this control technology, see the NOx Control Technologies section.

Petroleum Coke Calciner

Petroleum coke, the heaviest portion of crude oil, cannot be recovered in the normal oil refining process. Instead, it is processed in a delayed coker unit to generate a carbonaceous solid referred to as “green coke,” a commodity. To improve the quality of the product, if the green coke has a low metals content, it will be sent to a calciner to make calcined petroleum coke. Calcined petroleum coke can be used to make anodes for the aluminum, steel, and titanium smelting industry. If the green coke has a high metals content, it is used as fuel grade coke by the fuel, cement, steel, calciner and specialty chemicals industries.

As shown in Figure 2-3, the process of making calcined petroleum coke begins when the green coke feed produced by the delayed coker unit is screened and transported to the calciner unit where it is stored in a covered coke storage barn. The screened and dried green coke is introduced into the top end of a rotary kiln and is tumbled by rotation under high temperatures that range between 2000 and 2500 degrees Fahrenheit (^{o}F). The rotary kiln relies on gravity to move coke through the kiln countercurrent to a hot stream of combustion air produced by the combustion of natural gas or fuel oil. As the green coke flows to the bottom of the kiln, it rests in the kiln for approximately one additional hour to eliminate any remaining moisture, impurities, and hydrocarbons. Once discharged from the kiln, the calcined coke is dropped into a cooling chamber, where it is quenched with water, treated with de-dusting agents to minimize dust, carried by conveyors to storage tanks. Eventually, the calcined coke is transported by truck to the Port of Long Beach for export, or is loaded onto railcars for shipping to domestic customers. As the green coke is processed under high heat conditions in the rotary kiln, NOx emissions are generated. NOx is also generated from combusting fuel oil to generate high heating values in the rotary kiln.

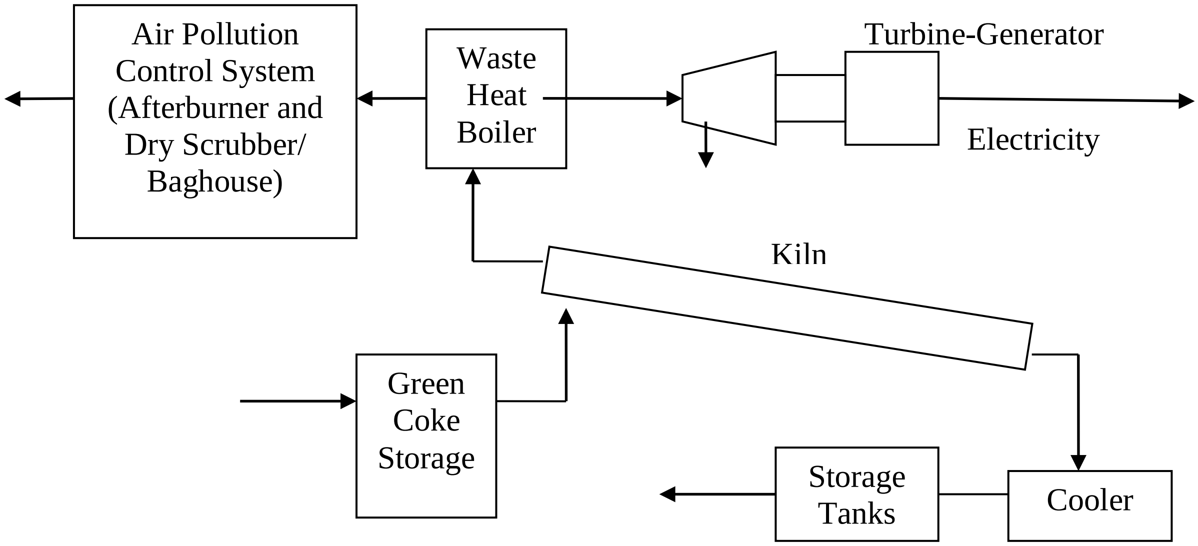

Figure 2-3: Coke Calciner Process

The Tesoro Wilmington coke calciner is the only petroleum coke calciner in the Basin and produces approximately 400,000 short tons per year of calcined products. This petroleum coke calciner is a global supplier of calcined coke to the aluminum industry, and fuel grade coke to the fuel, cement, steel, calciner, and specialty chemicals businesses. The existing control system also includes a spray dryer, a reverse-air baghouse, a slurry storage system, a slurry circulating system, and a pneumatic conveying system. Calcium hydroxide (CaOH) slurry is the absorbing medium for SO_2 control.

There are two commercially available multi-pollutant control technologies for the low temperature removal of NOx emissions from the coke calciner: 1) LoTOx^{TM} with scrubber; and, 2) UltraCat. For a full description of these control technologies, see the NOx Control Technologies section. The type of NOx control option to be utilized for the coke calciner in response to the proposed project will depend on this facility's individual operations and the current control technologies and techniques in place. Thus, the ~~Draft~~ Final PEA will evaluate the possibility that operators of the petroleum coke calcining facility may rely on either of the above-mentioned control technologies to further control NOx emissions in order to comply with the BARCT requirements for the petroleum coke calcining portion of the proposed project. For a full description of these control technologies, see the NOx Control Technologies section.

FCCUs

The purpose of an FCCU at a refinery is to convert or "crack" heavy oils (hydrocarbons), with the assistance of a catalyst, into gasoline and lighter petroleum products. Each FCCU consists of three main components: a reaction chamber, a catalyst regenerator and a fractionator. All six refineries each operate one FCCU.

As shown in Figure 2-4, the cracking process begins in the reaction chamber where fresh catalyst is mixed with pre-heated heavy oils (crude) known as the fresh feed. The catalyst typically used for cracking is a fine powder made up of tiny particles with surfaces covered by several microscopic pores. A high heat-generating chemical reaction occurs that converts the heavy oil liquid into a cracked hydrocarbon vapor mixed with catalyst. As the cracking reaction progresses, the cracked hydrocarbon vapor is routed to a distillation column or fractionator for further separation into lighter hydrocarbon components than crude such as light gases, gasoline, light gas oil, and cycle oil.

Towards the end of the reaction, the catalyst surface becomes inactive or spent because the pores are gradually coated with a combination of heavy oil liquid residue and solid carbon (coke), thereby reducing its efficiency or ability to react with fresh heavy liquid oil in the feed. To prepare the spent catalyst for re-use, the remaining oil residue is removed by steam stripping. The spent catalyst is later cycled to the second component of the FCCU, the regenerator, where hot air burns the coke layer off of the surface of each catalyst particle to produce reactivated or regenerated catalyst. Subsequently, the regenerated catalyst is cycled back to the reaction chamber and mixed with more fresh heavy liquid oil feed. Thus, as the heavy oils enter the cracking process through the reaction chamber and exit the fractionator as lighter components, the catalyst continuously circulates between the reaction chamber and the regenerator.

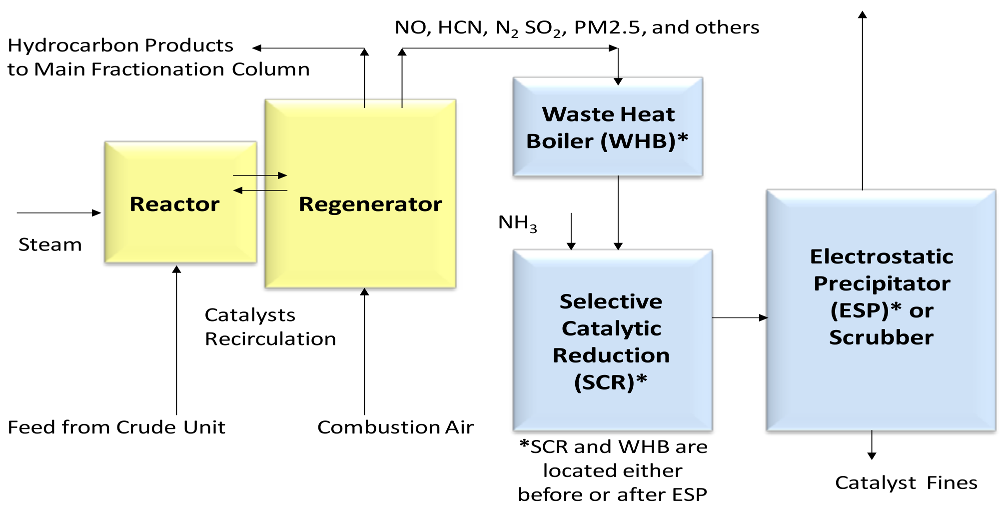

Figure 2-4: Simplified Schematic of FCCU Process

During the regeneration cycle, large quantities of catalyst are lost in the form of catalyst fines or particulates thus making FCCUs a major source of primary particulate emissions (PM10 and PM2.5) at refineries. In addition, particulate (PM) precursor emissions such as SOx (because crude oil naturally contains sulfur) and NOx, additional secondary particulates (i.e., formed as a result of various chemical reactions), plus carbon monoxide (CO) and carbon dioxide (CO_2) are produced due to coke burn-off during the regenerator process.

Approximately 90 percent of the NOx generated from the FCCUs is from the nitrogen in the feed that is accumulated in the coke which is then burned-off in the regenerator. This portion of the NOx is called “fuel” NOx. “Fuel” NOx is a combination of nitric oxide (NO), nitrogen dioxide (NO_2), and nitrous oxide (N_2O). The remaining 10 percent of the NOx generated from the FCCUs are “thermal” NOx which is generated in the high temperature zones in the regenerator, and “prompt” NOx generated from the reaction between nitrogen and oxygen in the combustion air.

Combustion in a FCCU regenerator generates various pollutants (e.g., NO, N_2O, NO_2, HCN, NH_3, SO_2, etc.) and their dynamic interaction with each other is complex. "Fuel" nitrogen in the coke is first converted to HCN. HCN is thermodynamically unstable and it is converted to NH_3, N_2, NO, N2O, and NO_2. The rates of these reactions depend heavily on the FCCU regenerator temperatures and configuration.

Currently, refineries may operate FCCUs by utilizing NOx reducing additives to promote the conversion of NOx, HCN, and NH_3 to elemental nitrogen (N_2) and reduce NOx emissions. The removal efficiency for NOx reducing additives can range between 50 percent and 80 percent. A simplified version of the chemical reactions in the FCCU regenerator is shown in Figure 2-5.

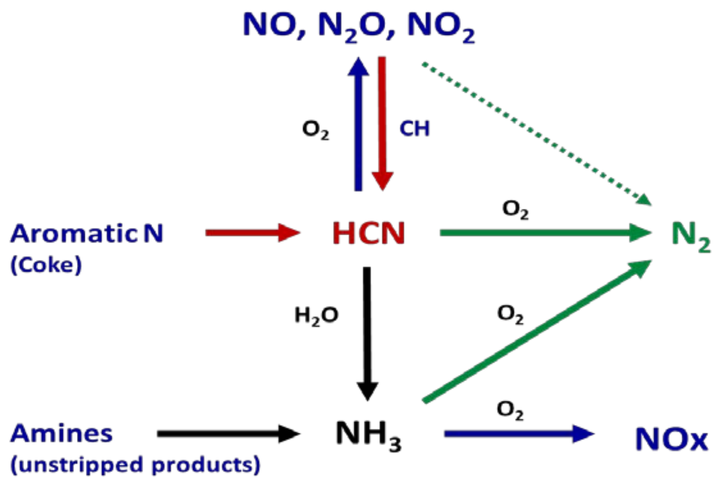

Figure 2-5: Nitrogen Chemistry in the FCCU Regenerator

When using NOx reducing additives, manufacturers recommend the following best practices to minimize the formation of NOx and simultaneously promote the conversion of CO to CO_2: 1) minimize excess oxygen since higher amounts of excess oxygen favors the undesirable formation of NOx rather than N_2; 2) reduce nitrogen in the feed stream; and, 3) utilize non-platinum CO promoters.

To further reduce NOx emissions from a FCCU (beyond what is currently being achieved through the use of NOx reducing additives, the potential available control technologies are either: 1) SCR; or, 2) LoTOx^{TM} with WGS. For a full description of these control technologies, see the NOx Control Technologies section.

NON-REFINERY / NON-POWER PLANT CATEGORY

Portland Cement Kilns

In the NOx RECLAIM program, there is one facility (CPCC) with two cement kilns capable of producing gray cement from limestone, sand, shale, and clay raw materials. The CPCC facility, under normal operation, has typically been among the highest NOx emitters in the RECLAIM program. The manufacturing of gray Portland cement follows a four-step process of: 1) acquiring raw materials; 2) preparing the raw materials to be blended into a raw mix; 3) pyroprocessing of the raw mix to make clinker; and, 4) grinding and milling clinker into cement. The raw materials used for manufacturing cement include calcium, silica, alumina and iron, with calcium having the highest concentration. These raw materials are obtained from a limestone quarry for calcium, sand for silica; and shale and clay for alumina and silica.

The raw materials are crushed, milled, blended into a raw mix and stored. Primary, secondary and tertiary crushers are used to crush the raw materials until they are about ¾-inch or smaller in size. Raw materials are then conveyed to rock storage silos. Belt conveyors are typically used for this transport. Roller mills or ball mills are used to blend and pulverize raw materials into fine powder. Pneumatic conveyors are typically used to transport the fine raw mix to be stored in silos until it is ready to be pyroprocessed.

The pyroprocess in a kiln consists of three phases during which clinker is produced from raw materials undergoing physical changes and chemical reactions. The first phase in a kiln, the drying and pre-heating zone, operates at a temperature between 70 ^{o}F and 1650 ^{o}F and evaporates any remaining water in the raw mix of materials entering the kiln. Essentially this is the warm-up phase which stabilizes the temperature of the refractory fire brick inside the mouth opening of the kiln. The second phase, the calcining zone, operates at a temperature between 1100 ^{o}F and 1650 ^{o}F and converts the calcium carbonate from the limestone in the kiln feed into calcium oxide and releases carbon dioxide. During the third phase, the burning zone operates on average at 2200 ^{o}F to 2700 ^{o}F (though the flame temperature can exceed 3400 ^{o}F) during which several reactions and side reactions occur. The first reaction is calcium oxide (produced during the calcining zone) with silicate to form dicalcium silicate and the second reaction is the melting of calcium oxide with alumina and iron oxide to form the liquid phase of the materials. Despite the high temperatures, the constituents of the kiln feed do not combust during pyroprocessing. As the materials move towards the discharge end of the kiln, the temperature drops and eventually clinker nodules form and volatile constituents, such as sodium, potassium, chlorides, and sulfates, evaporate. Any excess calcium oxide reacts with dicalcium silicate to form tricalcium silicate. The red hot clinker exits the kiln, is cooled in the clinker cooler, passes through a crusher and is conveyed to storage for protection from moisture. Since clinker is water reactive, if it gets wet, it will set into concrete.

Heat needed to operate CPCC's kilns is supplied through the combustion of different fuels such as coal, coke, oil, natural gas, and discarded automobile tires. The combustion gases are vented to a baghouse for dust control, and the collected dust is returned to the process or recycled if they meet certain criteria, or is discarded to landfills. CPCC does not currently have any post-combustion control for NOx emissions.

NOx emissions from the cement kilns are generated from the following: 1) combusting fuel to generate high heating values in the kilns; and, 2) oxidation of raw materials entering the cement kiln. As is the case with CPCC, long, dry cement kilns have achieved NOx reductions to the 2000 (Tier 1) level by utilizing low NOx burners and mid-kiln firing with tire-derived fuel (TDF). With TDF, whole tires are introduced at an inlet location about midway along the kiln's calcining zone. TDF lowers NOx emissions by lowering the flame temperatures and reducing thermal NOx with the introduction of a slower burning fuel.

On November 20, 2009, CPCC operators announced the shutdown of both cement kilns indicating at that time that the shutdown would not be permanent to the extent that when the economy improves, they plan to bring the cement kilns back on-line. At the time the NOP/IS was released for public review and comment, the NOP/IS acknowledged that in the event that CPCC operators decide to fire up its kilns, the type of NOx control technology to be utilized to comply with the proposed project will depend on CPCC's individual operations and how the kilns will function with the current control technologies and techniques in place at CPCC (e.g., the baghouse). The potential available control technologies to reduce NOx emissions from cement kilns were described in the NOP/IS as the following: 1) SCR with or without a WGS; 2) UltraCat; or, 3) SNCR. The NOP/IS committed that the ~~Draft~~ PEA would evaluate the possibility that CPCC operators may rely on the above-mentioned control technologies to further control NOx emissions from cement kilns to comply with the proposed project.

However, on April 9, 2015, after the release of the NOP/IS for public review and comment, CPCC operators have surrendered their operating permits for the cement kilns and have applied for Emission Reduction Credits (ERCs). Thus, because CPCC operators are no longer operating the cement kilns and they no longer hold current SCAQMD operating permits for these units, the existing setting or NOx emissions baseline for the cement kilns at CPCC is zero. Further, if CPCC operators decide to restart the cement kilns in the future, applications for new SCAQMD permits to operate would be required. Further, these permit applications would be subject to an extensive permit review process such that that the cement kilns would be treated as a new installation that would be subject to a new CEQA review and BACT requirements, instead of BARCT. Because of CPCC's current permitting status for these cement kilns, CPCC operators will not be able to retrofit the cement kilns with air pollution control equipment in response to the proposed project without first dealing with the permitting issues for the cement kilns. Thus, the installation of control technology and the secondary adverse environmental impacts that may be associated with such control technology is not a reasonably foreseeable consequence for CPCC under the present circumstances.

When evaluating the significance of the environmental effects of a project, the Lead Agency is required to consider direct physical changes in the environment which may be caused by the project and reasonably foreseeable indirect physical changes in the environment which may be caused by the project [CEQA Guidelines §15064 (d)]. Because the installation of control technology and the adverse environmental impacts that may be associated with such control technology for the CPCC facility are not reasonably foreseeable and because there are no other Portland cement kilns operating within the SCAQMD's jurisdiction, the SCAQMD, as Lead Agency for the proposed project, is not required to consider or analyze the effects of control technology for this facility. Thus, this PEA does not contain an environmental analysis of the control technologies that were originally contemplated in the NOP/IS for the CPCC facility.

<u>Container Glass Melting Furnaces</u>

In the NOx RECLAIM program there is one facility among the top NOx emitting facilities that operates glass melting furnaces. This facility produces container glass from dry, solid raw materials that are melted in the furnaces and then formed into glass container bottles.

A container glass melting furnace is the main equipment used for manufacturing glass products, such as bottles, glass wares, pressed and blown glass, tempered glass, and safety glass. The manufacturing process consists of four phases: 1) preparing the raw materials; 2) melting the mixture of raw materials in the furnace; 3) forming the desired shape; and, 4) finishing the final product. Raw materials, such as sand, limestone, and soda ash, are crushed and mixed with cullets (recycled glass pieces) to ensure homogeneous melting. The raw materials mixture is then conveyed to a continuous regenerative side-port melting furnace. As the mixture enters the furnace through a feeder, it melts and blends with the molten glass already in the furnace, and eventually flows to a refiner section, to a forming machine, and then, to annealing ovens. The final products undergo inspection, testing, packaging and storage. Any damaged or undesirable glass is transferred back to be recycled as cullet suitable for remelting.

NOx is generated from a container glass melting furnace in two ways: 1) during the decomposition of the silica in the raw materials; and, 2) from combusting fuel to generate high heating values in the furnace. The container glass melting furnace contributes over 99 percent of the total NOx emissions from a glass manufacturing plant. To effectively achieve the largest reduction of NOx emissions, SCR and UltraCat technologies are commercially available options for treating the flue gas of glass melting furnaces. For a full description of these control technologies, see the NOx Control Technologies section.

Sodium Silicate Furnace

In the NOx RECLAIM program, there is only one facility that produces sodium silicate in a melting furnace. Sodium silicate, a type of glass with a wide variety of industrial uses, should not to be confused with container or flat glass. Sodium silicate exists in a solid or liquid form, depending on the temperature. The combination of heating a batch-fed mixture of soda ash and sand causes the materials to produce sodium silicate and CO_2. NOx emissions are also created from combusting fuel needed to heat the furnace. In order to generate high heating values, the furnace is fired by several natural gas-fired burners. The flue gas then exits the furnace via a stack into the atmosphere.

Approximately 15 to 20 percent of NOx emission reductions can be achieved by utilizing blower air staging to lower the flue gas temperature in the furnace. To effectively achieve the largest reduction of NOx emissions, however, SCR technology is best suited for treating the flue gas of sodium silicate furnaces.

In addition, UltraCat, an alternate to SCR technology, is also available for multi-pollutant control. For a full description of these control technologies, see the NOx Control Technologies section.

Metal Heat Treating Furnaces

A metal heat treating furnace burns liquid or gaseous fuel to generate enough pre-heated air at a temperature high enough to melt solid metal and into a liquid molten consistency and to maintain the metal in a liquid state until it is ready for later use. The types of furnaces that are used for metal heat treating are reverberatory, cupola, induction, direct arc furnaces, sweat furnaces, and refining kettles. The burner flame and combustion products come in direct contact with the metal.

Heat treating operations are directly related to the metal producing and secondary metal processing industries. Materials handled by the heat treating industry are a variety of products provided by manufacturers that are used by other manufacturers, to make consumable or usable products. Typical materials used for heat treating are iron, steel, ferro-alloys, glass, and other nonferrous metals. Heat treatment furnaces are used for activities that include forging, hardening, tempering, annealing, normalizing, sintering, and case hardening of steels and solution and heat treatment of corrosion resistant and aluminum metals. Kilns are not considered heat treating furnaces. Among the top NOx emitting facilities in the NOx RECLAIM program, there is only one facility that processes steel in two metal heat treating furnaces with individual heat ratings above 150 mm BTU/hr.

As with all combustion sources, the type of burner used can affect the emissions. Some burners are lower NOx emitting than others. But for these types of furnaces, there are often dozens of burners that cumulatively require a high heat input. To achieve higher efficiency and to consume less fuel, recuperative and regenerative burners are used. These burners employ the principle of using preheated inlet air which is heated by the exhaust gases for more efficient combustion. However, to effectively achieve a substantial NOx reduction from these metal heat treating furnaces, SCR is the technology that is best suited for the flue gas treatment of NOx. For a full description of these control technologies, see the NOx Control Technologies section.

The ~~Draft~~ Final PEA will evaluate the possibility that the operator of the metal heat treating furnaces may rely on SCR technology to further control NOx emissions in order to comply with the BARCT requirements for the metal heat treating furnace portion of the proposed project. For a full description of this control technology, see the NOx Control Technologies section.

Gas Turbines (Non-Refinery/Non-Power Plant)

Stationary gas turbines are used primarily to drive compressors or to generate power. Gas turbines operate either in simple cycle or combined cycle. Simple cycle units use the mechanical energy of shaft work that is transferred to and used by a gas compressor, for example, or to run an electrical generator to produce electricity. A combined cycle unit adds an additional element of heat recovery from its exhaust gases to produce more power by way of a steam generator. Combined cycle units are more efficient due to their use of two work cycles from the same shaft operation. Gas turbines can operate on both gaseous and liquid fuels. Gaseous fuels include natural gas, process gas, and refinery gas. Liquid fuels typically include diesel. The units in this category are not power plant turbines (turbines that produce solely electric utility power). Some of these units are cogenerating units that, in addition to producing in-house power, also recover the useful energy from heat recovery for producing process steam.

Among the top non-power plant NOx emitting facilities in the RECLAIM universe, there are twenty gas turbines that are either major or large source units. Four of these units are currently utilizing some level of NOx control along with SCR. Six of these units are operated on an offshore oil drilling platform (outer continental shelf, or OCS). The OCS turbines, which are fired on diesel or process gas, have the highest NOx emission concentrations in this source category. Four of the OCS units with lower NOx parts per million (ppm) concentrations currently are equipped with SCR systems.

For the purpose of the analysis in this PEA, controlling NOx emissions from non-refinery/non power plant gas turbines is assumed to be accomplished with SCR technology. For a full description of this control technology, see the NOx Control Technologies section.

Internal Combustion Engines (Non-Refinery/Non-Power Plant)

Stationary Internal Combustion Engines (ICEs) are used primarily to drive pumps, compressors, or to generate power. There are generally two types of engines, spark-ignited (SI) or compression ignited (CI) engines. SI engines ignite the air/fuel mixture with a spark while CI engines use the heat of compression to ignite the fuel that is injected into the combustion chamber. Engines can run at either stoichiometrically rich burn or lean burn conditions, depending on the air to fuel ratio. Rich burn combustion corresponds to an air-to-fuel ratio that is fuel-rich while lean burn combustion corresponds to a fuel-lean air-to-fuel ratio. Small SI engines typically run as rich burn, but many larger units as well as CI engines operate under lean burn conditions. For lean burn engines, more air is inducted than is required for complete combustion and the resultant exhaust oxygen level is high (over five percent). Rich burn engines typically operate very close to stoichiometric conditions by drawing only the necessary air to combust the fuel. SI engines are typically fired on gaseous fuels such as natural gas, while CI engines are fired on liquid fuels such as diesel.

Among the top NOx emitting facilities in the RECLAIM universe, there are 31 engines that are either major or large source units. Currently, there are nine rich burn engines equipped non-selective catalytic reduction (NSCR). Of the remaining 22 engines, there are 16 SI lean burn engines units and six CI lean burn units. The CI lean burn units are all operated on an offshore oil drilling platform (outer continental shelf, or OCS). The engine sizes range from a little over 700 brake horsepower (bhp) to 5,500 bhp. Diesel-fueled CI engines have the highest NOx emission concentrations in this source category while two-stroke SI engines have higher NOx emissions than four-stroke SI engines since the higher efficiencies in two-stroke engines translate to a hotter combustion temperature that can create more NOx.

For the ICEs operating at the 238 remaining NOx RECLAIM faculties, the ICEs would also need to meet the BARCT levels on a programmatic basis. The ~~Draft~~ Final PEA will evaluate the possibility that the SCR technology may be relied up in order to comply with the stationary ICEs portion of the proposed project. For a full description of this control technology, see the NOx Control Technologies section.

NOx Control Technologies

As reducing NOx emissions is the main objective of the currently proposed amendments to the RECLAIM program, there are two primary approaches for reducing NOx emissions: 1) by combustion control techniques that minimize the amount of NOx formed by the combustion equipment; or, 2) by installing a device that controls the NOx after it has been generated or post-combustion. At the time the NOP/IS was released, the consultants hired to assess the BARCT control technology options had not yet provided their recommendations or finalized their reports. As such, the NOP/IS contained a comprehensive list of multiple types of potential BARCT control technology options. Subsequently, however, the consultants presented their findings and some of the BARCT control technology options presented in the NOP/IS are now no longer considered to be viable or cost-effective options for the proposed project. For the reader to see how the list of BARCT control technology options changed since the release of the NOP/IS, Table 2-3 summarizes the potential control technologies that were initially considered in the NOP/IS as potential candidates for the BARCT analysis and shows the actual control technologies that are being considered for the BARCT analysis in this PEA. The following discussions will elaborate on the various technologies listed in Table 2-3 for consideration in this PEA.

Table 2-3

BARCT Control Technology Options for Top NOx Emitting Equipment/Processes

Equipment/Process	BARCT Control Technology Options Identified in NOP/IS	BARCT Control Technology To Be Analyzed in PEA
FCCUs	1. SCR 2. LoTOx™ with scrubber 3. NOx reducing additives	1. SCR 2. LoTOx™ with WGS
Refinery Process Heaters and Boilers	1. SCR 2. LoTOx™ with scrubber 3. KnowNOx™ with scrubber 4. Great Southern Flameless Heaters 5. ClearSign 6. Cheng Low NOx	SCR
Refinery Gas Turbines	1. SCR 2. Ammonia Slip Catalyst (ASC) 3. CO Catalyst 4. Dry Low Emissions (DLE or DLN) 5. Cheng Low NOx	SCR
SRU/TGUs	1. SCR 2. LoTOx™ with scrubber 3. KnowNOx™ with scrubber	1. LoTOx™ with WGS 2. SCR
Petroleum Coke Calciner	1. LoTOx™ with scrubber 2. UltraCat with scrubber	1. LoTOx™ with scrubber 2. UltraCat with scrubber
Portland Cement Kilns	1. SCR with or without scrubber 2. UltraCat 3. SNCR	None[4]
Container Glass Melting Furnaces	1. SCR 2. UltraCat	1. SCR 2. UltraCat DGS
Sodium Silicate Furnaces	1. SCR 2. UltraCat	1. SCR 2. UltraCat DGS (without sorbent)
Metal Heat Treating Furnaces	SCR	SCR
ICEs (Non-Refinery/Non-Power Plant)	1. SCR 2. NSCR	SCR

[4] Because of CPCC's current permitting status for their Portland cement kilns (e.g., the permits were surrendered), CPCC operators will not be able to retrofit the Portland cement kilns with air pollution control equipment in response to the proposed project without first dealing with the permitting issues for the cement kilns. Thus, the installation of control technology and the secondary adverse environmental impacts that may be associated with such control technology is not a reasonably foreseeable consequence for CPCC under the present circumstances. Further, there are no other facilities in SCAQMD's jurisdiction that operate Portland cement kilns. Thus, this PEA does not contain an environmental analysis of the control technologies that were originally contemplated in the NOP/IS for the CPCC facility.

Table 2-3 (concluded)
BARCT Control Technology Options for Top NOx Emitting Equipment/Processes

Non-Refinery/Non-Power Plant Gas Turbines	1. SCR 2. Flue Gas Recirculation 3. Staged Combustion/Low NOx Burners 4. Water/Steam Injection 5. Dry Low Emissions (DLE or DLN)	SCR

<u>Selective Catalytic Reduction</u>
Selective Catalytic Reduction (SCR) is post-combustion control equipment that is considered to be BARCT, if cost-effective and feasible, for NOx control of existing combustion sources such as boilers, process heaters, and FCCUs as it is capable of reducing NOx emissions by as much as 95 percent or higher. A typical SCR system design consists of an ammonia storage tank, ammonia vaporization and injection equipment, a booster fan for the flue gas exhaust, an SCR reactor with catalyst, an exhaust stack plus ancillary electronic instrumentation and operations control equipment. The way an SCR system reduces NOx is by a matrix of nozzles injecting a mixture of ammonia and air directly into the flue gas exhaust stream from the combustion equipment. As this mixture flows into the SCR reactor that is replete with catalyst, the catalyst, ammonia, and oxygen (from the air) in the flue gas exhaust reacts primarily (i.e., selectively) with NO and NO_2 to form nitrogen and water in the presence of a catalyst. The amount of ammonia introduced into the SCR system is approximately a one-to-one molar ratio of ammonia to NOx for optimum control efficiency, though the ratio may vary based on equipment-specific NOx reduction requirements. There are two main types of catalysts: one in which the catalyst is coated onto a metal structure and a ceramic-based catalyst onto which the catalyst components are calcified. Commercial catalysts used in SCRs are available in two types of solid, block configurations or modules, plate or honeycomb type, and are comprised of a base material of titanium dioxide (TiO_2) that is coated with either tungsten trioxide (WO_3), molybdic anhydride (MoO_3), vanadium pentoxide (V_2O_5), iron oxide (Fe_2O_3), or zeolite catalysts. These catalysts are used for SCRs because of their high activity, insensitivity to sulfur in the exhaust, and useful life span of approximately five years or more. Ultimately, the material composition of the catalyst is dependent upon the application and flue gas conditions such as gas composition, temperature, et cetera.

For conventional SCRs, the minimum temperature for NOx reduction is 500 ^oF and the maximum operating temperature for the catalyst is 800 ^oF. Depending on the application, the type of fuel combusted, and the presence of sulfur compounds in the exhaust gas, the optimum flue gas temperature of an SCR system is case-by-case and will range between 550 ^oF and 750 ^oF to limit the occurrence of several undesirable side reactions at certain conditions. One of the major concerns with the SCR process is the poisoning of the catalyst due to the presence of sulfur and the oxidation of sulfur dioxide (SO_2) in the exhaust gas to sulfur trioxide (SO_3) and the subsequent reaction between SO_3 and ammonia to form ammonium bisulfate or ammonium sulfate. The formation of either ammonium bisulfate or ammonium sulfate depends on the amount of SO_3 and ammonia present in the flue gas and can cause equipment plugging downstream of the catalyst. The presence of particulates, heavy metals and silica in the flue gas exhaust can also limit catalyst performance.

However, minimizing the quantity of injected ammonia and maintaining the ammonia temperature within a predetermined range will help avoid these undesirable reactions while minimizing the production of unreacted ammonia which is commonly referred to as 'ammonia slip.' Depending on the type of combustion equipment utilizing SCR technology, the typical amount of ammonia slip can vary between less than five ppmv when the catalyst is fresh and 20 ppmv at the end of the catalyst life.

In addition to the conventional SCR catalysts, there are high temperature SCR catalysts that can withstand temperatures up to 1200 ^{o}F and low temperature SCR catalysts that can operate below 500 ^{o}F.

Further, SCR manufacturers have developed Ammonia Slip Catalyst (ASC) which is a layer of catalyst that is installed downstream of the SCR catalyst to enhance the selective reduction of NO to N2 and supporting the oxidation of CO to CO2 while suppressing the oxidation of NH3 to NOx. Early generation of ASCs were based on precious metal which is highly active for NH_3 oxidation. The use of ASCs allow for operations at higher NH_3/NOx ratios to ensure complete NOx conversion while maintaining low ammonia slip.

Similar to ASC, CO catalyst is used in conjunction with the SCR catalyst to concurrently reduce NOx to N2 and oxidize CO and hydrocarbon to CO2 and water. CO catalyst is typically made of platinum, palladium or rhodium, and is capable of removing approximately 90 percent of CO and 85 percent to 90 percent of hydrocarbon or hazardous air pollutants from an exhaust stream.

<u>Wet Gas Scrubbers (WGSs)</u>
WGS technology is a multi-pollutant control system that primarily controls SOx and PM emissions but can be installed to function with NOx control equipment. WGSs can be used to control emissions from FCCUs, refinery process heaters and boilers, SRU/TGUs, petroleum coke calciners, and cement kilns. There are two types of wet gas scrubbers: 1) caustic-based non-regenerative WGS; and, 2) regenerative WGS.

In non-regenerative wet gas scrubbing, caustic soda (sodium hydroxide - NaOH) or other alkaline reagents, such as soda ash, are used as an alkaline absorbing reagent (absorbent) to capture SO_2 emissions. The absorbent captures SO_2 and sulfuric acid mist (H_2SO4) and converts it to various types of sulfites and sulfates (e.g., $NaHSO_3$, Na_2SO_3, and Na_2SO_4). The absorbed sulfites and sulfates are later separated by a purge treatment system and the treated water, free of suspended solids, is either discharged or recycled.

One example of the caustic-based non-regenerative scrubbing system is the proprietary Electro Dynamic Venturi (EDV) scrubbing system offered by BELCO Technologies Corporation (see Figure 2-7). An EDV scrubbing system consists of three main modules: 1) a spray tower module; 2) a filtering module; and, 3) a droplet separator module. The flue gas enters the spray tower module, which is an open tower with multiple layers of spray nozzles. The nozzles supply a high density stream of caustic/water solution that is directed in a countercurrent flow to the gas flow and encircles, encompasses, wets, and saturates the flue gas. Multiple stages of liquid/gas absorption occur in the spray tower module and SO_2 and acid mist are captured and converted to sulfites and sulfates. Large particles in the flue gas are also removed by impaction with the water droplets.

The flue gas saturated with heavy water droplets continues to move up the wet scrubber to the filtering module where the flue gas reaches super-saturation. At this point, water continues to condense and the fine particles in the gas stream begin to cluster together, to form larger and heavier groups of particles. Next, the flue gas, super-saturated with heavy water droplets, enters the droplet separator module causing the water droplets to impinge on the walls of parallel spin vanes and drain to the bottom of the scrubber.

The spent caustic/water solution purged from the WGS is later processed in a purge treatment unit. The purge treatment unit contains a clarifier that removes suspended solids for disposal. The effluent from the clarifier is oxidized with agitated air to help convert sulfites to sulfates and also reduce the chemical oxygen demand (COD) so that the effluent can be safely discharged to a wastewater system.

A regenerative WGS removes SO_2 from the flue gas by using a buffer solution that can be regenerated. The buffer is then sent to a regenerative plant where the SO_2 is extracted as concentrated SO_2. The concentrated SO_2 is then sent to a sulfur recovery unit (SRU) to recover the liquid SO_2, sulfuric acid and elemental sulfur as a by-product. When the inlet SO_2 concentrations are high, a substantial amount of sulfur-based by-products can be recovered and later sold as a commodity for use in the fertilizer, chemical, pulp and paper industries. For this reason, the use of a regenerative WGS is favored over a non-regenerative WGS.

One example of a regenerative scrubber is the proprietary LABSORB offered by BELCO Technologies Corporation [5, 6]. The LABSORB scrubbing process uses a patented non-organic aqueous solution of sodium phosphate salts as a buffer. This buffer is made from two common available products, caustic and phosphoric acid. The LABSORB system consists of: 1) a quench pre-scrubber; 2) an absorber; and, 3) a regeneration section which typically includes a stripper and a heat exchanger.

In the scrubbing side of the regenerative scrubbing system, the quench pre-scrubber is used to wash out any large particles that are carried over, plus any acid components in the flue gas such as hydrofluoric acid (HF), hydrochloric acid (HCl), and SO_3. The absorption of SO_2 is carried out in the absorber. The absorber typically consists of one single, high-efficiency packed bed scrubber filled with high-efficiency structural packing material. However, if the inlet SO_2 concentration is low, a multiple-staged packed bed scrubber, or a spray-and-plate tower scrubber, may be used instead to achieve an ultra-low outlet SO_2 concentration.

The third step in the regenerative wet gas scrubbing system is the regenerative section in which the SO_2-rich buffer stream is steam heated to evaporate the water from the buffer. The buffer stream is then sent to a stripper/condenser unit to separate the SO_2 from the buffer. The buffer free of SO_2 is returned to the buffer mixing tank while the condensed-SO_2 gas stream is sent back to the SRU for further treatment.

Singhania of Singhania Technical Services Pvt., India, Presented at PETROTECH 6th International Petroleum Conference in India, January 2005.

LoTOx™ Application with Wet Gas Scrubber

The LoTOx™ is a registered trademark of Linde LLC (previously BOC Gases) and was later licensed to BELCO of Dupont for refinery applications. LoTOx™ stands for "Low Temperature Oxidation" process in which ozone (O_3) is used to oxidize insoluble NOx compounds into soluble NOx compounds which can then be removed by absorption in a caustic, lime or limestone solution. The LoTOx™ process is a low temperature application, optimally operating at about 325 ºF.

A typical combustion process produces about 95 percent NO and five percent NO_2. Because both NO and NO_2 are relatively insoluble in an aqueous solution, a WGS alone is not efficient in removing these insoluble compounds from the flue gas stream. However, with a LoTOx™ system and the introduction of O_3, NO and NO_2 can be easily oxidized into a highly soluble compound N_2O_5 (see Reactions 5 and 6) and subsequently converted to nitric acid (HNO_3) (see Reaction 7). Then, in a wet gas scrubber for example, the HNO_3 is rapidly absorbed in caustic (NaOH) (see Reaction 8), limestone or lime solution (see Reactions 9 and 10). In addition, because the rates of oxidizing reactions for NOx (see Reactions 5 and 6) are fast compared to the very slow SO_2 oxidation reaction (see Reaction 11), no ammonium bisulfate ($(NH_4)HSO_4$) or sulfur trioxide (SO_3) is formed.

$NO + O_3 \rightarrow NO_2 + O_2$	(Reaction 5 - Fast)
$2\ NO_2 + O_3 \rightarrow N_2O_5 + O_2$	(Reaction 6 – Fast)
$N_2O_5 + H_2O \rightarrow 2\ HNO_3$	(Reaction 7)
$HNO_3 + NaOH \rightarrow NaNO_3 + H_2O$	(Reaction 8)
$2HNO3 + CaCO3 \rightarrow Ca(NO_3)_2 + H_2O + CO_2$	(Reaction 9)
$2HNO3 + Ca(OH) \rightarrow Ca(NO_3)_2 + 2H_2O$	(Reaction 10)
$SO_2 + O_3 \rightarrow SO_3 + O_2$	(Reaction 11 - Very slow)

The LoTOx™ process requires a source of oxygen and generates O_3 on site. Typically oxygen (O_2) is stored as a liquid in vacuum-jacketed vessels or is delivered by pipeline. O_3 is an unstable gas and it is typically generated on demand from the O_2 supply using an O_3 generator. An O_3 generator is shaped similar to a shell and tube heat exchanger and uses a corona discharge to dissociate the O_2 molecules into individual atoms so that the individual oxygen atoms combine with each other to form O_3. The LoTOx™ process contains an ozone injection manifold designed to achieve uniform distribution and complete mixing. A ratio of 1.75 parts NOx to 2.5 parts O_3 is needed in order to achieve a NOx conversion and reduction of 90 percent to 95 percent. Since sulfur dioxide (SO_2) is an ozone scavenger because it readily bonds with O_3 to form sulfur trioxide (SO_3), the LoTOx™ process typically has a very low O_3 slip (excess O_3) that ranges from zero ppmv to three ppmv. Figure 2-6 shows a schematic of the O_3 generation process.

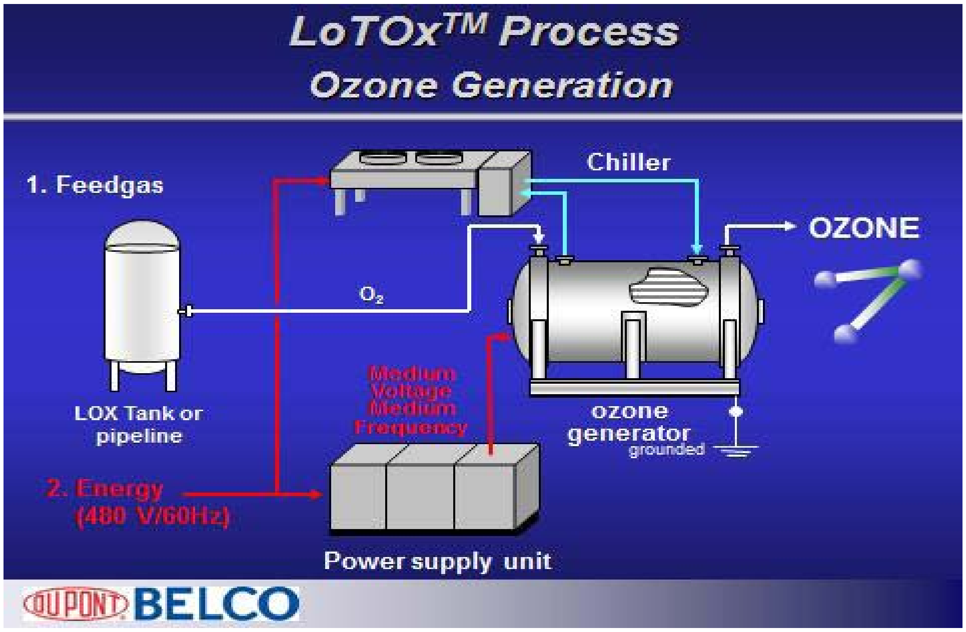

Figure 2-6: Ozone Generation Process

The LoTOx™ process can be integrated with any type of wet scrubbers (e.g., venturi, packed beds), semi-dry scrubbers, or wet electrostatic precipitators (ESPs). For example, Linde has engineered more than 24 LoTOx™ applications for EDV™ scrubbers engineered by BELCO since 2007 for refinery FCCU applications. A LoTOx™ system with an EDV™ scrubber is shown in Figure 2-7.

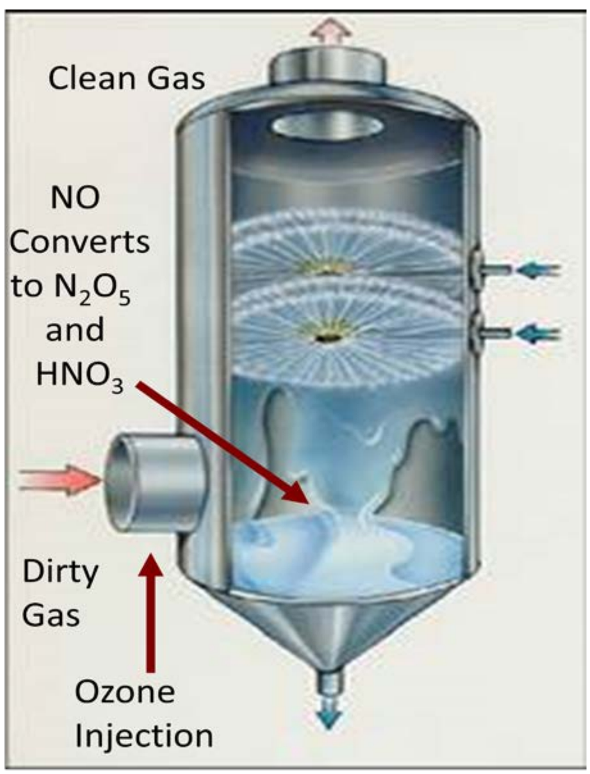

Figure 2-7: EDV Scrubber with LoTOx™ Application

In addition, MECS, BELCO's sister company, has engineered more than two dozen DynaWave scrubbers with LoTOx^{TM} systems specifically designed for refinery SRU/TGUs. Figure 2-8 shows a schematic for a DynaWave scrubber with a LoTOx^{TM} application.

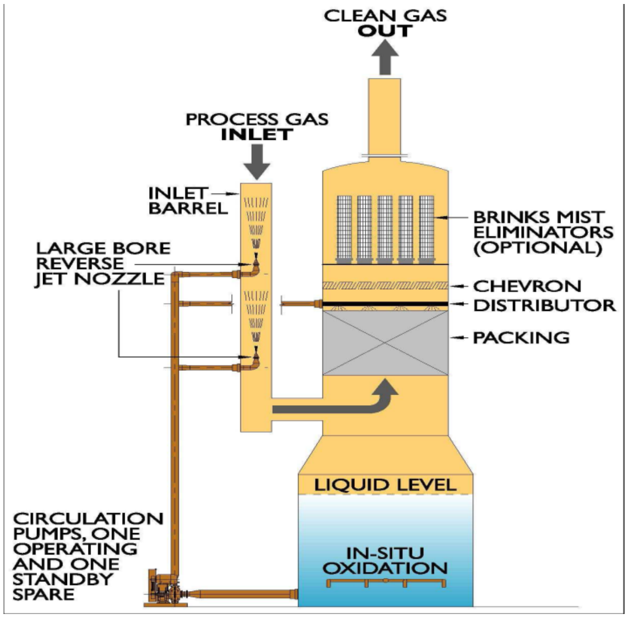

Figure 2-8: DynaWave Scrubber with LoTOx^{TM} Application

When compared to SCR technology, the LoTOx^{TM} application has several advantages, as follows:

- Unlike SCR which operates at high temperatures, LoTOx^{TM} is a low temperature operating system that does not require additional heat input to maintain operational efficiency and enable maximum heat recovery of high temperature combustion gases.
- Unlike SCR which is primarily designed to reduce only NOx, LoTOx^{TM} can be integrally connected to a scrubber (e.g., wet or semi-dry scrubber, or wet electrostatic ESP) and become a multi-component air pollution control system capable of reducing NOx, SOx and PM in one system.
- There is no formation of ammonia slip, SO_3, or $(NH_4)HSO_4$ with the LoTOx^{TM} process.

<u>UltraCat</u>

UltraCat is a commercially available multi-pollutant control technology designed to remove NOx and other pollutants such as SO_2, PM, HCl, Dioxins, and HAPs such as mercury in low temperature applications. UltraCat technology is comprised of filter tubes which are made of fibrous ceramic materials embedded with proprietary catalysts. The optimal operating temperature range of an UltraCat system is approximately 350 ^oF to 750 ^oF. In order to achieve a NOx removal efficiency of approximately 95 percent, aqueous ammonia is injected upstream of the UltraCat filters. In addition, to remove SO_2, HCl, and other acid gases with a removal efficiency ranging from 90 percent to 98 percent, dry sorbent such as hydrated lime, sodium bicarbonate or trona is also injected upstream of the UltraCat filters. UltraCat is also capable of controlling particulates to a level of 0.001 grains per standard cubic foot of dry gas (dscf).

The UltraCat filters are arranged in a baghouse configuration with a low pressure drop such as five inches water column (inH20) across the system. The UltraCat system is equipped with a reverse pulse-jet cleaning action that back flushes the filters with air and inert gas to dislodge the PM deposited on the outside of the filter tubes. Depending on the loading, catalytic filter tubes need to be replaced every five to 10 years. The UltraCat system is shown in Figure 2-9.

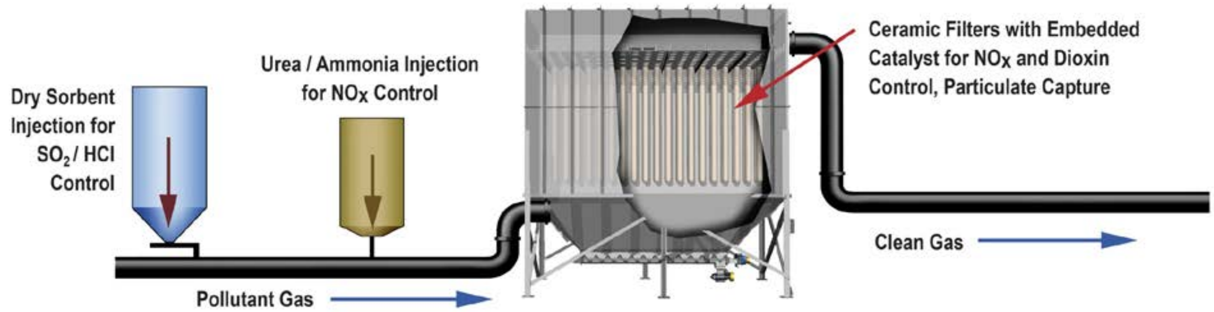

Figure 2-9: UltraCat System

CHAPTER 3

EXISTING SETTING

Introduction

Aesthetics

Air Quality and Greenhouse Gases

Energy

Hazards and Hazardous Materials

Hydrology and Water Quality

Solid and Hazardous Waste

Transportation and Traffic

3.0 INTRODUCTION

In order to determine the significance of the impacts associated with a proposed project, it is necessary to evaluate the project's impacts against the backdrop of the environment as it exists at the time the NOP/IS is published. CEQA Guidelines §15360 defines "environment" as "the physical conditions that exist within the area which will be affected by a proposed project including land, air, water, minerals, flora, fauna, ambient noise, and objects of historical or aesthetic significance" (see also Public Resources Code §21060.5). According to CEQA Guidelines §15125 (a), a CEQA document must include a description of the physical environmental conditions in the vicinity of the project, as they exist at the time the NOP is published from both a local and regional perspective. This environmental setting will normally constitute the baseline physical conditions by which a lead agency determines whether an impact is significant. The description of the environmental setting shall be no longer than is necessary to provide an understanding of the significant effects of the proposed project and its alternatives.

Since this CEQA document is programmatic in nature (e.g., PEA) that covers the SCAQMD's entire jurisdiction, the existing setting for each category of impact is described on a regional level. The following subchapters describe the existing environmental setting for those environmental areas identified in the NOP/IS (see Appendix E) that may be adversely affected by the proposed project. These areas include the following topics: aesthetics; air quality and GHGs; energy; hazards and hazardous materials; hydrology and water quality; solid and hazardous waste; and, transportation and traffic.

SUBCHAPTER 3.1

AESTHETICS

Regulatory Setting

Environmental Setting

3.1 AESTHETICS

This subchapter contains an overview of existing aesthetic resources, including scenic highways and coastal zones within the District.

3.1.1 Regulatory Setting

3.1.1.1 Federal

Aesthetic resources on federal lands are managed by the federal government using various visual resource management programs, depending on the type of federal land and/or the federal agency involved with a given project. Examples of federal visual resource management programs include the Visual Resource Management System utilized by the Federal Bureau of Land Management (BLM) and the Visual Management System utilized by the United States Forest Service (USFS).

3.1.1.2 State

California Coastal Act

The California Coastal Act of 1976 was enacted to regulate development projects within California's Coastal Zone. The act includes requirements that protect views and aesthetic resources through siting and design control measures, which are typically implemented at the local planning level through local coastal programs (LCPs) or land use plans (LUPs). According to the California Coastal Act:

> *The scenic and visual qualities of coastal areas shall be considered and protected as a resource of public importance. Permitted development shall be sited and designed to protect views to and along the ocean and scenic coastal areas, to minimize the alteration of natural land forms, to be visually compatible with the character of surrounding areas, and, where feasible, to restore and enhance visual quality in visually degraded areas. New development in highly scenic areas such as those designated in the California Coastline Preservation and Recreation Plan prepared by the Department of Parks and Recreation and by local government shall be subordinate to the character of its setting (Public Resources Code. California Coastal Act [Chapter 3 (Coastal Resources Planning and Management Policies) Article 6, §30251]).*

For local jurisdictions that do not have an approved LCP, regulation of development projects within the coastal zone remains under the jurisdiction of the California Coastal Commission (CCC).

State Scenic Highway Program

California's Scenic Highway Program was created by the California Legislature in 1963 to preserve and protect scenic highway corridors from change that would diminish the aesthetic value of land adjacent to those highways. When a city or county nominates an eligible scenic highway for official designation, it must adopt ordinances to preserve the scenic quality of the corridor or document such regulations that already exist in various portions of local codes. These ordinances make up the scenic corridor protection program.

Scenic corridor protection programs include policies intended to preserve the scenic qualities of the highway corridor, including regulation of land use and density of development, detailed land and site planning, control of outdoor advertising (including a ban on billboards), careful attention to and control of earthmoving and landscaping, and careful attention to design and appearance of structures and equipment (California Streets and Highways Code §260 et seq.).

3.1.1.3 Local

<u>Counties and Cities</u>

The geographic area encompassed by the District includes numerous cities and unincorporated communities in the counties of Los Angeles, Orange, San Bernardino, and Riverside. Each of these counties and incorporated cities has prepared a general plan, which is the primary document that establishes local land use policies and goals. Many of these general plans also establish local policies related to aesthetics and the preservation of scenic resources within their communities or subplanning areas, and may include local scenic highway programs.

<u>Local Coastal Programs</u>

The CCC and the local governments along the coast share responsibility for managing the state's coastal resources. Through coordination with the CCC, coastal cities and counties develop LCPs. These programs are the primary means for carrying out the policies of the California Coastal Act at the local level. In general, these policies are intended to promote public access and enhance recreational use of the coast as well as protection of natural resources in the coastal zone. Examples of counties, cities and local jurisdictions within the District that do have an approved LCP or LUP include Los Angeles County and the County of Orange and the cities of Santa Monica, El Segundo, Manhattan Beach, Hermosa Beach, Redondo Beach, Palos Verdes Estates, Rancho Palos Verdes, Long Beach, Avalon, Huntington Beach, Newport Beach, Irvine, Laguna Beach, Laguna Niguel, Dana Point, and San Clemente.

Following approval by the CCC, an LCP is certified and the local governments implement the programs. LCPs include two main components, a Land Use Plan and an Implementation Plan. These components may include policies or regulations that apply to preservation of visual and scenic resources within the coastal zone. Typically, these policies relate to preservation of views of the coast.

3.1.2 Environmental Setting

This environmental setting subchapter describes the aesthetics resources settings that may be adversely affected by the proposed project. Specifically, this environmental setting subchapter describes visual character and quality, visual resources, scenic highways, and coastal zones within the District.

3.1.2.1 Visual Character and Quality

Visual character and quality are defined by the built and natural environment. The ***visual character*** of a view is descriptive cataloguing of underlying landforms and landcover including the topography, general land use patterns, scale, form, and the presence of natural areas. Urban features, such as structures, roads, utility lines, and other development associated with human activities also help to define visual character. ***Visual quality*** is an evaluative appraisal of the aesthetics of a view and is established using a well-established approach to visual analysis adopted from the Federal Highway Administration (FHWA) based upon the relative degree of vividness, intactness, and unity found within the visual setting, as defined in the following bullet points (FHWA, 1981).

- Vividness is the visual power or memorability of landscape components as they combine in striking and distinctive patterns.
- Intactness is the visual integrity of the landscape and its freedom from encroaching elements; this factor can be present in well-kept urban and rural landscapes, as well as in natural settings.
- Unity is the degree to which the visual resources of the landscape join together to form a coherent, harmonious visual pattern. Unity refers to the compositional harmony or inter-compatibility between landscape elements.

Each of the three criteria is independent and intended to evaluate one aspect of visual quality; however, no one criterion considered alone equates to visual quality.

The perception of visual quality can vary significantly among viewers depending on their level of visual sensitivity (interest). Sensitive viewers' perceptions can vary seasonally and even hourly as weather, light, shadow, and the elements that compose the viewshed change. Form, line, color, and texture are the basic components used to describe visual character and quality for most visual assessments (FHWA, 1981). Sensitivity depends upon the length of time the viewer has access to a particular view. Typically, residential viewers have extended viewing periods and are often concerned about changes in views from their homes. Visual sensitivity is, therefore, considered to be high for neighborhood residential areas. Visual sensitivity is considered to be less important for commuters and other people driving along surrounding streets. Views from vehicles are generally more fleeting and temporary, yet under certain circumstances are sometimes considered important (e.g., viewers who are driving for pleasure, views/vistas from scenic corridors).

As discussed in the Subchapter 3.1 - Aesthetics, of the Final Program Environmental Impact Report (PEIR) prepared for the Southern California Association of Governments (SCAG) 2012-2035 Regional Transportation Plan/Sustainable Communities Strategy (RTP/SCS)[1], various jurisdictions within the SCAG region, which includes the jurisdiction of SCAQMD such as cities, counties, and federal or regional agencies, provide guidelines regarding the

[1] SCAG, Final PEIR for the 2012-2035 RTP/SCS, SCH# 2011051018; April 4, 2012. http://rtpscs.scag.ca.gov/Pages/Final-2012-PEIR.aspx

preservation and enhancement of visual quality in their plans or regulations[2]. An example of such guidance can be found in Caltrans Scenic Highway Guidelines which contains examples of visual intrusions[3], which are presented in Table 3.1-1. As the table illustrates, a given visual element may be considered desirable or undesirable, depending on design, location, use, and other considerations. Because of the size and diversity of the area within the SCAQMD's jurisdiction, it is not possible to apply uniform standards to all areas within the District.

TABLE 3.1-1

Caltrans Scenic Highway Guidelines – Examples of Visual Intrusions

Minor Intrusion	Moderate Intrusion	Major Intrusion
Buildings: *Residential, Commercial, and Industrial Developments*		
Widely dispersed buildings. Natural landscape dominates. Wide setbacks and buildings screened from roadway. Forms, exterior colors and materials are compatible with landscape. Buildings have cultural or historical significance.	Increased numbers of buildings, not well integrated into the landscape. Smaller setbacks and lack of roadway screening. Buildings do not dominate the landscape or obstruct scenic view.	Dense and continuous development. Highly reflective surfaces. Buildings poorly maintained. Visible blight. Development along ridgelines. Buildings dominate the landscape or obstruct scenic view.
Unsightly Land Uses: *Dumps, Quarries, Concrete Plants, Tank Farms, Auto Dismantling*		
Screened from view so that most of facility is not visible from the highway.	Not screened and visible but programmed/funded for removal and site restoration. Land use is visible but does not dominate the landscape or obstruct scenic view.	Not screened and visible by motorists. Will not be removed or modified. Land use dominates the landscape or obstructs scenic view.
Commercial Retail Development		
N/A	Neat and well landscaped. Single story. Generally blends with surroundings. Development is visible but does not dominate the landscape or obstruct scenic view.	Not harmonious with surroundings. Poorly maintained or vacant. Blighted. Development dominates the landscape or obstructs scenic view.

[2] California cities and counties are not required to include visual quality elements in their General Plans although many do. However, the General Plans are required to include a Conservation Element, which includes resources such as waterways and forests that frequently are also scenic resources.

[3] Caltrans, Scenic Highway Guidelines - Appendix E, October 2008; (Caltrans, 2008). http://www.dot.ca.gov/hq/LandArch/scenic/guidelines/scenic_hwy_guidelines_04-12-2012.pdf

TABLE 3.1-1 (Continued)
Caltrans Scenic Highway Guidelines – Examples of Visual Intrusions

Minor Intrusion	Moderate Intrusion	Major Intrusion
	Parking Lots	
Screened from view so that most of the vehicles and pavement are not visible from the highway.	Neat and well landscaped. Generally blends with surroundings. Pavement and/or vehicles visible but do not dominate the landscape or degrade scenic view.	Not screened or landscaped. Pavement and/or vehicles dominate the landscape or degrade scenic view.
	Off-Site Advertising Structures	
N/A	N/A	Billboards degrade or obstruct scenic view.
	Noise Barriers	
N/A	Noise barriers are well landscaped and complement the natural landscape. Noise barriers do not degrade or obstruct scenic view.	Noise barriers degrade or obstruct scenic view.
	Power Lines and Communication Facilities	
Not easily visible from road.	Visible, but do not dominate scenic view.	Towers, poles or lines dominate view. Scenic view is degraded.
	Agriculture: *Structures, Equipment, Crops*	
Generally blends in with scenic view. Is indicative of regional culture.	Not compatible with the natural landscape. Scale and appearance of structures and equipment visually competes with natural landscape.	Scale and appearance of structures and equipment are incompatible with and dominates natural landscape. Structures, equipment or crops degrade or obstruct scenic view.
	Exotic Vegetation	
Used as screening and landscaping. Generally is compatible with scenic view.	Competes with native vegetation for visual dominance.	Incompatible with and dominates natural landscape. Scenic view is degraded.
	Clearcutting	
N/A	Clearcutting or deforestation is evident, but is in the distant background.	Clearcutting or deforestation is evident. Scenic view is degraded.
	Erosion	
Minor soil erosion (i.e., rill erosion).	Rill erosion starting to form gullies.	Large slip outs and/or gullies with little or no vegetation. Scenic view is degraded.

TABLE 3.1-1 (Concluded)
Caltrans Scenic Highway Guidelines – Examples of Visual Intrusions

Minor Intrusion	Moderate Intrusion	Major Intrusion
Grading		
Grading generally blends with adjacent landforms and topography.	Some changes, less engineered appearance and restoration are taking place.	Extensive cut and fill. Unnatural appearance, scarred hillsides or steep slopes with little or no vegetation. Canyons filled in. Scenic view is degraded.
Road Design		
Blends in and complements scenic view. Roadway structures are suitable for location and compatible with landscape.	Large cut and fill slopes are visible. Scale and appearance of roadway, structures, and appurtenances are incompatible with landscape.	N/A

Source: Caltrans, 2008

The *viewshed* can be defined as all of the surface area visible from a particular location or sequence of locations, and is described in terms of the dominance of landforms, landcover, and manmade development constituting visual character. Views of high visual quality in urban settings generally have several of the following additional characteristics:

- Harmony in scale with the surroundings;
- Context sensitive architectural design; and,
- Impressive landscape design features.

Areas of medium visual quality have interesting forms but lack unique architectural design elements or landscape features. Areas of low visual quality have uninteresting features and/or undistinguished architectural design and /or other common elements.

3.1.2.2 Visual Resources

Visual resources include historic buildings that uniquely identify a setting, views identified as significant in local plans, and/or views from scenic highways. The importance of a view to viewers is related to the position of the viewers relative to the resource and the distinctiveness of a particular view. The visibility and visual dominance of landscape elements are usually described with respect to their placement in the viewshed.

Visual resources occur in a diverse array of environments within the boundaries of the District, ranging in character from urban centers to rural agricultural land, natural woodlands, and coastal views. The extraordinary range of visual features in the region is afforded by the mixture of climate, topography, flora, and fauna found in the natural environment, and the diversity of style, composition, and distribution of the built environment. Views of the coast from locations in Los Angeles and Orange counties are considered valuable visual resources, while views of various mountain ranges are prevalent throughout the District. Other natural features that may be visually significant in the District include rivers, streams, creeks, lakes, and reservoirs.

The Los Angeles County Draft 2014 General Plan 2035[4] identifies regional open space and recognized scenic areas, generally including the Santa Monica Mountains, as well as the San Gabriel Mountains, Verdugo Hills, Santa Susana Mountains, Simi Hills, Santa Monica Mountains, and Puente Hills. In addition, ridgelines and hillsides are generally considered to be scenic resources, with specific measures for the protection of these areas (LA County, 2014).

The Orange County General Plan[5] identifies the Santa Ana Mountains along with their distinctive twin peaks known as "Saddleback" as the county's signature landmark. The Plan designates 10 scenic "viewscape corridors," which include among others Pacific Coast Highway, Oso Parkway, Ortega Highway, Jamboree Road, Santiago Canyon Road, and Laguna Canyon Road. These designated viewscape corridors provide scenic views of the Santa Ana Mountains, Lomas de Santiago and the San Joaquin Hills, as well as numerous canyons and valleys including the Santa Ana Canyon, Capistrano Valley, Laguna, Aliso, Wood, Moro, San Juan, Trabuco Santiago, Modjeska, Silverado, Limestone, and Black Star Canyons. Finally, the General Plan identifies nearly 42 miles of coastline and approximately 33 miles of sandy beaches as defining scenic resources (Orange County, 2011).

The Riverside County General Plan[6] identifies regional scenic resources, including Santa Ana River basin, Lake Mathews, Lake Perris, Lake Elsinore, Lake Skinner, Vail Lake, the San Jacinto River, Murrieta Creek, the Santa Margarita River, the vineyard/citrus region near Temecula, the Diamond Valley Reservoir, Joshua Tree National Park, Whitewater River, the Santa Rosa Mountains, and a portion of the Salton Sea (Riverside County, 2014).

The County of San Bernardino 2007 General Plan[7] identifies several scenic areas, including the San Gabriel Mountains, the San Bernardino Mountains, La Loma Hills, Jurupa Hills, Chino Hills, Yucaipa Hills, Holcomb Valley, and the Mojave Desert. In addition, Big Bear Lake, Silverwood Lake, Lake Arrowhead, and Lake Gregory, along with associated waterways, serve as defining characteristics of the mountain regions within the County. San Bernardino County has a wide variety of scenic and wilderness areas respectively categorized as the Mountain, Valley, and Desert regions. Each region has its own defined measures for protecting the specific resources contained in this region. The County of San Bernardino also considers desert night-sky views to be scenic resources and has enacted measures to reflect this (San Bernardino County, 2014).

---

In addition to County plans, many of the cities within the District have general plan policies, and in some cases, ordinances, related to the protection of visual resources. In addition to the visual resources related to natural areas, many features of the built environment that may also have visual significance include individual or groups of structures that are distinctive due to their aesthetic, historical, social, or cultural significance or characteristics, such as architecturally appealing buildings or groups of buildings, landscaped freeways, bridges or overpasses, and historic resources.

3.1.2.3 Scenic Highways

Within the District, there are numerous officially designated state and county scenic highways and one historic parkway, as listed in Table 3.1-2.

There are also a number of roadways that have been determined eligible for state scenic highway designation, as listed in Table 3.1-3.

TABLE 3.1-2
Scenic Highways Within District Borders

Route	County	Location	Description	Miles	Designation
2	Los Angeles	From near La Cañada Flintridge north to the San Bernardino County line.	This U.S. Forest Service Scenic Byway and State Scenic Highway winds along the spine of the San Gabriel Mountains. It provides views of the mountain peaks, the Mojave Desert, and the Los Angeles Basin.	55	ODSSH[(a)]
38	San Bernardino	From east of South Fork Campground to State Lane.	This U.S. Forest Service Scenic Byway and State Scenic Highway crosses the San Bernardino Mountains at Onyx Summit. It features forested mountainsides with far-off desert vistas near the summit.	16	ODSSH
62	Riverside	From I-10 north to the San Bernardino County line.	This highway features high desert country scenery and leads to or from Joshua Tree National Monument. Large “windmill farms,” where wind power is used to generate electricity, can be seen along the way.	9	ODSSH

TABLE 3.1-2 (Continued)
Scenic Highways Within District Borders

Route	County	Location	Description	Miles	Designation
74	Riverside	From west boundary of the San Bernardino National Forest to SR-111 in Palm Desert.	This road goes from the southern Mojave Desert to oak and pine forests of San Bernardino National Forest. It offers views of the San Jacinto Valley and peaks of the San Jacinto Mountains.	48	ODSSH
91	Orange	From SR-55 to east of Anaheim city limit.	This freeway runs along the banks of the Santa Ana River. Views include residential and commercial development with intermittent riparian and chaparral vegetation.	4	ODSSH
243	Riverside	From SR-74 to the Banning city limit.	This U.S. Forest Service Scenic Byway and State Scenic Highway traverses forested mountain scenery along a ridge of the San Bernardino Mountains. It then drops in a series of switchbacks offering views of the San Bernardino Valley and the desert scenery.	28	ODSSH
N/A	Los Angeles	Mulholland Highway from SR- 1 to Kanan Dume Road and from west of Cornell Road to east of Las Virgenes Road.	With the dramatic canyons, oak woodlands, open spaces and ocean views of the Santa Monica Mountains, Mulholland Highway offers travelers views of the mountains, the Pacific Ocean, and historic sites along its stretch.	19	ODCSH[(b)]
N/A	Los Angeles	Malibu Canyon- Las Virgenes Highway from State Route 1 to Lost Hills Road.	The rugged terrain and ancient rock formations along this route have been a backdrop of many early California settlers. The formations have known presence dating to the original De Anza expedition of Spanish colonists.	7.4	ODCSH

3.1.2.4 Coastal Zones

According to the California Coastal Act of 1976, a coastal zone is the land and water area of the State of California from the Oregon border to the border of Mexico, extending seaward to the state's outer limit of jurisdiction, including all offshore islands, and extending inland generally 1,000 yards from the mean high tide line of the sea. In significant coastal estuarine, habitat, and recreational areas, the coastal zone extends inland to the first major ridgeline paralleling the sea or five miles from the mean high tide line of the sea, whichever is less, and in developed urban areas the coastal zone generally extends inland less than 1,000 yards.

The coastal zone within the District generally extends from Leo Carrillo State Park in Malibu in the northwestern corner of Los Angeles County to San Clemente Beach in San Clemente near the southern tip of Orange County.

Local Coastal Plans (LCPs) typically contain policies on visual access and site development review. LCPs are basic planning tools used by local governments to guide development in the coastal zone, in partnership with the California Coastal Commission. LCPs contain the ground rules for future development and protection of coastal resources in the 75 coastal cities and counties. The LCPs specify appropriate location, type, and scale of new or changed uses of land and water. Each LCP includes a land use plan and measures to implement the plan (such as zoning ordinances). Prepared by local government, these programs govern decisions that determine the short- and long-term conservation and use of coastal resources. While each LCP reflects unique characteristics of individual local coastal communities, regional and statewide interests and concerns must also be addressed in conformity with Coastal Act goals and policies.

SUBCHAPTER 3.2

AIR QUALITY AND GREENHOUSE GASES

Criteria Air Pollutants

Non-Criteria Air Pollutants

3.2 AIR QUALITY AND GREENHOUSE GASES

This subchapter provides an overview of the existing air quality setting for each criteria pollutant and their precursors, as well as the human health effects resulting from exposure to these pollutants. In addition, this subchapter includes a discussion of non-criteria pollutants such as TACs and GHGs, and climate change.

3.2.1 Criteria Air Pollutants and Identification of Health Effects

It is the responsibility of the SCAQMD to ensure that state and federal ambient air quality standards are achieved and maintained in its geographical jurisdiction. Health-based air quality standards have been established by California and the federal government for the following criteria air pollutants: ozone, carbon monoxide (CO), nitrogen dioxide (NO2), PM10, PM2.5, sulfur dioxide (SO2), and lead. These standards were established to protect sensitive receptors with a margin of safety from adverse health impacts due to exposure to air pollution. The California standards are commonly more stringent than the federal standards and in the case of PM10 and SO2, far more stringent. California has also established standards for sulfates, visibility reducing particles, hydrogen sulfide, and vinyl chloride. SCAQMD also has a general responsibility pursuant to Health & Safety Code (HSC) §41700 to control emissions of air contaminants and prevent endangerment to public health.

3.2.1.1 Regional Baseline

Air quality in the area of the SCAQMD's jurisdiction has shown substantial improvement over the last three decades. Nevertheless, some federal and state air quality standards are still exceeded frequently and by a wide margin. Of the National Ambient Air Quality Standards (NAAQS) established for seven criteria pollutants (ozone, CO, NO2, PM10, PM2.5, SO2, and lead), the area within the SCAQMD's jurisdiction is only in attainment with CO, SO2, PM10 and the annual NO2 standards. The SCAQMD is designated as unclassifiable/attainment for the hourly NO2 standard. The EPA intends to redesignate areas after sufficient air quality data are available.

Recent air quality data shows the 1997 PM2.5 standard (15 $\mu g/m^3$) is being met, but falls short in attaining the 2012 annual PM2.5 standard of 12 $\mu g/m^3$. Recent monitoring data also shows that the 2006 24-hour NAAQS for PM2.5 will not be achieved by 2015, due partially to drought conditions and to excessive emissions. The upcoming 2016 AQMP will evaluate PM2.5 emissions and possible control measures to attain the 2006 and 2012 standards by 2019 - 2025. The 2016 AQMP will also demonstrate attainment of the 2008 8-hour ozone standard (75 ppb) by year 2032, and provide an update to the previous 1997 8-hour standard (80 ppb) to be met by 2023. The 2016 AQMP must be submitted to the USEPA by July 20, 2016.

In 2010, a portion of Los Angeles County was designated as not attaining the NAAQS of 0.15 $\mu g/m^3$ for lead. SCAQMD identified two large lead-acid battery recycling facilities as possible sources of lead. One of the facilities was the main contributor to the area's nonattainment status. In response to the nonattainment designation, the State submitted the *Final 2012 Lead State Implementation Plan – Los Angeles County* to the USEPA on June

20, 2012. The plan outlines steps that will bring the area into attainment with the standard. As of February 11, 2014, the USEPA announced in the Federal Register (FR) final approval of the lead air quality plan, effective 30 days after publication (e.g., March 12, 2014).

The state and national ambient air quality standards for each of these pollutants and their effects on health are summarized in Table 3.2-1. The SCAQMD monitors levels of various criteria pollutants at 36 monitoring stations. The 2013 air quality data from SCAQMD's monitoring stations are presented in Table 3.2-2 for ozone, CO, NO2, PM10, PM2.5, SO2, lead and PM10 sulfate.

TABLE 3.2-1

State and Federal Ambient Air Quality Standards

Pollutant	Averaging Time	State Standard [a)]	Federal Primary Standard [b)]	Most Relevant Effects
Ozone (0_3)	1-hour	0.090 ppm (180 μg/m^3)	No Federal Standard	a) Short-term exposures: 1) Pulmonary function decrements and localized lung edema in humans and animals; and, 2) Risk to public health implied by alterations in pulmonary morphology and host defense in animals; b) Long-term exposures: Risk to public health implied by altered connective tissue metabolism and altered pulmonary morphology in animals after long-term exposures and pulmonary function decrements in chronically exposed humans; c) Vegetation damage; and, d) Property damage.
	8-hour	0.070 ppm (137 μg/m^3)	0.075 ppm (147 μg/m^3)	
Suspended Particulate Matter (PM10)	24-hour	50 μg/m^3	150 μg/m^3	a) Excess deaths from short-term exposures and exacerbation of symptoms in sensitive patients with respiratory disease; and, b) Excess seasonal declines in pulmonary function, especially in children.
	Annual Arithmetic Mean	20 μg/m^3	No Federal Standard	
Fine Particulate Matter (PM2.5)	24-hour	No State Standard	35 μg/m^3 [c)]	a) Increased hospital admissions and emergency room visits for heart and lung disease; b) Increased respiratory symptoms and disease; and, c) Decreased lung functions and premature death.
	Annual Arithmetic Mean	12 μg/m^3	12 μg/m^3	

TABLE 3.2-1 (continued)
State and Federal Ambient Air Quality Standards

Pollutant	Averaging Time	State Standard a)	Federal Primary Standard b)	Most Relevant Effects
Carbon Monoxide (CO)	1-Hour	20 ppm (23 mg/m^3)	35 ppm (40 mg/m^3)	a) Aggravation of angina pectoris and other aspects of coronary heart disease; b) Decreased exercise tolerance in persons with peripheral vascular disease and lung disease; c) Impairment of central nervous system functions; and, d) Possible increased risk to fetuses.
	8-Hour	9 ppm (10 mg/m^3)	9 ppm (10 mg/m^3)	
Nitrogen Dioxide (NO_2)	1-Hour	0.180 ppm (339 µg/m^3)	100 ppb d) (188 µg/m^3)	a) Potential to aggravate chronic respiratory disease and respiratory symptoms in sensitive groups; b) Risk to public health implied by pulmonary and extra-pulmonary biochemical and cellular changes and pulmonary structural changes; and, c) Contribution to atmospheric discoloration.
	Annual Arithmetic Mean	0.030 ppm (57 µg/m^3)	0.053 ppm (100 µg/m^3)	
Sulfur Dioxide (SO_2)	1-Hour	0.250 ppm (655 µg/m^3)	75 ppb e) (196 µg/m^3)	Broncho-constriction accompanied by symptoms which may include wheezing, shortness of breath and chest tightness, during exercise or physical activity in persons with asthma.
	24-Hour	0.040 ppm (105 µg/m^3)	No Federal Standard	
Sulfate	24-Hour	25 µg/m^3	No Federal Standard	a) Decrease in ventilatory function; b) Aggravation of asthmatic symptoms; c) Aggravation of cardio-pulmonary disease; d) Vegetation damage; e) Degradation of visibility; and, f) Property damage.
Hydrogen Sulfide (H_2S)	1-Hour	0.030 ppm (42 µg/m^3)	No Federal Standard	Odor annoyance.
Lead (Pb)	30-Day Average	1.5 µg/m^3	No Federal Standard	a) Increased body burden; and b) Impairment of blood formation and nerve conduction.
	Rolling 3-Month Average	No State Standard	0.150 µg/m^3	
Visibility Reducing Particles	8-Hour	Extinction coefficient of 0.23 per kilometer - visibility of ten miles or more due to particles when relative humidity is less than 70 percent.	No Federal Standard	The State standard is a visibility based standard not a health based standard and is intended to limit the frequency and severity of visibility impairment due to regional haze. Nephelometry and AISI Tape Sampler; instrumental measurement on days when relative humidity is less than 70 percent.

TABLE 3.2-1 (concluded)
State and Federal Ambient Air Quality Standards

Pollutant	Averaging Time	State Standard [a)]	Federal Primary Standard [b)]	Most Relevant Effects
Vinyl Chloride	24-Hour	0.010 ppm ($26\ \mu g/m^3$)	No Federal Standard	Highly toxic and a known carcinogen that causes a rare cancer of the liver.

a) The California ambient air quality standards for O3, CO, SO2 (1-hour and 24-hour), NO2, PM10, and PM2.5 are values not to be exceeded. All other California standards shown are values not to be equaled or exceeded.

b) The NAAQS, other than O3 and those based on annual averages, are not to be exceeded more than once a year. The O3 standard is attained when the expected number of days per calendar year with maximum hourly average concentrations above the standards is equal to or less than one.

c) The federal 24-hour PM2.5 standard is 35 $\mu g/m^3$ (98th percentile concentration).

d) The federal one-hour NO2 standard is 100 ppb or 0.100 ppm (98th percentile concentration).

e) The federal one-hour SO2 standard is 75 ppb or 0.075 ppm (99th percentile concentration).

KEY: ppb = parts per billion parts of air, by volume; ppm = parts per million parts of air, by volume; $\mu g/m^3$ = micrograms per cubic meter; mg/m^3 = milligrams per cubic meter

AAM = Annual Arithmetic Mean

\+ = High PM10 data sample (159 µg/m³ on August 23, 2013 at Indio) excluded due to the high wind in accordance with the EPA Exceptional Event Regulation. Also, multiple high PM10FEM data recorded in Coachella Valley and the Basin were excluded.

d) Federal Reference Method (FRM) PM10 samples were collected every six days at all sites except for Stations 4144 and 4157, where samples were collected every three days. PM10 statistics listed above are for the FRM data only. Federal Equivalent Method (FEM) PM10 continuous monitoring instruments were operated at some of the above locations. Max 24-hour average PM10 at sites with FEM monitoring was 153 µg/m³ at Indio (155 µg/m³ is needed to exceed the PM10 standards.

e) Federal annual PM10 standard (AAM > 50 µg/m³) was revoked in 2006. State standard is annual average (AAM) > 20 µg/m³.

++ = Higher lead concentrations were recorded at source-oriented monitoring sites immediately downwind of stationary lead sources. Maximum monthly and 3-month rolling averages recorded were 0.14 µg/m³ and 0.10 µg/m³, respectively.

h) Federal lead standard is 3-month rolling average > 0.15 µg/m³; and state standard is monthly average ≥ 1.5 µg/m³. Lead statistics listed above are for population-oriented sites only. Lead standards were not exceeded.

i) State sulfate standard is 24-hour ≥ 25 µg/m³. There is no federal standard for sulfate.

Carbon Monoxide

Carbon monoxide (CO) is a colorless, odorless, relatively inert gas. It is a trace constituent in the unpolluted troposphere, and is produced by both natural processes and human activities. In remote areas far from human habitation, CO occurs in the atmosphere at an average background concentration of 0.04 parts per million (ppm), primarily as a result of natural processes such as forest fires and the oxidation of methane. Global atmospheric mixing of CO from urban and industrial sources creates higher background concentrations (up to 0.20 ppm) near urban areas. The major source of CO in urban areas is incomplete combustion of carbon-containing fuels, mainly gasoline. Approximately 98 percent of the CO emitted into the Basin's atmosphere is from mobile sources. Consequently, CO concentrations are generally highest in the vicinity of major concentrations of vehicular traffic.

CO is a primary pollutant, meaning that it is directly emitted into the air, not formed in the atmosphere by chemical reaction of precursors, as is the case with ozone and other secondary pollutants. Ambient concentrations of CO in the Basin exhibit large spatial and temporal variations due to variations in the rate at which CO is emitted and in the meteorological conditions that govern transport and dilution. Unlike ozone, CO tends to reach high concentrations in the fall and winter months. The highest concentrations frequently occur on weekdays at times consistent with rush hour traffic and late night during the coolest, most stable portion of the day.

Individuals with a deficient blood supply to the heart are the most susceptible to the adverse effects of CO exposure. The effects observed include earlier onset of chest pain with exercise, and electrocardiograph changes indicative of worsening oxygen supply to the heart.

Inhaled CO has no direct toxic effect on the lungs, but exerts its effect on tissues by interfering with oxygen transport by competing with oxygen to combine with hemoglobin present in the blood to form carboxyhemoglobin (COHb). Hence, conditions with an increased demand for oxygen supply can be adversely affected by exposure to CO. Individuals most at risk include patients with diseases involving heart and blood vessels, fetuses (unborn babies), and patients with chronic hypoxemia (oxygen deficiency) as seen in high altitudes.

Reductions in birth weight and impaired neurobehavioral development have been observed in animals chronically exposed to CO resulting in COHb levels similar to those observed in smokers. Recent studies have found increased risks for adverse birth outcomes with exposure to elevated CO levels. These include pre-term births and heart abnormalities.

CO concentrations were measured at 26 locations in the Basin and neighboring Salton Sea Air Basin (SSAB) areas in 2013. Carbon monoxide concentrations did not exceed any of the federal or state standards in 2013. The highest eight-hour average carbon monoxide concentration recorded (3.5 ppm in the South Central Los Angeles County area) was 39 percent of the federal eight-hour carbon monoxide standard of 9.0 ppm. The state eight-hour standard is also 9.0 ppm.

The 2003 AQMP revisions to the SCAQMD's CO Plan served two purposes: 1) it replaced the 1997 attainment demonstration that lapsed at the end of 2000; and, 2) it provided the basis for a CO maintenance plan in the future. In 2004, the SCAQMD formally requested the USEPA to re-designate the Basin from non-attainment to attainment with the CO National Ambient Air Quality Standards. On February 24, 2007, USEPA published in the FR its proposed decision to re-designate the Basin from non-attainment to attainment for CO. The comment period on the re-designation proposal closed on March 16, 2007 with no comments received by the USEPA. On May 11, 2007, USEPA published in the FR its final decision to approve the SCAQMD's request for re-designation from non-attainment to attainment for CO, effective June 11, 2007.

Ozone

Ozone (O3), a colorless gas with a sharp odor, is a highly reactive form of oxygen. High ozone concentrations exist naturally in the stratosphere. Some mixing of stratospheric ozone downward through the troposphere to the earth's surface does occur; however, the extent of ozone transport is limited. At the earth's surface in sites remote from urban areas ozone concentrations are normally very low (e.g., from 0.02 ppm to 0.045 ppm), however recent studies indicate that the 'background' value of ozone may be rising due to the increased influence of pollution from global pollution produced outside of the SCAQMD[3, 4].

While ozone is beneficial in the stratosphere because it filters out skin-cancer-causing ultraviolet radiation, it is a highly reactive oxidant. It is this reactivity which accounts for its damaging effects on materials, plants, and human health at the earth's surface.

The propensity of ozone for reacting with organic materials causes it to be damaging to living cells and ambient ozone concentrations in the Basin are frequently sufficient to cause health effects. Ozone enters the human body primarily through the respiratory tract and causes respiratory irritation and discomfort, makes breathing more difficult during exercise, and reduces the respiratory system's ability to remove inhaled particles and fight infection.

Individuals exercising outdoors, children and people with preexisting lung disease, such as asthma and chronic pulmonary lung disease, are considered to be the most susceptible subgroups for ozone effects. Short-term exposures (lasting for a few hours) to ozone at levels typically observed in southern California can result in breathing pattern changes, reduction of breathing capacity, increased susceptibility to infections, inflammation of the lung tissue, and some immunological changes. In recent years, a correlation between elevated ambient ozone levels and increases in daily hospital admission rates, as well as mortality, has also been reported. An increased risk for asthma has been found in children who participate in multiple sports and live in high ozone communities. Elevated ozone levels are also associated with increased school absences.

[3] Fiore et al, "Background Ozone Over the United States in Summer: Origin, Trend, and Contribution to Pollution Episodes," Journal of Geophysical Research - Atmospheres, Vol. 107 - D15, 2002, pp. ACH 11-1–ACH 11-25. http://onlinelibrary.wiley.com/doi/10.1029/2001JD000982/abstract

[4] R. Vingarzan, "A Review of Surface Ozone Background Levels and Trends," Atmospheric Environment, Volume 38,2004, pp. 3431–3442. http://www.sciencedirect.com/science/article/pii/S1352231004002808

Ozone exposure under exercising conditions is known to increase the severity of the abovementioned observed responses. Animal studies suggest that exposures to a combination of pollutants which include ozone may be more toxic than exposure to ozone alone. Although lung volume and resistance changes observed after a single exposure diminish with repeated exposures, biochemical and cellular changes appear to persist, which can lead to subsequent lung structural changes.

In 2013, the SCAQMD regularly monitored ozone concentrations at 31 locations in the Basin and SSAB. Maximum ozone concentrations for all areas monitored were below the stage 1 episode level (0.20 ppm). Maximum ozone concentrations in the SSAB areas monitored by the SCAQMD were lower than the maximum values found in the Basin.

In 2013, the maximum ozone concentrations in the Basin continued to exceed federal standards by wide margins. The maximum one-hour ozone concentration was 0.151 ppm and the maximum eight-hour ozone concentration was 0.122 ppm; both were recorded in the Central San Bernardino Valley 1 area. The federal one-hour ozone standard was revoked and replaced by the eight-hour average ozone standard effective June 15, 2005. Effective May 27, 2008, the USEPA revised the federal eight-hour ozone standard from 0.84 ppm to 0.075 ppm. The maximum eight-hour concentration was 163 percent of the current federal standard. The maximum one-hour concentration was 168 percent of the one-hour state ozone standard of 0.09 ppm. The maximum eight-hour concentration was 174 percent of the eight-hour state ozone standard of 0.070 ppm.

Nitrogen Dioxide

Nitrogen Dioxide (NO2) is a reddish-brown gas with a bleach-like odor. Nitric oxide (NO) is a colorless gas, formed from the nitrogen (N2) and oxygen (O2) in air under conditions of high temperature and pressure which are generally present during combustion of fuels; NO reacts rapidly with the oxygen in air to form NO2. NO2 is responsible for the brownish tinge of polluted air. The two gases, NO and NO2, are referred to collectively as NOx. In the presence of sunlight, NO2 reacts to form nitric oxide and an oxygen atom. The oxygen atom can react further to form ozone, via a complex series of chemical reactions involving hydrocarbons. Nitrogen dioxide may also react to form nitric acid (HNO3) which reacts further to form nitrates, components of PM2.5 and PM10.

Population-based studies suggest that an increase in acute respiratory illness, including infections and respiratory symptoms in children (not infants), is associated with long-term exposures to NO2 at levels found in homes with gas stoves, which are higher than ambient levels found in southern California. Increase in resistance to air flow and airway contraction is observed after short-term exposure to NO2 in healthy subjects. Larger decreases in lung functions are observed in individuals with asthma and/or chronic obstructive pulmonary disease (e.g., chronic bronchitis, emphysema) than in healthy individuals, indicating a greater susceptibility of these sub-groups. More recent studies have found associations between NO2 exposures and cardiopulmonary mortality, decreased lung function, respiratory symptoms and emergency room asthma visits.

In animals, exposure to levels of NO_2 considerably higher than ambient concentrations results in increased susceptibility to infections, possibly due to the observed changes in cells involved in maintaining immune functions. The severity of lung tissue damage associated with high levels of ozone exposure increases when animals are exposed to a combination of ozone and NO_2.

In 2013, NO_2 concentrations were monitored at 26 locations. No area of the Basin or SSAB exceeded the federal or state standards for nitrogen dioxide. The Basin has not exceeded the federal standard for nitrogen dioxide (0.0534 ppm) since 1991, when the Los Angeles County portion of the Basin recorded the last exceedance of the standard in any county within the U.S.

In 2013, the maximum annual average concentration was 22.5 parts per billion (ppb) recorded in the Pomona/Walnut Valley area. Effective March 20, 2008, CARB revised the nitrogen dioxide one-hour standard from 0.25 ppm (250 ppb) to 0.18 ppm (180 ppb) and established a new annual standard of 0.030 ppm (30 ppb). In addition, USEPA has established a new federal one-hour NO_2 standard of 100 ppb (98th percentile concentration), effective April 7, 2010. The highest one-hour maximum concentration recorded in 2013 (90.3 ppb in Central Los Angeles County area) was 50 percent of the state one-hour standard. The highest one-hour 98th percentile concentration, recorded in 2013 (71.3 ppb in the South Coastal Los Angeles County area near the ports of Los Angeles and Long Beach), was 40 percent of the state one-hour standard and 71 percent of the federal one-hour standard. NO_x emission reductions continue to be necessary because it is a precursor to both ozone and PM ($PM_{2.5}$ and PM_{10}) concentrations.

<u>Sulfur Dioxide</u>

Sulfur dioxide (SO_2) is a colorless gas with a sharp odor. It reacts in the air to form sulfuric acid (H_2SO_4), which contributes to acid precipitation, and sulfates, which are components of PM_{10} and $PM_{2.5}$. Most of the SO_2 emitted into the atmosphere is produced by burning sulfur-containing fuels.

Exposure of a few minutes to low levels of SO_2 can result in airway constriction in some asthmatics. All asthmatics are sensitive to the effects of SO_2. In asthmatics, increase in resistance to air flow, as well as reduction in breathing capacity leading to severe breathing difficulties, is observed after acute higher exposure to SO_2. In contrast, healthy individuals do not exhibit similar acute responses even after exposure to higher concentrations of SO_2.

Animal studies suggest that despite SO_2 being a respiratory irritant, it does not cause substantial lung injury at ambient concentrations. However, very high levels of exposure can cause lung edema (fluid accumulation), lung tissue damage, and sloughing off of cells lining the respiratory tract.

Some population-based studies indicate that the mortality and morbidity effects associated with fine particles show a similar association with ambient SO_2 levels. In these studies, efforts to separate the effects of SO_2 from those of fine particles have not been successful.

It is not clear whether the two pollutants act synergistically or one pollutant alone is the predominant factor.

No exceedances of federal or state standards for SO2 occurred in 2013 at any of the eight monitoring locations. The maximum one-hour SO2 concentration was 21.8 ppb, as recorded in the South Coastal Los Angeles County 1 area. The USEPA revised the federal sulfur dioxide standard by establishing a new one-hour standard of 0.075 ppm (75 ppb) and revoking the existing annual arithmetic mean (0.03 ppm) and the 24-hour average (0.14 ppm), effective August 2, 2010. The state standards are 0.25 ppm (250 ppb) for the one-hour average and 0.04 ppm (40 ppb) for the 24-hour average. Though SO2 concentrations remain well below the standards, SO2 is a precursor to sulfate, which is a component of fine particulate matter, PM10, and PM2.5. Because historical measurements have consistently showed concentrations to be well below standards, monitoring has been limited to locations within the District that may have higher concentrations and higher potential exposures to the pollutant.

Particulate Matter (PM10 and PM2.5)

Of great concern to public health are the particles small enough to be inhaled into the deepest parts of the lung. Respirable particles (particulate matter less than about 10 micrometers in diameter) can accumulate in the respiratory system and aggravate health problems such as asthma, bronchitis and other lung diseases. Children, the elderly, exercising adults, and those suffering from asthma are especially vulnerable to adverse health effects of PM10 and PM2.5.

A consistent correlation between elevated ambient fine particulate matter (PM10 and PM2.5) levels and an increase in mortality rates, respiratory infections, number and severity of asthma attacks and the number of hospital admissions has been observed in different parts of the U.S. and various areas around the world. Studies have reported an association between long-term exposure to air pollution dominated by fine particles (PM2.5) and increased mortality, reduction in life-span, and an increased mortality from lung cancer.

Daily fluctuations in fine particulate matter concentration levels have also been related to hospital admissions for acute respiratory conditions, to school and kindergarten absences, to a decrease in respiratory function in normal children and to increased medication use in children and adults with asthma. Studies have also shown lung function growth in children is reduced with long-term exposure to particulate matter. In addition to children, the elderly, and people with pre-existing respiratory and/or cardiovascular disease appear to be more susceptible to the effects of PM10 and PM2.5.

The SCAQMD monitored PM10 concentrations at 21 locations in 2013. The federal 24-hour PM10 standard (150 $\mu g/m^3$) was not exceeded at any of the locations monitored in 2013. The federal annual PM10 standard has been revoked, effective 2006. A maximum 24-hour PM10 concentration of 147 $\mu g/m^3$ was recorded in the Mira Loma area and was 98 percent of the federal standard and 294 percent of the much more stringent state 24-hour PM10 standard (50 $\mu g/m^3$). The state 24-hour PM10 standard was exceeded at 17 of the 21 monitoring stations. A maximum annual average PM10 concentration of 41.1 $\mu g/m^3$ was recorded in Mira Loma. The maximum annual average PM10 concentration in Mira Loma was 206 percent of the state standard of 20 µg/m^3. The USEPA published approval of SCAQMD's PM10 request for redesignation for attainment on June 26, 2013, with an implementation date of July 26, 2013.

In 2013, PM2.5 concentrations were monitored at 20 locations throughout the district. USEPA revised the federal 24-hour PM2.5 standard from 65 µg/m^3 to 35 µg/m^3, effective December 17, 2006, and retained the form of the standard using the 98th percentile each year, averaged over three years. In 2013, the 98th percentile PM2.5 concentrations in the Basin exceeded the current federal 24-hour PM2.5 standard in two of the 20 locations. A 98th percentile 24-hour PM2.5 concentration of 37.5 µg/m^3 was recorded in the Metropolitan Riverside County 1 area, which represents 107 percent of the federal standard of 35 µg/m^3. Further, in July 2015, SCAQMD staff submitted a letter to EPA requesting a change in its attainment status to 'Serious' non-attainment due to high 24-hour concentrations of PM2.5 persisting through 2015. A maximum annual average PM2.5 concentration of 14.12 µg/m^3 was recorded in Mira Loma, which represents 118 percent of both the federal and state standard of 12 µg/m^3.

Similar to PM10 concentrations, PM2.5 concentrations were higher in the inland valley areas of San Bernardino and Metropolitan Riverside counties. However, PM2.5 concentrations were also high in Central Los Angeles County and the East San Gabriel Valley. The high PM2.5 concentrations in Los Angeles County are mainly due to the secondary formation of smaller particulates resulting from mobile and stationary source activities. In contrast to PM10, PM2.5 concentrations were low in the Coachella Valley area of SSAB. PM10 concentrations are normally higher in the desert areas due to windblown and fugitive dust emissions.

<u>Lead</u>

Under the federal Clean Air Act, lead is classified as a "criteria pollutant." Lead has observed adverse health effects at ambient concentrations. Lead is also deemed a carcinogenic toxic air contaminant (TAC) by the Office of Environmental Health Hazard Assessment (OEHHA). The USEPA has thoroughly reviewed the lead exposure and health effects research, and has prepared substantial documentation in the form of a Criteria Document to support the selection of the 2008 NAAQS for lead. The Criteria Document used for the development of the 2008 NAAQS for lead states that studies and evidence strongly substantiate that blood lead levels in a range of 5-10 µg/dL, or possibly lower, could likely result in neurocognitive effects in children. The report further states that "there is no level of lead exposure that can yet be identified with confidence, as clearly not being associated with some risk of deleterious health effects[5]."

Fetuses, infants, and children are more sensitive than others to the adverse effects of lead exposure. Exposure to low levels of lead can adversely affect the development and function of the central nervous system, leading to learning disorders, distractibility, inability to follow simple commands, and lower intelligence quotient. In adults, increased lead levels are

---

5 Environmental Protection Agency, Office of Research and Development, "Air Quality Criteria Document for Lead, Volumes I-II," October 2006.

associated with increased blood pressure. Chronic health effects include nervous and reproductive system disorders, neurological and respiratory damage, cognitive and behavioral changes, and hypertension. Exposure to lead can also potentially increase the risk of contracting cancer or result in other adverse health effects. Lead has been classified as a probable human carcinogen by the International Agency for Research on Cancer, based mainly on sufficient animal evidence, and as reasonably anticipated to be a human carcinogen by the U.S. National Toxicology Program. Young children are especially susceptible to the effects of environmental lead because their bodies accumulate lead more readily than do those of adults, and because they are more vulnerable to certain biological effects of lead including learning disabilities, behavioral problems, and deficits in IQ.

Lead poisoning can cause anemia, lethargy, seizures, and death. Lead can be stored in the bone from early-age environmental exposure, and elevated blood lead levels can occur due to breakdown of bone tissue during pregnancy, hyperthyroidism (increased secretion of hormones from the thyroid gland), and osteoporosis (breakdown of bone tissue). Fetuses and breast-fed babies can be exposed to higher levels of lead because of previous environmental lead exposure of their mothers.

Lead in the atmosphere is present as a mixture of a number of lead compounds. Leaded fuels and lead smelters have traditionally been the main sources of lead emitted into the air. Due to the phasing out of leaded fuels, there was a dramatic reduction in atmospheric lead in the Basin over the past three decades.

As a result, the federal and current state standards for lead were not exceeded in any area of the district in 2013. There have been no violations of these standards at the SCAQMD's regular air monitoring stations since 1982, as a result of removal of lead from fuels.

On November 12, 2008, USEPA published new NAAQS for lead, which became effective January 12, 2010. The existing national lead standard, 1.5 $\mu g/m^3$, was reduced to 0.15 $\mu g/m^3$, averaged over a rolling three-month period.

The maximum 3-month rolling average lead concentration (0.011 $\mu g/m^3$ was recorded at monitoring stations in Central Los Angeles, South San Gabriel Valley, and South Central LA County areas) was seven percent of the federal 3-month rolling lead standard (0.15 $\mu g/m^3$). The maximum monthly average lead concentration (0.014 $\mu g/m^3$ in South Central Los Angeles County area), measured at special monitoring sites immediately adjacent to stationary sources of lead was 0.9 percent of the state monthly average lead standard (1.5 $\mu g/m^3$). No lead data were obtained at SSAB and Orange County stations in 2013. Because historical lead data showed concentrations in SSAB and Orange County areas to be well below the standard, measurements have been discontinued at these locations.

In 2010, a portion of Los Angeles County was designated as not attaining the NAAQS of 0.15 $\mu g/m^3$ for lead based on monitored air quality data from 2007 to 2009 that indicated a violation of the NAAQS near and due to one of two large lead-acid battery recycling facilities in the District. However, the new federal standard was not exceeded at any source/receptor location the following year (in 2011).

Nevertheless, based on the monitored emissions from the two battery recycling facilities, USEPA designated the Los Angeles County portion of the Basin as non-attainment for the new lead standard, effective December 31, 2010. In response to the new federal lead standard, the SCAQMD adopted Rule 1420.1 – Emissions Standard for Lead from Large Lead-Acid Battery Recycling Facilities, in November 2010, to ensure that lead emissions do not exceed the new federal standard.

In response to the nonattainment designation, the State submitted the *Final 2012 Lead State Implementation Plan – Los Angeles County* (2012 Lead SIP) to the USEPA on June 20, 2012. The plan outlines steps that will bring the area into attainment with the federal lead standard before December 31, 2015. As of February 11, 2014, the USEPA announced in the Federal Register (FR) final approval of the lead air quality plan, to be effective 30 days after publication (e.g., March 12, 2014).

In 2013, higher lead concentrations continued to be recorded at source-oriented monitoring sites immediately downwind of stationary lead sources. The maximum monthly and 3-month rolling averages recorded in 2013 were 0.14 $\mu g/m^3$ and 0.10 $\mu g/m^3$, respectively.

In May 2014, the USEPA released its "Policy Assessment for the Review of the Lead National Ambient Air Quality Standards," reaffirming the primary (health-based) and secondary (welfare-based) staff conclusions regarding whether to retain the current standards. In January 2015, the USEPA announced that the ambient lead concentration standard of 0.15 $\mu g/m^3$ averaged over a rolling 3-month period would remain unchanged. The 90-day comment period for this proposal ended on April 6, 2015 and requires further action by the USEPA.

To continue to pursue reducing lead emissions from large lead-acid battery recycling facilities, in March 2015, Rule 1420.1 was amended to further lower the ambient lead concentration limit to 0.120 $\mu g/m^3$ effective January 1, 2016 and 0.100 $\mu g/m^3$ effective January 1, 2017 and the point source lead emission rate to 0.023 pounds per hour, as well as adding additional housekeeping and maintenance requirements.

On April 7, 2015, the larger of the two lead-acid battery recycling facilities withdrew its California Department of Toxic Substance Control (DTSC) permit application and provided notification of its intent to permanently close.

While Rule 1420.1 will be effective in reducing emissions from the large lead-acid battery recycling industry, lead emissions from the broader industry source category of metal melting is still a concern because the metal melting industry is the most significant stationary source of reported lead emissions. While existing federal and state regulations currently control lead emissions from the metal melting industry, additional requirements similar to those that have effectively reduced emissions from large lead-acid battery recyclers are also necessary to adequately protect public health by minimizing public exposure to lead emissions and preventing exceedances of the lead NAAQS in the Basin. As a result, the SCAQMD is proposing to adopt Rule 1420.2 – Emission Standards for Lead from Metal Melting Facilities which is scheduled to be considered by the SCAQMD Governing Board at its September 4, 2015 public hearing.

Sulfates

Sulfates (SOx) are chemical compounds which contain the sulfate ion and are part of the mixture of solid materials which make up PM10. Most of the sulfates in the atmosphere are produced by oxidation of SO2. Oxidation of sulfur dioxide yields sulfur trioxide (SO3) which reacts with water to form sulfuric acid, which contributes to acid deposition. The reaction of sulfuric acid with basic substances such as ammonia yields sulfates, a component of PM10 and PM2.5.

Most of the health effects associated with fine particles and SO2 at ambient levels are also associated with SOx. Thus, both mortality and morbidity effects have been observed with an increase in ambient SOx concentrations. However, efforts to separate the effects of SOx from the effects of other pollutants have generally not been successful.

Clinical studies of asthmatics exposed to sulfuric acid suggest that adolescent asthmatics are possibly a subgroup susceptible to acid aerosol exposure. Animal studies suggest that acidic particles such as sulfuric acid aerosol and ammonium bisulfate are more toxic than non-acidic particles like ammonium sulfate. Whether the effects are attributable to acidity or to particles remains unresolved.

In 2013, the state 24-hour sulfate standard (25 $\mu g/m^3$) was not exceeded in any of the monitoring locations in the district. There is no federal sulfate standard.

Hydrogen Sulfide

Hydrogen Sulfide (H2S) is a colorless gas with the characteristic foul odor of rotten eggs. H2S is heavier than air, very poisonous, corrosive, flammable, and explosive. H2S is naturally occurring in crude oil and natural gas, but H2S can also be created from the bacterial breakdown of organic matter in the absence of oxygen (e.g., in swamps and sewers). For example, on September 9, 2012, a thunderstorm over the Salton Sea caused odors to be released across the Coachella Valley. The SCAQMD received over 235 complaints of sulfur and rotten egg type odors in response to this natural event. Air samples were taken at several locations around the Salton Sea area to confirm source of odors and results of sampling showed total sulfur gas concentration of 149 ppb. The State air quality standard for H2S is 30 ppb, averaged over one-hour, and the odor threshold for H2S is approximately eight ppb. In response to potential for increasing odor complaints in the future, in October 2013, the SCAQMD installed two H2S monitors in the Coachella Valley to monitor the presence of H2S during odor events at the Salton Sea. The monitors are located at Saul Martinez Elementary School in Mecca and on the Torres Martinez Desert Cahuilla Indian Tribal land near the north end of the Salton Sea.

Vinyl Chloride

Vinyl chloride is a colorless, flammable gas at ambient temperature and pressure. It is also highly toxic and is classified as a carcinogen by the state Office of Environmental Health Hazard Assessment (OEHHA), in addition to the designations by the American Conference of Governmental Industrial Hygienists (confirmed carcinogen in humans) and by the International Agency for Research on Cancer (known to be a human carcinogen). At room temperature, vinyl chloride is a gas with a sickly sweet odor that is easily condensed. However, it is stored as a liquid. Due to the hazardous nature of vinyl chloride to human health there are no end products that use vinyl chloride in its monomer form. Vinyl chloride is a chemical intermediate, not a final product. It is an important industrial chemical chiefly used to produce the polymer polyvinyl chloride (PVC). The process involves vinyl chloride liquid fed to polymerization reactors where it is converted from a monomer to a polymer PVC. The final product of the polymerization process is PVC in either a flake or pellet form. Billions of pounds of PVC are sold on the global market each year. From its flake or pellet form, PVC is sold to companies that heat and mold the PVC into end products such as PVC pipe and bottles.

In the past, vinyl chloride emissions have been associated primarily with sources such as landfills. Risks from exposure to vinyl chloride are considered to be a localized impacts rather than regional impacts. Because landfills in the district are subject to SCAQMD 1150.1 – Control of Gaseous Emissions from Municipal Solid Waste Landfills, which contains stringent requirements for landfill gas collection and control, potential vinyl chloride emissions are below the level of detection. Therefore, the SCAQMD does not monitor for vinyl chloride at its monitoring stations.

Volatile Organic Compounds

It should be noted that there are no state or national ambient air quality standards for volatile organic compounds (VOCs) because they are not classified as criteria pollutants. VOCs are regulated, however, because limiting VOC emissions reduces the rate of photochemical reactions that contribute to the formation of O3, which is a criteria pollutant. VOCs are also transformed into organic aerosols in the atmosphere, contributing to higher PM10 and lower visibility levels.

Although health-based standards have not been established for VOCs, health effects can occur from exposures to high concentrations of VOCs because of interference with oxygen uptake. In general, ambient VOC concentrations in the atmosphere are suspected to cause coughing, sneezing, headaches, weakness, laryngitis, and bronchitis, even at low concentrations. Some hydrocarbon components classified as VOC emissions are thought or known to be hazardous. Benzene, for example, one hydrocarbon component of VOC emissions, is known to be a human carcinogen.

Visibility

In 2005, annual average visibility at Rubidoux (Riverside), the worst case, was just over 10 miles. With the exception of Lake County, which is designated in attainment, all of the air districts in California are currently designated as unclassified with respect to the CAAQS for visibility reducing particles.

In Class-I wilderness areas, which typically have visual range measured in tens of miles, the deciview metric is used to estimate an individual's perception of visibility. The deciview index works inversely to visual range which is measured in miles or kilometers whereby a lower deciview is optimal. In the South Coast Air Basin, the Class-I areas are typically restricted to higher elevations (greater than 6,000 feet above sea level) or far downwind of the metropolitan emission source areas. Visibility in these areas is typically unrestricted due to regional haze despite being in close proximity to the urban setting. The 2005 baseline deciview mapping of the Basin is presented in Figure 3.2-1. All of the Class-I wilderness areas reside in areas having average deciview values less than 20 with many portions of those areas having average deciview values less than 10. By contrast, Rubidoux, in the Basin has a deciview value exceeding 30.

Federal Regional Haze Rule: The federal Regional Haze Rule, established by the USEPA pursuant to CAA §169A establishes the national goal to prevent future and remedy existing impairment of visibility in federal Class I areas (such as federal wilderness areas and national parks). USEPA's visibility regulations (40 CFR Parts 51.300 - 51.309), require states to develop measures necessary to make reasonable progress towards remedying visibility impairment in these federal Class I areas. CAA §169A and USEPA's visibility regulations also require Best Available Retrofit Technology (BART) for certain large stationary sources that were put in place between 1962 and 1977. (See Regional Haze Regulations and Guidelines for BART Determinations, 70 FR 39104, July 6, 2005).

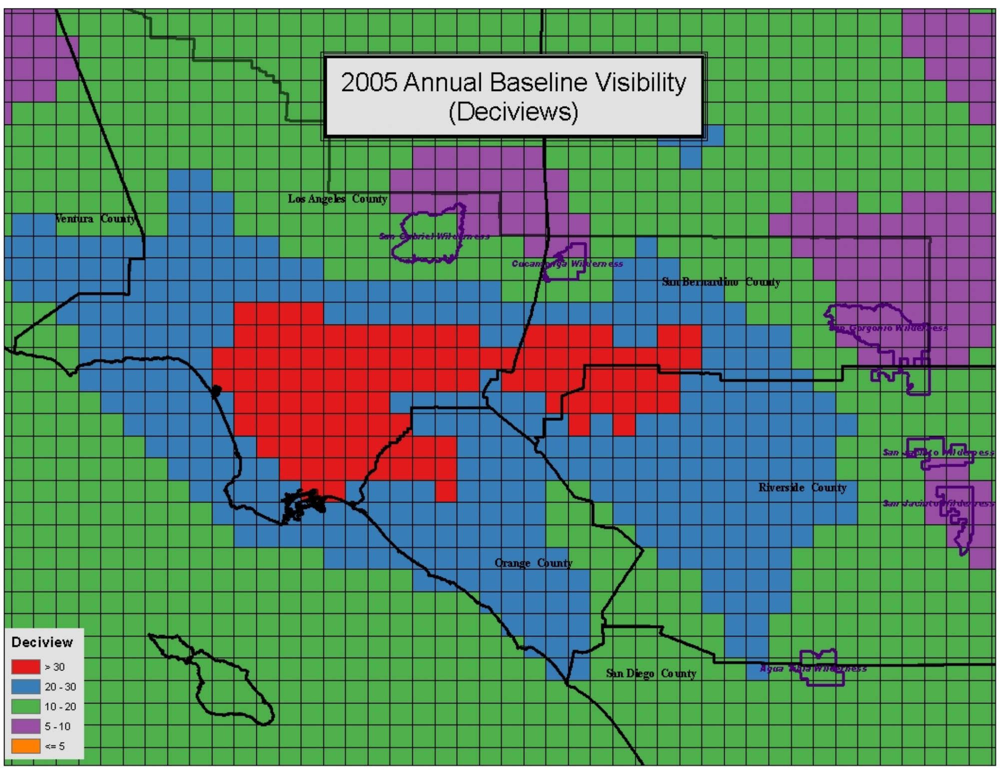

FIGURE 3.2-1
2005 Annual Baseline Visibility

California Air Resources Board: Since deterioration of visibility is one of the most obvious manifestations of air pollution and plays a major role in the public's perception of air quality, the state of California has adopted a standard for visibility or visual range.

Until 1989, the standard was based on visibility estimates made by human observers. The standard was changed to require measurement of visual range using instruments that measure light scattering and absorption by suspended particles.

The visibility standard is based on the distance that atmospheric conditions allow a person to see at a given time and location. Visibility reduction from air pollution is often due to the presence of sulfur and nitrogen oxides, as well as particulate matter. Visibility degradation occurs when visibility reducing particles are produced in sufficient amounts such that the extinction coefficient is greater than 0.23 inverse kilometers (to reduce the visual range to less than 10 miles) at relative humidity less than 70 percent, 8-hour average (from 10:00 a.m. to 6:00 p.m.) according to the state standard. Future-year visibility in the Basin is projected empirically using the results derived from a regression analysis of visibility with air quality measurements. The regression data set consisted of aerosol composition data collected during a special monitoring program conducted concurrently with visibility data collection (prevailing visibility observations from airports and visibility measurements from district monitoring stations). A full description of the visibility analysis is given in Appendix V of the 2012 AQMP.

With future year reductions of PM2.5 from implementation of all proposed emission controls for 2015, the annual average visibility would improve from 10 miles (calculated for 2008) to over 20 miles at Rubidoux, for example. Visual range in 2021 at all other Basin sites is expected to equal or exceed the Rubidoux visual range. Visual range is expected to double from the 2008 baseline due to reductions of secondary PM2.5, directly emitted PM2.5 (including diesel soot) and lower NO2 concentrations as a result of 2007 AQMP controls.

To meet Federal Regional Haze Rule requirements, CARB adopted the California Regional Haze Plan on January 22, 2009, addressing California's visibility goals through 2018. As shown in Table 3.2-1, California's statewide standard (applicable outside of the Lake Tahoe area) for Visibility Reducing Particles is an extinction coefficient of 0.23 per kilometer over an 8-hour averaging period. This translates to visibility of ten miles or more due to particles when relative humidity is less than 70 percent.

3.2.2 Non-Criteria Pollutants

Although the SCAQMD's primary mandate is attaining the State and National Ambient Air Quality Standards for criteria pollutants within the district, SCAQMD also has a general responsibility pursuant to HSC §41700 to control emissions of air contaminants and prevent endangerment to public health. Additionally, state law requires the SCAQMD to implement airborne toxic control measures (ATCM) adopted by CARB, and to implement the Air Toxics "Hot Spots" Act. As a result, the SCAQMD has regulated pollutants other than criteria pollutants such as TACs, greenhouse gases and stratospheric ozone depleting compounds. The SCAQMD has developed a number of rules to control non-criteria pollutants from both new and existing sources. These rules originated through state directives, CAA requirements, or the SCAQMD rulemaking process.

In addition to promulgating non-criteria pollutant rules, the SCAQMD has been evaluating AQMP control measures as well as existing rules to determine whether or not they would affect, either positively or negatively, emissions of non-criteria pollutants. For example, rules in which VOC components of coating materials are replaced by a non-photochemically reactive chlorinated substance would reduce the impacts resulting from ozone formation, but could increase emissions of toxic compounds or other substances that may have adverse impacts on human health.

The following subsections summarize the existing setting for the two major categories of non-criteria pollutants: compounds that contribute to TACs, global climate change, and stratospheric ozone depletion.

3.2.2.1 Air Quality – Toxic Air Contaminants

Federal

Under the CAA §112, the USEPA is required to regulate sources that emit one or more of the 187 federally listed hazardous air pollutants (HAPs). HAPs are air toxic pollutants identified in the CAA, which are known or suspected of causing cancer or other serious health effects. The federal HAPs are listed on the USEPA website at http://www.epa.gov/ttn/atw/orig189.html. In order to implement the CAA, approximately 100 National Emission Standards for Hazardous Air Pollutants (NESHAPs) have been promulgated by USEPA for major sources (sources emitting greater than 10 tons per year of a single HAP or greater than 25 tons per year of multiple HAPs). The SCAQMD can either directly implement NESHAPs or adopt rules that contain requirements at least as stringent as the NESHAP requirements. However, since NESHAPs often apply to sources in the district that are already controlled by state-mandated air toxics control measures or by local district rules, many of the sources that would have been subject to federal requirements already comply.

In addition to the major source NESHAPs, USEPA has also controlled HAPs from urban areas by developing Area Source NESHAPs under their Urban Air Toxics Strategy. USEPA defines an area source as a source that emits less than 10 tons annually of any single hazardous air pollutant or less than 25 tons annually of a combination of hazardous air pollutants. The CAA requires the USEPA to identify a list of at least 30 air toxics that pose the greatest potential health threat in urban areas. USEPA is further required to identify and establish a list of area source categories that represent 90 percent of the emissions of the 30 urban air toxics associated with area sources, for which Area Source NESHAPs are to be developed under the CAA. USEPA has identified a total of 70 area source categories with regulations promulgated for more than 30 categories so far.

The federal toxics program recognizes diesel engine exhaust as a health hazard, however, diesel particulate matter itself is not one of their listed toxic air contaminants (TACs). Rather, each toxic compound in the speciated list of compounds in exhaust is considered separately. Although there are no specific NESHAP regulations for diesel PM, diesel particulate emission reductions are realized through federal regulations including diesel fuel standards and emission standards for stationary, marine, and locomotive engines; and idling controls for locomotives.

State

The California air toxics program was based on the CAA and the original federal list of hazardous air pollutants. The state program was established in 1983 under the Toxic Air Contaminant (TAC) Identification and Control Act, Assembly Bill (AB) 1807, Tanner. Under the state program, TACs are identified through a two-step process of risk identification and risk management. This two-step process was designed to protect residents from the health effects of toxic substances in the air.

Control of TACs under the TAC Identification and Control Program: California's TAC identification and control program, adopted in 1983 as AB 1807, is a two-step program in which substances are identified as TACs, and air toxic control measures (ATCMs) are adopted to control emissions from specific sources. CARB has adopted a regulation designating all 187 federal HAPs as TACs.

ATCMs are developed by CARB and implemented by the SCAQMD and other air districts through direct implementation or the adoption of regulations of equal or greater stringency. Generally, the ATCMs reduce emissions to achieve exposure levels below a determined health threshold. If no such threshold levels are determined, emissions are reduced to the lowest level achievable through the best available control technology unless it is determined that an alternative level of emission reduction is adequate to protect public health.

Under California law, a federal NESHAP automatically becomes a state ATCM, unless CARB has already adopted an ATCM for the source category. Once a NESHAP becomes an ATCM, CARB and each air pollution control or air quality management district have certain responsibilities related to adoption or implementation and enforcement of the NESHAP/ATCM.

Control of TACs under the Air Toxics "Hot Spots" Act: The Air Toxics Hot Spots Information and Assessment Act of 1987 (AB 2588) establishes a state-wide program to inventory and assess the risks from facilities that emit TACs and to notify the public about significant health risks associated with the emissions. Facilities are phased into the AB 2588 program based on their emissions of criteria pollutants or their occurrence on lists of toxic emitters compiled by the SCAQMD. Phase I consists of facilities that emit over 25 tons per year of any criteria pollutant and facilities present on the SCAQMD's toxics list. Phase I facilities entered the program by reporting their air TAC emissions for calendar year 1989. Phase II consists of facilities that emit between 10 and 25 tons per year of any criteria pollutant, and submitted air toxic inventory reports for calendar year 1990 emissions. Phase III consists of certain designated types of facilities which emit less than 10 tons per year of any criteria pollutant, and submitted inventory reports for calendar year 1991 emissions. Inventory reports are required to be updated every four years under the state law.

Air Toxics Control Measures: As part of its risk management efforts, CARB has passed state ATCMs to address air toxics from mobile and stationary sources. Some key ATCMs for stationary sources include reductions of benzene emissions from service stations, hexavalent chromium emissions from chrome plating, perchloroethylene emissions from dry cleaning, ethylene oxide emissions from sterilizers, and multiple air toxics from the automotive painting and repair industries.

Many of CARB's recent ATCMs are part of the CARB Risk Reduction Plan to Reduce Particulate Matter Emissions from Diesel-Fueled Engines and Vehicles (DRRP) which was adopted in September 2000 (http://www.arb.ca.gov/diesel/documents/rrpapp.htm) with the goal of reducing diesel particulate matter emissions from compression ignition engines and associated health risk by 75 percent by 2010 and 85 percent by 2020. The DRRP includes strategies to reduce emissions from new and existing engines through the use of ultra-low sulfur diesel fuel, add-on controls, and engine replacement. In addition to stationary source engines, the plan addresses diesel PM emissions from mobile sources such as trucks, buses, construction equipment, locomotives, and ships.

SCAQMD

SCAQMD has regulated criteria air pollutants using either a technology-based or an emissions limit approach. The technology-based approach defines specific control technologies that may be installed to reduce pollutant emissions. The emission limit approach establishes an emission limit, and allows industry to use any emission control equipment, as long as the emission requirements are met. The regulation of TACs often uses a health risk-based approach, but may also require a regulatory approach similar to criteria pollutants, as explained in the following subsections.

Rules and Regulations: Under the SCAQMD's toxic regulatory program there are 15 source-specific rules that target toxic emission reductions that regulate over 10,000 sources such as metal finishing, spraying operations, dry cleaners, film cleaning, gasoline dispensing, and diesel-fueled stationary engines to name a few. In addition, other source-specific rules targeting criteria pollutant reductions also reduce toxic emissions, such as SCAQMD Rule 461 – Gasoline Transfer and Dispensing, which reduces benzene emissions from gasoline dispensing and SCAQMD Rule 1124 – Aerospace Assembly and Component Manufacturing Operations, which reduces perchloroethylene, trichloroethylene, and methylene chloride emissions from aerospace operations.

New and modified sources of TACs in the district are subject to SCAQMD Rule 1401 - New Source Review of Toxic Air Contaminants and SCAQMD Rule 212 - Standards for Approving Permits. Rule 212 requires notification of the SCAQMD's intent to grant a permit to construct a significant project, defined as a new or modified permit unit located within 1000 feet of a school (a state law requirement under AB 3205), a new or modified permit unit posing an maximum individual cancer risk of one in one million (1×10^{-6}) or greater, or a new or modified facility with criteria pollutant emissions exceeding specified daily maximums. Distribution of notice is required to all addresses within a 1/4-mile radius, or other area deemed appropriate by the SCAQMD. Rule 1401 currently controls emissions of carcinogenic and non-carcinogenic (health effects other than cancer) air contaminants from new, modified and relocated sources by specifying limits on cancer risk and hazard index (explained further in the following discussion), respectively. Rule 1401 lists nearly 300 TACs that are evaluated during the SCAQMD's permitting process for new, modified or relocated sources. During the past decade, more than 80 compounds have been added or had risk values amended. The addition of diesel particulate matter from diesel-fueled internal combustion engines as a TAC in March 2008 was one of the most substantial amendments to the rule. SCAQMD Rule 1401.1 – Requirements for New and Relocated Facilities Near Schools, sets risk thresholds for new and relocated facilities near schools. The requirements are more stringent than those for other air toxics rules in order to provide additional protection to school children.

Air Toxics Control Plan: In March 2000, the SCAQMD Governing Board approved the Air Toxics Control Plan (ATCP) which was the first comprehensive plan in the nation to guide future toxic rulemaking and programs. The ATCP was developed to lay out the SCAQMD's air toxics control program which built upon existing federal, state, and local toxic control programs as well as co-benefits from implementation of State Implementation Plan (SIP) measures. The concept for the plan was an outgrowth of the Environmental Justice principles and the Environmental Justice Initiatives adopted by the SCAQMD Governing Board in October 1997. Monitoring studies and air toxics regulations that were created from these initiatives emphasized the need for a more systematic approach to reducing TACs. The intent of the plan was to reduce exposure to air toxics in an equitable and cost-effective manner that promotes clean, healthful air in the district. The plan proposed control strategies to reduce TACs in the district implemented between years 2000 and 2010 through cooperative efforts of the SCAQMD, local governments, CARB and USEPA.

2003 Cumulative Impact Reduction Strategies: The SCAQMD Governing Board approved a cumulative impacts reduction strategy in September 2003. The resulting 25 cumulative impacts strategies were a key element of the 2004 Addendum to the ATCP (see next section). The strategies included rules, policies, funding, education, and cooperation with other agencies. Some of the key SCAQMD accomplishments related to the cumulative impacts reduction strategies were:

- SCAQMD Rule 1401.1 - Requirements for New and Relocated Facilities Near Schools. which set more stringent health risk requirements for new and relocated facilities near schools
- SCAQMD Rule 1470 – Requirements for Stationary Diesel-Fueled Internal Combustion and Other Compression Ignition Engines, which established diesel PM emission limits and other requirements for diesel-fueled engines
- SCAQMD Rule 1469.1 – Spraying Operations Using Coatings Containing Chromium, which regulated chrome spraying operations
- SCAQMD Rule 410 – Odors From Transfer Stations and Material Recovery Facilities, which addresses odors from transfer stations and material recovery facilities
- Intergovernmental Review comment letters for CEQA documents

- SCAQMD's land use guidance document
- Additional protection in toxics rules for sensitive receptors, such as more stringent requirements for chrome plating operations and diesel engines located near schools

2004 Addendum to the ATCP: An addendum to the ATCP was adopted by the SCAQMD Governing Board in 2004 (referred to herein as the 2004 Addendum to the ATCP) and served as a status report regarding implementation of the various mobile and stationary source strategies in the 2000 ATCP and introduced new measures to further address air toxics. The main elements of the 2004 Addendum to the ATCP were to address the progress made in implementation of the 2000 ATCP control strategies; provide a historical perspective of air toxic emissions and current air toxic levels; incorporate the Cumulative Impact Reduction Strategies approved by the SCAQMD Governing Board in 2003 and additional measures identified in the 2003 AQMP; project future air toxic levels to the extent feasible; and, summarize future efforts to develop the next ATCP. Significant progress had been made in implementing most of the SCAQMD strategies from the 2000 ATCP and the 2004 Addendum to the ATCP. CARB has also made notable progress in mobile source measures via its Diesel Risk Reduction Plan, especially for goods movement related sources, while the USEPA continued to implement their air toxic programs applicable to stationary sources

Clean Communities Plan: On November 5, 2010, the SCAQMD Governing Board approved the 2010 Clean Communities Plan (CCP). The CCP was an update to the 2000 Air Toxics Control Plan (ATCP) and the 2004 Addendum. The objective of the 2010 CCP is to reduce the exposure to air toxics and air-related nuisances throughout the district, with emphasis on cumulative impacts. The elements of the 2010 CCP are community exposure reduction, community participation, communication and outreach, agency coordination, monitoring and compliance, source-specific programs, and nuisance. The centerpiece of the 2010 CCP is a pilot study through which the SCAQMD staff will work with community stakeholders to identify and develop solutions community-specific to air quality issues in two communities: 1) the City of San Bernardino; and, 2) Boyle Heights and surrounding areas.

Control of TACs under the Air Toxics "Hot Spots" Act: In October 1992, the SCAQMD Governing Board adopted public notification procedures for Phase I and II facilities. These procedures specify that AB 2588 facilities must provide public notice when exceeding the following risk levels:

- Maximum Individual Cancer Risk (MICR): greater than 10 in one million (10 x 10^{-6})
- Total Hazard Index (HI): greater than 1.0 for TACs except lead, or > 0.5 for lead

Public notice is to be provided by letters mailed to all addresses and all parents of children attending school in the impacted area. In addition, facilities must hold a public meeting and provide copies of the facility risk assessment in all school libraries and a public library in the impacted area.

The AB2588 Toxics "Hot Spots" Program is implemented through SCAQMD Rule 1402 – Control of Toxic Air Contaminants from Existing Sources. The SCAQMD continues to review health risk assessments submitted. Notification is required from facilities with a significant risk under the AB 2588 program based on their initial approved health risk assessments and will continue on an ongoing basis as additional and subsequent health risk assessments are reviewed and approved.

There are currently about 600 facilities in the SCAQMD's AB2588 program. Since 1992 when the state Health and Safety Code incorporated a risk reduction requirement in the program, the SCAQMD has reviewed and approved over 300 HRAs, 44 facilities were required to do a public notice, and 21 facilities were subject to risk reduction. Currently, over 96 percent of the facilities in the program have cancer risks below ten in a million and over 98 percent have acute and chronic hazard indices of less than one.

CEQA Intergovernmental Review Program: The SCAQMD staff, through its Intergovernmental Review (IGR) provides comments to lead agencies on air quality analyses and mitigation measures in CEQA documents. The following are some key programs and tools that have been developed more recently to strengthen air quality analyses, specifically as they relate to exposure of mobile source air toxics:

- SCAQMD's Mobile Source Committee approved the "Health Risk Assessment Guidance for Analyzing Cancer Risks from Mobile Source Diesel Emissions" (August 2002). This document provides guidance for analyzing cancer risks from diesel particulate matter from truck idling and movement (e.g., truck stops, warehouse and distribution centers, or transit centers), ship hotelling at ports, and train idling.

- CalEPA and CARB's "Air Quality and Land Use Handbook: A Community Health Perspective" (April 2005), provides recommended siting distances for incompatible land uses.

- Western Riverside Council of Governments Air Quality Task Force developed a policy document titled, "Good Neighbor Guidelines for Siting New and/or Modified Warehouse/Distribution Facilities" (September 2005). This document provides guidance to local government on preventive measures to reduce neighborhood exposure to TACs from warehousing facilities.

Environmental Justice: Environmental justice (EJ) has long been a focus of the SCAQMD. In 1990, the SCAQMD formed an Ethnic Community Advisory Group that has since been restructured as the Environmental Justice Advisory Group (EJAG). EJAG's mission is to advise and assist SCAQMD in protecting and improving public health in SCAQMD's most impacted communities through the reduction and prevention of air pollution.

In 1997, the SCAQMD Governing Board adopted four guiding principles and ten initiatives (http://www.aqmd.gov/ej/history.htm) to ensure environmental equity. Also in 1997, the SCAQMD Governing Board expanded the initiatives to include the "Children's

Air Quality Agenda" focusing on the disproportionate impacts of poor air quality on children. Some key initiatives that have been implemented were the Multiple Air Toxics Exposure Studies (MATES, MATES II and MATES III); the Clean Fleet Rules, the Cumulative Impacts strategies; funding for lower emitting technologies under the Carl Moyer Program; the Guidance Document for Addressing Air Quality Issues in General Plans and Local Planning; a guidance document on Air Quality Issues in School Site Selection; and the 2000 ATCP and the 2004 Addendum to the ATCP. Key initiatives focusing on communities and residents include the Clean Air Congress; the Clean School Bus Program; Asthma and Air Quality Consortium; Brain and Lung Tumor and Air Pollution Foundation; air quality presentations to schools and community and civic groups; and Town Hall meetings. Technological and scientific projects and programs have been a large part of the SCAQMD's EJ program since its inception. Over time, the EJ program's focus on public education, outreach, and opportunities for public participation have greatly increased. Public education materials and other resources for the public are available on the SCAQMD's website (www.aqmd.gov).

AB 2766 Subvention Funds: AB2766 subvention funds are monies collected by the state as part of vehicle registration and passed through to the SCAQMD for funding projects of local cities, among others, that reduce motor vehicle air pollutants. The Clean Fuels Program, funded by a surcharge on motor vehicle registrations in the SCAQMD, reduces TAC emissions through co-funding projects to develop and demonstrate low-emission clean fuels and advanced technologies, and to promote commercialization and deployment of promising or proven technologies in Southern California.

Carl Moyer Program: Another program that targets diesel emission reductions is the Carl Moyer Program which provides grants for projects that achieve early or extra emission reductions beyond what is required by regulations. Examples of eligible projects include cleaner on-road, off-road, marine, locomotive, and stationary agricultural pump engines. Other endeavors of the SCAQMD's Technology Advancement Office help to reduce diesel PM emissions through co-funding research and demonstration projects of clean technologies, such as low-emitting locomotives.

Control of TACs with Risk Reduction Audits and Plans: SB 1731, enacted in 1992 and codified at HSC §44390 et seq., amended AB 2588 to include a requirement for facilities with significant risks to prepare and implement a risk reduction plan which will reduce the risk below a defined significant risk level within specified time limits. SCAQMD Rule 1402 was adopted on April 8, 1994 to implement the requirements of SB 1731.

In addition to the TAC rules adopted by SCAQMD under authority of AB 1807 and SB 1731, the SCAQMD has adopted source-specific TAC rules, based on the specific level of TAC emitted and the needs of the area. These rules are similar to the state's ATCMs because they are source-specific and only address emissions and risk from specific compounds and operations.

Multiple Air Toxics Exposure Studies (MATES): In 1986, SCAQMD conducted the first MATES Study to determine the Basin-wide risks associated with major airborne carcinogens. At the time, the state of technology was such that only twenty known air toxic compounds could be analyzed and diesel exhaust particulate did not have an agency accepted carcinogenic health risk value. TACs are determined by the USEPA, and by the CalEPA, including the Office of Environmental Health Hazard Assessment and the ARB. For purposes of MATES, the California carcinogenic health risk factors were used. The maximum combined individual health risk for simultaneous exposure to pollutants under the study was estimated to be 600 to 5,000 in one million.

Multiple Air Toxics Exposure Study II (MATES II): At its October 10, 1997 meeting, the SCAQMD Governing Board directed staff to conduct a follow up to the MATES study to quantify the magnitude of population exposure risk from existing sources of selected air toxic contaminants at that time. The follow up study, MATES II, included a monitoring program of 40 known air toxic compounds, an updated emissions inventory of TACs (including microinventories around each of the 14 microscale sites), and a modeling effort to characterize health risks from hazardous air pollutants. The estimated basin-wide carcinogenic health risk from ambient measurements was 1,400 per million people. About 70 percent of the basin wide health risk was attributed to diesel particulate emissions; about 20 percent to other toxics associated with mobile sources (including benzene, butadiene, and formaldehyde); about 10 percent of basin wide health risk was attributed to stationary sources (which include industrial sources and other certain specifically identified commercial businesses such as dry cleaners and print shops.)

Multiple Air Toxics Exposure Study III (MATES III): MATES III was a follow up to previous air toxics studies in the Basin and was part of the SCAQMD Governing Board's 2003-04 Environmental Justice Workplan. The MATES III Study consists of several elements including a monitoring program, an updated emissions inventory of TACs, and a modeling effort to characterize carcinogenic health risk across the Basin. Besides toxics, additional measurements include organic carbon, elemental carbon, and total carbon, as well as, PM, including PM2.5. It did not estimate mortality or other health effects from particulate exposures. MATES III revealed a general downward trend in air toxic pollutant concentrations with an estimated basin-wide lifetime carcinogenic health risk of 1,200 in one million. Mobile sources accounted for 94 percent of the basin-wide lifetime carcinogenic health risk with diesel exhaust particulate contributing to 84 percent of the mobile source basin-wide lifetime carcinogenic health risk. Non-diesel carcinogenic health risk declined by 50 percent from the MATES II values.

Multiple Air Toxics Exposure Study IV (MATES IV): Monitoring began in June 2012 and a Technical Advisory Group formed. The 10 sites from Mates III would continue to be monitored for trends in the data. A new focus of Mates IV is the inclusion of measurements of ultrafine particle concentrations and localized impacts of combustion sources. The focus of these measurements will be on assessing the exposures to ultrafine particles and black carbon very near sources such as airports, freeways, railyards, busy intersections and warehouse operations.

Carcinogenic Health Risks from Toxic Air Contaminants: One of the primary health risks of concern due to exposure to TACs is the risk of contracting cancer. The carcinogenic potential of TACs is a particular public health concern because it is currently believed by many scientists that there is no "safe" level of exposure to carcinogens. Any exposure to a carcinogen poses some risk of causing cancer. It is currently estimated that about one in four deaths in the U.S. is attributable to cancer. About two percent of cancer deaths in the U.S. may be attributable to environmental pollution (Doll and Peto 1981). The proportion of cancer deaths attributable to air pollution has not been estimated using epidemiological methods.

Non-Cancer Health Risks from Toxic Air Contaminants: Unlike carcinogens, for most TAC non-carcinogens it is believed that there is a threshold level of exposure to the compound below which it will not pose a health risk. CalEPA's Office of Environmental Health Hazard Assessment (OEHHA) develops Reference Exposure Levels (RELs) for TACs which are health-conservative estimates of the levels of exposure at or below which health effects are not expected. The non-cancer health risk due to exposure to a TAC is assessed by comparing the estimated level of exposure to the REL. The comparison is expressed as the ratio of the estimated exposure level to the REL, called the hazard index (HI).

3.2.2.2 Climate Change

Global climate change is a change in the average weather of the earth, which can be measured by wind patterns, storms, precipitation, and temperature. Historical records have shown that temperature changes have occurred in the past, such as during previous ice ages. Data indicate that the current temperature record differs from previous climate changes in rate and magnitude.

Gases that trap heat in the atmosphere are often called greenhouse gases (GHGs), comparable to a greenhouse, which captures and traps radiant energy. GHGs are emitted by natural processes and human activities. The accumulation of greenhouse gases in the atmosphere regulates the earth's temperature. Global warming is the observed increase in average temperature of the earth's surface and atmosphere. The primary cause of global warming is an increase of GHGs in the atmosphere. The six major GHGs are carbon dioxide (CO2), methane (CH4), nitrous oxide (N2O), sulfur hexafluoride (SF6), hydrofluorocarbons (HFCs), and perfluorocarbon (PFCs). The GHGs absorb longwave radiant energy emitted by the Earth, which warms the atmosphere. The GHGs also emit longwave radiation both upward to space and back down toward the surface of the Earth. The downward part of this longwave radiation emitted by the atmosphere is known as the "greenhouse effect." Emissions from human activities such as fossil fuel combustion for electricity production and vehicles have elevated the concentration of these gases in the atmosphere.

CO2 is an odorless, colorless greenhouse gas. Natural sources include the following: decomposition of dead organic matter; respiration of bacteria, plants, animals, and fungus; evaporation from oceans; and volcanic outgassing. Anthropogenic (human caused) sources of CO2 include burning coal, oil, gasoline, natural gas, and wood.

CH4 is a flammable gas and is the main component of natural gas. N2O, also known as laughing gas, is a colorless greenhouse gas. Some industrial processes such as fossil fuel-fired power plants, nylon production, nitric acid production, and vehicle emissions also contribute to the atmospheric load of N2O. HFCs are synthetic man-made chemicals that are used as a substitute for chlorofluorocarbons (whose production was stopped as required by the Montreal Protocol) for automobile air conditioners and refrigerants. The two main sources of PFCs are primary aluminum production and semiconductor manufacture. SF6 is an inorganic, odorless, colorless, nontoxic, nonflammable gas. SF6 is used for insulation in electric power transmission and distribution equipment, in the magnesium industry, in semiconductor manufacturing, and as a tracer gas for leak detection.

Scientific consensus, as reflected in recent reports issued by the United Nations Intergovernmental Panel on Climate Change, is that the majority of the observed warming over the last 50 years can be attributable to increased concentration of GHGs in the atmosphere due to human activities. Industrial activities, particularly increased consumption of fossil fuels (e.g., gasoline, diesel, wood, coal, etc.), have heavily contributed to the increase in atmospheric levels of GHGs. The United Nations Intergovernmental Panel on Climate Change constructed several emission trajectories of greenhouse gases needed to stabilize global temperatures and climate change impacts. It concluded that a stabilization of greenhouse gases at 400 to 450 ppm carbon dioxide-equivalent concentration is required to keep global mean warming below two degrees Celsius, which has been identified as necessary to avoid dangerous impacts from climate change.

The potential health effects from global climate change may arise from temperature increases, climate-sensitive diseases, extreme events, air quality impacts, and sea level rise. There may be direct temperature effects through increases in average temperature leading to more extreme heat waves and less extreme cold spells. Those living in warmer climates are likely to experience more stress and heat-related problems (e.g., heat rash and heat stroke). In addition, climate sensitive diseases may increase, such as those spread by mosquitoes and other disease carrying insects. Those diseases include malaria, dengue fever, yellow fever, and encephalitis. Extreme events such as flooding, hurricanes, and wildfires can displace people and agriculture, which would have negative consequences. Drought in some areas may increase, which would decrease water and food availability. Global warming may also contribute to air quality problems from increased frequency of smog and particulate air pollution.

The impacts of climate change will also affect projects in various ways. Effects of climate change are rising sea levels and changes in snow pack. The extent of climate change impacts at specific locations remains unclear. It is expected that Federal, State and local agencies will more precisely quantify impacts in various regions. As an example, it is expected that the California Department of Water Resources will formalize a list of foreseeable water quality issues associated with various degrees of climate change. Once state government agencies make these lists available, they could be used to more precisely determine to what extent a project creates global climate change impacts.

Federal

Greenhouse Gas Endangerment Findings: On December 7, 2009, the USEPA Administrator signed two distinct findings regarding greenhouse gases pursuant to CAA §202 (a). The Endangerment Finding stated that CO2, CH4, N2O, HFCs, PFCs, and SF6 taken in combination endanger both the public health and the public welfare of current and future generations. The *Cause or Contribute Finding* stated that the combined emissions from motor vehicles and motor vehicle engines contribute to the greenhouse gas air pollution that endangers public health and welfare. These findings were a prerequisite for implementing GHG standards for vehicles. The USEPA and the National Highway Traffic Safety Administration (NHTSA) finalized emission standards for light-duty vehicles in May 2010 and for heavy-duty vehicles in August of 2011.

Renewable Fuel Standard: The Renewable Fuel Standard (RFS) program was established under the Energy Policy Act (EPAct) of 2005, and required 7.5 billion gallons of renewable-fuel to be blended into gasoline by 2012. Under the Energy Independence and Security Act (EISA) of 2007, the RFS program was expanded to include diesel, required the volume of renewable fuel blended into transportation fuel be increased from nine billion gallons in 2008 to 36 billion gallons by 2022, established new categories of renewable fuel and required USEPA to apply lifecycle GHG performance threshold standards so that each category of renewable fuel emits fewer greenhouse gases than the petroleum fuel it replaces. The RFS is expected to reduce greenhouse gas emissions by 138 million metric tons[6], about the annual emissions of 27 million passenger vehicles, replacing about seven percent of expected annual diesel consumption and decreasing oil imports by $41.5 billion.

GHG Tailoring Rule: On May 13, 2010, USEPA finalized the GHG Tailoring Rule to phase in the applicability of the Prevention of Significant Deterioration (PSD) and Title V operating permit programs for GHGs. The GHG Tailoring Rule was tailored to include the largest GHG emitters, while excluding smaller sources (restaurants, commercial facilities and small farms). The first phase (from January 2, 2011 to June 30, 2011) addressed the largest sources that contributed 65 percent of the stationary GHG sources. Title V GHG requirements were triggered only when affected facility owners/operators were applying, renewing or revising their permits for non-GHG pollutants. PSD GHG requirements were applicable only if sources were undergoing permitting actions for other non-GHG pollutants and the permitted action would increase GHG emission by 75,000 metric tons of CO2 equivalent emissions (CO2e) per year or more.

The second phase (from July 1, 2011 to June 30, 2013) included sources that emit or have the potential to emit 100,000 of CO2e metric tons per year or more. Newly constructed sources that are not major sources for non-GHG pollutants would not be subject to PSD GHG requirements unless it emits 100,000 metric tons of CO2e per year or more. Modifications to a major source would not be subject to PSD GHG requirements unless it generates a net increase of 75,000 metric tons of CO2e per year or more. Sources not subject to Title V would not be subject to Title V GHG requirements unless 100,000 metric tons of CO2e per year or more would be emitted.

[6] One metric ton is equal to 2, 205 pounds.

The third phase of the GHG Tailoring Rule, finalized on July 12, 2012, determined not to lower the current PSD and Title V applicability thresholds for GHG-emitting sources established in the GHG Tailoring Rule for phases 1 and 2. The GHG Tailoring Rule also promulgated regulatory revisions for better implementation of the federal program for establishing plantwide applicability limitations (PALs) for GHG emissions, which will improve the administration of the GHG PSD permitting programs. Recently, the U.S. Supreme Court held that EPA was limited to Step 1.

GHG Reporting Program: USEPA issued the Mandatory Reporting of Greenhouse Gases Rule (40 CFR Part 98) under the 2008 Consolidated Appropriations Act. The Mandatory Reporting of Greenhouse Gases Rule requires reporting of GHG data from large sources and suppliers under the Greenhouse Gas Reporting Program (GHGRP). Suppliers of certain products that would result in GHG emissions if released, combusted or oxidized; direct emitting source categories; and facilities that inject CO2 underground for geologic sequestration or any purpose other than geologic sequestration are included. Facilities that emit 25,000 metric tons or more per year of GHGs as CO2e are required to submit annual reports to USEPA. For the 2010 calendar, there were 6,260 entities that reported GHG data under this program, and 467 of the entities were from California. Of the 3,200 million metric tons of CO2e that were reported nationally, 112 million metric tons of CO2e were from California. Power plants were the largest stationary source of direct U.S. GHG emissions with 2,326 million metric tons of CO2e, followed by refineries with 183 million metric tons of CO2e. CO2 emissions accounted for largest share of direct emissions with 95 percent, followed by CH4 with four percent, and N2O and fluorinated gases representing the remaining one percent.

State

Executive Order S-3-05: In June 2005, Governor Schwarzenegger signed Executive Order S-3-05, which established emission reduction targets. The goals would reduce GHG emissions to 2000 levels by 2010, then to 1990 levels by 2020, and to 80 percent below 1990 levels by 2050.

AB 32 - Global Warming Solutions Act: On September 27, 2006, AB 32, the California Global Warming Solutions Act of 2006, was signed by Governor Schwarzenegger. AB 32 expanded on Executive Order S-3-05. The California legislature stated that “global warming poses a serious threat to the economic well-being, public health, natural resources, and the environment of California.” AB 32 represents the first enforceable state-wide program in the U.S. to cap all GHG emissions from major industries that includes penalties for non-compliance. While acknowledging that national and international actions will be necessary to fully address the issue of global warming, AB 32 lays out a program to inventory and reduce greenhouse gas emissions in California and from power generation facilities located outside the state that serve California residents and businesses. AB 32 requires CARB to:

- Establish a statewide GHG emissions cap for 2020, based on 1990 emissions by January 1, 2008;

- Adopt mandatory reporting rules for significant sources of GHG by January 1, 2008;
- Adopt a GHG emissions reduction plan by January 1, 2009, indicating how the GHG emissions reductions will be achieved via regulations, market mechanisms, and other actions; and
- Adopt regulations to achieve the maximum technologically feasible and cost-effective reductions of GHG by January 1, 2011.

The combination of Executive Order S-3-05 and AB 32 will require significant development and implementation of energy efficient technologies and shifting of energy production to renewable sources.

Consistent with the requirement to develop an emission reduction plan, CARB prepared a Scoping Plan indicating how GHG emission reductions will be achieved through regulations, market mechanisms, and other actions. The Scoping Plan was released for public review and comment in October 2008 and approved by CARB on December 11, 2008. The Scoping Plan calls for reducing GHG emissions to 1990 levels by 2020. This means cutting approximately 30 percent from business-as-usual (BAU) emission levels projected for 2020, or about 15 percent from today's levels. Key elements of CARB staff's recommendations for reducing California's GHG emissions to 1990 levels by 2020 contained in the Scoping Plan include the following:

- Expansion and strengthening of existing energy efficiency programs and building and appliance standards;
- Expansion of the Renewables Portfolio Standard to 33 percent;
- Development of a California cap-and-trade program that links with other Western Climate Initiative (WCI) partner programs to create a regional market system;
- Establishing targets for transportation-related greenhouse gases and pursuing policies and incentives to achieve those targets;
- Adoption and implementation of existing state laws and policies, including California's clean car standards, goods movement measures, and the Low Carbon Fuel Standard (LCFS); and
- Targeted fees, including a public good charge on water use, fees on high global warming potential (GWP) gases and a fee to fund the state's long-term commitment to AB 32 administration.

In response to the comments received on the Draft Scoping Plan and at the November 2008 public hearing, CARB made a few changes to the Draft Scoping Plan, primarily to:

- State that California "will transition to 100 percent auction" of allowances and expects to "auction significantly more [allowances] than the Western Climate Initiative minimum;"

- Make clear that allowance set-asides could be used to provide incentives for voluntary renewable power purchases by businesses and individuals and for increased energy efficiency;

- Make clear that allowance set-asides can be used to ensure that voluntary actions, such as renewable power purchases, can be used to reduce greenhouse gas emissions under the cap;

- Provide allowances are not required from carbon neutral projects; and

- Mandate that commercial recycling be implemented to replace virgin raw materials with recyclables.

SB 97 – CEQA, Greenhouse Gas Emissions: On August 24, 2007, Governor Schwarzenegger signed into law SB 97 – CEQA: Greenhouse Gas Emissions, and stated, "This bill advances a coordinated policy for reducing greenhouse gas emissions by directing the Office of Planning and Research (OPR) and the Resources Agency to develop CEQA guidelines on how state and local agencies should analyze, and when necessary, mitigate greenhouse gas emissions." As directed by SB 97, the Natural Resources Agency adopted amendments to the CEQA Guidelines for GHG emissions on December 30, 2009 to provide guidance to public agencies regarding the analysis and mitigation of the effects of GHG emissions in draft CEQA documents. The amendments did not establish a threshold for significance for GHG emissions. The amendments became effective on March 18, 2010.

***OPR - Technical Advisory on CEQA and Climate Change*:** Consistent with SB 97, on June 19, 2008, OPR released its "Technical Advisory on CEQA and Climate Change," which was developed in cooperation with the Resources Agency, the CalEPA, and the CARB. According to OPR, the "Technical Advisory" offers the informal interim guidance regarding the steps lead agencies should take to address climate change in their CEQA documents, until CEQA guidelines are developed pursuant to SB 97 on how state and local agencies should analyze, and when necessary, mitigate greenhouse gas emissions.

According to OPR, lead agencies should determine whether greenhouse gases may be generated by a proposed project, and if so, quantify or estimate the GHG emissions by type and source. Second, the lead agency must assess whether those emissions are individually or cumulatively significant. When assessing whether a project's effects on climate change are "cumulatively considerable" even though its GHG contribution may be individually limited, the lead agency must consider the impact of the project when viewed in connection with the effects of past, current, and probable future projects. Finally, if the lead agency determines that the GHG emissions from the project as proposed are potentially significant, it must investigate and implement ways to avoid, reduce, or otherwise mitigate the impacts of those emissions.

In 2009, total California greenhouse gas emissions were 457 million metric tons of CO2e (MMTCO2e); net emissions were 453 MMTCO2e, reflecting the influence of sinks (net

CO2 flux from forestry). While total emissions have increased by 5.5 percent from 1990 to 2009, emissions decreased by 5.8 percent from 2008 to 2009 (485 to 457 MMTCO2e). The total net emissions between 2000 and 2009 decreased from 459 to 453 MMTCO2e, representing a 1.3 percent decrease from 2000 and a 6.1 percent increase from the 1990 emissions level. The transportation sector accounted for approximately 38 percent of the total emissions, while the industrial sector accounted for approximately 20 percent. Emissions from electricity generation were about 23 percent with almost equal contributions from in-state and imported electricity.

Per capita emissions in California have slightly declined from 2000 to 2009 (by 9.7 percent), but the overall nine percent increase in population during the same period offsets the emission reductions. From a per capita sector perspective, industrial per capita emissions have declined 21 percent from 2000 to 2009, while per capita emissions for ozone depleting substance (ODS) substitutes saw the highest increase (52 percent).

From a broader geographical perspective, the state of California ranked second in the U.S. for 2007 greenhouse gas emissions, only behind Texas. However, from a per capita standpoint, California had the 46th lowest GHG emissions. On a global scale, California had the 14th largest carbon dioxide emissions and the 19th largest per capita emissions. The GHG inventory is divided into three categories: stationary sources, on-road mobile sources, and off-road mobile sources.

AB 1493 Vehicular Emissions - CO2: Prior to the USEPA and NHTSA joint rulemaking, Governor Schwarzenegger signed Assembly Bill AB 1493 (2002). AB 1493 requires that CARB develop and adopt, by January 1, 2005, regulations that achieve "the maximum feasible reduction of greenhouse gases emitted by passenger vehicles and light-duty trucks and other vehicles determined by CARB to be vehicles whose primary use is noncommercial personal transportation in the state."

CARB originally approved regulations to reduce GHGs from passenger vehicles in September 2004, with the regulations to take effect in 2009 (see amendments to CCR Title 13 §§1900 and 1961 (13 CCR 1900, 1961), and the adoption of CCR Title 13 §1961.1 (13 CCR 1961.1)). California's first request to the USEPA to implement GHG standards for passenger vehicles was made in December 2005 and subsequently denied by the USEPA in March 2008. The USEPA then granted California the authority to implement GHG emission reduction standards for new passenger cars, pickup trucks and sport utility vehicles on June 30, 2009.

On April 1, 2010, CARB filed amended regulations for passenger vehicles as part of California's commitment toward the national program to reduce new passenger vehicle GHGs from 2012 through 2016. The amendments will prepare California to harmonize its rules with the federal Light-Duty Vehicle GHG Standards and CAFE Standards.

SB 1368: SB 1368 is the companion bill of AB 32 and was signed by Governor Schwarzenegger in September 2006. SB 1368 required the CPUC to establish a GHG emission performance standard for baseload generation from investor owned utilities by February 1, 2007. The CEC was also required to establish a similar standard for local publicly owned utilities by June 30, 2007. These standards cannot exceed the greenhouse gas emission rate from a baseload combined-cycle natural gas fired plant. The legislation further required that all electricity provided to California, including imported electricity, must be generated from plants that meet the standards set by the PUC and CEC.

Executive Order S-1-07: Governor Schwarzenegger signed Executive Order S-1-07 in 2007 which established the transportation sector as the main source of GHG emissions in California. Executive Order S-1-07 proclaims that the transportation sector accounts for over 40 percent of statewide GHG emissions. Executive Order S-1-07 also establishes a goal to reduce the carbon intensity of transportation fuels sold in California by a minimum of 10 percent by 2020.

In particular, Executive Order S-1-07 established the LCFS and directed the Secretary for Environmental Protection to coordinate the actions of the CEC, CARB, the University of California, and other agencies to develop and propose protocols for measuring the "life-cycle carbon intensity" of transportation fuels. The analysis supporting development of the protocols was included in the SIP for alternative fuels (State Alternative Fuels Plan adopted by CEC on December 24, 2007) and was submitted to CARB for consideration as an "early action" item under AB 32. CARB adopted the LCFS on April 23, 2009.

SB 375: SB 375, signed into law in September 2008, aligns regional transportation planning efforts, regional GHG reduction targets, and land use and housing allocation. As part of the alignment, SB 375 requires Metropolitan Planning Organizations (MPOs) to adopt a Sustainable Communities Strategy (SCS) or Alternative Planning Strategy (APS) which prescribes land use allocation in that MPO's Regional Transportation Plan (RTP). CARB, in consultation with MPOs, is required to provide each affected region with reduction targets for GHGs emitted by passenger cars and light trucks in the region for the years 2020 and 2035. These reduction targets will be updated every eight years but can be updated every four years if advancements in emissions technologies affect the reduction strategies to achieve the targets. CARB is also charged with reviewing each MPO's SCS or APS for consistency with its assigned GHG emission reduction targets. If MPOs do not meet the GHG reduction targets, transportation projects located in the MPO boundaries would not be eligible for funding programmed after January 1, 2012.

CARB appointed the Regional Targets Advisory Committee (RTAC), as required under SB 375, on January 23, 2009. The RTAC's charge was to advise CARB on the factors to be considered and methodologies to be used for establishing regional targets. The RTAC provided its recommendation to CARB on September 29, 2009. CARB was required to adopt final targets by September 30, 2010.

Executive Order S-13-08: Governor Schwarzenegger signed Executive Order S-13-08 on November 14, 2008 which directed California to develop methods for adapting to climate change through preparation of a statewide plan. Executive Order S-13-08 directed OPR, in cooperation with the Resources Agency, to provide land use planning guidance related to sea level rise and other climate change impacts by May 30, 2009. Executive Order S-13-08 also directed the Resources Agency to develop a state Climate Adaptation Strategy by June 30, 2009 and to convene an independent panel to complete the first California Sea Level Rise Assessment Report. The assessment report was required to be completed by December 1, 2010 and required to meet the following four criteria:

1. Project the relative sea level rise specific to California by taking into account issues such as coastal erosion rates, tidal impacts, El Niño and La Niña events, storm surge, and land subsidence rates;
2. Identify the range of uncertainty in selected sea level rise projections;
3. Synthesize existing information on projected sea level rise impacts to state infrastructure (e.g., roads, public facilities, beaches), natural areas, and coastal and marine ecosystems; and
4. Discuss future research needs relating to sea level rise in California.

SB 1078, SB 107 and Executive Order S-14-08: SB 1078 (Chapter 516, Statutes of 2002) requires retail sellers of electricity, including investor owned utilities and community choice aggregators, to provide at least 20 percent of their supply from renewable sources by 2017. SB 107 (Chapter 464, Statutes of 2006) changed the target date to 2010. In November 2008, Governor Schwarzenegger signed Executive Order S-14-08, which expands the state's Renewable Portfolio Standard to 33 percent renewable power by 2020.

SB X-1-2: SB X1-2 was signed by Governor Brown in April 2011. SB X1-2 created a new Renewables Portfolio Standard (RPS), which pre-empted CARB's 33 percent Renewable Electricity Standard. The new RPS applies to all electricity retailers in the state including publicly owned utilities (POUs), investor-owned utilities, electricity service providers, and community choice aggregators. These entities must adopt the new RPS goals of 20 percent of retails sales from renewables by the end of 2013, 25 percent by the end of 2016, and the 33 percent requirement by the end of 2020.

<u>SCAQMD</u>

The SCAQMD adopted a "Policy on Global Warming and Stratospheric Ozone Depletion" on April 6, 1990. The policy commits the SCAQMD to consider global impacts in rulemaking and in drafting revisions to the AQMP. In March 1992, the SCAQMD Governing Board reaffirmed this policy and adopted amendments to the policy to include support of the adoption of a California GHG emission reduction goal.

Basin GHG Policy and Inventory: The SCAQMD has established a policy, adopted by the SCAQMD Governing Board at its September 5, 2008 meeting, to actively seek opportunities to reduce emissions of criteria, toxic, and climate change pollutants. The policy includes the intent to assist businesses and local governments implementing climate change measures, decrease the agency's carbon footprint, and provide climate change information to the public. The SCAQMD will take the following actions:

1. Work cooperatively with other agencies/entities to develop quantification protocols, rules, and programs related to greenhouse gases;

2. Share experiences and lessons learned relative to SCAQMD Regulation XX - Regional Clean Air Incentives Market (RECLAIM), to help inform state, multi-state, and federal development of effective, enforceable cap-and-trade programs. To the extent practicable, staff will actively engage in current and future regulatory development to ensure that early actions taken by local businesses to reduce greenhouse gases will be treated fairly and equitably. SCAQMD staff will seek to streamline administrative procedures to the extent feasible to facilitate the implementation of AB 32 measures;
3. Review and comment on proposed legislation related to climate change and greenhouse gases, pursuant to the 'Guiding Principles for SCAQMD Staff Comments on Legislation Relating to Climate Change' approved at the SCAQMD Governing Board's Special Meeting in April 2008;
4. Provide higher priority to funding Technology Advancement Office (TAO) projects or contracts that also reduce greenhouse gas emissions;
5. Develop recommendations through a public process for an interim greenhouse gas CEQA significance threshold, until such time that an applicable and appropriate statewide greenhouse gas significance level is established. Provide guidance on analyzing greenhouse gas emissions and identify mitigation measures. Continue to consider GHG impacts and mitigation in SCAQMD lead agency documents and in comments when SCAQMD is a responsible agency;
6. Revise the SCAQMD's Guidance Document for Addressing Air Quality Issues in General Plans and Local Planning to include information on greenhouse gas strategies as a resource for local governments. The Guidance Document will be consistent with state guidance, including CARB's Scoping Plan;
7. Update the Basin's greenhouse gas inventory in conjunction with each Air Quality Management Plan. Information and data used will be determined in consultation with CARB, to ensure consistency with state programs. Staff will also assist local governments in developing greenhouse gas inventories;
8. Bring recommendations to the SCAQMD Governing Board on how the agency can reduce its own carbon footprint, including drafting a Green Building Policy with recommendations regarding SCAQMD purchases, building maintenance, and other areas of products and services. Assess employee travel as well as other activities that are not part of a GHG inventory and determine what greenhouse gas emissions these activities represent, how they could be reduced, and what it would cost to offset the emissions;
9. Provide educational materials concerning climate change and available actions to reduce greenhouse gas emissions on the SCAQMD website, in brochures, and other venues to help cities and counties, businesses, households, schools, and others learn about ways to reduce their electricity and water use through conservation or other efforts, improve energy efficiency, reduce vehicle miles traveled, access alternative mobility resources, utilize low emission vehicles and implement other climate friendly strategies; and

10. Conduct conferences, or include topics in other conferences, as appropriate, related to various aspects of climate change, including understanding impacts, technology advancement, public education, and other emerging aspects of climate change science.

On December 5, 2008, the SCAQMD Governing Board adopted the staff proposal for an interim GHG significance threshold for projects where the SCAQMD is lead agency. SCAQMD's recommended interim GHG significance threshold proposal uses a tiered approach to determining significance. Tier 1 consists of evaluating whether or not the project qualifies for any applicable exemption under CEQA. Tier 2 consists of determining whether or not the project is consistent with a GHG reduction plan that may be part of a local general plan, for example. Tier 3 establishes a screening significance threshold level to determine significance using a 90 percent emission capture rate approach, which corresponds to 10,000 metric tons of CO2 equivalent emissions per year (MTCO2e/year). Tier 4, to be based on performance standards, is yet to be developed. Under Tier 5 the project proponent would allow offsets to reduce GHG emission impacts to less than the proposed screening level. If CARB adopts statewide significance thresholds, SCAQMD staff plans to report back to the SCAQMD Governing Board regarding any recommended changes or additions to the SCAQMD's interim threshold.

Table 3.2-3 presents the GHG emission inventory by major source categories in calendar year 2008, as identified in the 2012 AQMP for the South Coast Air Basin. The emissions reported herein are based on in-basin energy consumption and do not include out-of-basin energy production (e.g., power plants, crude oil production) or delivery emissions (e.g., natural gas pipeline loss). Three major GHG pollutants have been included: CO2, N2O, and CH4. These GHG emissions are reported in MMTCO2e. Mobile sources generate 59.4 percent of the emissions, and include airport equipment, and oil and gas drilling equipment. The remaining 40.6 percent of the total Basin GHG emissions are from stationary and area sources. The largest stationary/area source is fuel combustion, which is 27.8 percent of the total Basin GHG emissions (68.6 percent of the GHG emissions from the stationary and area source category).

3.2.2.3 Air Quality – Ozone Depletion

The Montreal Protocol on Substances that Deplete the Ozone Layer (Montreal Protocol) is an international treaty designed to phase out halogenated hydrocarbons such as chlorofluorocarbons (CFCs) and hydrochlorofluorocarbons (HCFCs), which are considered ODSs. The Montreal Protocol was first signed in September 16, 1987 and has been revised seven times. The U.S. ratified the original Montreal Protocol and each of its revisions.

Federal

Under the CAA Title VI, the USEPA is assigned responsibility for implementing programs that protect the stratospheric ozone layer. 40 CFR Part 82 contains USEPA's regulations specific to protecting the ozone layer. These USEPA regulations phase out the production and import of ozone depleting substances (ODSs) consistent with the Montreal Protocol. ODSs are typically used as refrigerants or as foam blowing agents. ODS are regulated as Class I or Class II controlled substances. Class I substances have a higher ozone-depleting potential and have been completely phased out in the U.S., except for exemptions allowed under the Montreal Protocol. Class II substances are HCFCs, which are transitional substitutes for many Class I substances and are being phased out.

State

AB 32 - Global Warming Solutions Act: Some ODSs exhibit high global warming potentials. CARB developed a cap and trade regulation under AB 32. The cap and trade regulation includes the Compliance Offset Protocol Ozone Depleting Substances Projects, which provides methods to quantify and report GHG emission reductions associated with the destruction of high global warming potential ODS sourced from and destroyed within the U.S. that would have otherwise been released to the atmosphere. The protocol must be used to quantify and report GHG reductions under the ARB's GHG Cap and Trade Regulation.

Refrigerant Management Program: As part implementing AB 32, CARB also adopted a Refrigerant Management Program in 2009. The Refrigerant Management Program is designed to reduce GHG emissions from stationary sources through refrigerant leak detection and monitoring, leak repair, system retirement and retrofitting, reporting and recordkeeping, and proper refrigerant cylinder use, sale, and disposal.

HFC Emission Reduction Measures for Mobile Air Conditioning - Regulation for Small Containers of Automotive Refrigerant: The Regulation for Small Containers of Automotive Refrigerant applies to the sale, use, and disposal of small containers of automotive refrigerant with a GWP greater than 150. Emission reductions are achieved through implementation of four requirements: 1) use of a self-sealing valve on the container, 2) improved labeling instructions, 3) a deposit and recycling program for small containers, and 4) an education program that emphasizes best practices for vehicle recharging. This regulation went into effect on January 1, 2010 with a one-year sell-through period for containers manufactured before January 1, 2010. The target recycle rate is initially set at 90 percent, and rose to 95 percent beginning January 1, 2012.

SCAQMD

The SCAQMD adopted a "Policy on Global Warming and Stratospheric Ozone Depletion" on April 6, 1990. The policy targeted a transition away from CFCs as an industrial refrigerant and propellant in aerosol cans. In March 1992, the SCAQMD Governing Board reaffirmed this policy and adopted amendments to the policy to include the following directives for ODSs:

- phase out the use and corresponding emissions of CFCs, methyl chloroform (1,1,1-trichloroethane or TCA), carbon tetrachloride, and halons by December 1995;
- phase out the large quantity use and corresponding emissions of HCFCs by the year 2000;
- develop recycling regulations for HCFCs; and
- develop an emissions inventory and control strategy for methyl bromide.

SCAQMD Rule 1122 – Solvent Degreasers: SCAQMD Rule 1122 applies to all persons who own or operate batch-loaded cold cleaners, open-top vapor degreasers, all types of conveyorized degreasers, and air-tight and airless cleaning systems that carry out solvent degreasing operations with a solvent containing VOCs or with a NESHAP halogenated solvent. Some ODSs such as carbon tetrachloride and TCA are NESHAP halogenated solvents.

SCAQMD Rule 1171 – Solvent Cleaning Operations: SCAQMD Rule 1171 reduces emissions of VOCs, TACs, and stratospheric ozone-depleting or globalwarming compounds from the use, storage and disposal of solvent cleaning materials in solvent cleaning operations and activities

SCAQMD Rule 1411 - Recovery or Recycling of Refrigerants from Motor Vehicle Air Conditioners: Rule 1411 prohibits release or disposal of refrigerants used in motor vehicle air conditioners and prohibits the sale of refrigerants in containers which contain less than 20 pounds of refrigerant.

SCAQMD Rule 1415 - Reduction of Refrigerant Emissions from Stationary Air Conditioning Systems: Rule 1415 reduces emissions of high-global warming potential refrigerants from stationary air conditioning systems by requiring persons subject to this rule to reclaim, recover, or recycle refrigerant and to minimize refrigerant leakage.

SCAQMD Rule 1418 - Halon Emissions from Fire Extinguishing Equipment: Rule 1418 reduce halon emissions by requiring the recovery and recycling of halon from fire extinguishing systems, by limiting the use of halon to specified necessary applications, and by prohibiting the sale of portable halon fire extinguishers that contain less than five pounds of halon.

SUBCHAPTER 3.3

ENERGY

Regulatory Setting

Energy Trends in General (Statewide)

Alternative Clean Transportation Fuels

Renewable Energy

Consumptive Uses

3.3 ENERGY

This subchapter describes existing regulatory setting relative energy production and demand, including alternative and renewable fuels, and trends within California and the SCAQMD.

3.3.1 Regulatory Setting

Federal and state agencies regulate energy use and consumption through various means and programs. On the federal level, the United States Department of Transportation (USDOT), United States Department of Energy (USDOE), and United States Environmental Protection Agency (USEPA) are three agencies with substantial influence over energy policies and programs. Generally, federal agencies influence transportation energy consumption through establishment and enforcement of fuel economy standards for automobiles and light trucks, through funding of energy related research and development projects, and through funding for transportation infrastructure projects.

On the state level, the California Public Utilities Commission (CPUC) and California Energy Commission (CEC) are two agencies with authority over different aspects of energy. The CPUC regulates privately-owned utilities in the energy, rail, passenger transportation, telecommunications, and water fields. The CEC collects and analyzes energy-related data, prepares state-wide energy policy recommendations and plans, promotes and funds energy efficiency and renewable energy resources programs, plans and directs state response to energy emergencies, and regulates the power plant siting and transmission process. Some of the more relevant federal and state transportation-energy-related laws and plans are discussed in the following subsections.

3.3.1.1 Federal Regulations

Energy Policy and Conservation Act

The Energy Policy and Conservation Act of 1975 sought to ensure that all vehicles sold in the U.S. would meet certain fuel economy goals. Through this Act, Congress established the first fuel economy standards for on-road motor vehicles in the U.S. Pursuant to the Act, the National Highway Traffic and Safety Administration, which is part of the USDOT, is responsible for establishing additional vehicle standards and for revising existing standards. Since 1990, the fuel economy standard for new passenger cars has been 27.5 miles per gallon. Since 1996, the fuel economy standard for new light trucks (gross vehicle weight of 8,500 pounds or less) has been 20.7 miles per gallon. Heavy-duty vehicles (e.g., vehicles and trucks over 8,500 pounds gross vehicle weight) are not currently subject to fuel economy standards. Compliance with federal fuel economy standards is not determined for each individual vehicle model, but rather, compliance is determined on the basis of each manufacturer's average fuel economy for the portion of their vehicles produced for sale in the U.S. The Corporate Average Fuel Economy (CAFE) program, which is administered by USEPA, was created to determine vehicle manufacturers' compliance with the fuel economy standards. The USEPA calculates a CAFE value for each manufacturer based on city and highway fuel economy test results and vehicle sales. Based on the information generated under the CAFE program, the USDOT is authorized to assess penalties for noncompliance.

National Energy Act

The National Energy Act of 1978 included the following statues: Energy Tax Act, National Energy Conservation Policy Act, Power Plant and Industrial Fuel Use Act, and the National Gas Policy Act. The Power Plant and Industrial Fuel Use Act restricted the fuel used in power plants, however, these restrictions were lifted in 1987. The Energy Tax Act was superseded by the Energy Policy Acts of 1992 and 2005. The National Gas Policy Act gave the Federal Energy Regulatory Commission authority over natural gas production and established pricing guidelines. The National Energy Conservation Policy Act (NECPA) set minimum energy performance standards, which replaced those in the EPCA. The federal standards preempted state standards. The NECPA was amended by the Energy Policy and Conservation Act Amendments of 1985.

Public Utility Regulatory Policies Act of 1978 (Public Law 95-617)

The Public Utility Regulatory Policies Act of 1978 (PURPA) was passed in response to the unstable energy climate of the late 1970s. PURPA sought to promote conservation of electric energy. Additionally, PURPA created a new class of nonutility generators, small power producers, from which, along with qualified co-generators, utilities are required to buy power.

PURPA was in part intended to augment electric utility generation with more efficiently produced electricity and to provide equitable rates to electric consumers. Utility companies are required to buy all electricity from qualifying facilities (Qfs) at avoided cost (avoided costs are the incremental savings associated with not having to produce additional units of electricity). PURPA expanded participation of nonutility generators in the electricity market and demonstrated that electricity from nonutility generators could successfully be integrated with a utility's own supply. PURPA requires utilities to buy whatever power is produced by Qfs (usually cogeneration or renewable energy). The Fuel Use Act (FUA) of 1978 (repealed in 1987) also helped Qfs become established. Under the FUA, utilities were not allowed to use natural gas to fuel new generating technologies, but Qfs, which were by definition not utilities, were able to take advantage of abundant natural gas and abundant new technologies (such as combined-cycle).

Energy Policy Act of 1992

The Energy Policy Act of 1992 is comprised of twenty-seven titles. It addressed clean energy use and overall national energy efficiency to reduce dependence on foreign energy, incentives for clean, radioactive waste protection standards, and renewable energy and energy conservation in buildings and efficiency standards for appliances.

Energy Policy Act of 2005

The Energy Policy Act of 2005 addresses energy efficiency; renewable energy requirements; oil, natural gas and coal; alternative-fuel use; tribal energy, nuclear security; vehicles and vehicle fuels, hydropower and geothermal energy, and climate change technology. The Act provides revised annual energy reduction goals (two percent per year beginning in 2006), revised renewable energy purchase goals, federal procurement of Energy Star or Federal

Energy Management Program-designated products, federal green building standards, and fuel cell vehicle and hydrogen energy system research and demonstration.

Clean Air Act

The Clean Air Act (CAA), §211 (o), as amended by the Energy Policy Act of 2005, requires the Administrator of the U.S. Environmental Protection Agency (USEPA) to annually determine a renewable fuel standard (RFS), which is applicable to refiners, importers, and certain blenders of gasoline, and publish the standard in the FR by November 30 of each year. On the basis of this standard, each obligated party determines the volume of renewable fuel that it must ensure is consumed as motor vehicle fuel. This standard is calculated as a percentage, by dividing the amount of renewable fuel that the CAA requires to be blended into gasoline for a given year by the amount of gasoline expected to be used during that year, including certain adjustments specified by the CAA.

Corporate Average Fuel Economy Program

Compliance with federal fuel economy standards is determined on the basis of each manufacturer's average fuel economy for the portion of their vehicles produced for sale in the U.S. The Corporate Average Fuel Economy (CAFE) program, which is administered by the USEPA, was created to determine vehicle manufacturers' compliance with the fuel economy standards. The USEPA calculates a CAFE value for each manufacturer based on city and highway fuel economy test results and vehicle sales. Based on the information generated under the CAFE program, the USDOT is authorized to assess penalties for noncompliance.

Energy Independence and Security Act of 2007

The Energy Independence and Security Act (EISA) of 2007 was signed into law by President George W. Bush on December 19, 2007. The Acts objectives are to move the United States toward greater energy independence and security, increase the production of clean renewable fuels, protect consumers, increase the efficiency of products, buildings and vehicles, promote greenhouse gas research, improve the energy efficiency of the Federal government, and improve vehicle fuel economy.

The renewable fuel standard in EISA requires 36 billion gallons of ethanol per year by 2022, with corn-based ethanol limited to 15 billion gallons. The new CAFE standard for light duty vehicles is 35 miles per gallon by 2020. EISA also specifies that vehicle attribute-based standards are to be developed separately for cars and light trucks. EISA creates a CAFE credit and transfer program among manufacturers and across a manufacturer's fleet. It would allow an extension through 2019 of the CAFE credits specified under the Alternative Motor Fuels Act. It establishes appliance energy efficiency standards for boilers, dehumidifiers, dishwashers, clothes washers, external power supplies, commercial walk-in coolers and freezers, federal buildings; lighting energy efficiency standards for general service incandescent lighting in 2012; and standards for industrial electric motor efficiency.

3.3.1.2 State Regulations

The CEC and CPUC have jurisdiction over the investor-owned utilities (IOUs) in California. Within the district, the CEC also collects information for the Los Angeles Department of Water and Power (LADWP) and the Burbank, Glendale and Pasadena Municipal Utilities. The applicable state regulations, laws, and executive orders relevant to energy use are discussed below.

<u>California Building Energy Efficiency Standards</u>

California established statewide building energy efficiency standards in CCR, Title 24 - California Building Standards Code in response to a legislative mandate to reduce California's energy consumption. Title 24 contains the regulations that govern the construction of buildings in California. The legislation required the standards to be cost-effective based on the building life cycle and to include both prescriptive and performance-based approaches. The standards are updated approximately every three years by the CEC to allow consideration and possible incorporation of new energy efficiency technologies and methods. The 2005 Building Energy Efficiency Standards were first adopted in November 2003, and took effect October 1, 2005. Subsequently the standards have undergone two updates, one in 2008 and one in 2013. The 2013 Building Energy Efficiency Standards will go into effect on July 1, 2014.

<u>AB 1007 - Alternative Fuels Plan</u>

AB 1007 (Pavley, Chapter 371, Statutes of 2005) requires the CEC to prepare an Alternative Fuels Plan for the state to increase the use of alternative fuels in California. The CEC prepared the plan in partnership with CARB, and in consultation with other state, federal and local agencies in December 2007. The Alternative Fuels Plan assessed various alternative fuels and developed fuel portfolios to meet California's goals to reduce petroleum consumption, increase alternative fuels use, reduce GHG emissions, and increase in-state production of biofuels without causing a significant degradation of public health and environmental quality.

<u>AB 1493 - Vehicle Climate Change Standards</u>

AB 1493 required California to develop and adopt regulations that achieve the maximum feasible and cost-effective reduction of climate change emissions emitted by passenger vehicles and light-duty trucks. Regulations that were designed to improve fuel efficiency were adopted by CARB in September 2004.

<u>SB 1368 - Emission Performance Standards</u>

On September 29, 2006, Governor Schwarzenegger signed into law SB 1368 – Emissions Performance Standards (Perata, Chapter 598, Statutes of 2006). SB 1368 limits long-term investments in baseload generation by California's utilities to power plants that meet an emissions performance standard (EPS) jointly established by the CEC and the CPUC. SB 1368 establishes a standard for baseload generation owned by, or under long-term contract to publicly owned utilities, of 1,100 lbs CO2 per MWh to encourage the development of power plants that meet California's growing energy needs while minimizing their emissions of greenhouse gases.

California Solar Initiative

On January 12, 2006, the CPUC approved the California Solar Initiative (CSI), which provides $2.9 billion in incentives between 2007 and 2017. CSI is part of the Go Solar California campaign, and builds on 10 years of state solar rebates offered to California's IOU territories: Pacific Gas and Electric (PG&E), Southern California Edison (SCE), and San Diego Gas and Electric (SDG&E). The CSI is overseen by the CPUC, and includes a $2.5 billion program for commercial and existing residential customers, funded through revenues and collected from gas and electric utility distribution rates. Furthermore, the CEC will manage $350 million targeted for new residential building construction, utilizing funds already allocated to the CEC to foster renewable projects between 2007 and 2011.

Current incentives provide an upfront, capacity-based payment for a new system. In its August 24, 2006 decision, the CPUC shifted the program from volume-based to performance-based incentives and clarified many elements of the program's design and administration. These changes were enacted in 2007, when the CSI incentive system changed to performance-based payments.

Reducing California's Petroleum Dependence

The CEC and CARB produced a joint report "Reducing California's Petroleum Dependence" to highlight petroleum consumption and to establish a performance based goal to reduce petroleum consumption in California over the next thirty years. The report includes the following recommendations to the Governor and Legislature regarding petroleum:

- Adopt the recommended statewide goal of reducing demand for on-road gasoline and diesel to 15 percent below the 2003 demand level by 2020 and maintaining that level for the foreseeable future.
- Work with the California delegation and other states to establish national fuel economy standards that double the fuel efficiency of new cars, light trucks, and sport utility vehicles.
- Establish a goal to increase the use of non-petroleum fuels to 20 percent of on-road fuel consumption by 2020, and 30 percent by 2030.

The CEC will use these recommendations when developing its series of recommendations to the Governor and Legislature for the integrated energy plan for electricity, natural gas, and transportation fuels.

Renewables Portfolio Standard

California's renewables portfolio standard (RPS) requires retail sellers of electricity to increase their procurement of eligible renewable energy resources by at least one percent per year so that 20 percent of their retail sales are procured from eligible renewable energy resources by 2017. If a seller falls short in a given year, they must procure more renewables in succeeding years to make up the shortfall. Once a retail seller reaches 20 percent, they need not increase their procurement in succeeding years. RPS was enacted via SB 1078 (Sher), signed in September 2002 by Governor Davis. The CEC and the CPUC are jointly implementing the standard. In 2006, RPS was modified by SB 107 to require retail sellers of electricity to reach the 20 percent renewables goal by 2010. In 2011, RPS was further modified by SB 2 to require retailers to reach 33 percent renewable energy by 2020.

California Environmental Quality Act (CEQA)

Appendix F of the CEQA Guidelines describes the types of information and analyses related to energy conservation that are to be included in EIRs (or equivalent documents) that are prepared pursuant to CEQA. Energy conservation is described in Appendix F of CEQA Guidelines in terms of decreased per capita energy consumption, decreased reliance on natural gas and oil, and increased reliance on renewable energy sources. To assure that energy implications are considered in project decisions, EIRs (or equivalent documents) must include a discussion of the potentially significant energy impacts of proposed projects, with particular emphasis on avoiding or reducing inefficient, wasteful and unnecessary consumption of energy.

3.3.1.3 Local Regulations

Clean Cities Program

The USDOE Clean Cities Program promotes voluntary, locally based government/industry partnerships for the purpose of expanding the use of alternatives to gasoline and diesel fuel by accelerating the deployment of alternative fuel vehicles and building a local alternative fuel vehicle refueling infrastructure. The mission of the Clean Cities Program is to advance the nation's energy security by supporting local decisions to adopt practices that contribute to the reduction of petroleum consumption. Clean Cities carries out this mission through a network of more than 80 volunteer coalitions, which develop public/private partnerships to promote alternative fuels and vehicles, fuel blends, fuel economy, hybrid vehicles, and idle reduction.

San Gabriel Valley Energy Efficiency Partnership

In April 2006, the SCAG's Regional Council authorized SCAG's Executive Director to enter into a partnership with SCE to incentivize energy efficiency programs in the San Gabriel Valley Subregion. The San Gabriel Valley Energy Wise Program (SGVEWP) agreement was fully executed on October 20, 2006 with the main goal to save a combined three million kilowatt-hours (kWh) by providing technical assistance and incentive packages to cities by 2008. The program has been extended seeks to reduce energy usage in the region by approximately five million kWh by 2012. The SGVEWP is funded by California utility customers and administered by SCE under the auspices of the CPUC.

3.3.2 Energy Trends In General (Statewide)

Figure 3.3-1 shows California's major sources of energy. In 2010, 71 percent of the electricity came from in-state sources, while 29 percent was imported into the state. In 2012, the electricity generated in-state totaled 199,101 gigawatt hours (GWh)[1] while imported electricity totaled 102,866 GWh, with 39,470 GWh coming from the Pacific Northwest, and 63,396 GWh coming from the Southwest (CEC, 2013e)[2]. For natural gas in 2012, 35 percent came from the Southwest, 16 percent came from Canada, nine percent came from in-state, and 40 percent came from the Rocky Mountains (CEC, 2013c)[3]. Also in 2013, 37 percent of the crude oil came from in-state, with 12 percent coming from Alaska, and 51 percent being supplied by foreign sources (CEC, 2011a)[4].

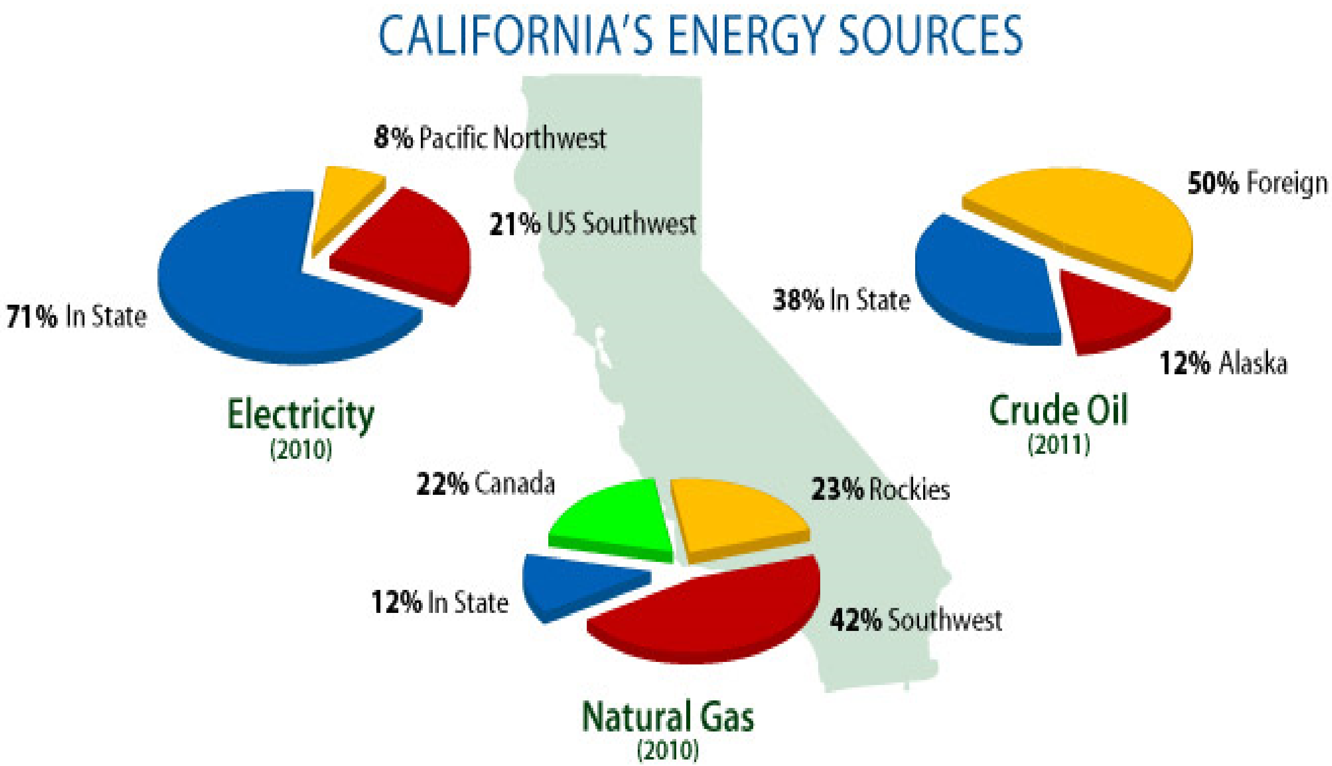

FIGURE 3.3-1
California's Major Sources of Energy[5]

[5] California's Major Sources of Energy, CEC Energy Almanac, last updated April 7, 2011. http://energyalmanac.ca.gov/overview/energy_sources.html.

3.3.2.1 Electricity

Power plants in California provided approximately 66 percent of the total in-state electricity demand in 2012 of which 17 percent came from renewable sources such as biomass, geothermal, small hydro, solar, and wind. The Pacific Northwest provided another 13 percent of the total electricity demand of which 24 percent came from renewable sources. The Southwest provided 21 percent of the total electricity demand, with five percent coming from renewable sources. In total, 15.4 percent of the total in-state electricity demand for 2012 came from renewable sources (CEC, 2013e).

Four of the state's largest power plants are located in Basin (CEC, 2014e)[6]. The largest power plants in California are located in northern California: the Moss Landing Natural Gas Power Plant (2,484 megawatts (MW)) is located in Monterey Bay in Monterey County and the Diablo Canyon Nuclear Plant (2,323 MW) is located in Avila Beach in San Luis Obispo County. The third and fourth largest power plants in California are located inside the Basin: the AES Alamitos Natural Gas Power Generating Station (1,970 MW) in Long Beach in Los Angeles County and Haynes Natural Gas Power Plant (net summer capacity 1,724 MW) in Long Beach. The fifth and sixth largest power plants in California are located outside of the Basin: the Ormond Beach Natural Gas Power Plant (1,613 MW) in City of Oxnard within Ventura County and Pittsburg Natural Gas Power Plant (1,370 MW) in the City of Pittsburg within Contra Costa County. The LADWP operates the state's seventh and eighth largest power plants: the AES Redondo Beach Natural Gas Power Plant (1,343 MW) in Redondo Beach and the Castaic Pump-Storage Power Plant[7] in Castaic (1,331 MW). The ninth and tenth largest power plants in California are also located outside of the Basin: the Helms Pumped Storage Facility (1,212 MW) in Sierra National Forest of Fresno County and La Paloma Generating Project (1,200 MW) in West Elk Hills within Kern County.

Local electricity distribution service is provided to customers within southern California by one of two investor-owned utilities – either SCE or SDG&E – or by a publicly owned utility, such as the LADWP and the Imperial Irrigation District. The SCE is the largest electric utility company in Southern California with a service area that covers all or nearly all of Orange, San Bernardino, and Ventura Counties, and most of Los Angeles and Riverside Counties. The SCE delivers 78 percent of the retail electricity sales to residents and businesses in southern California. The SDG&E provides local distribution service to the southern portion of Orange County (SCAG, 2012)[8].

The LADWP is the largest of the publicly owned electric utilities in southern California. The LADWP provides electricity service to the most of the customers located in the City of Los Angeles and provides approximately 20 percent of the total electricity demand in the Basin. The other publicly owned utilities in southern California include Anaheim, Azusa,

3.3.2.2 Natural Gas

Four regions supply California with natural gas: California, the Southwest, the Rocky Mountains, and Canada. The Southwest, the Rocky Mountains, and Canada combined supplied 91 percent of all the natural gas consumed in California in 2012. The remainder is produced in California (CEC, 2013c).

Southern California Gas Company (SoCalGas), an investor-owned utility company, provides natural gas service throughout the district, except for the southern portion of Orange County, portions of San Bernardino County, and the City of Long Beach. The Long Beach Gas and Oil Department (LBGOD) is municipally owned and operated by the City of Long Beach, providing gas service to approximately 500,000 residents and businesses in the cities of Long Beach and Signal Hill (LBGOD, 2014)[9]. The SDG&E provides natural gas services to the southern portion of Orange County. In San Bernardino County, Southwest Gas Corporation provides natural gas services to Victorville, Big Bear, Barstow, and Needles (SCAG, 2012).

[9] Welcome to the Long Beach Gas & Oil Department. Long Beach Gas & Oil Department (LBGOD); accessed August 2014. http://admin.longbeach.gov/lbgo/default.asp

In 2012, about 50 percent of the natural gas consumed in California was for electric generation purposes (801,345 million cubic feet) (USEIA, 2012)[10]. Table 3.3-2 provides the estimated use of natural gas in California by residential, commercial and industrial sectors.

TABLE 3.3-2
California Natural Gas Demand 2014
(Million Cubic Feet per Day – MMcf/day)

Sector	Utility	Non-Utility	Total

3.3.2.3 Liquid Petroleum Fuels

California relies on oil produced within the state, Alaska, and foreign nations to supply its refineries and produce the petroleum that is used in automobiles and for other purposes. The percentage of oil that is imported from foreign nations has increased dramatically over the past 20 years. For example, in 1991, California imported just four percent of oil from foreign sources (30.7 million barrels out of a total of 683.5 million barrels), and in 2011, California imported 49.9 percent of oil from foreign sources (300 million barrels out of a total of 600.7 million barrels).

As of April 2014, California is currently ranked third among the oil producing states, behind Texas and North Dakota, respectively (USEIA, 2014a)[11]. California also ranked third in the

[10] Table 5.12 - Consumption of Natural Gas for Electricity Generation by State, by Sector, 2012; U.S. Energy Information Administration (USEIA); accessed August 2014. http://www.eia.gov/electricity/annual/html/epa_05_12.html

[11] U.S. States, State Profiles and Energy Estimates, Rankings: Crude Oil Production; May 2014, USEIA, accessed August 2014. http://www.eia.gov/state/rankings/?sid=US&CFID=16318874&CFTOKEN=ae573cdc61654233-EE9BD34F-25B3-1C83-54586F32B366D836&jsessionid=8430a691f97d1894bc33d35305b7d1c231a9#/series/46

nation in refining capacity as of January 2014, with a combined capacity of almost two million barrels per calendar day from its 18 operable refineries (USEIA, 2014b)[12].

California also ranked first in the consumption of petroleum products used by the transportation sector (USEIA, 2012a)[13]. Most gasoline and diesel fuel sold in California for on-road motor vehicles is refined in California to meet state-specific formulations required by CARB. Major petroleum refineries in California are concentrated in three counties: Contra Costa County in northern California, Kern County in central California, and Los Angeles County in southern California. In Los Angeles County, petroleum refineries are located mostly in the southern portion of the county (SCAG, 2012). In fiscal year 2013, 14,443,650,668 gallons of gasoline[14] and 2,637,184,371 gallons of diesel fuel[15] were sold in California (California State Board of Equalization, 2013). The volume of gasoline also includes aviation fuel. In 2012, 14,480 million gallons of gasoline and 1,587 million gallons of diesel were sold by retail facilities throughout California. Retail sales data reported does not include commercial fleets, government entities, private cardlocks (facilities open only to participating companies and not the general public), or rental facilities/equipment yards. The state total and sales by the four counties within SCAQMD's jurisdiction are presented in Table 3.3.-3.

TABLE 3.3-3
Retail Motor Fuel Sales in California by County (CEC, 2012i)[16]
(millions of gallons per year)

3.3.3 Alternative Clean Transportation Fuels

The demand for transportation fuels in California is increasing at a rapid rate and is projected to grow by almost 35 percent over the next 20 years. Unless habits change, petroleum will be the

[12] California State Profile and Energy Estimates, Quick Facts; USEIA; accessed August 2014. http://www.eia.gov/state/?sid=CA&CFID=16957926&CFTOKEN=f27a8712ad923a0a-6D522B58-237D-DA68-24E25846F72A3365&jsessionid=84301d78ae226ef8ee07326b113a3b1a7331

[15] Taxable Diesel Gallons 10 Year Report; 2013 data; California State Board of Equalization; Fuel Taxes Statistics & Reports, Motor Vehicle Fuel; accessed August 2014. http://www.boe.ca.gov/sptaxprog/reports/Diesel_10_Year_Report.pdf

[16] Retail Fuel Report and Data for California; CEC; accessed August 2014. http://energyalmanac.ca.gov/gasoline/piira_retail_survey.html

primary source of California's transportation fuels for the foreseeable future. As demand continues to rise and in-state and Alaskan petroleum supplies diminish, California will rely more and more on foreign imports of crude oil (Consumer Energy Center, 2012)[17].

Alternative fuels, as defined by the Energy Policy Act of 1992, include ethanol, natural gas, propane, hydrogen, biodiesel, electricity, methanol, and P-Series fuels, a family of renewable, non-petroleum liquid fuels that can substitute for gasoline. These fuels are being used worldwide in a variety of vehicle applications. Use of these fuels for transportation can generally reduce air pollutant emissions and can be domestically produced and, in some cases, derived from renewable sources. The Energy Policy Act of 2005 directed the USDOE to carry out a study to plan for the transition from petroleum to hydrogen in a significant percentage of vehicles sold by 2020.

Use of renewable and other alternative fuels in the United States and California is expected to continue growing, primarily as a consequence of federal and state regulations mandating ever-increasing levels of renewable content in gasoline and diesel fuel, carbon reduction rules, and incentives for increasing alternative fuel consumption.

3.3.3.1 Biodiesel

Biodiesel is a domestically produced, renewable fuel that can be manufactured from vegetable oils, animal fats, or recycled restaurant greases. According to the USDOE, pure biodiesel (B100) is considered an alternative fuel under Energy Policy Act. Lower-level biodiesel blends are not considered alternative fuels, but covered fleets can earn one Energy Policy Act credit for every 450 gallons of B100 purchased for use in blends of 20 percent or higher (SCAG, 2012).

Biodiesel is the only alternative fuel to have fully completed the health effects testing requirements under the Clean Air Act (CCA). The use of biodiesel in a conventional diesel engine results in substantial reductions of unburned hydrocarbons, carbon monoxide, and particulate matter compared to emissions from diesel fuel (Consumer Energy Center, 2012a)[18].

Production of biodiesel in the United States dramatically increased in response to federal legislation that went into effect in 2005 included a $1 per gallon blending credit for all biodiesel blended with conventional diesel fuel, but declined in 2009 and 2010 with the temporary loss of the subsidy in conjunction with poor production economics (high feedstock costs relative to market price of diesel fuel). Output has rebounded as refiners and other obligated parties strive to meet biodiesel blending requirements mandated by the RFS. According to the CEC, at least a sixfold increase in biodiesel production to 188 million

[17] Consumer Energy Center, 2012. Alternative Fuel Vehicles, June 2012. http://www.consumerenergycenter.org/transportation/afvs/

[18] Consumer Energy Center, 2012a. Biodiesel as a Transportation Fuel. http://www.consumerenergycenter.org/transportation/afvs/biodiesel.html

gallons per year and renewable diesel production and delivery to more than 300 million gallons per year in California by 2020 (CEC, 2013)[19].

Biodiesel use in California gradually increasing over the past few years in California, but there is a potential constraint in securing enough low-carbon intensity feedstock to produce biodiesel and renewable diesel. The bulk of the renewable diesel is produced in Singapore and shipped to California (CEC, 2013). As such, biodiesel use in California is estimated to have been nearly 136 million gallons in 2013. Table 3.3-4 shows the reported retail sale of biodiesel was 1,673,555 gallons in 2010 (CEC, 2014h)[20]. Retail sales do not include distributed by commercial fleets, government entities, private cardlocks (unattended dispensing facilities not open to the public), rental facilities/equipment yards, and special user groups. The combination of RFS requirements for obligated parties, substantial renewable identification number (RIN) credit values, availability of sufficient biofuel resources, and California's LCFS will compel development of low-carbon biofuel projects in the state and shift of low-carbon biofuels to California (CEC, 2013).

Source: CEC, 2014h

3.3.3.2 Natural Gas

Natural gas is a mixture of hydrocarbons comprised mainly of methane (CH4) and is produced either from gas wells or in conjunction with crude oil production worldwide and locally at relatively low cost. The interest in natural gas as an alternative fuel for automobiles stems mainly from its clean burning qualities, its domestic resource base, and its commercial availability to end users. Because of the gaseous nature of this fuel, it must be stored onboard a vehicle in either a compressed gaseous state as compressed natural gas (CNG) or in a liquefied state as liquefied natural gas (LNG) (SCAG, 2012).

Natural gas vehicles have been introduced in a wide variety of commercial applications, from light-duty trucks and sedans (e.g., taxi cabs), to heavy-duty vehicles (e.g., transit buses, street sweepers, and school buses). In California, transit agency buses are some of the most visible CNG vehicles.

[19] 2013 Integrated Energy Policy Report. Transportation Energy Trends. CEC, 2013. http://www.energy.ca.gov/2013_energypolicy/

[20] Retail Biodiesel and E-85 Sales, CEC, Energy Almanac, accessed August 2014. http://energyalmanac.ca.gov/gasoline/retail_fuel_outlet_survey/retail_biodiesel+e85_sales.html

With consumption of natural gas vehicles increasing by 26 percent nationwide and 35 percent in California from 2008 to 2013 (U.S. EIA, 2013)[21], and the probability of a sixfold increase in natural gas vehic~~v~~les and natural gas consumption from 2012 levels by 2020, the fueling infrastructure for natural gas vehicles continues to grow (CEC, 2013). California currently has 281 compressed and 45 liquid natural gas fueling stations. In southern California alone, there are more than 230 natural gas fueling stations in major metropolitan areas from Los Angeles to the Mexican border (USDOE, 2012)[22] .

3.3.3.3 Electricity

Electricity can be used as a transportation fuel to power battery electric and fuel cell vehicles. When used to power electric vehicles (EVs), electricity is stored in an energy storage device such as a battery. Fuel cell vehicles use electricity produced from an electrochemical reaction that takes place when hydrogen and oxygen are combined in the fuel cell "stack." The production of electricity using fuel cells takes place without combustion or pollution and leaves only two byproducts, heat and water.

Electric vehicles have several different charging systems: 120-volt, 240-volt, direct-current, and inductive charging. An electric vehicle that accepts 120-volt power can do so from any standard electrical outlet with a 12- or 16-amp dedicated branch circuit (with no other receptacles or loads on the circuit). A 240-volt system requires the installation of a home charging station and is available at most public charging stations. Direct current (DC) fast charging equipment (480 volt) provides 50 kW to the battery. This option enables charging along heavy traffic corridors and at public stations. Inductive charging equipment was installed for all electric vehicles in the early 1990s, such as the GM/Saturn EV-1, Toyota RAV4 EV, and the Chevy S10, and is still being used in certain areas. Some companies are working on inductive charging options for future electric drive vehicles. The most common types of EVs use either 120-volt or 240-volt electrical systems (SCAG, 2012).

The USDOE's Advanced Vehicle Testing Activity (AVTA) promotes the use of EVs in commercial fleets in the United States. During 1996, AVTA requested and received proposals from interested groups to become qualified vehicle testers (QVT). SCE headed one QVT. According to SCE, California's approximately 20,000 megawatts of excess off-peak (nighttime) electricity capacity would allow the charging of millions of electro-drive technologies without the need for new power generation facilities (SCAG, 2012).

As of mid-2013, 32,000 plug-in electric vehicles (PEVs) and an additional 14,000 neighborhood electric vehicles are on the roads. More than 8,000 electric vehicle charge points have been funded by the CEC and the air quality management districts in California. The Governor's ZEV Executive Order[23] and CARB's ZEV mandate, combined with a federal tax credit and incentives for electric vehicle rebates and electric charger installations, are advancing the electric vehicle market penetration in California (CEC, 2013).

---

21 Natural Gas Consumption by End Use, U.S.EIA 2014. http://www.eia.gov/dnav/ng/ng_cons_sum_dcu_nus_a.htm

22 Alternative Fueling Station Locator, U.S. DOE, 2014. http://www.afdc.energy.gov/afdc/locator/stations/state

23 The Executive Order calls for California to ensure infrastructure is developed to support one million zero-emission vehicles by 2020 and 1.5 million by 2025.

One of the attractions of PEVs compared to internal combustion engine vehicles is the convenience of home charging instead of fueling at a gas station. ICF International estimates that in the early market, roughly 95 percent of charging will either be at home or at fleet facilities. Charging at home may require additional equipment and the broad consensus is that residential charging is the highest priority for deployment because consumers like the convenience and it encourages charging during periods of off-peak electrical demand. The CEC will consider providing PEV consumers with incentives to help defray the cost of home electric vehicle supply equipment (EVSE) (CEC, 2011)[24].

3.3.3.4 Ethanol and E85

Ethanol, or ethyl alcohol, is a clear, colorless liquid that is the same alcohol that is found in alcoholic beverages. In California, ethanol is blended into gasoline up to 10 percent for use by most automobiles. Ethanol is also be used in a more pure state as an alternative fuel when the blend is 85 percent ethanol and 15 percent gasoline (E85).

Most ethanol used for fuel in California is being blended into gasoline at concentrations from five to ten percent, and has replaced methyl tertiary butyl ether (MTBE) as a gasoline component. Most gasoline supplied in the state today contains at least six percent ethanol (Consumer Energy Center, 2012b)[25].

Blends of at least 85 percent ethanol are considered alternative fuels under the Energy Policy Act. E85, a blend of 85 percent ethanol and 15 percent gasoline is used in flexible fuel vehicles (FFVs) that are currently offered by most major auto manufacturers. FFVs can run on gasoline, E85, or any combination of the two and qualify as alternative fuel vehicles under Energy Policy Act regulations (SCAG, 2012).

In the United States, ethanol is most widely produced through fermentation and distillation of corn. As of January 1, 2013, the U.S. fuel ethanol production capacity is reported as nearly 14 billion gallons per year. Since 2009, three of the five existing ethanol facilities in California have begun regular operations. Of the two remaining, one has been shut down and dismantled, and the other is operating intermittently. California uses roughly 1.5 billion gallons of ethanol per year, of which nearly 175 million gallons per year are produced in California and the remainder is imported corn ethanol from the Midwest and foreign sources (CEC, 2013).

As of 2013, there are about 500,000 FFVs operating in California. Although there is a large population of FFVs in California, there are a modest but growing number of retail stations that offer E85. As of 2009, there were approximately 83 stations that offered E85 to the public. According to the CEC, California nearly sold 6.5 million gallons of E85 in 2012 (CEC, 2013). As of July 2011, there were approximately 60 stations that offered E85 to the public. Table 3.3-5 shows the reported retail sale of E85 was 1,995,812 gallons in 2010 (CEC, 2014h). Retail sales do not include E85 that is distributed by commercial fleets,

[24] Transportation Energy Forecasts and Analyses for the 2011 Integrated Energy Policy Report, August 2011. http://www.energy.ca.gov/2011publications/CEC-600-2011-007/CEC-600-2011-007-SD.pdf

[25] Ethanol as a Transportation Fuel, Consumer Energy Center, 2014. http://www.consumerenergycenter.org/transportation/afvs/ethanol.html

government entities, private cardlocks (unattended dispensing facilities not open to the public), rental facilities/equipment yards, and special user groups. With upgraded infrastructure and increasing availability of E85, sales in California are forecast to rise from 13.2 million gallons in 2009 to more than three billion gallons by 2030 (CEC, 2011).

TABLE 3.3-5
Reported Retail E85 Sales in California in 2010
(gallons per year)

Conventional Fuel Component)	Ethanol Component	Total E85 Throughput	Count of Facilities
299,372	1,696,440	1,995,812	36

Source: CEC, 2012h

During 2010, rail imports represented 95.8 percent of the ethanol consumed and in-state production represented 4.2 percent. There were no marine imports of ethanol during 2010 due to unfavorable economics in foreign source countries. However, ethanol imports from Brazil are projected to displace from 250 million to 400 million gallons per year of corn-based ethanol imports because Brazilian sugarcane ethanol is the largest near-term contributor that can achieve the standards mandated by the RFS and LCFS because of its lower carbon intensity value when compared to corn-based ethanol (CEC, 2011).

3.3.3.5 Methanol and M85

Methanol, also known as wood alcohol, can be used as an alternative fuel in flexible fuel vehicles that run on M85 (a blend of 85 percent methanol and 15 percent gasoline). Methanol was sold in California as part of a public-private partnership demonstration program between the state of California and oil companies. After the demonstration program ended, however, the oil companies discontinued selling M85. M85 is no longer available.

3.3.3.6 Hydrogen as a Transportation Fuel

Hydrogen is the simplest and lightest fuel. At atmospheric pressure and ambient temperatures hydrogen is a colorless, odorless, tasteless, and non-toxic gas that burns invisibly. Hydrogen is being explored for use in combustion engines and fuel cell electric vehicles. The ability to create hydrogen from a variety of resources and its clean-burning properties make it a desirable alternative fuel.

In 2011, there were approximately 250 hydrogen fuel cell vehicles (FCVs) operating in California, compared to only 15 registered in 2009. These vehicles use stored hydrogen, which is combined with oxygen from the atmosphere through an electrochemical reaction to produce electricity, which is then used to power an electric motor. Like battery electric vehicles, FCVs produce no tailpipe emissions and store the hydrogen fuel in on-board pressure tanks. Today's FCVs hold enough hydrogen in their on-board tanks to support driving ranges of roughly 250 miles. Current refueling is relatively quick, taking about three to five minutes per fill for a 700 bar tank (CEC, 2011).

As of August 2014, California has 10 public hydrogen fueling stations, 11 private hydrogen fueling stations, and 46 hydrogen fueling stations in development (USDOE, 2014). Without a substantial transportation distribution system in place for hydrogen transportation use, hydrogen could be transported and delivered using the established hydrogen infrastructure. However, for significant market penetration, the infrastructure will need further development (SCAG, 2012).

3.3.3.7 Propane

Propane (C3H8) is a three-carbon alkane gas used as a clean-burning, high-energy alternative fuel for decades to power light-, medium-, and heavy-duty propane vehicles. Propane, also known as liquefied petroleum gas (LPG) or autogas, is produced as a by-product of natural gas processing and petroleum refining. As an alternative fuel, it is stored under pressure inside a tank, as a colorless, odorless liquid and as pressure is released, the liquid propane vaporizes and turns into gas that is used for combustion. Propane has a high octane rating and excellent properties for spark-ignited internal combustion engines. It is non-toxic and presents no threat to soil, surface water, or groundwater.

Propane is a popular fuel choice for vehicles because there is already an infrastructure of pipelines, processing facilities, and storage for its efficient distribution. Domestic availability, high-energy density, clean-burning qualities, and its relatively low cost also add to its popularity.

Propane is the third most commonly used transportation fuel used in the United States, behind gasoline and diesel. Over time, propane has been used in several niche applications such as for fork-lifts, both inside and outside warehouses, and at construction sites. Use of propane can result in lower vehicle maintenance costs, lower emissions, and fuel costs savings when compared to conventional gasoline and diesel. In California, the state-wide fleet operated around 13.37 million vehicles that use propane as an alternative fuel (US EIA, 2014)[26]. According to the CEC's survey of retail fuel stations and sales, 805 retail fuel stations sold 25.44 million gallons of propane in 2012 (CEC, 2014i)[27].

3.3.4 Renewable Energy

Renewable energy is energy that comes from sources that regenerate and can be sustained indefinitely, unlike fossil fuels, which are exhaustible. The five most common renewable sources are biomass, hydropower, geothermal, wind, and solar. Unlike fossil fuels, non-biomass renewable sources of energy do not directly emit greenhouse gasses.

The production and use of renewable fuels has grown quickly in recent years as a result of higher prices for oil and natural gas, and a number of state and federal government incentives, including the Energy Policy Acts of 2002 and 2005. The use of renewable fuels is expected to continue to grow over the next 30 years, although projections show that reliance on non-renewable fuels to meet most energy needs will continue.

---

26 Alternative Fuel Vehicle Data. http://www.eia.gov/renewable/afv/users.cfm#tabs_charts-5

27 Retail Fuel Report and Data for California. http://energyalmanac.ca.gov/gasoline/piira_retail_survey.html

In 2012, consumption of renewable resources in the United States totaled about nine quadrillion British thermal units (Btu) or about nine percent of all energy used nationally. About 12 percent of U.S. electricity was generated from renewable resources in 2012 (U.S. EIA, 2013a)[28]. In 2012, 20 percent of all electricity came from renewable resources in California (CEC, 2014g)[29].

The RPS requires investor-owned utilities, electric service providers, and community choice aggregators regulated by the CPUC to procure 33 percent of retail sales per year from eligible renewable sources by 2020. CPUC issues quarterly renewable energy progress report to the state Legislature, showing that the state's utilities have met the goal of serving 20 percent of their electricity with renewable energy and are already on track to far surpass that goal in 2012 (CEC, 2014g). The quarterly reports report focuses on California's three large investor-owned utilities: PG&E, SCE, and SDG&E. These investor-owned utilities currently provide approximately 68 percent of the state's electric retail sales and analyzing this data provides significant insight into the state's RPS progress. On April 1, 2014, the large investor owned utilities reported in their 33% RPS Procurement Progress Reports that they served 20.9 percent of their retail electric load with RPS-eligible generations during the first compliance period (CP 1) from 2011 to 2013 (CEC, 2014g). Table 3.3-6 shows the renewable electricity use in Los Angeles, Orange, Riverside and San Bernardino in 2013.

3.3.4.1 Hydroelectric Power

Hydroelectric power, or hydropower, is generated when hydraulic turbines connected to electrical generators are turned by the force of flowing or falling water. In 2013, hydroelectric-produced electricity used by California totaled nearly 27,176 GWh or 9.15 percent of the total system power. In-state production accounted for around 90 percent of all hydroelectricity, while imports from other states totaled 10 percent (CEC, 2013e).

---

28 Renewable Energy Explained. http://www.eia.gov/energyexplained/index.cfm?page=renewable_home
29 Renewables Portfolio Standard: Quarterly Report. http://www.cpuc.ca.gov/NR/rdonlyres/93E7E363-75A6-40C8-997D-705C53A2713D/0/2014Q1RPSReportFINAL.pdf

California has nearly 265[30] hydroelectric facilities with an installed capacity of approximately 13,882 MW[31]. Hydro facilities are divided into two categories with larger than 30 MW capacity facilities (e.g., "large hydro") and smaller than 30 MW capacity facilities (e.g., "small hydro") that are totaled into the renewable energy portfolio standards. The amount of hydroelectricity produced varies each year, largely dependent on rainfall. During the drought from 1986 to 1992, production fell to less than 22,400 GWh (CEC, 2014f)[32], while total generation increased from 211,028 GWh to 245,535 GWh over the same period of time.

The larger hydro plants located on dams in California (such as Shasta, Folsom, Oroville, etc.) are operated by the U.S. Bureau of Reclamation and the DWR. Small hydro plants are operated by utilities, mainly PG&E and Sacramento Municipal Utility District. The licensing of hydro plants is done by the Federal Energy Regulatory Commission with input from state and federal energy, environmental protection, fish and wildlife, and water quality agencies.

3.3.4.2 Geothermal Energy

Geothermal energy technologies use the clean, sustainable heat from the earth. Geothermal resources include the heat retained in shallow ground, hot water and rock found a few miles beneath the Earth's surface, and extremely high-temperature molten rock, also known as magma, located deep in the Earth. Geothermal energy can be used to generate electricity or used directly in many commercial and industrial applications.

The energy from high-temperature reservoirs (e.g., from 225 degrees Fahrenheit (°F) to 600 °F) can be used by three different types of geothermal power plants to produce electricity. Dry steam plants use steam from underground wells to rotate a turbine which activates a generator to produce electricity. Binary cycle plants use the heat from lower-temperature reservoirs (e.g., from 225 °F to 360 °F) to boil a working fluid, which is then vaporized in a heat exchanger and used to power a generator. The water, which never comes into direct contact with the working fluid, is then injected back into the ground to be reheated. The flash stream plant, the most common type of geothermal power plant, uses water at temperatures above 360 °F. As hot water flows up through wells in the ground, the decrease in pressure causes some of the water to boil into steam which is then used to power a generator (USDOE, 2014a)[33].

The most developed of the high-temperature resource areas of the state is the Geysers. North of San Francisco, the Geysers were first tapped as a geothermal resource to generate electricity in 1960. It is one of only two locations in the world where a high-temperature, dry steam is found that can be directly used to turn turbines and generate electricity. Dry

32 Overview of Natural Gas in California, 2014. http://www.energyalmanac.ca.gov/naturalgas/overview.html

33 Energy Basics: Geothermal Electricity Production. http://energy.gov/eere/energybasics/articles/geothermal-technology-basics

steam does not create condensation, which damages steam turbine blades. Other major geothermal locations in the state include the Imperial Valley area east of San Diego and the Coso Hot Springs area near Bakersfield.

Because of its location on the Pacific's "ring of fire" and because of tectonic plate conjunctions, California contains the largest amount of geothermal generating capacity in the United States. In2013, geothermal energy in California produced 12,485GWh of electricity. Combined with another 707 GWh of imported geothermal electricity, the geothermal energy produced 4.44percent of the state's total system power. A total of 43[34]operating geothermal power plants with an installed capacity of 2,703 MW[35] are in California, about two-thirds of the total United States' geothermal generation (CEC, 2014b).

Direct use systems harness the energy from low to moderate temperature reservoirs (e.g., from 68 °F to 302 °F) for various commercial and industrial uses, such as heating buildings, growing plants in greenhouses, drying crops, heating water at fish farms, and pasteurizing milk. Usually, a well is drilled into a geothermal reservoir to provide a steady stream of hot water. The water is brought up through the well, and a mechanical system that utilizes piping, heat exchangers and controls to deliver the heat directly for its intended use. A disposal system then either injects the cooled water underground or disposes of it on the surface (CEC, 2014b)[36].

Forty-six of California's 58 counties have lower temperature resources for direct-use geothermal. In fact, the City of San Bernardino has developed one of the largest geothermal direct-use projects in North America, heating at least three dozen buildings, including a 15-story high-rise and government facilities, with fluids distributed through 15 miles of pipelines (Consumer Energy Center, 2012c)[37].

3.3.4.3 Biomass Electricity

Biomass technologies break down organic matter to release stored energy from the sun. There are many types of biomass - organic matter such as plants, residue from agriculture and forestry, and the organic component of municipal and industrial wastes - that can now be used to produce fuels, chemicals, and power. This flexibility has resulted in the increased use of biomass technologies with 53 percent of all renewable energy consumed in the U.S. in 2007 coming from biomass (USDOE, 2013a)[38].

Biopower is the production of electricity or heat from biomass resources by technologies including direct combustion, co-firing, and anaerobic digestion.

---

[37] Geothermal Energy. http://www.consumerenergycenter.org/renewables/geothermal/index.html

[38] Biomass Technology Basics. http://energy.gov/eere/energybasics/articles/biomass-technology-basics

Direct Combustion

Direct combustion using conventional boilers is the most common method of producing electricity from biomass. Boilers primarily burn waste wood products from the agriculture and wood-processing industries to produce steam that spins a turbine connected to a generator to produce electricity. Municipal solid waste power plants use direct combustion to create electricity through three methods:

- Mass Burn: Sorted municipal refuse is fed into a hopper to feed a boiler. The heat from the combustion process is used to turn water into steam to power a turbine-generator.

- Refuse-Derived Fuel: Pelletized or fluff municipal refuse, which comes from a by-product of a resource recovery operation where non-combustible materials are removed, are used to feed a boiler. The heat from the combustion process is used to turn water into steam to power a turbine-generator.

- Pyrolysis/Thermal Gasification: Related technologies where thermal decomposition of organic material at elevated temperatures with little (Thermal Gasification) to no (Pyrolysis) oxygen or air produces combustible gases. The gases are combusted to produce heat and turn water into steam to power a turbine-generator.

Co-Firing

Co-firing involves replacing a portion of the petroleum-based fuel in high-efficiency coal-fired boilers with biomass. Co-firing has been successfully demonstrated in most boiler technologies, including pulverized coal, cyclone, fluidized bed, and spreader stoker units. Co-firing biomass can significantly reduce the sulfur dioxide emissions of coal-fired power plants and is a least-cost renewable energy option for many power producers.

Anaerobic Digestion

Anaerobic digestion, or methane recovery, is a common technology used to convert organic waste to electricity or heat. It is widely used in the agriculture, municipal waste, and brewing industries. In anaerobic digestion, organic matter is decomposed by bacteria in the absence of oxygen to produce methane and other byproducts that form a renewable natural gas (USDOE, 2013)[39].

The Los Angeles County Sanitation District (LACSD) operates a combined cycle turbine facility in Carson that uses digester gas to produce 20 MW. In addition, the LACSD operates a landfill gas Rankine cycle steam plant at the Puente Hills Landfill to produce approximately 48 MW.

Lastly, Royal Farms No. 1 in Tulare, California is a third example of anaerobic digestion use. Hog manure is slurried and sent to a Hypalon-covered lagoon for biogas generation. The collected biogas fuels a 70 kW engine-generator and a 100 kW engine-generator which

[39] Anaerobic Digestion Basics. http://energy.gov/eere/energybasics/articles/anaerobic-digestion-basics

helps the farm to be able to meet its own monthly electric and heat energy demand (CEC, 2014j)[40].

There are about 132 waste-to-energy plants in California, with a total capacity of almost 1,000 MW. In 2007, 6,236 GWh of electricity in homes and businesses was produced from biomass: burning forestry, agricultural, and urban biomass; converting methane-rich landfill gas to energy; and, processing wastewater and dairy biogas into useful energy. Biomass power plants produced 2.1 percent of the total electricity in California in 2007, or about one-fifth of all the renewable energy (CEC, 2014j).

3.3.4.4 Wind Power

Wind power is the conversion of the kinetic energy of the wind into a useful form of energy. Wind can be harnessed by wind turbines, windmills, windpumps, or sails. These technologies use wind power for practical purposes such as generating electricity, grinding grain, pumping water, or propelling a boat.

A wind turbine works much like the propeller of an airplane. The blades of a turbine are tilted at an angle and contoured such that the movement of the air is channeled creating low and high pressures on the blade that force it to move. The blade is connected to a shaft, which in turn is connected to an electrical generator. The mechanical energy of the turning blades is changed into electricity.

California has several wind farms, a group of wind turbines in the same location used to produce electricity, strategically placed in windy areas, as one of the problems with using wind to generate power is that wind is not always constant.

Wind energy plays an integral role in California's electricity portfolio. In 2007, turbines in wind farms generated 9.75 GWh[41] of electricity. Additionally, hundreds of homes and farms are using smaller wind turbines to produce electricity (CEC, 2014k)[42].

There are many windy areas in California. Problems with using wind to generate power are that it is not windy all year long nor is the wind speed constant. It is usually windier during the summer months when wind rushes inland from cooler areas, such as near the ocean, to replace hot rising air in California's warm central valleys and deserts. By placing wind turbines in these windy areas, California’s wind power supply variance can be minimized. Utility-scale wind power generation facilities can be found in Altamont Pass, Solano, Pacheco Pass, the Tehachapi Ranges, and San Gorgonio Pass.

3.3.4.5 Solar (Photovoltaic Cells)

Solar energy technologies produce electricity from the energy of the sun through photovoltaic (PV) cells, also known as solar cells. PV cells are electricity-producing devices

[40] Waste to Energy & Biomass in California. http://www.energy.ca.gov/biomass/index.html
[41] U.S. EIA, 2012b. Table 3.17 Net Generation from Wind. http://www.eia.gov/electricity/annual/html/epa_03_17.html
[42] Wind Energy in California. http://www.energy.ca.gov/wind/index.html

made of semiconductor materials coming in many sizes and shapes, often connected together to ultimately form PV systems. When light shines on a PV cell, the energy of absorbed light transfers to electrons in the atoms of the PV cell semiconductor material causing electrons to escape from their normal positions in the atoms and become part of the electric flow, or current, in an electrical circuit. While small PV systems can provide electricity for homes, businesses, and remote power needs, larger PV systems provide much more electricity for contribution to the electric power system.

The PV cells for small systems can be purchased in two formats: 1) as a stand-alone module that is attached to the roof or on a separate system; or, 2) using integrated roofing materials with dual functions as a regular roofing shingle and as a solar cell making electricity.

California's cumulative installed capacity of PV systems in 1998 was 6.3 MW. As of 2013, the capacity of PV systems reached about 3,072 MW[43], producing 5,389 GWh of electricity for the California (CEC, 2013d).

3.3.4.6 Solar Thermal Energy

Solar thermal energy (STE) is the technology for converting the sun's energy into thermal energy (heat) through solar thermal collectors. The U.S. EIA classifies solar thermal collectors into three categories:

- Low-temperature: Flat plate collectors are used to warm homes, buildings, and swimming pools.
- Medium-temperature: Flat plate collectors are used to heat water or air for residential and commercial uses.
- High-temperature: Mirrors or lenses are used to concentrate STE for electric power production.

Low and medium-temperature collectors can be further classified as either passive or active heating systems. In a passive system, air is circulated past a solar heat surface and through the building by convection (meaning that less dense warm air tends to rise while denser cool air moves downward). No mechanical equipment is needed for passive solar heating. Active heating systems require a collector to absorb and collect solar radiation. Fans or pumps are used to circulate the heated air or heat absorbing fluid. Active systems often include some type of energy storage system.

High-temperature systems used in solar thermal power plants use the sun's rays to heat a fluid to very high temperatures through the use of mirrors or lenses. The fluid is then circulated through pipes so it can transfer its heat to water to produce steam. The steam, in turn, is converted into mechanical energy in a turbine and into electricity by a conventional generator coupled to the turbine.

California has 11 of the 13 solar thermal power plants in the United States. These facilities are concentrated in the desert areas of the state in the Mojave area. Solar thermal plants

[43] CEC, 2013b. Electric Generation Capacity & Energy. http://energyalmanac.ca.gov/electricity/electric_generation_capacity.html

produced 675 GWh in 2007, or 0.22 percent of the state's total electricity production (CEC, 2014d)[44].

California's electric utility companies are required to use renewable energy to produce 20 percent of their power by 2010 and 33 percent by 2020 and a main source of the required renewable energy will be solar energy. Many large solar energy projects are being proposed in California's desert area on federal Bureau of Land Management (BLM) land. The developments of 34 large solar thermal power plants have been proposed with a planned combined capacity of 24,000 MW (CEC, 2014d).

3.3.5 Consumptive Uses

3.3.5.1 Transportation

Transportation (i.e., the movement of people and goods from place to place) is an important end use of energy in California, accounting for approximately 40 percent of total statewide energy consumption in 2012, and 11 percent of total U.S. energy consumption (U.S. EIA, 2012)[45]. Nonrenewable energy products derived from crude oil, including gasoline, diesel, kerosene, and residual fuel, provide most of the energy consumed for transportation purposes by on-road motor vehicles (e.g., automobiles and trucks), locomotives, aircraft, and ships. In addition, energy is consumed in connection with construction and maintenance of transportation infrastructure, such as highways, rail facilities, runways, and shipping terminals. Trends in transportation-related technology foretell increased use of electricity and natural gas for transportation purposes.

Gasoline is the most-used transportation fuel in California. Within the transportation sector, gasoline is used primarily by light-duty vehicles. In 2010, California consumed gasoline at a rate of 40.7 million gallons per day, or 10.7 percent of the national demand of 379.4 million gallons per day. SCAG is leading a regional effort with the goal of accelerating fleet conversion to near zero and zero-emission transportation technologies. Alternative fuels for transportation include, but are not limited to: biodiesel, electricity, ethanol, hydrogen, natural gas, propane, biobutanol, biogas, hydrogenation-derived renewable diesel (HDRD), methanol, P-Series, and xTL Fuels (Fischer-Tropsch). The Ports, vehicle manufacturers, and other entities are demonstrating new zero-emission truck technologies including battery-electric, fuel-cell, and hybrid-electric trucks with all electric range (AER) (SCAG, 2012a)[46].

3.3.5.2 Residential, Commercial, Industrial, and Other Uses

Major energy consumption sectors (in addition to transportation) include residential, commercial, industrial uses as well as street lighting, mining, and agriculture. Unlike transportation, these sectors primarily consume electricity and natural gas. In 2013, the total annual electricity consumption in the district was approximately 116,947 million kWh (36,109 million kWh for residential uses and 80,838 million kWh for non-residential uses)

---

45 California: State Profile & Estimates. http://www.eia.gov/state/?sid=CA
46 Regional Transportation Plan 2012-2035. http://rtpscs.scag.ca.gov/Documents/2012/final/f2012RTPSCS.pdf

(CEC, 2013). Table 3.3-7 shows the electricity use in Los Angeles, Orange, Riverside and San Bernardino counties in 2013.

TABLE 3.3-7
2013 Electricity Use in the District by County (in millions of kWh)

Sector	Los Angeles	Orange	Riverside	San Bernardino	Total
Residential	19,456	6,301	6,125	4,227	**36,109**
Non-Residential	48,654	13,721	8,566	9,897	**80,838**
Total	**68,110**	**20,022**	**14,691**	**14,124**	**116,947**

Source: CEC, Energy Consumption Data Management System, Energy Consumption by County, 2013. http://www.ecdms.energy.ca.gov/elecbycounty.aspx

Within the residential sector, lighting, small appliances, and refrigeration account for most (approximately 60 percent) of the electricity consumption, and within the industrial and commercial sector, lighting, motors, and air cooling account for most (approximately 65 percent) of the electricity consumption. Electricity use by households varies depending on the local climate and on the housing type (e.g., single-family vs. multi-family), as per the four distinct geographic zones in the SCAG region: the cooler and more temperate coastal zone; an inland valley zone; the California central valley zone, and the desert zone, where temperatures are more extreme.

Based on CEC 2013 Revised High Energy Demand, California consumed approximately 12,767 million therms of natural gas per year in 2013. The SoCal Gas planning area is composed of the SCE, Burbank and Glendale, Pasadena, and LADWP electric planning areas. According to the SoCal Gas Baseline Natural Gas Forecast, approximately 7,357 million therms of natural gas were consumed. The CEC expects residential natural gas use to increase by approximately 1.5 percent per year and commercial natural gas use to increase by approximately3.9 percent per year (CEC, 2014a)[47]. Industrial natural gas demand has also increased such that the most recent data from the CEC show that the residential sector uses the largest amount of natural gas, both across the state and in the SCAG region. Statewide, the industrial sector was second in the amount of natural gas consumed. The commercial sector falls behind residential, mining, and industrial uses in natural gas consumption in the SCAG region and statewide. The agricultural sector accounts for only one percent of the natural gas use statewide and in the SCAG region.

3.3.5.3 Consumption Reduction Efforts

There are various policies and initiatives to reduce petroleum vehicle fuel consumption and increase the share of renewable energy generation and use in the region. These strategies include energy efficient building practices, smarter land use with access to public transportation, increasing automobile fuel efficiency, and participating in energy efficiency incentive program. All publicly-owned utilities and most municipal-owned utilities that provide electric and natural gas service also administer energy conservation programs.

[47] California Energy Demand: 2014-2024. http://www.energy.ca.gov/2013publications/CEC-200-2013-004/CEC_200-2013-004-SD-V1-REV.pdf

These programs typically include home energy audits; incentives for replacement of existing appliances with new, energy-efficient models; provision of resources to inform businesses on development and operation of energy-efficient buildings; and construction of infrastructure to accommodate increased use of motor vehicles powered by natural gas or electricity (CEC, 2014)[48].

SUBCHAPTER 3.4

HAZARDS AND HAZARDOUS MATERIALS

Hazardous Materials Regulations

Emergency Response to Hazardous Materials and Waste Incidents

Hazardous Materials Incidents

Hazards Associated with Air Pollution Control and Alternative Fuels

3.4 HAZARDS AND HAZARDOUS MATERIALS

Implementation of PR 4001, while intended to improve overall air quality, may have direct or indirect hazards and hazardous materials impacts associated with their implementation. Hazard concerns are related to the potential for fires, explosions or the release of hazardous materials/substances in the event of an accident or upset conditions.

The potential for hazards exist in the production, use, storage, and transportation of hazardous materials. Hazardous materials may be found at industrial production and processing facilities. Some facilities produce hazardous materials as their end product, while others use such materials as an input to their production process. Examples of hazardous materials used as consumer products include gasoline, solvents, and coatings/paints. Hazardous materials are stored at facilities that produce such materials and at facilities where hazardous materials are a part of the production process. Specifically, storage refers to the bulk handling of hazardous materials before and after they are transported to the general geographical area of use. Currently, hazardous materials are transported throughout the district via all modes of transportation including rail, highway, water, air, and pipeline.

The Recirculated NOP/IS identified he following adverse hazards and hazardous materials impacts specific to the implementation of the proposed project: use of alternative fuels in place of conventional fuels could result in increased hazards associated the increased transport; and, use and handling of alternative fuels. Potential exposure to a toxic air contaminant (ammonia) would be associated with installation and operation of control equipment that utilize selective catalytic reduction (SCR) or selective non-catalytic reduction (SNCR) on industrial combustion sources such as boilers and heaters, as well as large diesel engines on mobile sources to reduce NOx, including off-road diesel engines (e.g., locomotive engines and marine vessel engines).

3.4.1 Hazardous Materials Regulations

Incidents of harm to human health and the environment associated with hazardous materials have created a public awareness of the potential for adverse effects from careless handling and/or use of these substances. As a result, the use, storage and transport of hazardous materials are subject to numerous laws and regulations at all levels of government. The most relevant existing hazardous materials laws and regulations include hazardous materials management planning, hazardous materials transportation, hazardous materials worker safety requirements, hazardous waste handling requirements and emergency response to hazardous materials and waste incidents. Potential risk of upset is a factor in the production, use, storage and transportation of hazardous materials. Risk of upset concerns are related to the risks of explosions or the release of hazardous substances in the event of an accident or upset. The most relevant hazardous materials laws and regulations are summarized in the following subsection of this section.

3.4.1.1 Definitions

A number of properties may cause a substance to be hazardous, including toxicity, ignitability, corrosivity, and reactivity. The term "hazardous material" is defined in different ways for different regulatory programs. For the purposes of this document, the term hazardous material refers to both hazardous materials and hazardous wastes. A hazardous material is defined as hazardous if it appears on a list of hazardous materials prepared by a federal, state, or local regulatory agency or if it has characteristics defined as hazardous by such an agency. Hazardous material is defined in HSC §25501 (k) as follows:

> Hazardous material means any material that because of its quantity, concentrations, or physical or chemical characteristics, poses a significant present or potential hazard to human health and safety or to the environment if released into the workplace or the environment. Hazardous materials include but are not limited to hazardous substances, hazardous waste, and any material which a handler or the administering agency has a reasonable basis for believing would be injurious to the health and safety of persons or harmful to the environment if released into the workplace or the environment.

Examples of the types of materials and wastes considered hazardous are hazardous chemicals (e.g., toxic, ignitable, corrosive, and reactive materials), radioactive materials, and medical (infectious) waste. The characteristics of toxicity, ignitability, corrosivity, and reactivity are defined in CCR Title 22 §66261.20-66261.24 and are summarized below:

> **Toxic Substances:** Toxic substances may cause short-term or long-lasting health effects, ranging from temporary effects to permanent disability, or even death. For example, such substances can cause disorientation, acute allergic reactions, asphyxiation, skin irritation, or other adverse health effects if human exposure exceeds certain levels. (The level depends on the substances involved and are chemical-specific.) Carcinogens (substances that can cause cancer) are a special class of toxic substances. Examples of toxic substances include benzene (a component of gasoline and a suspected carcinogen) and methylene chloride (a common laboratory solvent and a suspected carcinogen).
>
> **Ignitable Substances:** Ignitable substances are hazardous because of their ability to burn. Gasoline, hexane, and natural gas are examples of ignitable substances.
>
> **Corrosive Materials:** Corrosive materials can cause severe burns. Corrosives include strong acids and bases such as sodium hydroxide (lye) or sulfuric acid (battery acid).
>
> **Reactive Materials:** Reactive materials may cause explosions or generate toxic gases. Explosives, pure sodium or potassium metals (which react violently with water), and cyanides are examples of reactive materials.

3.4.1.2 Federal Regulations

The USEPA is the primary federal agency charged with protecting human health and with safeguarding the natural environment over air, water, and land. The USEPA works to develop and enforce regulations that implement environmental laws enacted by Congress. The USEPA is responsible for researching and setting national standards for a variety of environmental programs, and delegates to states and Indian tribes the responsibility for issuing permits and for monitoring and enforcing compliance. Since 1970, Congress has enacted numerous environmental laws that pertain to hazardous materials, for the USEPA to implement as well as to other agencies at the federal, state and local level, as described in the following subsections.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) was enacted by Congress in 1976 (see 15 U.S.C. §2601 et seq.) and gave the USEPA the authority to protect the public from unreasonable risk of injury to health or the environment by regulating the manufacture, sale, and use of chemicals currently produced or imported into the United States. The TSCA, however, does not address wastes produced as byproducts of manufacturing. The types of chemicals regulated by the act fall into two categories: existing and new. New chemicals are defined as "any chemical substance which is not included in the chemical substance list compiled and published under [TSCA] section 8(b)." This list included all of chemical substances manufactured or imported into the U.S. prior to December 1979. Existing chemicals include any chemical currently listed under section 8 (b). The distinction between existing and new chemicals is necessary as the act regulates each category of chemicals in different ways. The USEPA repeatedly screens both new and existing chemicals and can require reporting or testing of those that may pose an environmental or human-health hazard. The USEPA can ban the manufacture and import of those chemicals that pose an unreasonable risk.

Emergency Planning and Community Right-to-Know Act

The Emergency Planning and Community Right-to-Know Act (EPCRA) is a federal law adopted by Congress in 1986 that is designed to help communities plan for emergencies involving hazardous substances. EPCRA establishes requirements for federal, state and local governments, Indian tribes, and industry regarding emergency planning and "Community Right-to-Know" reporting on hazardous and toxic chemicals. The Community Right-to-Know provisions help increase the public's knowledge and access to information on chemicals at individual facilities, their uses, and releases into the environment. States and communities, working with facilities, can use the information to improve chemical safety and protect public health and the environment. There are four major provisions of EPCRA:

1) Emergency Planning (§§301 – 303) requires local governments to prepare chemical emergency response plans, and to review plans at least annually. These sections also require state governments to oversee and coordinate local planning efforts. Facilities that maintain Extremely Hazardous Substances (EHS) on-site (see 40 CFR Part 355 for the list of EHS chemicals) in quantities greater than corresponding "Threshold Planning Quantities" must cooperate in the preparation of the emergency plan.

2) Emergency Release Notification (§304) requires facilities to immediately report accidental releases of EHS chemicals and hazardous substances in quantities greater than corresponding Reportable Quantities (RQs) as defined under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) to state and local officials. Information about accidental chemical releases must be made available to the public.

3) Hazardous Chemical Storage Reporting (§§311 – 312) requires facilities that manufacture, process, or store designated hazardous chemicals to make Material Safety Data Sheets (MSDSs) describing the properties and health effects of these chemicals available to state and local officials and local fire departments. These sections also require facilities to report to state and local officials and local fire departments, inventories of all on-site chemicals for which MSDSs exist. Lastly, information about chemical inventories at facilities and MSDSs must be available to the public.

4) Toxic Chemical Release Inventory (§313) requires facilities to annually complete and submit a Toxic Chemical Release Inventory Form for each Toxic Release Inventory (TRI) chemical that are manufactured or otherwise used above the applicable threshold quantities.

Implementation of EPCRA has been delegated to the State of California. The California Emergency Management Agency requires facilities to develop a Hazardous Materials Business Plan if they handle hazardous materials in quantities equal to or greater than 55 gallons, 500 pounds, or 200 cubic feet of gas or extremely hazardous substances above the threshold planning quantity. The Hazardous Materials Business Plan is provided to State and local emergency response agencies and includes inventories of hazardous materials, an emergency plan, and implements a training program for employees.

Hazardous Materials Transportation Act

The Hazardous Material Transportation Act (HMTA), adopted in 1975 (see 49 U.S.C. §§5101 – 5127), gave the Secretary of Transportation the regulatory and enforcement authority to provide adequate protection against the risks to life and property inherent in the transportation of hazardous material in commerce. The USDOT (see 49 CFR Parts 171-180) oversees the movement of hazardous materials at the federal level. The HMTA requires that carriers report accidental releases of hazardous materials to USDOT at the earliest practical moment. Other incidents that must be reported include deaths, injuries requiring hospitalization, and property damage exceeding $50,000. The hazardous material regulations also contain emergency response provisions which include incident reporting requirements. Reports of major incidents go to the National Response Center, which in turn is linked with CHEMTREC, a public service hotline established by the chemical manufacturing industry for emergency responders to obtain information and assistance for emergency incidents involving chemicals and hazardous materials.

Hazardous materials regulations are implemented by the Research and Special Programs Administration (RSPA) branch of the USDOT. The regulations cover the definition and classification of hazardous materials, communication of hazards to workers and the public, packaging and labeling requirements, operational rules for shippers, and training. These regulations apply to interstate, intrastate, and foreign commerce by air, rail, ships, and motor vehicles, and also cover hazardous waste shipments. The Federal Aviation Administration Office of Hazardous Materials Safety is responsible for overseeing the safe handling of hazardous materials aboard aircraft. The Federal Railroad Administration oversees the transportation of hazardous materials by rail. The U.S. Coast Guard regulates the bulk transport of hazardous materials by sea. The Federal Highway Administration (FHWA) is responsible for highway routing of hazardous materials and issuing highway safety permits.

<u>Hazardous Materials Waste Regulations</u>

Resource Conservation and Recovery Act: The Resource Conservation and Recovery Act (RCRA) was adopted in 1976 (see 40 CFR Parts 238-282) and authorizes the USEPA to control the generation, transportation, treatment, storage, and disposal of hazardous waste. The RCRA regulation specifies requirements for generators, including waste minimization methods, as well as for transporters and for treatment, storage, and disposal facilities. The RCRA regulation also includes restrictions on land disposal of wastes and used oil management standards. Under RCRA, hazardous wastes must be tracked from the time of generation to the point of disposal. In 1984, RCRA was amended with addition of the Hazardous and Solid Waste Amendments, which authorized increased enforcement by the USEPA, more strict hazardous waste standards, and a comprehensive UST program. Likewise, the Hazardous and Solid Waste Amendments focused on waste reduction and corrective action for hazardous releases. The use of certain techniques for the disposal of some hazardous wastes was specifically prohibited by the Hazardous and Solid Waste Amendments. Individual states may implement their own hazardous waste programs under RCRA, with approval by the USEPA.

Comprehensive Environmental Response, Compensation and Liability Act: The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), which is often commonly referred to as Superfund, is a federal statute that was enacted in 1980 to address abandoned sites containing hazardous waste and/or contamination. CERCLA was amended in 1986 by the Superfund Amendments and Reauthorization Act, and by the Small Business Liability Relief and Brownfields Revitalization Act of 2002.

CERCLA contains prohibitions and requirements concerning closed and abandoned hazardous waste sites; establishes liability of persons responsible for releases of hazardous waste at these sites; and creates a trust fund to provide for cleanup when no responsible party can be identified. The trust fund is funded largely by a tax on the chemical and petroleum industries. CERCLA also provides federal jurisdiction to respond directly to releases or impending releases of hazardous substances that may endanger public health or the environment.

CERCLA also enabled the revision of the National Contingency Plan (NCP) which provided the guidelines and procedures needed to respond to releases and threatened releases of hazardous substances, pollutants, or contaminants. The NCP also established the National Priorities List, which identifies hazardous waste sites eligible for long-term remedial action financed under the federal Superfund program.

Prevention of Accidental Releases and Risk Management Programs: Requirements pertaining to the prevention of accidental releases are promulgated in §112 (r) of the Clean Air Act Amendments of 1990 [42 U.S.C. §7401 et. seq.]. The objective of these requirements was to prevent the accidental release and to minimize the consequences of any such release of a hazardous substance. Under these provisions, facilities that produce, process, handle or store hazardous substance have a duty to: 1) identify hazards which may result from releases using hazard assessment techniques; 2) design and maintain a safe facility and take steps necessary to prevent releases; and, 3) minimize the consequence of accidental releases that occur.

In accordance with the requirements in §112 (r), USEPA adopted implementing guidelines in 40 CFR Part 68. Under this part, stationary sources with more than a threshold quantity of a regulated substance shall be evaluated to determine the potential for and impacts of accidental releases from any processes subject to the federal risk management requirements. Under certain conditions, the owner or operator of a stationary source may be required to develop and submit a Risk Management Plan (RMP). RMPs consist of three main elements: a hazard assessment that includes off-site consequences analyses and a five-year accident history, a prevention program, and an emergency response program.

Hazardous Material Worker Safety Requirements

Occupational Safety and Health Administration Act: The federal Occupational Safety and Health Administration (OSHA) is an agency of the United States Department of Labor that was created by Congress under the Occupational Safety and Health Act in 1970. OSHA is the agency responsible for assuring worker safety in the handling and use of chemicals in the workplace. Under the authority of the Occupational Safety and Health Act of 1970, OSHA has adopted numerous regulations pertaining to worker safety (see 29 CFR Part 1910). These regulations set standards for safe workplaces and work practices, including the reporting of accidents and occupational injuries. Some OSHA regulations contain standards relating to hazardous materials handling to protect workers who handle toxic, flammable, reactive, or explosive materials, including workplace conditions, employee protection requirements, first aid, and fire protection, as well as material handling and storage. For example, facilities which use, store, manufacture, handle, process, or move hazardous materials are required to conduct employee safety training, have available and know how to use safety equipment, prepare illness prevention programs, provide hazardous substance exposure warnings, prepare emergency response plans, and prepare a fire prevention plan.

Procedures and standards for safe handling, storage, operation, remediation, and emergency response activities involving hazardous materials and waste are promulgated in 29 CFR Part 1910, Subpart H. Some key subsections in 29 CFR Part 1910, Subpart H are §1910.106 -Flammable Liquids and §1910.120 - Hazardous Waste Operations and Emergency Response. In particular, the Hazardous Waste Operations and Emergency Response regulations contain requirements for worker training programs, medical surveillance for workers engaging in the handling of hazardous materials or wastes, and waste site emergency and remediation planning, for those who are engaged in specific clean-up, corrective action, hazardous material handling, and emergency response activities (see 29 CFR Part 1910 Subpart H, §1910.120 (a)(1)(i-v) and §1926.65 (a)(1)(i-v)).

Process Safety Management: As part of the numerous regulations pertaining to worker safety adopted by OSHA, specific requirements that pertain to Process Safety Management (PSM) of Highly Hazardous Chemicals were adopted in 29 CFR Part 1910 Subpart H, §1910.119 and 8 CCR §5189 to protect workers at facilities that have toxic, flammable, reactive or explosive materials. PSM program elements are aimed at preventing or minimizing the consequences of catastrophic releases of chemicals and include process hazard analyses, formal training programs for employees and contractors, investigation of equipment mechanical integrity, and an emergency response plan. Specifically, the PSM program requires facilities that use, store, manufacture, handle, process, or move hazardous materials to conduct employee safety training; have an inventory of safety equipment relevant to potential hazards; have knowledge on use of the safety equipment; prepare an illness prevention program; provide hazardous substance exposure warnings; prepare an emergency response plan; and prepare a fire prevention plan.

Emergency Action Plan: An Emergency Action Plan (EAP) is a written document required by OSHA standards promulgated in 29 CFR Part 1910, Subpart E, §1910.38 (a) to facilitate and organize a safe employer and employee response during workplace emergencies. An EAP is required by all that are required to have fire extinguishers. At a minimum, an EAP must include the following: 1) a means of reporting fires and other emergencies; 2) evacuation procedures and emergency escape route assignments; 3) procedures to be followed by employees who remain to operate critical plant operations before they evacuate; 4) procedures to account for all employees after an emergency evacuation has been completed; 5) rescue and medical duties for those employees who are to perform them; and, 6) names or job titles of persons who can be contacted for further information or explanation of duties under the plan.

National Fire Regulations: The National Fire Codes (NFC), Title 45, published by the National Fire Protection Association (NFPA) contains standards for laboratories using chemicals, which are not requirements, but are generally employed by organizations in order to protect workers. These standards provide basic protection of life and property in laboratory work areas through prevention and control of fires and explosions, and also serve to protect personnel from exposure to non-fire health hazards.

In addition to the NFC, the NFPA adopted a hazard rating system which is promulgated in NFPA 704 - Standard System for the Identification of the Hazards of Materials for Emergency Response. NFPA 704 is a "standard (that) provides a readily recognized, easily understood system for identifying specific hazards and their severity using spatial, visual, and numerical methods to describe in simple terms the relative hazards of a material. It addresses the health, flammability, instability, and related hazards that may be presented as short-term, acute exposures that are most likely to occur as a result of fire, spill, or similar emergency[1]." In addition, the hazard ratings per NFPA 704 are used by emergency personnel to quickly and easily identify the risks posed by nearby hazardous materials in order to help determine what, if any, specialty equipment should

[1] NFPA, FAQ for Standard 704, 2007 edition. http://www.nfpa.org/Assets/files/AboutTheCodes/704/704-2007_FAQs.pdf

be used, procedures followed, or precautions taken during the first moments of an emergency response. The scale is divided into four color-coded categories, with blue indicating level of health hazard, red indicating the flammability hazard, yellow indicating the chemical reactivity, and white containing special codes for unique hazards such as corrosivity and radioactivity. Each hazard category is rated on a scale from 0 (no hazard; normal substance) to 4 (extreme risk). Table 3.4-1 summarizes what the codes mean for each hazards category.

TABLE 3.4-1
NFPA 704 Hazards Rating Codes

Hazard Rating Code	Health (Blue)	Flammability (Red)	Reactivity (Yellow)	Special (White)
4 = Extreme	Very short exposure could cause death or major residual injury (extreme hazard)	Will rapidly or completely vaporize at normal atmospheric pressure and temperature, or is readily dispersed in air and will burn readily. Flash point below 73 °F.	Readily capable of detonation or explosive decomposition at normal temperatures and pressures.	~~W~~ = Reacts with water in an unusual or dangerous manner.
3 = High	Short exposure could cause serious temporary or moderate residual injury	Liquids and solids that can be ignited under almost all ambient temperature conditions. Flash point between 73 °F and 100 °F.	Capable of detonation or explosive decomposition but requires a strong initiating source, must be heated under confinement before initiation, reacts explosively with water, or will detonate if severely shocked.	**OXY** = Oxidizer
2 = Moderate	Intense or continued but not chronic exposure could cause temporary incapacitation or possible residual injury.	Must be moderately heated or exposed to relatively high ambient temperature before ignition can occur. Flash point between 100 °F and 200 °F.	Undergoes violent chemical change at elevated temperatures and pressures, reacts violently with water, or may form explosive mixtures with water.	**SA** = Simple asphyxiant gas (includes nitrogen, helium, neon, argon, krypton and xenon).
1 = Slight	Exposure would cause irritation with only minor residual injury.	Must be heated before ignition can occur. Flash point over 200 °F.	Normally stable, but can become unstable at elevated temperatures and pressures	Not Applicable
0 = Insignificant	Poses no health hazard, no precautions necessary	Will not burn	Normally stable, even under fire exposure conditions, and is not reactive with water.	Not applicable

In addition to the above information, there are also a number of other physical or chemical properties may cause a substance to be a fire hazard. With respect to determining whether any substance is classified as a fire hazard, MSDS lists the National Fire Protection Association 704 flammability hazard ratings (e.g., NFPA 704). NFPA 704 is a standard that provides a readily recognized, easily understood system for identifying flammability hazards and their severity using spatial, visual, and numerical methods to describe in simple terms the relative flammability hazards of a material.

Although substances can have the same NFPA 704 Flammability Ratings Code, other factors can make each substance's fire hazard very different from each other. For this reason, additional chemical characteristics, such as auto-ignition temperature, boiling point, evaporation rate, flash point, lower explosive limit (LEL), upper explosive limit (UEL), and vapor pressure, are also considered when determining whether a substance is fire hazard. The following is a brief description of each of these chemical characteristics.

Auto-ignition Temperature: The auto-ignition temperature of a substance is the lowest temperature at which it will spontaneously ignite in a normal atmosphere without an external source of ignition, such as a flame or spark.

Boiling Point: The boiling point of a substance is the temperature at which the vapor pressure of the liquid equals the environmental pressure surrounding the liquid. Boiling is a process in which molecules anywhere in the liquid escape, resulting in the formation of vapor bubbles within the liquid.

Evaporation Rate: Evaporation rate is the rate at which a material will vaporize (evaporate, change from liquid to a vapor) compared to the rate of vaporization of a specific known material. This quantity is a represented as a unitless ratio. For example, a substance with a high evaporation rate will readily form a vapor which can be inhaled or explode, and thus have a higher hazard risk. Evaporation rates generally have an inverse relationship to boiling points (i.e., the higher the boiling point, the lower the rate of evaporation).

Flash Point: Flash point is the lowest temperature at which a volatile liquid can vaporize to form an ignitable mixture in air. Measuring a liquid's flash point requires an ignition source. At the flash point, the vapor may cease to burn when the source of ignition is removed. There are different methods that can be used to determine the flashpoint of a solvent but the most frequently used method is the Tagliabue Closed Cup standard (ASTM D56), also known as the TCC. The flashpoint is determined by a TCC laboratory device which is used to determine the flash point of mobile petroleum liquids with flash point temperatures below 175 degrees Fahrenheit (79.4 degrees Centigrade).

Flash point is a particularly important measure of the fire hazard of a substance. For example, the Consumer Products Safety Commission (CPSC) promulgated Labeling and Banning Requirements for Chemicals and Other Hazardous Substances in 15 U.S.C. §1261 and 16 CFR Part 1500. Per the CPSC, the flammability of a product is defined in 16 CFR Part 1500.3 (c)(6) and is based on flash point. For example, a liquid needs to be labeled as: 1) "Extremely Flammable" if the flash point is below 20 degrees Fahrenheit; 2) "Flammable" if the flash point is above 20 degrees Fahrenheit but less than 100 degrees Fahrenheit; or, 3) "Combustible" if the flash point is above 100 degrees Fahrenheit up to and including 150 degrees Fahrenheit.

Lower Explosive Limit (LEL): The lower explosive limit of a gas or a vapor is the limiting concentration (in air) that is needed for the gas to ignite and explode or the lowest concentration (percentage) of a gas or a vapor in air capable of producing a flash of fire in presence of an ignition source (e.g., arc, flame, or heat). If the concentration of a substance in air is below the LEL, there is not enough fuel to continue an explosion. In other words, concentrations lower than the LEL are "too lean" to burn. For example, methane gas has a LEL of 4.4 percent (at 138 degrees Centigrade) by volume, meaning 4.4 percent of the total volume of the air consists of methane. At 20 degrees Centigrade, the LEL for methane is 5.1 percent by volume. If the atmosphere has less than~~t~~ 5.1 percent methane, an explosion cannot occur even if a source of ignition is present. When the concentration of methane reaches 5.1 percent, an explosion can occur if there is an ignition source.

Upper Explosive Limit (UEL): The upper explosive limit of a gas or a vapor is the highest concentration (percentage) of a gas or a vapor in air capable of producing a flash of fire in presence of an ignition source (e.g., arc, flame, or heat). Concentrations of a substance in air above the UEL are "too rich" to burn.

Vapor Pressure: Vapor pressure is an indicator of a chemical's tendency to evaporate into gaseous form.

Health Hazards Guidance: In addition to fire impacts, health hazards can also be generated due to exposure of chemicals present in both conventional as well as reformulated products. Using available toxicological information to evaluate potential human health impacts associated with conventional solvents and potential replacement solvents, the toxicity of the conventional solvents can be compared to solvents expected to be used in reformulated products. As a measure of a chemical's potential health hazards, the following values need to be considered: the Threshold Limit Values (TLVs) established by the American Conference of Governmental Industrial Hygiene (ACGIH), OSHA's Permissible Exposure Limits (PELs), the Immediately Dangerous to Life and Health (IDLH) levels recommended by the National Institute for Occupational Safety and Health (NIOSH), permissible exposure limits (PEL) established by OSHA, and health hazards developed by the National Safety Council. The following is a brief description of each of these values.

Threshold Limit Values (TLVs): The TLV of a chemical substance is a level to which it is believed a worker can be exposed day after day for a working lifetime without adverse health effects. The TLV is an estimate based on the known toxicity in humans or animals of a given chemical substance, and the reliability and accuracy of the latest sampling and analytical methods. The TLV for chemical substances is defined as a concentration in air, typically for inhalation or skin exposure. Its units are in parts per million (ppm) for gases and in milligrams per cubic meter (mg/m^3) for particulates. The TLV is a recommended guideline by ACGIH.

Permissible Exposure Limits (PEL): The PEL is a legal limit, usually expressed in ppm, established by OSHA to protect workers against the health effects of exposure to hazardous substances. PELs are regulatory limits on the amount or concentration of a substance in the air. A PEL is usually given as a time-weighted average (TWA), although some are short-term exposure limits (STEL) or ceiling limits. A TWA is the average exposure over a specified period of time, usually eight hours. This means that, for limited periods, a worker may be exposed to concentrations higher than the PEL, so long as the average concentration over eight hours remains lower. A short-term exposure limit is one that addresses the average exposure over a 15 to 30 minute period of maximum exposure during a single work shift. A ceiling limit is one that may not be exceeded for any period of time, and is applied to irritants and other materials that have immediate effects. The OSHA PELs are published in 29 CFR 1910.1000, Table Z1.

Immediately Dangerous to Life and Health (IDLH): IDLH is an acronym defined by NIOSH as exposure to airborne contaminants that is "likely to cause death or immediate or delayed permanent adverse health effects or prevent escape from such an environment." IDLH values are often used to guide the selection of breathing apparatus that are made available to workers or firefighters in specific situations.

Oil and Pipeline Regulations and Oversight

Oil Pollution Act: The Oil Pollution Act was signed into law in 1990 to give the federal government authority to better respond to oil spills (see 33 U.S.C. §2701). The Oil Pollution Act improved the federal government's ability to prevent and respond to oil spills, including provision of money and resources. The Oil Pollution Act establishes polluter liability, gives states enforcement rights in navigable waters of the State, mandates the development of spill control and response plans for all vessels and facilities, increases fines and enforcement mechanisms, and establishes a federal trust fund for financing clean-up.

The Oil Pollution Act also establishes the National Oil Spill Liability Trust Fund to provide financing for cases in which the responsible party is either not readily identifiable, or refuses to pay the cleanup/damage costs. In addition, the Oil Pollution Act expands provisions of the National Oil and Hazardous Substances Pollution Contingency Plan, more commonly called the National Contingency Plan, requiring the federal government to direct all public and private oil spill response efforts. It also requires area committees, composed of federal, state, and local government officials, to develop detailed, location-specific area contingency plans. In addition, the Oil Pollution Act directs owners and operators of vessels, and certain facilities that pose a serious threat to the environment, to prepare their own specific facility response plans. The Oil Pollution Act increases penalties for regulatory non-compliance by responsible parties; gives the federal government broad enforcement authority; and provides individual states the authority to establish their own laws governing oil spills, prevention measures, and response methods. The Oil Pollution Act requires oil storage facilities and vessels to submit to the Federal government plans detailing how they will respond to large discharges. The USEPA has published regulations for aboveground storage facilities and the Coast Guard has done the same for oil tankers.

Oil Pollution Prevention Regulation: In 1973, the USEPA issued the Oil Pollution Prevention regulation (see 40 CFR 112)**,** to address the oil spill prevention provisions contained in the Clean Water Act of 1972. The Spill Prevention, Control, and Countermeasure (SPCC) Rule is part of the Oil Pollution Prevention regulations (see 40 CFR Part 112, Subparts A - C). Specifically, the SPCC rule includes requirements for oil spill prevention, preparedness, and response to prevent oil discharges to navigable waters and adjoining shorelines. The rule requires specific facilities to prepare, amend, and implement SPCC Plans. SPCC Plans require applicable facilities to take steps to prevent oil spills including: 1) using suitable storage containers/tanks; 2) providing overfill prevention (e.g., high-level alarms); 3) providing secondary containment for bulk storage tanks; 4) providing secondary containment to catch oil spills during transfer activities; and, 5) periodically inspecting and testing pipes and containers.

U.S. Department of Transportation, Office of Pipeline Safety: The Office of Pipeline Safety, within the USDOT, Pipeline and Hazards Material Safety Administration, has jurisdictional responsibility for developing regulations and standards to ensure the safe and secure movement of hazardous liquid and gas pipelines under its jurisdiction in the United States. The Office of Pipeline Safety has the following key responsibilities:

- Support the operation of, and coordinate with the United States Coast Guard on the National Response Center and serve as a liaison with the Department of Homeland Security and the Federal Emergency Management Agency on matters involving pipeline safety;

- Develop and maintain partnerships with other federal, state, and local agencies, public interest groups, tribal governments, and the regulated industry and other underground utilities to address threats to pipeline integrity, service, and reliability and to share responsibility for the safety of communities;

- Administer pipeline safety regulatory programs and develops regulatory policy involving pipeline safety;

- Oversee pipeline operator implementation of risk management and risk-based programs and administer a national pipeline inspection and enforcement program;

- Provide technical and resource assistance for state pipeline safety programs to ensure oversight of intrastate pipeline systems and educational programs at the local level; and,

- Support the development and conduct of pipeline safety training programs for federal and state regulatory and compliance staff and the pipeline industry.

49 CFR Parts 178 – 185 relates to the role of transportation, including pipelines, in the United States. 49 CFR Parts 186-199 establishes minimum pipeline safety standards. The Office of the State Fire Marshal works in partnership with the Federal Pipeline and Hazardous Materials Safety Administration to assure pipeline operators are meeting requirements for safe, reliable, and environmentally sound operation of their facilities for intrastate pipelines within California.

Chemical Facility Anti-Terrorism Standards: The Federal Department of Homeland Security is responsible for implementing the Chemical Facility Anti-Terrorism Standards that were adopted in 2007 (see 6 CFR Part 27). These standards establish risk-based performance standards for the security of chemical facilities and require covered chemical facilities to prepare Security Vulnerability Assessments, which identify facility security vulnerabilities, and to develop and implement Site Security Plans.

3.4.1.3 State Regulations

Hazardous Materials and Waste Regulations

Hazardous Waste Control Law: California's Hazardous Waste Control Law is administered by the California Environmental Protection Agency (CalEPA) to regulate hazardous wastes within the State of California. While the California Hazardous Waste Control Law is generally more stringent than RCRA, both the state and federal laws apply in California. The California Department of Toxic Substances Control (DTSC) is the primary agency in charge of enforcing both the federal and state hazardous materials laws in California. The DTSC regulates hazardous waste, oversees the cleanup of existing contamination, and pursues avenues to reduce hazardous waste produced in California. The DTSC regulates hazardous waste in California under the authority of RCRA, the Hazardous Waste Control Law, and the HSC. Under the direction of the CalEPA, the DTSC maintains the Cortese and Envirostor databases of hazardous materials and waste sites as specified under Government Code §65962.5.

The Hazardous Waste Control Law (22 CCR Chapter 11, Appendix X) also lists 791 chemicals and approximately 300 common materials which may be hazardous; establishes criteria for identifying, packaging, and labeling hazardous wastes; prescribes management controls; establishes permit requirements for treatment, storage, disposal, and transportation; and identifies some wastes that cannot be disposed of in landfills.

California Occupational Safety and Health Administration: The California Occupational Safety and Health Administration (CalOSHA) is the primary state agency responsible for worker safety in the handling and use of chemicals in the workplace. CalOSHA requires employers to monitor worker exposure to listed hazardous substances and notify workers of exposure (8 CCR §§337 - 340). The regulations specify requirements for employee training, availability of safety equipment, accident-prevention programs, and hazardous substance exposure warnings. CalOSHA's standards are generally more stringent than federal regulations.

Hazardous Materials Release Notification: Many state statutes require emergency notification when a hazardous chemical is released, including:

- California HSC §25270.7, §25270.8, and §25507;
- California Vehicle Code §23112.5;
- California Public Utilities Code §7673 (General Orders #22-B, 161);
- California Government Code §51018 and §8670.25.5 (a);
- California Water Code §13271 and §13272; and,
- California Labor Code §6409.1 (b)(10).

California Accident Release Prevention (CalARP) Program: The California Accident Release Prevention Program (19 CCR Division 2, Chapter 4.5) requires the preparation of Risk Management Plans (RMPs). CalARP requires stationary sources with more than a threshold quantity of a regulated substance to be evaluated to determine the potential for and impacts of accidental releases from any processes subject to state risk management requirements. RMPs are documents prepared by the owner or operator of a stationary source containing detailed information including: 1) regulated substances held onsite at the stationary source; 2) offsite consequences of an accidental release of a regulated substance; 3) the accident history at the stationary source; 4) the emergency response program for the stationary source; 5) coordination with local emergency responders; 6) hazard review or process hazard analysis; 7) operating procedures at the stationary source; 8) training of the stationary source's personnel; 9) maintenance and mechanical integrity of the stationary source's physical plant; and, 10) incident investigation. The CalARP program is implemented at the local government level by Certified Unified Program Agencies (CUPAs) also known as Administering Agencies (AAs). Typically, local fire departments are the administering agencies of the CalARP program because they frequently are the first responders in the event of a release.

Unified Hazardous Waste and Hazardous Materials Management Regulatory Program: The Unified Hazardous Waste and Hazardous Materials Management Regulatory Program (Unified Program) as promulgated by CalEPA in CCR, Title 27, Chapter 6.11 requires the administrative consolidation of six hazardous materials and waste programs (program elements) under one agency, a CUPA. The Unified Program administered by the State of California consolidates, coordinates, and makes consistent the administrative requirements, permits, inspections, and enforcement activities for the state's environmental and emergency management programs, which include Hazardous Waste Generator and On-Site Hazardous Waste Treatment Programs ("Tiered Permitting"); Above ground SPCC Program; Hazardous Materials Release Response Plans and Inventories (business plans); the CalARP Program; the UST Program; and the Uniform Fire Code Plans and Inventory Requirements. The Unified Program is implemented at the local government level by CUPAs.

Hazardous Materials Management Act: California HSC, Division 20, Chapter 6.95 requires any business handling more than a specified amount of hazardous or extremely hazardous materials, termed a "reportable quantity," to submit a Hazardous Materials Business Plan to its CUPA. Business plans must include an inventory of the types, quantities, and locations of hazardous materials at the facility. Businesses are required to update their business plans at least once every three years and the chemical portion of their plans every year. Also, business plans must include emergency response plans and procedures to be used in the event of a significant or threatened significant release of a hazardous material. These plans need to identify the procedures to follow for immediate notification to all appropriate agencies and personnel of a release, identification of local emergency medical assistance appropriate for potential accident scenarios, contact information for all company emergency coordinators, a listing and location of emergency equipment at the business, an evacuation plan, and a training program for business personnel. The requirements for hazardous materials business plans are specified in the California HSC and 19 CCR.

Hazardous Materials Transportation in California: California regulates the transportation of hazardous waste originating or passing through the State in Title 13, CCR. The California Highway Patrol (CHP) and the California Department of Transportation (Caltrans) have primary responsibility for enforcing federal and State regulations and responding to hazardous materials transportation emergencies. The CHP enforces materials and hazardous waste labeling and packing regulations that prevent leakage and spills of material in transit and provide detailed information to cleanup crews in the event of an incident. Vehicle and equipment inspection, shipment preparation, container identification, and shipping documentation are all part of the responsibility of the CHP. Caltrans has emergency chemical spill identification teams at locations throughout California.

California Fire Code: While NFC Standard 45 and NFPA 704 are regarded as nationally recognized standards, the California Fire Code (24 CCR) also contains state standards for the use and storage of hazardous materials and special standards for buildings where hazardous materials are found. Some of these regulations consist of amendments to NFC Standard 45. State Fire Code regulations require emergency pre-fire plans to include training programs in first aid, the use of fire equipment, and methods of evacuation.

3.4.1.4 Local Regulations

<u>SCAQMD</u>

SCAQMD Rule 1166 – Volatile Organic Compound Emissions from Decontamination of Soil: SCAQMD Rule 1166 establishes requirements to control the emission of VOCs from excavating, grading, handling, and treating soil contaminated from leakage, spillage, or other means of VOCs deposition. Rule 1166 stipulates that any parties planning on excavating, grading, handling, transporting, or treating soils contaminated with VOCs must first apply for and obtain, and operate pursuant to, a mitigation plan approved by the Executive Officer prior to commencement of operation. BACT is required during all phases of remediation of soil contaminated with VOCs. Rule 1166 also sets forth testing, record keeping and reporting procedures that must be followed at all times. Non-compliance with Rule 1166 can result in the revocation of the approved mitigation plan, the owner and/or the operator being served with a Notice of Violation for creating a public nuisance, or an order to halt the offending operation until the public nuisance is mitigated to the satisfaction of the Executive Officer.

<u>Regulations From Other Local Agencies</u>

In addition to the SCAQMD, other local agencies throughout the four counties in the district and their respective fire departments have a variety of local laws that regulate reporting, storage and handling of hazardous materials and wastes.

Los Angeles County: The Office of Emergency Management is responsible for organizing and directing the preparedness efforts of the Emergency Management Organization of Los Angeles County. Los Angeles County's policies towards hazardous materials management include enforcing stringent site investigations for factors related to hazards; limiting the development in high hazard areas, such as floodplains, high fire hazard areas, and seismic hazard zones; facilitating safe transportation, use, and storage of hazardous materials; supporting lead paint abatement; remediating Brownfield sites; encouraging the purchase of homes on the Federal Emergency Management Agency (FEMA) Repeat Hazard list and designating the land as open space; enforcing restrictions on access to important energy sites; limiting development downslope from aqueducts; promoting safe alternatives to chemical-based products in households; and prohibiting development in floodways. The county has defined effective emergency response management capabilities to include supporting county emergency providers with reaching their response time goals; promoting the participation and coordination of emergency response management between cities and other counties at all levels of government; coordinating with other county and public agency emergency planning and response activities; and encouraging the development of an early warning system for tsunamis, floods and wildfires.

Orange County: The regulatory agency responsible for enforcement, as well as inspection of pipelines transporting hazardous materials, is the California State Fire Marshal's Office, Hazardous Liquid Pipeline Division. The Orange County Health Care Agency (OCHCA) has been designated by the Board of Supervisors as the agency to enforce the UST program. The OCHCA UST Program regulates approximately 7,000 of the 9,500 underground tanks in Orange County. The program includes conducting regular inspections of underground tanks; oversight of new tank installations; issuance of permits; regulation of repair and closure of tanks; ensuring the mitigation of leaking USTs; pursuing enforcement action; and educating and assisting the industries and general public as to the laws and regulations governing USTs.

Under mandate from the California HSC, the Orange County Fire Authority is the designated agency to inventory the distribution of hazardous materials in commercial or industrial occupancies, develop and implement emergency plans, and require businesses that handle hazardous materials to develop emergency plans do deal with these materials.

Orange County's Hazardous Materials Program Office is responsible for facilitating the coordination of various parts of the County's hazardous materials program; assisting in coordinating County hazardous materials activities with outside agencies and organization; providing comprehensive, coordinated analysis of hazardous materials issues; and directing the preparation, implementation, and modification of the county's Hazardous Waste Management Plan. With regard to San Onofre Nuclear Generating Station, in an effort to prepare those who live and work in areas outside, but adjacent to SONGS, the federal and state governments have established three levels of emergency zones. Orange County is responsible for its own emergency plans concerning a nuclear power plant accident, and the Incident Response Plan is updated regularly.

San Bernardino County: San Bernardino County's Hazardous Waste Management Plan (HWMP) serves as the primary planning document for the management of hazardous waste in San Bernardino County. The HWMP identifies the types and amounts of wastes generated; establishes programs for managing these wastes; identifies an application review process for the siting of specified hazardous waste facilities; identifies mechanisms for reducing the amount of waste generated; and identifies goals, policies, and actions for achieving effective hazardous waste management. One of the county's stated goals is to minimize the generation of hazardous waste and reduce the risk posed by storage, handling, transportation, and disposal of hazardous wastes. In addition, the county will protect its residents and visitors from injury and loss of life and protect property from fires by deploying firefighters and requiring new land developments to prepare site-specific fire protection plans.

Riverside County: Through its membership in the Southern California Hazardous Waste Management Authority (SCHWMA), the County of Riverside has agreed to work on a regional level to solve problems involving hazardous waste. SCHWMA was formed through a joint powers agreement between Santa Barbara, Ventura, San Bernardino, Orange, San Diego, Imperial, and Riverside Counties and the Cities of Los Angeles and San Diego. Working within the concept of "fair share," each SCHWMA county has agreed to take responsibility for the treatment and disposal of hazardous waste in an amount that is at least equal to the amount generated within that county. This responsibility can be met by siting hazardous waste management facilities (transfer, treatment, and/or repository) capable of processing an amount of waste equal to or larger than the amount generated within the county, or by creating intergovernmental agreements between counties to provide compensation to a county for taking another county's waste, or through a combination of both facility siting and intergovernmental agreements. When and where a facility is to be sited is primarily a function of the private market. However, once an application to site a facility has been received, the county will review the requested facility and its location against a set of established siting criteria to ensure that the location is appropriate and may deny the application based on the findings of this review. The County of Riverside does not presently have any of these facilities within its jurisdiction and, therefore, must rely on intergovernmental agreements to fulfill its fair share responsibility to SCHWMA.

3.4.2 Emergency Response To Hazardous Materials And Waste Incidents

The California Emergency Management Agency (CalEMA) exists to enhance safety and preparedness in California through strong leadership, collaboration, and meaningful partnerships. The goal of CalEMA is to protect lives and property by effectively preparing for, preventing, responding to, and recovering from all threats, crimes, hazards, and emergencies. CalEMA under the Fire and Rescue Division coordinates statewide implementation of hazardous materials accident prevention and emergency response programs for all types of hazardous materials incidents and threats. In response to any hazardous materials emergency, CalEMA is called upon to provide state and local emergency managers with emergency coordination and technical assistance.

Pursuant to the Emergency Services Act, the State of California has developed an Emergency Response Plan to coordinate emergency services provided by federal, state, and local government agencies and private persons. Response to hazardous materials incidents is one part of this plan. The Plan is administered by CalEMA which coordinates the responses of other agencies. Six mutual aid and Local Emergency Planning Committee (LEPC) regions have been identified for California that are divided into three areas of the state designated as the Coastal (Region II, which includes 16 counties with 151 incorporated cities and a population of about eight million people.), Inland (Region III, Region IV and Region V, which includes 31 counties with 123 incorporated cities and a population of about seven million people), and Southern (Region I and Region VI, which includes 11 counties with 226 incorporated cities and a population of about 21.6 million people). The SCAQMD jurisdiction covers portions of Region I and Region VI.

In addition, pursuant to the Hazardous Materials Release Response Plans and Inventory Law of 1985, local agencies are required to develop "area plans" for response to releases of hazardous materials and wastes. These emergency response plans depend to a large extent on the business plans submitted by persons who handle hazardous materials. An area plan must include pre-emergency planning of procedures for emergency response, notification, coordination of affected government agencies and responsible parties, training, and follow-up.

3.4.3 Hazardous Materials Incidents

Hazardous materials move through southern California by a variety of modes including truck, rail, air, ship, and pipeline. The movement of hazardous materials implies a degree of risk, depending on the materials being moved, the mode of transport, and numerous other factors (e.g., weather).

Hazardous materials move through the region by a variety of modes: Truck, rail, air, ship, and pipeline. According to the USDOT Office of Hazardous Materials Safety (OHMS), hazardous materials shipments can be regarded as equivalent to deliveries, but any given shipment may involve one or more movements or trip segments that may occur by different routes (e.g., rail transport with final delivery by truck). According to the Commodity Flow Survey data (USDOT, 2010), there were approximately 2.3 billion tons of hazardous materials shipments in the United States in 2007. Table 3.4-2 indicates that trucks move more than 50 percent of total hazardous materials shipped via all transportation modes from a location in the U.S. By contrast, rail accounts of only six percent of total shipments of hazardous materials (USDOT, 2010).

TABLE 3.4-2
Hazardous Material Shipments in the United States

Mode	Total Commercial Freight (thousand tons)	Hazardous Materials Shipped (thousand tons)	Percent of Hazardous Materials Shipped
Truck	8,778,713	1,202,825	13.7%
Rail	1,861,307	129,743	7.0%
Water	403,639	149,794	37.1%
Pipeline	650,859	628,905	96.6%
TOTAL	**11,694,518**	**2,111,267**	**18.1%**

Source: USDOT, 2010.

The movement of hazardous materials through the U.S. transportation system represents almost 18 percent of total tonnage for all freight shipments as measured by the Commodity Flow Survey. The total commercial freight moved in 2007 in California by all transportation modes was 900,817 thousand tons, of which about 738,550 thousand tons were moved by truck (USDOT, 2010).

The California Hazardous Materials Incident Reporting System (CHMIRS) is a post-incident reporting system to collect data on incidents involving the accidental release of hazardous materials in California. Information on accidental releases of hazardous materials are reported to and maintained by CalEMA. While information on accidental releases are reported to CalEMA, according to discussions with Mr. Greg Renick of CalEMA on July 25, 2012, CalEMA no longer conducts statistical evaluations of the releases (e.g., total number of releases per year) for the entire State, or data by county. The USDOT Pipeline and Hazardous Materials Safety Administration provides access to retrieve data from the Incident Reports Database, which also includes non-pipeline incidents (e.g., truck and rail events). Incident data and summary statistics (e.g., release date, geographical location for state and county) and type of material released, are available online from the Hazardous Materials Incident Report Form 5800.1.

Table 3.4-3 provides a summary of the reported hazardous material incidents for Los Angeles, Orange, Riverside, and San Bernardino counties for 2010 and 2011 from the Hazardous Materials Incident Report Form 5800.1. Data presented is for the entire county and not limited to the portion of the county located within the jurisdiction of the SCAQMD.

In 2010, there were a total of 672 incidents reported for Los Angeles, Orange, Riverside and San Bernardino counties, and in 2011 a total of 698 incidents four these four counties. San Bernardino and Los Angeles counties accounted for the largest number of incidents, followed by Orange and Riverside counties.

TABLE 3.4-3
Reported Hazardous Materials Incidents for 2010 and 2011

County	2010	2011
Los Angles	273	256
Orange	71	93
Riverside	46	51
San Bernardino	282	298
Total	**672**	**698**

3.4.4 Hazards Associated With Air Pollution Control and Alternative Fuels

The SCAQMD has evaluated the hazards associated with previous AQMPs, proposed SCAQMD rules, and non-SCAQMD projects where the SCAQMD is the Lead Agency pursuant to CEQA. The analyses covered a range of potential air pollution control technologies and equipment. EIRs prepared for the previous AQMPs have specifically evaluated hazard impacts from: 1) add-on control equipment; and, 2) alternative fuels.

Add-on pollution control technologies which have been previously analyzed for hazards include: carbon adsorption, incineration, post-combustion flue-gas treatment, SCR and SNCR, scrubbers, bag filters, and electrostatic precipitators. The use of add-on pollution control equipment may concentrate or utilize hazardous materials. A malfunction or accident when using add-on pollution control equipment could potentially expose people to hazardous materials, explosions, or fires. The SCAQMD has determined that the transport, use, and storage of ammonia, both aqueous and anhydrous, (used in SCR and SNCR systems) may have significant hazard impacts in the event of an accidental release. Further analyses have indicated that the use of aqueous ammonia (instead of anhydrous ammonia) can usually reduce the hazards associated with ammonia use in SCR and SNCR systems to less than significant.

Alternative fuels may be used to reduce emissions from both stationary source equipment and motor vehicles. The alternative fuels which have been analyzed include reformulated gasoline, methanol, compressed natural gas, LPG or propane, and electrically charged batteries. Like conventional fossil fuels, alternative fuels may create fire hazards, explosions or accidental releases during fuel transport, storage, dispensing, and use. Electric batteries also present a slight fire and explosion hazards due to the presence of reactive compounds, which may be subjected to high temperatures.

Ammonia

Ammonia is the primary hazardous chemical identified with the use of air pollution control equipment (e.g., SCR and SNCR systems). Ammonia, though not a carcinogen, can have chronic and acute health impacts. Therefore, a potential increase in the use of ammonia may increase the current existing risk setting associated with deliveries (e.g., truck and road accidents) and onsite or offsite spills for each facility that currently uses or will begin to use ammonia. Exposure to a toxic gas cloud is the potential hazard associated with this type of control equipment. A toxic gas cloud is the release of a volatile chemical such as anhydrous ammonia that could form a cloud that migrates off-site, thus exposing individuals.

Anhydrous ammonia is heavier than air such that when released into the atmosphere, would form a cloud at ground level rather than be dispersed "Worst-case" conditions tend to arise when very low wind speeds coincide with the accidental release, which can allow the chemicals to accumulate rather than disperse. While there are existing facilities that are currently permitted to use anhydrous ammonia, for new construction, however, current SCAQMD policy no longer allows the use of anhydrous ammonia for the operation of air pollution control equipment. Instead, to minimize the hazards associated with ammonia used in the SCR or SNCR process, aqueous ammonia, 19 percent by volume, is typically required as a permit condition associated with the installation of SCR or SNCR equipment for the following reasons: 1) 19 percent aqueous ammonia does not travel as a dense gas like anhydrous ammonia; and, 2) 19 percent aqueous ammonia is not on any acutely hazardous material lists unlike anhydrous ammonia or aqueous ammonia at higher percentages.

LNG

LNG is essentially no different from the natural gas used in homes and businesses every day, except that it has been refrigerated to -259 °F at which point it becomes a clear, colorless, and odorless liquid. LNG currently is used as a combustion fuel in both stationary and mobile sources. As a liquid, natural gas occupies only one six-hundredth of its gaseous volume and can be transported economically between continents in special tankers. LNG weighs slightly less than half as much as water, so it floats on fresh or sea water. However, when LNG comes in contact with any warmer surface such as water or air, it evaporates very rapidly ("boil"), returning to its original, gaseous volume. As the LNG vaporizes, a vapor cloud resembling ground fog will form under relatively calm atmospheric conditions. The vapor cloud is initially heavier than air since it is so cold, but as it absorbs more heat, it becomes lighter than air, rises, and can be carried away by the wind. An LNG vapor cloud cannot explode in the open atmosphere, but it could burn.

LNG is considered a hazardous material. The primary safety concerns are the potential consequences of an LNG spill. LNG hazards result from three of its properties:

- Cryogenic temperatures
- Dispersion characteristics
- Flammability characteristics

The extreme cold of LNG can directly cause injury or damage. Although momentary contact on the skin can be harmless, extended contact will cause severe freeze burns. On contact with certain metals, such as ship decks, LNG can cause immediate cracking. Although not poisonous, exposure to the center of a vapor cloud could cause asphyxiation due to the absence of oxygen. LNG vapor clouds can ignite within the portion of the cloud where the concentration of natural gas is between a five and a 15 percent (by volume) mixture with air. To catch fire, however, this portion of the vapor cloud must encounter an ignition source. Otherwise, the LNG vapor cloud will simply dissipate into the atmosphere. An ignited LNG vapor cloud is very dangerous, because of its tremendous radiant heat output. Furthermore, as a vapor cloud continues to burn, the flame could burn back toward the evaporating pool of spilled liquid, ultimately burning the quickly evaporating natural gas immediately above the pool, giving the appearance of a "burning pool" or "pool fire." An ignited vapor cloud or a large LNG pool fire can cause extensive damage to life and property.

Spilled LNG would disperse faster on the ocean than on land, because water spills provide very limited opportunity for containment. Furthermore, LNG vaporizes more quickly on water, because the ocean provides an enormous heat source. For these reasons, most analysts conclude that the risks associated with shipping, loading, and off-loading LNG are much greater than those associated with land-based storage facilities. Preventing spills and responding immediately to spills should they occur are major factors in the design of LNG facilities (CEC, 2003).

Beyond routine industrial hazards and safety considerations, LNG presents specific safety considerations. In the event of an accidental release of LNG, the safety zone around a facility protects neighboring communities from personal injury, property damage or fire. The one and only case of an accident that affected the public was in Cleveland, Ohio in 1944. Research stemming from the Cleveland incident has influenced safety standards used today. Indeed, during the past four decades, growth in LNG use worldwide has led to a number of technologies and practices that will be used in the U.S. and elsewhere in North America as the LNG industry expands. Generally, multiple layers of protection create four critical safety conditions, all of which are integrated with a combination of industry standards and regulatory compliance. The four requirements for safety – primary containment, secondary containment, safeguard systems and separation distance apply across the LNG value chain, from production, liquefaction and shipping, to storage and re-gasification. The term "containment" means safe storage and isolation of LNG (Foss, 2003).

LPG

More than 350,000 light-and medium-duty vehicles travel the nation's highways using liquefied petroleum gas (LPG), while over four million vehicles use it worldwide. LPG is a mixture of several gases that is generally called "propane," in reference to the mixture's chief ingredient. LPG changes to the liquid state at the moderately high pressures found in an LPG vehicle's fuel tank. LPG is formed naturally, interspersed with deposits of petroleum and natural gas. Natural gas contains LPG, water vapor, and other impurities that must be removed before it can be transported in pipelines as a salable product. About 55 percent of the LPG processed in the U.S. is from natural gas purification. The other 45 percent comes from crude oil refining. Since a sizable amount of U.S. LPG is derived from petroleum, LPG does less to relieve the country's dependency on foreign oil than some other alternative fuels. However, because over 90 percent of the LPG used in the United States is produced here, LPG does help address the national security component of the nation's overall petroleum dependency problem.

Propane vehicles emit about one-third fewer reactive organic gases than gasoline-fueled vehicles. Nitrogen oxide and carbon monoxide emissions are also 20 percent and 60 percent less, respectively. Unlike gasoline-fueled vehicles, there are no evaporative emissions while

LPG vehicles are running or parked, because LPG fuel systems are tightly sealed. Small amounts of LPG may escape into the atmosphere during refueling, but these vapors are 50 percent less reactive than gasoline vapors, so they have less of a tendency to generate smog-forming ozone. LPG's extremely low sulfur content means that the fuel does not contribute significantly to acid rain.

Many propane vehicles are converted gasoline vehicles. The relatively inexpensive conversion kits include a regulator/vaporizer that changes liquid propane to a gaseous form and an air/fuel mixer that meters and mixes the fuel with filtered intake air before the mixture is drawn into the engine's combustion chambers. Also included in conversion kits is closed-loop feedback circuitry that continually monitors the oxygen content of the exhaust and adjusts the air/fuel ratio as necessary. This device communicates with the vehicle's onboard computer to keep the engine running at optimum efficiency. LPG vehicles additionally require a special fuel tank that is strong enough to withstand the LPG storage pressure of about 130 pounds per square inch. The gaseous nature of the fuel/air mixture in an LPG vehicle's combustion chambers eliminates the cold-start problems associated with liquid fuels. In contrast to gasoline engines, which produce high emission levels while running cold, LPG engine emissions remain similar whether the engine is cold or hot. Also, because LPG enters an engine's combustion chambers as a vapor, it does not strip oil from cylinder walls or dilute the oil when the engine is cold. This helps LPG powered engines to have a longer service life and reduced maintenance costs. Also helping in this regard is the fuel's high hydrogen-to-carbon ratio (C3H8), which enables propane powered vehicles to have less carbon build-up than gasoline- and diesel powered vehicles. LPG delivers roughly the same power, acceleration, and cruising speed characteristics as gasoline. It does yield a somewhat reduced driving range, however, because it contains only about 70-75 percent of the energy content of gasoline. Its high octane rating (around 105) means, though, that an LPG engine's power output and fuel efficiency can be increased beyond what would be possible with a gasoline engine without causing destructive "knocking." Such fine-tuning can help compensate for the fuel's lower energy density. Fleet owners find that propane costs are typically five to 30 percent less than those of gasoline. The cost of constructing an LPG fueling station is also similar to that of a comparably sized gasoline dispensing system. Fleet owners not wishing to establish fueling stations of their own may avail themselves of over 3,000 publicly accessible fueling stations nationwide.

Propane is an odorless, nonpoisonous gas that has the lowest flammability range of all alternative fuels. High concentrations of propane can displace oxygen in the air, though, causing the potential for asphyxiation. This problem is mitigated by the presence of ethyl mercaptan, which is an odorant that is added to warn of the presence of gas. While LPG itself does not irritate the skin, the liquefied gas becomes very cold upon escaping from a high-pressure tank, and may therefore cause frostbite, should it contact unprotected skin. As with gasoline, LPG can form explosive mixtures with air. Since the gas is slightly heavier than air, it may form a continuous stream that stretches a considerable distance from a leak or open container, which may lead to a flashback explosion upon contacting a source of ignition (USDOE, 2003).

While LPG is classified as a fire hazard, it is not classified as a toxic or as a hazardous air pollutant. LPG is a regulated substance subject to both the California and Federal RMP programs in accordance with the CCR, Title 19, §2770.4.1 and Chapter 40 of the CFR Part 68, §68.126[2]. A RMP is a document prepared by the owner or operator of a stationary source containing detailed information including, but not limited to:

- Regulated substances held onsite at the stationary source;
- Offsite consequences of an accidental release of a regulated substance;
- The accident history at the stationary source;
- The emergency response program for the stationary source;
- Coordination with local emergency responders;
- Hazard review or process hazard analysis;
- Operating procedures at the stationary source;
- Training of the stationary source's personnel;
- Maintenance and mechanical integrity of the stationary source's physical plant; and
- Incident investigation.

The threshold quantity for LPG (as propane) as a regulated substance for accidental release prevention is 10,000 pounds. However, when LPG is used as a fuel by an end user (as is frequently the case with residential portable and stationary storage tanks), or when it is held for retail sale as a fuel, it is excluded from these RMP requirements, even if the amount exceeds the threshold quantity.

On June 1, 2012, SCAQMD adopted Rule 1177 - Liquefied Petroleum Gas Transfer and Dispensing to reduce fugitive VOC emissions released during the transfer and dispensing of LPG at residential, commercial, industrial, chemical, agricultural and retail sales facilities. Rule 1177 applies to the transfer of LPG to and from stationary storage tanks, cylinders and cargo tanks, including bobtails, truck transports and rail tank cars, and into portable refillable cylinders. In addition, Rule 1177 requires the use of low emission fixed liquid level gauges or equivalent alternatives during filling of LPG-containing tanks and cylinders, use of LPG low emission connectors, routine leak checks and repairs of LPG transfer and dispensing equipment, and recordkeeping and reporting to demonstrate compliance.

With respect to suppliers and sellers of LPG, HSC §25506 specifically requires all businesses handling hazardous materials to submit a business emergency response plan to assist local administering agencies in the emergency release or threatened release of a hazardous material. Business emergency response plans generally require the following:

2 The federal RMP program is administered in California through the California Accidental Release Prevention (CalARP) program (HSC §§ 25531 -25543.3 and CCR, Title 19 §§ 2735.1 to 2785.1).

1. Identification of individuals who are responsible for various actions, including reporting, assisting emergency response personnel and establishing an emergency response team;

2. Procedures to notify the administering agency, the appropriate local emergency rescue personnel, and the California Office of Emergency Services;

3. Procedures to mitigate a release or threatened release to minimize any potential harm or damage to persons, property or the environment;

4. Procedures to notify the necessary persons who can respond to an emergency within the facility;

5. Details of evacuation plans and procedures;

6. Descriptions of the emergency equipment available in the facility;

7. Identification of local emergency medical assistance; and

8. Training (initial and refresher) programs for employees in:

    a. The safe handling of hazardous materials used by the business;

    b. Methods of working with the local public emergency response agencies;

    c. The use of emergency response resources under control of the handler; and

    d. Other procedures and resources that will increase public safety and prevent or mitigate a release of hazardous materials.

In general, every county or city and all facilities using a minimum amount of hazardous materials are required to formulate detailed contingency plans to eliminate, or at least minimize, the possibility and effect of fires, explosion, or spills. In conjunction with the California Office of Emergency Services, local jurisdictions have enacted ordinances that set standards for area and business emergency response plans. These requirements include immediate notification, mitigation of an actual or threatened release of a hazardous material, and evacuation of the emergency area.

Lastly, operators who currently transfer and dispense LPG are well aware of the hazardous nature of LPG, including its flammability and receive periodic training for the safe handling of LPG for the following reasons. Facility operators with a dispensing system for LPG are required to comply with operating pressures pursuant to the standards developed by the American Society of Mechanical Engineers (ASME) Pressure Vessel Code, Section 8; NFPA 58 with regard to venting LPG to the atmosphere; and for LPG tanks that are subject to RMP requirements, the operators must obtain permits from, and submit RMPs to the local Certified Unified Program Agency (CUPA) with is typically the city or county fire department. For similar reasons, industrial and commercial customers on the receiving end of LPG deliveries are also well aware of the safety issues associated with LPG. Residential customers, through warning labels on the portable cylinders and on the units to which the portable cylinders connect, are notified of the flammability dangers associated with LPG.

HYDROLOGY AND WATER QUALITY

Regulatory Background

Hydrology

Water Demand and Forecasts

Water Supply

Water Conservation

Water Quality

Wastewater Treatment

3.5 HYDROLOGY AND WATER QUALITY

This subchapter describes existing regulatory setting relative to hydrology and water quality, including water supply, water demand, and drought trends within California and the SCAQMD.

3.5.1 Regulatory Background

Water resources are regulated by an overlapping network of local, state, federal and international laws and regulations. As a result, the authority to address a given discharge or activity is not always clear. Therefore, the regulatory background is broken down by the following topics: Water Quality; Regional Water Quality Management; Watershed Management; Wastewater Treatment; Drinking Water Standards; and, local regulations.

3.5.1.1 Water Quality

The principal laws governing water quality in southern California are the federal Clean Water Act (CWA) and the corresponding California law, the Porter-Cologne Water Quality Act. The USEPA is the federal agency responsible for water quality management and administration of the federal CWA. The USEPA has delegated most of the administration of the CWA in California to the California State Water Resources Control Board (SWRCB). The SWRCB was established through the California Porter-Cologne Water Quality Act of 1969, and is the primary State agency responsible for water quality management issues in California. Much of the responsibility for implementation of the SWRCB's policies is delegated to the nine Regional Water Quality Control Boards (RWQCBs).

National Pollutant Discharge Elimination System Permit Program

The CWA §402 established the National Pollutant Discharge Elimination System (NPDES) to regulate discharges into "navigable waters" of the United States. The USEPA authorized the SWRCB to issue NPDES permits in the State of California in 1974. The NPDES permit establishes discharge pollutant thresholds and operational conditions for industrial facilities and wastewater treatment plants. For point source discharges (e.g., wastewater treatment facilities), the RWQCBs prepare specific effluent limitations for constituents of concern such as toxic substances, total suspended solids (TSS), bio-chemical oxygen demand (BOD), and organic compounds. The limitations are based on the Basin Plan objectives and are tailored to the specific receiving waters, allowing some discharges, for instance deep water outfalls in the Pacific Ocean, more flexibility with certain constituents due to the ability of the receiving waters to accommodate the effluent without significant impact.

Non-point source NPDES permits are also required for municipalities and unincorporated communities of populations greater than 100,000 to control urban stormwater runoff. These municipal permits include Storm Water Management Plans (SWMPs). A key part of the SWMP is the development of Best Management Practices (BMPs) to reduce pollutant loads. Certain businesses and projects within the jurisdictions of these municipalities are required to prepare Storm Water Pollution Prevention Plans (SWPPPs) which establish the appropriate BMPs to gain coverage under the municipal permit. On October 29, 1999, the USEPA finalized the Storm Water Phase II rule which requires smaller urban communities with a population less than 100,000 to acquire individual storm water discharge permits.

The Phase II rule also requires construction activities on one to five acres to be permitted for storm water discharges. Individual storm water NPDES permits are required for specific industrial activities and for construction sites greater than five acres. Statewide general storm water NPDES permits have been developed to expedite discharge applications. They include the statewide industrial permit and the statewide construction permit. A prospective applicant may apply for coverage under one of these permits and receive Waste Discharge Requirements (WDRs) from the appropriate RWQCB. WDRs establish the permit conditions for individual dischargers. The Stormwater Phase II Rule automatically designates, as small construction activity under the NPDES stormwater permitting program, all operators of construction site activities that result in a land disturbance of equal to or greater than one and less than five acres. Site activities that disturb less than one acre are also regulated as small construction activity if they are part of a larger common plan of development or sale with a planned disturbance of equal to or greater than one acre and less than five acres, or if they are designated by the NPDES permitting authority. The NPDES permitting authority or USEPA Region may designate construction activities disturbing less than one acre based on the potential for contribution to a violation of a water quality standard or for significant contribution of pollutants to waters of the United States (USEPA, 2005)[1].

Municipal Stormwater and Urban Runoff Discharge Permits

The Municipal Stormwater Permitting Program regulates stormwater discharges from municipal separate storm sewer systems (MS4s). The RWQCB, with oversight by USEPA, administers the MS4 permitting program in the Los Angeles area. The MS4 permits require the municipal discharger (typically, a city or county) to develop and implement a SWMP with the goal of reducing the discharge of pollutants to the maximum extent practicable. The SWMP program specifies what BMPs will be applied to address certain program areas such as public education and outreach, illicit discharge detection and elimination, construction and port-construction, and good housekeeping for municipal operations. MS4 permits also generally include a monitoring program.

CWA §303 – Total Maximum Daily Loads

The CWA §303(d) requires the SWRCB to prepare a list of impaired water bodies in the State and determine total maximum daily loads (TMDLs) for pollutants or other stressors impacting water quality of these impaired water bodies. A TMDL is a quantitative assessment of water quality conditions, contributing sources, and the load reductions or control actions needed to restore and protect bodies of water in order to meet their beneficial uses. All sources of the pollutants that caused each body of water to be included on the list, including point sources and non-point sources, must be identified. The California §303 (d) list was completed in March 1999. On July 25, 2003, USEPA gave final approval to California's 2002 revision of §303 (d) List of Water Quality Limited Segments. A priority schedule has been developed to determine TMDLs for impaired waterways. TMDL projects are in various stages throughout the district for most of the identified impaired water bodies.

[1] Stormwater Phase II Final Rule, Small Construction Program Overview. EPA 833-F-00-013. January, 2000 (revised December 2005), U.S. EPA, 2005.

The RWQCBs will be responsible for ensuring that total discharges do not exceed TMDLs for individual water bodies as well as for entire watersheds.

State Water Quality Certification Program

The RWQCBs also coordinate the State Water Quality Certification program, or CWA §401. Under CWA §401, states have the authority to review any federal permit or license that will result in a discharge or disruption to wetlands and other waters under state jurisdiction to ensure that the actions will be consistent with the state's water quality requirements. This program is most often associated with CWA §404 which obligates the U.S. Army Corps of Engineers to issue permits for the movement of dredge and fill material into and from "waters of the United States".

3.5.1.2 Regional Water Quality Management

Water quality of regional surface water and groundwater resources is affected by point source and non-point source discharges occurring throughout individual watersheds. Regulated point sources, such as wastewater treatment effluent discharges, usually involve a single discharge into receiving waters. Non-point sources involve diffuse and non-specific runoff that enters receiving waters through storm drains or from unimproved natural landscaping. Common non-point sources include urban runoff, agriculture runoff, resource extraction (on-going and historical), and natural drainage. Within the regional Basin Plans, the RWQCBs establish water quality objectives for surface water and groundwater resources and designate beneficial uses for each identified water body.

The Basin Plan (Water Quality Control Plan: Los Regional Basin Plan for the Coastal Watersheds of Los Angeles and Ventura Counties) (LARWQCB, 1994) is designed to preserve and enhance water quality and to protect beneficial uses of regional waters. The Basin Plan designates beneficial uses of surface water and ground water, such as contact recreation or municipal drinking water supply. The Basin Plan also establishes water quality objectives, which are defined as "the allowable limits or levels of water quality constituents or characteristics which are established for the reasonable protection of beneficial uses of water or the prevention of nuisance in a specific area." The Basin Plan specifies objectives for specific constituents, including bioaccumulation, chemical constituents, dissolved oxygen, oil and grease, pesticides, pH, polychlorinated biphenyls, suspended solids, toxicity, and turbidity.

California Water Code, Division 7, Chapter 5.6 established a comprehensive program within the SWRCB to protect the existing and future beneficial uses of California's enclosed bays and estuaries. The Bay Protection and Toxic Cleanup Plan (BPTCP) has provided a new focus on the SWRCB and the RWQCBs' efforts to control pollution of the State's bays and estuaries by establishing a program to identify toxic hot spots and plans for their cleanup. In June 1999, the SWRCB published a list of known toxic hot spots in estuaries, bays, and coastal waters.

Other statewide programs run by the SWRCB to monitor water quality include the California State Mussel Watch Program and the Toxic Substances Monitoring Program.

The Department of Fish and Game collects water and sediment samples for the SWRCB for both of these programs and provides extensive statewide water quality data reports annually. In addition, the RWQCBs conduct water sampling for Water Quality Assessments required by the CWA and for specific priority areas under restoration programs such as the Santa Monica Bay Restoration Program.

3.5.1.3 Watershed Management

In February 1998, the Clean Water Action Plan (CWAP) was established to require states and tribes, with assistance from federal agencies and input from stakeholders and private citizens, to convene and work collaboratively to develop Unified Watershed Assessments (UWA). The CWAP designated watersheds to one of the following categories:

Category I: Watersheds that are candidates for increased restoration because of poor water quality or the poor status of natural resources.

Category II: Watersheds that have good water quality but can still improve.

Category III: Watersheds with sensitive areas on federal, state, or tribal lands that need protection.

Category IV: Watersheds for which there is insufficient information to categorize them.

Targeted watersheds and watershed priorities and activities were identified for each of California's nine RWQCBs. Examples of targeted watersheds include the Santa Monica Bay Restoration Commission and the Malibu Creek Watershed Non-Point Source Pilot Project.

3.5.1.4 Wastewater Treatment

The federal government enacted the CWA to regulate point source water pollutants, particularly municipal sewage and industrial discharges, to waters of the United States through the NPDES permitting program. In addition to establishing a framework for regulating water quality, the CWA authorized a multibillion dollar Clean Water Grant Program, which together with the California Clean Water Bond funding, assisted communities in constructing municipal wastewater treatment facilities. These financing measures made higher levels of wastewater treatment possible for both large and small communities throughout California, significantly improving the quality of receiving waters statewide. Wastewater treatment and water pollution control laws in California are codified in the CWC and CCR, Titles 22 and 23. In addition to federal and state restrictions on wastewater discharges, most incorporated cities in California have adopted local ordinances for wastewater treatment facilities. Local ordinances generally require treatment system designs to be reviewed and approved by the local agency prior to construction. Larger urban areas with elaborate infrastructure in place would generally prefer new developments to hook into the existing system rather than construct new wastewater treatment facilities. Other communities promote individual septic systems to avoid construction of potentially growth accommodating treatment facilities. The RWQCBs generally delegate management responsibilities of septic systems to local jurisdictions. Regulation of wastewater treatment includes the disposal and reuse of biosolids.

3.5.1.5 Drinking Water Standards

The federal Safe Drinking Water Act, enacted in 1974 and implemented by the USEPA, imposes water quality and infrastructure standards for potable water delivery systems nationwide. The primary standards are health-based thresholds established for numerous toxic substances. Secondary standards are recommended thresholds for taste and mineral content. The State of California was first granted primary enforcement responsibility for public water systems under section 1413 of the Safe Drinking Water Act on June 2, 1978 (43 FR 25180, June 9, 1978).

The California Safe Drinking Water Act, enacted in 1976, is codified in Title 22 of the CCR. The California Safe Drinking Water Act provides for the operation of public water systems and imposes various duties and responsibilities for the regulation and control of drinking water in the State of California including enforcing provisions of the federal Safe Drinking Water Act. The California Safe Drinking Water Program was originally implemented by the California Department of Public Health until July 1, 2014 when the program was transferred to the SWRCB via an act of legislation, SB 861. This transfer of authority means that the SWRCB has regulatory and enforcement authority over drinking water standards and water systems under Health and Safety Code §116271.

Potable water supply is managed through the following agencies and water districts: the California Department of Water Resources (DWR), the California Department of Health Services (DHS), the SWRCB, the USEPA, and the U.S. Bureau of Reclamation. Water right applications are processed through the SWRCB for properties claiming riparian rights. The DWR manages the State Water Project (SWP) and compiles planning information on water supply and water demand within the state. Primary drinking water standards are promulgated in the CWA §304 and these standards require states to ensure that potable water retailed to the public meets these standards. Standards for a total of 88 individual constituents, referred to as Maximum Contaminant Levels (MCLs) have been established under the Safe Drinking Water Act as amended in 1986 and 1996. The USEPA may add additional constituents in the future. The MCL is the concentration that is not anticipated to produce adverse health effects after a lifetime of exposure. State primary and secondary drinking water standards are codified in CCR Title 22 §§64431 - 64501. Secondary drinking water standards incorporate non-health risk factors including taste, odor, and appearance. The 1991 Water Recycling Act established water recycling as a priority in California. The Water Recycling Act encourages municipal wastewater treatment districts to implement recycling programs to reduce local water demands. The DHS enforces drinking water standards in California.

3.5.1.6 Local Regulations

In addition to federal and state regulations, cities, counties and water districts may also provide regulatory advisement regarding water resources. Many jurisdictions incorporate policies related to water resources in their municipal codes, development standards, storm water pollution prevention requirements, and other regulations.

3.5.2 Hydrology

3.5.2.1 Water Sources

The DWR divided California into ten hydrologic regions corresponding to the state's major water drainage basins. The hydrologic regions define a river basin drainage area and are used as planning boundaries, which allows consistent tracking of water runoff, and the accounting of surface water and groundwater supplies (DWR, 2010)[2].

The Basin lies within the South Coast Hydrologic Region. The South Coast Hydrologic Region is California's most urbanized and populous region. More than half of the state's population resides in the region (about 19.6 million people or about 54 percent of the state's population), which covers 11,000 square miles or seven percent of the state's total land. The South Coast Hydrologic Region extends from the Pacific Ocean east to the Transverse and Peninsular Ranges, and from the Ventura-Santa Barbara County line south to the international border with Mexico and includes all of Orange County and portions of Ventura, Los Angeles, San Bernardino, Riverside, and San Diego counties (DWR, 2010).

Topographically, most of the South Coast Hydrologic Region is composed of several large, undulating coastal and interior plains. Several prominent mountain ranges comprise its northern and eastern boundaries and include the San Gabriel and San Bernardino mountains. Most of the region's rivers drain into the Pacific Ocean, and many terminate in lagoons or wetland areas that serve as important coastal habitat. Many river segments on the coastal plain, however, have been concrete-lined and in other ways modified for flood control operations (DWR, 2010).

There are 19 major rivers and watersheds in the South Coast Hydrologic Region. Many of these watersheds have densely urbanized lowlands with concrete-lined channels and dams controlling floodflows. The headwaters for many rivers, however, are within coastal mountain ranges and have remained largely undeveloped (DWR, 2010).

The cities of Ventura, Los Angeles, Long Beach, Santa Ana, San Bernardino, and Big Bear Lake are among the many urban areas in this section of the state, which contain moderate-sized mountains, inland valleys, and coastal plains. The Santa Clara, Los Angeles, San Gabriel, and Santa Ana rivers are among the area's hydrologic features. In addition to water sources within the South Coast Hydrologic Region, imported water makes up a major portion of the water used in the Basin. Water is brought into the South Coast Hydrologic Region from three major sources: the Sacramento-San Joaquin Delta (Delta), Colorado River, and Owens Valley/Mono Basin. Most lakes in this area are actually reservoirs, made to hold water coming from the SWP, the Los Angeles Aqueduct (LAA), and the Colorado River Aqueduct (CRA) including Castaic Lake, Lake Mathews, Lake Perris, Silverwood Lake, and Diamond Valley Lake. In addition to holding water, Lake Casitas, Big Bear Lake, and Morena Lake regulate local runoff.

[2] California Water Plan Update, 2009. Integrated Water Management. Bulletin 160-109, DWR, 2010.

3.5.2.2 Surface Water Hydrology

Surface water hydrology refers to surface water systems, including watersheds, floodplains, rivers, streams, lakes and reservoirs, and the inland Salton Sea.

Watersheds

Watersheds refer to areas of land, or basin, in which all waterways drain to one specific outlet, or body of water, such as a river, lake, ocean, or wetland. Watersheds have topographical divisions such as ridges, hills or mountains. All precipitation that falls within a given watershed, or basin, eventually drains into the same body of water (SCAG, 2012)[3]. There are 20 major watersheds within southern California region, all of which are outlined and shaped by the various topographic features of the region. Given the physiographic characteristics of the region, most of the watersheds are located along the Transverse and Peninsular Ranges, and only a small number are in the desert areas (Mojave and Colorado Desert) (SCAG, 2012). Figure 3.5-1 presents a map of the watersheds within the SCAQMD.

Rivers

Because the climate of Southern California is predominantly arid, many of the natural rivers and creeks are intermittent or ephemeral, drying up in the summer or flowing only after periods of precipitation. For example, annual rainfall amounts vary depending on elevation and proximity to the coast. Some waterways such as Ballona Creek and the Los Angeles River maintain a perennial flow due to agricultural irrigation and urban landscape watering (SCAG, 2012). Figure 3.5-2 presents a map of the major rivers within the district.

Major natural streams and rivers in the South Coast Hydrologic Region include the Ventura River, Santa Clara River, Los Angeles River, San Gabriel River, Santa Ana River, San Jacinto River, and upstream portions of the Santa Margarita River.

The Ventura River, located outside of the district, is fed by Lake Casitas on the western border of Ventura County and empties out into the ocean. It is the northern-most river system in Southern California, supporting a large number of sensitive aquatic species. Water quality decreases in the lower reaches due to urban and industrial impacts.

The Santa Clara River starts in Los Angeles County, flows through the center of Ventura County, and remains in a relatively natural state. Threats to water quality include increasing development in floodplain areas, flood control measures such as channeling, erosion, and loss of habitat.

The Los Angeles River is a highly disturbed system due to the flood control features along much of its length. Due to the high urbanization in the area around the Los Angeles River, runoff from industrial and commercial sources as well as illegal dumping contribute to reduce the channel's water quality.

[3] Draft Program Environmental Impact Report for the 2012 – 2035 RTP/SCS. SCAG, 2012.

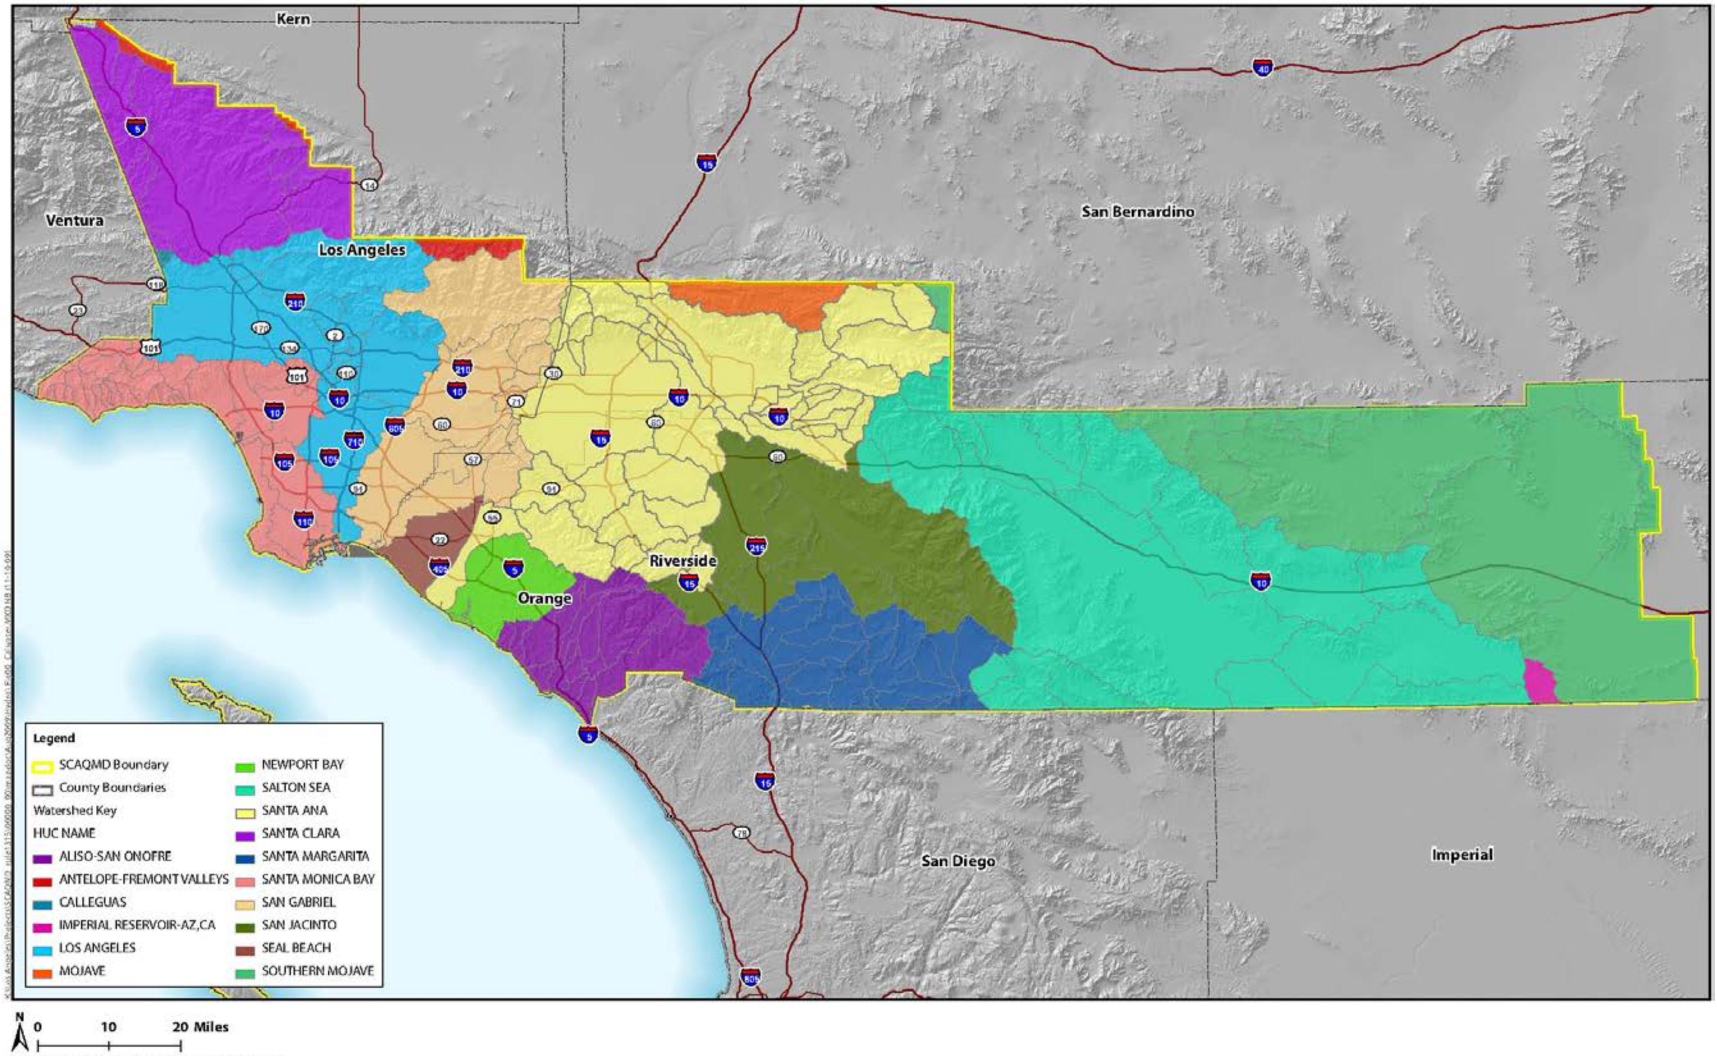

FIGURE 3.5-1
USGS Watersheds within the SCAQMD

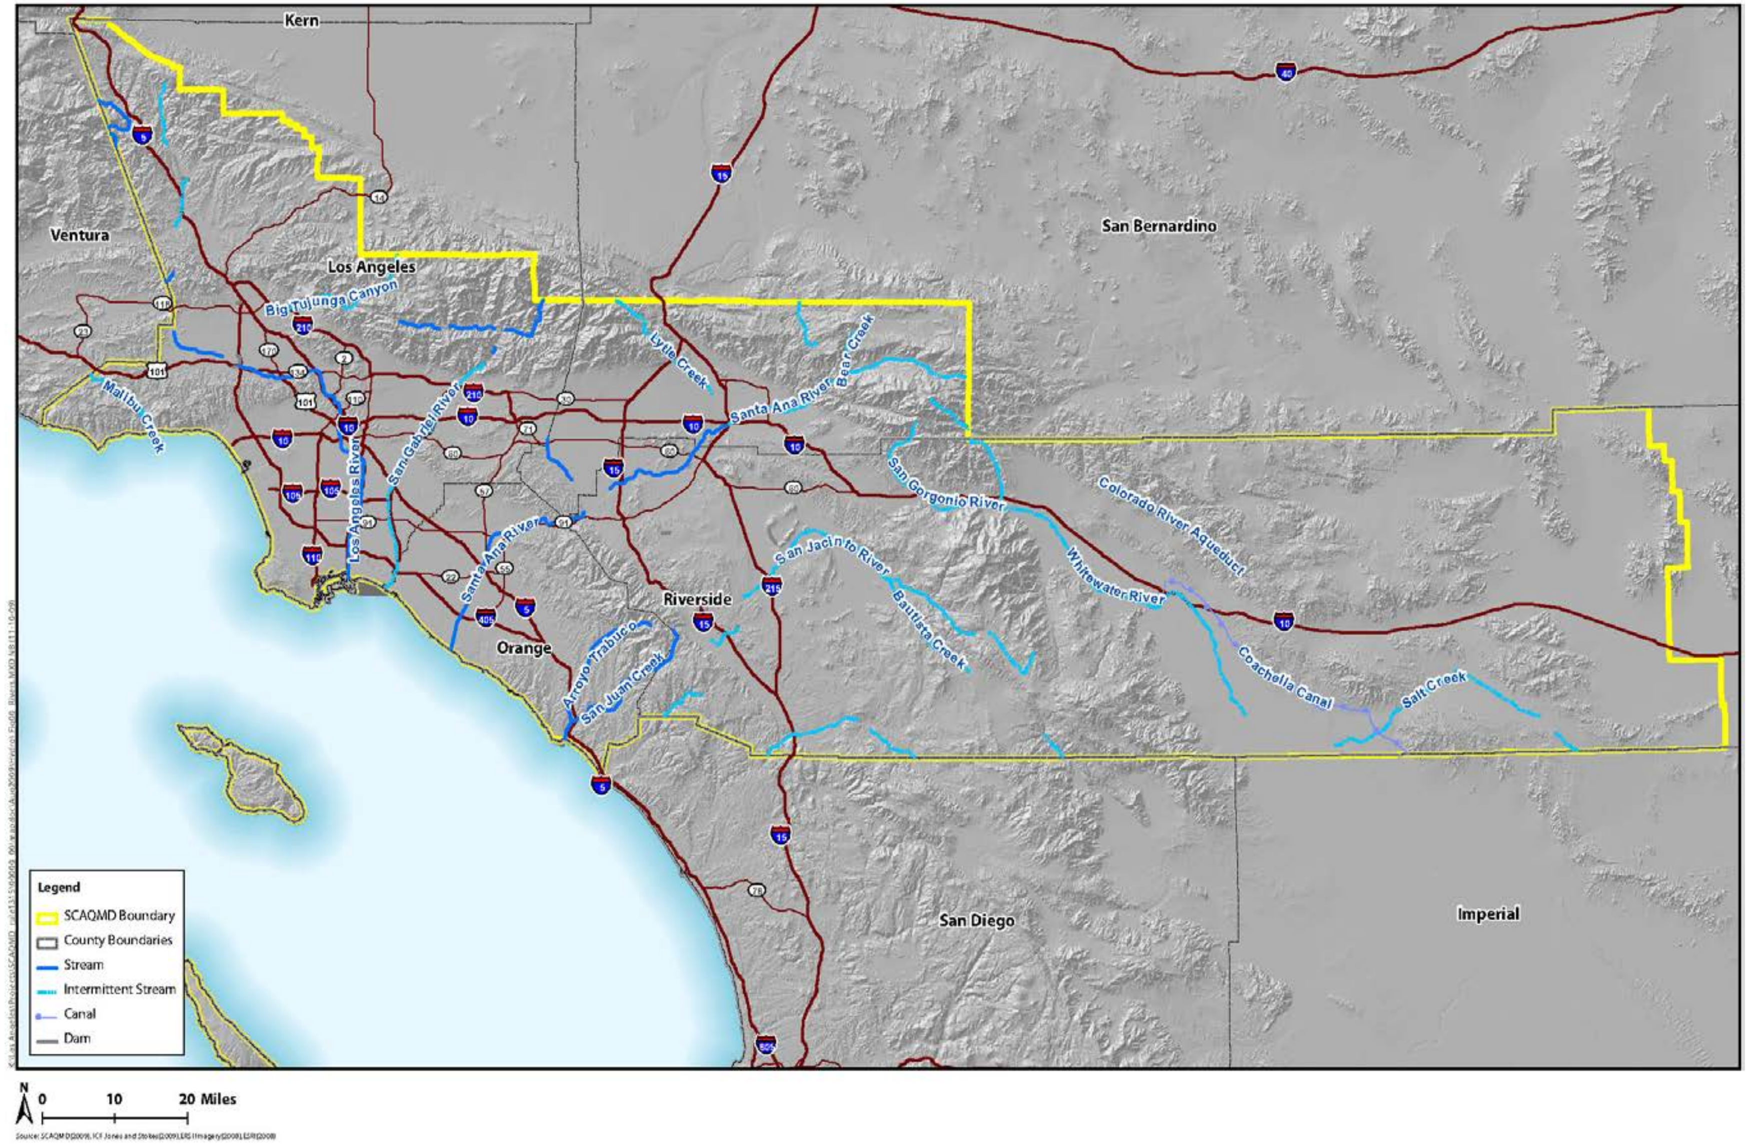

FIGURE 3.5-2
Rivers within the SCAQMD

The San Gabriel River is similarly altered with concrete flood control embankments and impacted by urban runoff.

The Santa Ana River drains the San Bernardino Mountains, cuts through the Santa Ana Mountains, and flows onto the Orange County coastal plain. Recent flood control projects along the river have established reinforced embankments for much of the river's path through urbanized Orange County.

The Santa Margarita River begins in Riverside County, draining portions of the San Jacinto Mountains and flowing to the ocean through northern San Diego County.

Lakes and Reservoirs

Since southern California is a semi-arid region, many of its lakes are drinking water reservoirs, created either through damming of rivers, or manually dug and constructed. Reservoirs also serve as flood control for downstream communities. Some of the most significant lakes, including reservoirs, in the Basin are Big Bear Lake, Lake Arrowhead, Lake Casitas, Castaic Lake, Pyramid Lake, Lake Elsinore, Diamond Valley Lake, and the Salton Sea (SCAG, 2012).

Big Bear Lake is a reservoir in San Bernardino County, in the San Bernardino Mountains. It was created by a granite dam in 1884, which was expanded in 1912, and holds back approximately 73,000 acre-feet[4] of water. The lake has no tributary inflow, and is replenished entirely by snowmelt. It provides water for the community of Big Bear, as well as nearby communities (SCAG, 2012).

Lake Arrowhead is also in San Bernardino County, at the center of an unincorporated community also called Lake Arrowhead. The lake is a man-made reservoir, with a capacity of approximately 48,000 acre-feet of water. In 1922, the dam at Lake Arrowhead was completed, with the intention of turning the area into a resort. It is now used for recreation and as a potable water source for the surrounding community (SCAG, 2012).

Lake Casitas is in Ventura County, and was formed by the Casitas Dam on the Coyote Creek just before it joins the Ventura River. The dam, completed in 1959, holds back nearly 255,000 acre-feet of water. The water is used for recreation, as well as drinking water and irrigation (SCAG, 2012).

Castaic Lake is on the Castaic Creek, and was formed by the completion of the Castaic Dam. The lake is in northwestern Los Angeles County. It is the terminus of the West Branch of the California Aqueduct, and holds over 323,000 acre-feet of water. Much of the water is distributed throughout northern Los Angeles County, though some is released into Castaic Lagoon, which feeds Castaic Creek. The creek is a tributary of the Santa Clara River (SCAG, 2012).

Pyramid Lake is just above Castaic Lake, and water flows from Pyramid into Castaic through a pipeline, generating electricity during the day. At night, when electricity demand

[4] One acre-foot of water is equivalent to 325,851 gallons.

and prices are low, water is pumped back up into Pyramid Lake. Pyramid Lake is on Piru Creek, and holds 180,000 acre-feet of water (SCAG, 2012).

Lake Elsinore is in the City of Lake Elsinore, in Riverside County. While the lake has been dried up and subsequently replenished throughout the last century, it now manages to maintain a consistent water level with outflow piped into the Temescal Canyon Wash (SCAG, 2012).

Diamond Valley Lake is Southern California's newest and largest reservoir. Located in Riverside County, it was a project of Metropolitan Water District (MWD) to expand surface storage capacity in the region. A total of three dams were required to create the lake. Completed in 1999, it was full by 2002, holding 800,000 acre-feet of water, effectively doubling MWD's surface water storage in the region. The lake is connected to the existing water infrastructure of the SWP. The lake is situated at approximately 1,500 feet above sea level, well above most of the users of the lake's water which enables the lake to also provide hydroelectric power, as water flows through the lowest dam (SCAG, 2012).

The Salton Sea is California's largest lake, nearly 400 square miles in size. The lake is over 200 feet below sea level, and has flooded and evaporated many times over, when the Colorado overtops its banks during extreme flood years. This cycle of flooding and evaporation has re-created the Salton Sea several times during the last thousand years and has resulted in high levels of salinity. The lake's most recent formation occurred in 1905 after an irrigation canal was breached and the Colorado River flowed into the basin for 18 months, creating the current lake (SCAG, 2012).

The principle inflow to the Salton Sea is from agricultural drainage, which is high in dissolved salts; approximately four million tons of dissolved salts flow into the Salton Sea every year. The evaporation of the Salton Sea's water, plus the addition of highly saline water from agriculture, has created one of the saltiest bodies of water in the world. The Sea has been a highly successful fishery and is a habitat and migratory stopping and breeding area for 380 different bird species; however, the high, and ever-increasing, salinity of the Sea has resulted in declining fish populations that inhabit it, resulting in declining local and migratory bird that rely on the fish as a food source (SCAG, 2012).

The major surface waters in this section are presented in Table 3.5-1.

3.5.2.3 Groundwater Hydrology

Groundwater is the part of the hydrologic cycle representing underground water sources. Groundwater is present in many forms: in reservoirs, both natural and constructed; in underground streams; and, in the vast movement of water in and through sand, clay, and rock beneath the earth's surface. The place where groundwater comes closest to the surface is called the water table, which in some areas may be very deep, and in others may be right at the surface. Groundwater hydrology is, therefore, connected to surface water hydrology, and cannot be treated as a separate system. One example of how groundwater hydrology can directly impact surface water hydrology is when surface streams are partly filled by groundwater. When that groundwater is pumped out and removed from the system, the stream levels will fall, or even dry up entirely, even though no water was removed from the stream itself (SCAG, 2012).

Groundwater represents most of the Basin's fresh water supply, making up approximately 30 percent of total water use, depending on precipitation levels. Groundwater basins are replenished mainly through infiltration – precipitation soaking into the ground and making its way into the groundwater. Two threats to the function of this system are increases in impervious surface and overdraft (SCAG, 2012).

Impervious surface decreases the area available for groundwater recharge, as precipitation runoff flows off of streets, buildings, and parking lots directly into storm sewers, and straight into either river channels or into the ocean. This prevents the natural recharge of groundwater, effectively removing groundwater from the system without any pumping. Impervious surface also deteriorates the quality of the water, as it moves over streets and buildings, gathering pollutants and trash before entering streams, rivers, and the ocean (SCAG, 2012).

To prevent seawater intrusion in coastal basins in Orange County, recycled water is injected into the ground to form a mound of groundwater between the coast and the main groundwater basin. In Los Angeles County, imported and recycled water is injected to maintain a seawater intrusion barrier (SCAG, 2012).

VOCs and other non-organic contaminants such as perchlorates have created groundwater impairments in industrialized portions of the San Gabriel and San Fernando Valley groundwater basins, where some locations have been declared federal Superfund sites. Subsequently, perchlorate contamination was found in the San Gabriel Valley, and is being removed. The USEPA continues to oversee installation of a groundwater cleanup system, components of which were installed beneath the cities of La Puente and Industry in 2006. Similar problems exist in the Bunker Hills sub-basin of the Upper Santa Ana Valley groundwater basin. Perchlorate contamination has also been found in wells in the cities of Rialto, Colton, and Fontana in San Bernardino County. The presence of contamination in the source water does not necessarily require the closure of a groundwater well. Water systems can implement water treatment accompanied by monthly monitoring for contaminants and/or may blend the problematic water with other "cleaner" water in order to reduce the concentration of the contaminants of concern in the water that is ultimately to be delivered to the end-users (SCAG, 2012). For these reasons, groundwater continues to be used as the predominant source of water supply in these areas (SCAG, 2012).

3.5.3 Water Demand and Forecasts

Estimating total water use in the district is difficult because the boundaries of supplemental water purveyors' service areas bear little relation to the boundaries of the district and there are dozens of individual water retailers within the district. Water demand in California can generally be divided between urban, agricultural, and environmental uses. In southern California, approximately 75 percent of potable water is provided from imported sources. Annual water demand fluctuates in relation to available supplies. During prolonged periods of drought, water demand can be reduced significantly through conservation measures, while in years of above average rainfall demand for imported water usually declines. In 2000, a 'normal' year in terms of annual precipitation, the demand for water in the State was between approximately 82 and 83 million acre-feet. Of this total, southern California accounted for approximately 9.8 million acre-feet (SCAG, 2012).

The increase in California's water demand is due primarily to the increase in population. By employing a multiple future scenario analysis, the California Water Plan Update 2009 (DWR, 2010) provides a growth range for future annual water demand. According to the California Water Plan Update 2009, statewide future annual water demands range from an increase of fewer than 1.5 million acre-feet for the Slow and Strategic Growth scenario, to an increase of about 10 million acre-feet under the Expansive Growth scenario by year 2050. If southern California maintains its share of 12 percent of the state's water demand, the region could be expected to require an additional 500,000 acre-feet by 2030 (SCAG, 2012).

On June 4, 2008, Governor Arnold Schwarzenegger issued Executive Order S-06-08 and declared an official drought for California[5]. Further, California Water Code §71460 et seq. states that a water district may restrict the use of water during any emergency caused by drought, or other threatened or existing water shortage, and may prohibit the use of water during such periods for any purpose other than household uses or such other restricted uses as determined to be necessary. The water district may also prohibit the use of water during such periods for specific uses which it finds to be nonessential. On February 27, 2009, Governor Schwarzenegger proclaimed a state of emergency regarding the drought and the availability and future sustainability of California's water resources[6]. The proclamation directed all state government agencies to utilize their resources, implement a state emergency plan and provide assistance for people, communities and businesses impacted by the drought. The proclamation further requested that all urban water users immediately increase their water conservation activities in an effort to reduce their individual water use by 20 percent.

Following substantial increases in statewide rainfall and mountain snowpack, on March 30, 2011, Governor Jerry Brown officially rescinded Executive Order S-06-08, issued on June 4, 2008 and ended the States of Emergency regarding the drought on June 12, 2008, and on February 27, 2009. The fourth snow survey of the season was conducted by the DWR and found that water content in California's mountain snowpack was 165 percent of the April 1 full season average. At that time, a majority of the state's major reservoirs were also above normal storage levels. Based on this data, DWR estimated it will be able to deliver 70 percent of requested SWP water for 2011.

In 2012, an uptick in water use occurred due to a dry winter and a below-normal snowpack. Statewide hydrologic conditions at the end of June 2012 showed 80 percent of average

[5] Executive Order S-06-08; http://gov.ca.gov/news.php?id=9797
[6] State of Emergency – Water Shortage; http://gov.ca.gov/news.php?id=11557

precipitation to date; runoff at 65 percent of average to date; and reservoir storage at 100 percent of average for the date. However, impacts of drought are typically felt first by those most reliant on annual rainfall such as small water systems lacking a reliable source, rural residents relying on wells in low-yield rock formations, or ranchers engaged in dryland grazing. As of mid-July 2012, 75-percent of California's pasture and range land was reported to be experiencing "poor" or "very poor" water conditions. Over half of the contiguous U.S. is experiencing drought conditions, the largest percentage of the nation experiencing drought conditions in the 12-year record of the U.S. Drought Monitor.

This trend in water shortfall has continued throughout California. In May 2013, Governor Brown issued Executive Order B-21-13 to direct state water officials to expedite the review and processing of voluntary transfers of water and water rights[7]. In December 2013, the Governor formed a Drought Task Force to review expected water allocations, California's preparedness for water scarcity and whether conditions merit a drought declaration. In January 2014, the year 2013 was recorded as the driest year in California's history with California's river and reservoirs below their record lows as well as the snowpack's statewide water content at about 20 percent of normal average. Subsequently, on January 17, 2014, Governor Brown proclaimed a State of Emergency and directed state officials to take all necessary actions to prepare for drought conditions[8]. The proclamation directs state officials to assist farmers and communities that are economically impacted by dry conditions and to ensure the state can respond if there are drinking water shortages. The proclamation also directs state agencies to use less water and hire more firefighters and to initiate a greatly expanded water conservation public awareness campaign. Lastly, the proclamation gives state water officials more flexibility to manage supply throughout California under drought conditions. In response to Governor Brown's proclamation, the DWR took actions to conserve the state's water resources by supplying everyone (e.g., farmers, fish, and people throughout California's cities and towns) with less water[9]. It is important to note that almost all areas served by the SWP have other sources of water, such as groundwater, local reservoirs, and other supplies.

On March 1, 2014, Governor Brown signed a drought relief package [10] which provided $687.4 million to support drought relief, including money for housing and food for workers directly impacted by the drought, bond funds for projects to help local communities more efficiently capture and manage water and funding for securing emergency drinking water supplies for drought-impacted communities. In addition, the legislation increased funding for state and local conservation corps to assist communities with efficiency upgrades and reduce fire fuels in fire risk areas, and includes $1 million for the Save Our Water public awareness campaign to enhance its mission to inform Californians how they can do their part to conserve water. In addition, the legislation required the California Department of Public Health (DPH) to adopt new groundwater replenishment regulations by July 1, 2014, and for the State Water Resources

Control Board and the DPH to work on additional measures to allow for the use of recycled water and storm water capture for increasing water supply availability. The legislation also made statutory changes to: 1) ensure existing water rights laws are followed; 2) include streamlined authority to enforce water rights laws; and, 3) increase penalties for illegally diverting water during drought conditions. The legislation also provided the California Department of Housing and Community Development with the greatest flexibility to maximize migrant housing units[11].

As of May 29, 2014, the SWRCB issued a curtailment order for 2,648 water agencies and users (e.g., farms, cities and other property owners with so-called "junior" water rights, or those issued by the state after 1914, in the Sacramento River and its tributaries in the Sacramento Valley) to stop pumping water from the American, Feather and Yuba rivers as well as dozens of small streams[12]. Rain and snow from February and March storms have allowed the DWR to increase water contract allocations for SWP deliveries from zero to five percent. Precipitation from these recent storms also eliminated the need for rock barriers to be constructed in the Delta to prevent saltwater intrusion. Additional flexibility in salinity control requirements is being sought as an alternative to the Delta rock barriers that is less harmful for fish, wildlife, and other Delta water users. The Department of Fish and Wildlife (DFW) announced that it will fast-track actions to manage and reduce the drought's impact on fish[13].

On April 25, 2014, Governor Brown proclaimed a second State of Emergency, which waived compliance with CEQA and the state water code for a number of actions, including water transfers, wastewater treatment projects, habitat improvements for winter-run Chinook salmon imperiled by the drought and curtailment of water rights[14]. Furthermore, the order also suspended competitive bidding requirements for drought-related projects undertaken by a number of state agencies, including the DWR, DFW, and DPH. The proclamation closed a loophole that previously allowed homeowner associations to require residents to water lawns, even if the watering conflicted with local water agency rules, and to fine them if they did not comply. On September 16, 2014, Governor Brown signed legislation for California to begin regulating groundwater, a historic change that could lead to restrictions on pumping in some areas to prevent aquifers from dwindling and wells from running dry. The package of three laws put local agencies in charge of managing groundwater supplies, while giving the state new authority to step in when necessary to stabilize declining water tables. The new laws went into effect on January 1, 2015 and target areas where groundwater is being depleted faster than it is being replenished. Local agencies will then have until 2020 or 2022, depending on the severity of the situation, to develop plans for managing groundwater[15].

Water districts, in response to the drought, have also taken actions throughout the state such as: 1) asking for voluntary reductions; 2) imposing mandatory restrictions or declaring a local emergency; 3) imposing agricultural rationing; 4) imposing drought rates, surcharges and fines; 5) limiting new development and requiring water efficient landscaping; 6) implementing a conservation campaign; 7) stopping water pumping from various streams; and, 8) adjusting water contract allocations. In addition, water shortages have prompted cities to begin infrastructure improvements to secure future water supplies.

3.5.3.1 Water Suppliers

Southern California is served by many water suppliers, both retail and wholesale with MWD being the largest. Created by the California legislature in 1931, MWD serves the urbanized coastal plain from Ventura in the north to the Mexican border in the south to parts of the rapidly urbanizing counties of San Bernardino and Riverside in the east. MWD provides water to about 90 percent of the urban population of southern California. MWD is comprised of 26 member agencies, with 12 supplying wholesale water to retail agencies and other wholesalers. The remaining 14 agencies are individual cities which directly supply water to their residents. A list of the major water suppliers operating within the district is provided in Table 3.5-2.

MWD's largest water customers are the San Diego County Water Authority (28 percent of MWD's supplies based on 2005-2009 average), the LADWP (15 percent) and the Municipal Water District of Orange County (13 percent). The reliance on MWD's water supplies varies by agency. For example, in recent years, Upper San Gabriel received as little as five percent (in fiscal year 2008/09) of its total water supply from MWD, while Beverly Hills received over 93 percent. However, this relative share of local and imported supplies varies from year to year based on supply and demand conditions (MWD, 2010)[16].

MWD monitors demographics in its service area since water demand is heavily influenced by population size, geographical distribution, variation in precipitation levels, and water conservation practices. In 1990, the population of MWD's service area was approximately 14.8 million people. By 2010, it had reached an estimated 19.1 million, representing about 50 percent of the state's population. Growth has generally been around 200,000 persons per year since 2002. The MWD service area is estimated to reach an estimated population of 21.3 million in 2025, and 22.5 million by 2035 (MWD, 2010). Average per capita water usage generally ranges from 170 to 285 gallons per day (SCAG, 2012).

Actual retail water demands within MWD's service area have increased from 3.1 million acre-feet in 1980 to a projected 4.0 million acre-feet in 2010. This represents an estimated annual increase of about 1.0 percent. A similar gradual increase in estimated total retail water demand is expected between 2010 and 2035 (see Table 3.5-2) (MWD, 2010).

Of the estimated 4.0 million acre-feet of total retail water use in 2010, 93 percent is due to municipal and industrial uses, with agriculture accounting for the other seven percent. The relative share of municipal and industrial water use has increased over time at the expense of

[16] The Regional Urban Water Management Plan. MWD, 2010.

agricultural use which has declined due to urbanization and market factors. By 2035, it is estimated that agriculture will account for only about four percent of total MWD retail demands. It is estimated that total municipal and industrial water use will grow from an annual average of 4.0 million acre-feet in 2010 to 4.7 million acre-feet in 2035. All water demand projections assume normal weather conditions. Future changes in estimated water demand assumes continued water savings due to conservation measures such as water savings resulting from plumbing codes, price effects, and the continuing implementation of utility-funded conservation Best Management Practices (BMPs) (MWD, 2010) (see Table 3.5-2).

3.5.3.2 Water Uses

While most land use in the region is urban, other land uses include national forest and a small percentage of irrigated crop acreage (DWR, 1998)[17]. The South Coast Hydrologic Region is the most populous and urbanized region in California. In some portions of the region, water users consume more water than is locally available, which has resulted in an overdraft of groundwater resources and increasing dependence on imported water supplies. The distribution of water uses, however, varies dramatically across the South Coast's

[17] The California Water Plan, DWR, 1998.

planning areas. As a result of recent droughts, South Coast water users have generally become more water efficient. Municipal water agencies are engaged in aggressive water conservation and efficiency programs to reduce per capita water demand. As a result of changes in plumbing codes, energy and water efficiency innovations in appliances, and trends toward more water efficient landscaping practices, urban water demand has become more efficient (DWR, 2010).

For the South Coast region, urban water uses are the largest component of the developed water supply, while agricultural water use is a smaller but significant portion of the total. Imported water supplies and groundwater are the major components of the water supply for this region, with minor supplies from local surface waters and recycled water (DWR, 2010).

Of the total water supply to the region, more than half is either used by native vegetation; evaporates to the atmosphere; provides some of the water for agricultural crops and managed wetlands (effective precipitation); or flows to the Pacific Ocean and salt sinks like saline groundwater aquifers. The remaining portion is distributed among urban and agricultural uses and for diversions to managed wetlands (DWR, 2010).

Residential Water Use

While single-family homes are estimated to account for about 61 percent of the total occupied housing stock in 2010, they are responsible for about 74 percent of total residential water demands. This is consistent with the fact that single-family households are known to use more water than multifamily households (e.g., those residing in duplexes, triplexes, apartment buildings and condo developments) on a per housing-unit basis. This is because single-family households tend to have more persons living in the household; they are likely to have more water-using appliances and fixtures; and they tend to have more landscaping (MWD, 2010).

Non-residential Water Use

Nonresidential water use represents an approximately 25 percent of the total municipal and industrial demands in MWD's service area. This includes water that is used by businesses, services, government, institutions (such as hospitals and schools), and industrial (or manufacturing) establishments. Within the commercial/institutional category, the top water users include schools, hospitals, hotels, amusement parks, colleges, laundries, and restaurants. In southern California, major industrial users include electronics, aircraft, petroleum refining, beverages, food processing, and other industries that use water as a major component of the manufacturing process (MWD, 2010).

Agricultural Water Use

Agricultural water use currently constitutes about seven percent of total regional water demand in MWD’s service area. Agricultural water use accounted for 19 percent of total regional water demand in 1970, 16 percent in 1980, 12 percent in 1990 and five percent in 2008. Part of the reduction seen in 2008 was a 30 percent mandatory reduction in MWD’s Interim Agricultural Water Program deliveries, which continued into 2009 and a 25 percent reduction in 2010 (MWD, 2010). Improved technology has allowed growers to more accurately distribute water to the individual trees. In addition, pressure compensating valves and emitters have enabled growers to irrigate on steep slopes with better precision. Maximizing agricultural irrigation systems lowers the growers' irrigation demands (DWR, 2010).

3.5.4 Water Supply

To meet current and growing demands for water, the South Coast region is leveraging all available water resources: imported water, water transfers, conservation, captured surface water, groundwater, recycled water, and desalination. Given the level of uncertainty about water supply from the Delta and Colorado River, local agencies have emphasized diversification. Local water agencies now utilize a diverse mixture of local and imported sources and water management strategies to adequately meet urban and agricultural demands each year (DWR, 2010).

Water used in MWD's service area comes from both local and imported sources. Local sources include groundwater, surface water, and recycled water. Sources of imported water include the Colorado River, the SWP, and the Owens Valley/Mono Basin. Local sources meet about 45 percent of the water needs in MWD's service area, while imported sources supply the remaining 55 percent (MWD, 2010).

The City of Los Angeles imports water from the eastern Owens Valley/Mono Basin in the Sierra Nevada through the LAA. This water currently meets about seven percent of the region's water needs based on a five-year average from 2005-2009, but is dedicated for use by the city of Los Angeles. Contractually and for planning purposes, MWD treats the LAA as a local supply, although physically its water is imported from outside the region. Other supplies come from local sources, and MWD provides imported water supplies to meet the remaining 47 percent of the region's water needs based on the same five-year period. These imported supplies are received from MWD's CRA and the SWP's California Aqueduct (MWD, 2010).

3.5.4.1 Imported Water Supplies

Water is brought into the South Coast region from three major sources: the Delta, Colorado River, and Owens Valley/Mono Basin. All three are facing water supply cutbacks due to climate change and environmental issues. Although historically imported water served to help the South Coast region grow, it is today relied upon to sustain the existing population and economy. As such, parties in the South Coast region are working closely with other regions, the State, and federal agencies to address the challenges facing these imported supplies. Meanwhile, the South Coast region is working to develop new local supplies to meet the needs of future population and economic growth (DWR, 2010).

Most MWD member agencies and retail water suppliers depend on imported water for a portion of their water supply. For example, Los Angeles and San Diego (the largest and second largest cities in the state) have historically (1995-2004) obtained about 85 percent of their water from imported sources. These imported water requirements are similar to those of other metropolitan areas within the state, such as San Francisco and other cities around the San Francisco Bay (MWD, 2010). A list of major water suppliers operating within the district region is given in Table 3.5-3.

TABLE 3.5-3
Major Water Suppliers in the District Region

Water Agency	Land Area (square miles)	Sources of Water Supply
Antelope Valley and East Kern District	2,300	SWP, groundwater, reclaimed water
Bard Irrigation District (and Yuma Project Reservation Division)	23	Colorado River
Castaic Lake Water Agency	125	SWP and groundwater
Coachella Valley Water District	974	SWP, Colorado River, and local
Crestline Lake Arrowhead	78	SWP
Desert Water Agency	324	SWP, Colorado River, and groundwater
Imperial Irrigation District	1,658	Colorado River
Littlerock Creek Irrigation District	16	SWP, groundwater, and surface water
Metropolitan Water District of Southern California	5,200	SWP, Colorado River
Mojave Water Agency	4,900	SWP and groundwater
Palmdale Water Agency	187	SWP and groundwater
Palo Verde Irrigation District	189	Colorado River
San Bernardino Municipal Water	328	SWP and groundwater

http://rtpscs.scag.ca.gov/Documents/peir/2012/draft/2012dPEIR_3_13_WaterResources.pdf

State Water Project

The SWP is an important source of water for the South Coast region wholesale and retail suppliers. SWP contractors in the region take delivery of and convey the supplies to regional wholesalers and retailers. Contractors in the region are MWD, Castaic Lake Water Agency, San Bernardino Valley Municipal Water District, Littlerock Creek Irrigation District, Palmdale Water District, Crestline – Lake Arrowhead Water Agency, San Gorgonio Pass Water Agency, Desert Water Agency, Coachella Valley Water District, and San Gabriel Valley Municipal Water District (DWR, 2011).

The SWP provides imported water to the MWD service area. Since 2002, SWP deliveries have accounted for as much as 70 percent of its water. In accordance with its contract with the DWR, MWD has a "Table A" allocation of about 1.91 million acre-feet per year under contract from the SWP. Actual deliveries have never reached this amount because they depend on the availability of supplies as determined by DWR. The availability of SWP supplies for delivery through the California Aqueduct over the next 18 years is estimated according to the historical record of hydrologic conditions, existing system capabilities as may be influenced by environmental permits, requests from state water contractors and SWP contract provisions for allocating Table A, Article 21 and other SWP deliveries. The estimates of SWP deliveries to MWD are based on DWR's most recent SWP reliability estimates contained in its SWP Delivery Reliability Report 200716 and the December 2009 draft of the biannual update (MWD, 2010). The amount of precipitation and runoff in the Sacramento and San Joaquin watersheds, system reservoir storage, regulatory requirements, and contractor demands for SWP supplies impact the quantity of water available to MWD (MWD, 2010).

MWD and 28 other public entities have contracts with the State of California for SWP water. These contracts require the state, through its DWR, to use reasonable efforts to develop and maintain the SWP supply. The state has constructed 28 dams and reservoirs, 26 pumping and generation plants, and about 660 miles of aqueducts. More than 25 million California residents benefit from water from the SWP. DWR estimates that with current facilities and regulatory requirements, the project will deliver approximately 2.3 million acre-feet under average hydrology considering impacts attributable to the combined Delta smelt and salmonid species biological opinions (MWD, 2010). Under the water supply contract, DWR is required to use reasonable efforts to maintain and increase the reliability of service to its users.

<u>Colorado River System</u>

Another key imported water supply source for the South Coast region is the Colorado River. California water agencies are entitled to 4.4 million acre-feet annually of Colorado River water. Of this amount, 3.85 million acre-feet are assigned in aggregate to agricultural users; 550,000 acre-feet is MWD's annual entitlement. Until a few years ago, MWD routinely had access to 1.2 million acre-feet annually because Arizona and Nevada had not been using their full entitlement and the Colorado River flow was often adequate enough to yield surplus water (DWR, 2010).

A number of water agencies within California have rights to divert water from the Colorado River. Through the Seven Party Agreement (1931), seven agencies recommended apportionments of California's share of Colorado River water within the state. Table 3.5-4 shows the historic apportionment of each agency, and the priority accorded that apportionment.

The water is delivered to MWD's service area by way of the CRA, which has a capacity of nearly 1,800 cubic feet per second or 1.3 million acre-feet per year. The CRA conveys water 242 miles from its Lake Havasu intake to its terminal reservoir, Lake Mathews, near the city of Riverside. Conveyance losses along the Colorado River Aqueduct of 10 thousand acre-feet per year reduce the amount of Colorado River water received in the coastal plain (MWD, 2010).

TABLE 3.5-4
Priorities of the Seven Party Agreement

Priority	Description	TAF[(a)] Annually
1	Palo Verde Irrigation District – gross area of 104,500 acres of land in the Palo Verde Valley	3,850
2	Yuma Project (Reservation Division) – not exceeding a gross area of 25,000 acres in California	
3(a)	Imperial Irrigation District and land in Imperial and Coachella Valleys[b] to be served by All American Canal	
3(b)	Palo Verde Irrigation District—16,000 acres of land on the Lower Palo Verde Mesa	
4	Metropolitan Water District of Southern California for use on the coastal plain of Southern California[c]	550
Subtotal		**4,400**
5(a)	Metropolitan Water District of Southern California for use on the coastal plain of Southern California	550
5(b)	Metropolitan Water District of Southern California for use on the coastal plain of Southern California[c]	112
6(a)	Imperial Irrigation District and land in Imperial and Coachella Valleys to be served by the All American Canal	300
6(b)	Palo Verde Irrigation District—16,000 acres of land on the Lower Palo Verde Mesa

(a) TAF = thousand acre-feet.

(b) The Coachella Valley Water District now serves Coachella Valley

(c) In 1946, the City of San Diego, the San Diego County Water Authority, Metropolitan, and the Secretary of the Interior entered into a contract that merged and added the City of San Diego's rights to store and deliver Colorado River water to the rights of MWD. The conditions of that agreement have long since been satisfied.

Since the date of the original contract, several events have occurred that changed the dependable supply that MWD expects from the CRA. The most significant event was the 1964 U.S. Supreme Court decree in Arizona v. California that reduced MWD's dependable supply of Colorado River water to 550 thousand acre-feet per year. The reduction in dependable supply occurred with the commencement of Colorado River water deliveries to the Central Arizona Project (MWD, 2010). The court decision lead to a number of other contracts and agreements on how Colorado River water is divided among various users, the key ones of which are summarized below (MWD, 2010).

- In 1987, MWD entered into a contract with the United States Bureau of Reclamation (USBR) for an additional 180 thousand acre-feet per year of surplus water, and 85 thousand acre-feet per year through a conservation program with the Imperial Irrigation District.
- In 1979, the Present Perfected Rights of certain Indian reservations, cities, and individuals along the Colorado River were quantified.

- In 1999, California's Colorado River Water Use Plan was developed to provide a framework for how California would make the transition from relying on surplus water supplies from the Colorado to living within its normal water supply apportionment. To implement these plans, the Quantification Settlement Agreement (QSA) and several other related agreements were executed. The QSA quantifies the use of water under the third priority of the Seven Party Agreement and allows for implementation of agricultural conservation, land management, and other programs identified in MWD's 1996 Integrated Water Resources Plan (IRP). The QSA has helped California reduce its reliance on Colorado River water above its normal apportionment.
- In October 2004, the Southern Nevada Water Authority and MWD entered into a storage and interstate release agreement. Under this program, Nevada can request that MWD to store unused Nevada apportionment in MWD's service area. The stored water provides flexibility to MWD for blending Colorado River water with SWP water and improves near-term water supply reliability.
- In December 2007, the Secretary of the Interior approved the adoption of specific interim guidelines for reductions in Colorado River water deliveries during declared shortages and coordinated operations of Lake Powell and Lake Mead.
- In May 2006, the MWD and the USBR executed an agreement for a demonstration program that allowed the MWD to leave conserved water in Lake Mead that MWD would otherwise have used in 2006 and 2007. As of January 1, 2010, MWD had nearly 80 thousand acre-feet of conservation water stored in Lake Mead (MWD, 2010).
- The December 2007 federal guidelines provided the Colorado River contractors with the ability to create system efficiency projects. By funding a portion of the reservoir projects at Imperial Dam, an additional 100 thousand acre-feet of water was allocated to MWD.

MWD is undertaking ongoing efforts to maintain and improve the flexibility and quality of its water supply from the Colorado River. MWD recognizes that in the short-term, programs are not yet in place to provide the full targeted amount, even with the programs adopted under the QSA and the opportunities to store conserved water in Lake Mead. The December 2007 federal guidelines concerning the operation of the Colorado River system reservoirs provide more certainty to MWD with respect to the determination of a shortage, normal, or surplus condition for the operation of Lake Mead (MWD, 2010).

<u>Owens Valley Mono Basin (Los Angeles Aqueduct)</u>

High-quality water from the Mono Basin and Owens Valley is delivered through the LAA to the City of Los Angeles. Construction of the original 233-mile aqueduct from the Owens Valley was completed in 1913, with a second aqueduct completed in 1970 to increase capacity. Approximately 480,000 acre-feet per year of water can be delivered to the City of Los Angeles each year; however the amount of water the aqueducts deliver varies from year to year due to fluctuating precipitation in the Sierra Nevada Mountains and mandatory instream flow requirements (DWR, 2010).

Diversion of water from Mono Lake has been reduced following State Water Board Decision 1631. Exportation of water from the Owens Valley is limited by the Inyo-Los Angeles Long Term Water Agreement (and related Memorandum of Understanding) and the Great Basin Air Pollution Control District/City of Los Angeles Memorandum of Understanding (to reduce particulate matter air pollution from the Owens Lake bed) (DWR, 2010).

Over time, environmental considerations have required that the City reallocate approximately one-half of the LAA water supply to environmental mitigation and enhancement projects. As a result, the City of Los Angeles has used approximately 205,800 acre-feet of water supplies for environmental mitigation and enhancement in the Owens Valley and Mono Basin regions in 2010, which is in addition to the almost 107,300 acre-feet per year supplied for agricultural, stockwater, and Native American Reservations. Limiting water deliveries to the City of Los Angeles from the LAA has directly led to increased dependence on imported water supply from MWD. LADWP's purchases of supplemental water from MWD in FY 2008/09 reached an all-time high (LADWP, 2010).

LAA deliveries comprise 39 percent of the total runoff in the eastern Sierra Nevada in an average year. The vast majority of water collected in the eastern Sierra Nevada stays in the Mono Basin, Owens River, and Owens Valley for ecosystem and other uses (LADWP, 2010).

Annual LAA deliveries are dependent on snowfall in the eastern Sierra Nevada. Years with abundant snowpack result in larger quantities of water deliveries from the LAA, and typically lower supplemental water purchases from MWD. Unfortunately, a given year's snowpack cannot be predicted with certainty, and thus, deliveries from the LAA system are subject to significant hydrologic variability (LADWP, 2010).

The impact to LAA water supplies due to varying hydrology in the Mono Basin and Owens Valley is amplified by the requirements to release water for environmental restoration efforts in the eastern Sierra Nevada. Since 1989, when City water exports were significantly reduced to restore the Mono Basin's ecosystem, LAA deliveries from the Mono Basin and Owens Valley have ranged from 108,503 acre-feet in 2008/09 to 466,584 acre-feet in 1995/96. Average LAA deliveries since 1989/90 have been approximately 264,799 acre-feet, about 42 percent of the City of Los Angeles' total water needs (LADWP, 2010).

3.5.4.2 Local Water Supplies

Approximately 50 percent of the region's water supplies come from resources controlled or operated by local water agencies. These resources include water extracted from local groundwater basins, catchment of local surface water, non-MWD imported water supplied through the Los Angeles Aqueduct, and Colorado River water exchanged for MWD supplies (MWD, 2010).

Local sources of water available to the region include surface water, groundwater, and recycled water. Some of the major river systems in southern California have been developed into systems of dams, flood control channels, and percolation ponds for supplying local water and recharging groundwater basins. For example, the San Gabriel and Santa Ana rivers capture over 80 percent of the runoff in their watersheds. The Los Angeles River system, however, is not as efficient in capturing runoff. In its upper reaches, which make up 25 percent of the watershed, most runoff is captured with recharge facilities. In its lower reaches, which comprise the remaining 75 percent of the watershed, the river and its tributaries are lined with concrete, so there are no recharge facilities. The Santa Clara River in Ventura County is outside of MWD's service area, but it replenishes groundwater basins used by water agencies within MWD's service area. Other rivers in MWD's service area, such as the Santa Margarita and San Luis Rey, are essentially natural replenishment systems (MWD, 2010).

3.5.4.3 Surface Water

Local surface capture plays an important water resource role in the South Coast region. More than 75 impound structures are used to capture local runoff for direct use or groundwater recharge, operational or emergency storage for imported supplies, or flood protection. While precipitation contributes most of the annual volume of streamflow to the region’s waterways, urban runoff, wastewater discharges, agricultural tailwater, and surfacing groundwater are the prime sources of surface flow during non-storm periods. The South Coast has experienced a trend of increasing dry weather flows during the past 30 years as the region has developed, due to increased imported water use and associated urban runoff (DWR, 2011).

Surface water runoff augments groundwater and surface water supplies. However, the regional demand far surpasses the potential natural recharge capacity. The arid climate, summer drought, and increased urbanization contribute to the inadequate natural recharge. Urban and agricultural runoff can contain pollutants, which decrease the quality of local water supplies. Local agencies maintain surface reservoir capacity to capture local runoff. The average yield captured from local watersheds is estimated at approximately 90 thousand acre-feet per year. The majority of this supply comes from reservoirs within the service area of the San Diego County Water Authority (MWD, 2010).

3.5.4.4 Groundwater

During the first half of the 20th century, groundwater was an important factor in the expansion of the urban and agricultural sectors in the South Coast region. Today, it remains important for the Santa Clara, MWD Los Angeles and Santa Ana planning areas, but only a small source for San Diego. Court adjudications recharge operations, and other management programs are helping to maintain the supplies available from many of the region’s groundwater basins. Since the 1950s, conjunctive management and groundwater storage has been utilized to increase the reliability of supplies, particularly during droughts. Using the region’s other water resources, groundwater basins are being recharged through spreading basins and injection wells. During water shortages of the imported supplies, more groundwater would be extracted to make up the difference. Water quality issues have impacted the reliability of supplies from some basins. However, major efforts are underway to address the problems and increase supplies for these basins (DWR, 2010).

The groundwater basins that underlie the region provide approximately 86 percent of the local water supply in southern California. The major groundwater basins in the region provide an annual average supply of approximately 1.35 million acre-feet. Most of this water recharges naturally, but approximately 200 thousand acre-feet has historically been replenished each year through MWD imported supplies. By 2025, estimates show that groundwater production will increase to 1.65 million acre-feet (MWD, 2010).

Because the groundwater basins contain a large volume of stored water, it is possible to produce more than the natural recharge of 1.16 million acre-feet and the imported replenishment amount for short periods of time. During a dry year, imported replenishment deliveries can be postponed, but doing so requires that the shortfall be restored in wet years. Similarly, in dry years the level of the groundwater basins can be drawn down, as long as the balance is restored to the natural recharge level by increasing replenishment in wet years. Thus, the groundwater basins can act as a water bank, allowing deposits in wet years and withdrawals in dry years (MWD, 2010).

3.5.4.5 Recycled Water

Local water recycling projects involve further treatment of secondary treated wastewater that would be discharged to the ocean or streams and use it for direct non-potable uses such as landscape and agricultural irrigation, commercial and industrial purpose and for indirect potable uses such as groundwater recharge, seawater intrusion barriers, and surface water augmentation (MWD, 2010).

Within MWD's service area, there are approximately 355,000 acre-feet of planned and permitted uses of recycled water supplies. Actual use is approximately 209,000 acre-feet, which includes golf course, landscape, and cropland irrigation; industrial uses; construction applications; and groundwater recharge, including maintenance of seawater barriers in coastal aquifers. MWD projects the development of 500,000 acre-feet of recycled water supplies (including groundwater recovery) by 2025 (DWR, 2010).

Current average annual recycled water production in the MWD Los Angeles Planning Area is approximately 225 million gallons per day (mgd), which represents approximately 25 percent of the current average annual effluent flows. The Water Replenishment District (WRD) is permitted to recharge up to 50,000 acre-feet per year (45 mgd) of Title 22 recycled water for ground water replenishment of the Montebello Forebay. West Basin Municipal Water District's (WBMWD) Edward Little Water Recycling Facility in El Segundo, which produced approximately 24,500 acre-feet in 2004-2005, recently completed its Phase IV Expansion Project. Approximately 12,500 acre-feet per year of the water produced at this facility is purchased by WRD and injected into the West Coast Barrier. The use of recycled water by LADWP is projected to be approximately 50,000 acre-feet per year by 2019 (DWR, 2010).

Recycled water currently represents approximately four percent of the total water demands in the Santa Ana Planning Area. Eastern Municipal Water District (EMWD) recycles effluent from four wastewater treatment plants. EMWD is also investigating the feasibility of indirect potable reuse through groundwater recharge. The Irvine Ranch Water District

(IRWD) has developed an extensive recycled water treatment and delivery system and will expand capacity through 2013 to meet expected recycled water demand. The Inland Empire Utilities Agency is expanding its water recycling with a goal of meeting 20 percent of their demand or 50,000 acre-feet with recycled water. The Western Water Recycling Facility, owned and operated by Western Municipal Water District, is currently being upgraded and expanded. As infrastructure is further developed, recycled water is projected to surpass surface water as a water supply source for the planning area. The Orange County Water District (OCWD) and Orange County Sanitation District's Groundwater Replenishment System provides 72,000 acre-feet per year of recycled water for groundwater recharge and injection along the seawater barrier (DWR, 2010).

The San Diego Planning Area contains a number of recycled water facilities. In Riverside County, water reclamation facilities include Santa Rosa and Temecula Valley which provide non-potable supplies for local use. Seventeen recycled water tertiary treatment facilities are located within San Diego County. The use of tertiary treated recycled water within the San Diego area is projected to increase from 11,500 acre-feet per year in 2005 to 47,600 acre-feet per year in 2030. In September 2008, the City of San Diego approved funding for a demonstration project that releases advanced treated wastewater to San Vicente Reservoir for blending and subsequent additional treatment prior to redistribution (DWR, 2010).

3.5.4.6 Desalination Plants

In the MWD Los Angeles Planning Area, the Robert W. Goldsworthy Desalter, owned and operated by the WRD, processes approximately 2.75 mgd of brackish groundwater desalination for the purpose of remediating a saline plume located within the West Coast sub-basin and providing a reliable local water source to Torrance (DWR, 2010).

The potential for groundwater banking in the Santa Ana Planning Area is substantial, but the volume of clean water that can be stored may be hindered by high salt concentrations in the existing groundwater. In the Santa Ana watershed, three groundwater desalination plants have been constructed and are producing a total of 24 mgd. The Temescal plant, constructed and operated by the City of Corona, has a capacity of 15 mgd. The Menifee and Perris Desalters, owned and operated by EMWD, are producing seven MGD. The Chino Basin Desalter Authority operates Chino I and Chino II Desalters, which are producing 24 mgd (26,000 acre-feet per year) (DWR, 2010).

The Irvine Desalter Project, a joint groundwater quality restoration project by Irvine Ranch Water District and Orange County Water District, yields 7,700 acre-feet per year of potable drinking water and 3,900 acre-feet per year of non-potable water. The Tustin Seventeenth Street Desalter, owned and operated by the City of Tustin yields approximately 2,100 acre-feet per year. The Arlington Desalter, managed by Western Municipal Water District (WMWD), delivers approximately 6,400 acre-feet of treated groundwater annually to the City of Norco (DWR, 2010).

3.5.5 Water Conservation

In the MWD Los Angeles Planning Area, MWD assists member agencies with implementation of water conservation programs. MWD's conservation programs focus on two main areas: residential programs, and commercial, industrial and institutional programs.

Water conservation continues to be a key factor in water resource management in southern California. For MWD, water-use efficiency is anchored by the adopted Long-Term Conservation Plan (LTCP) (August 2011) and the Local Resources Program (LRP). The LTCP sets goals to help retailers achieve water conservation savings, and at the same time, support technology innovation and transform public perception about the value of water. This plan is market oriented and has both incentive and non-incentive drivers to ultimately change how water is used by southern California consumers. Additionally, the LRP encourages the development and increased use of recycled water through incentives (MWD, 2012)[18].

Outdoor water use is a key focus as watering landscapes and gardens accounts for about half of household water use in MWD's service area. MWD will work with water agencies, landscape equipment manufacturers and other stakeholders to make proper irrigation control more effective and easier to understand. A similar effort will be made to reach out to the region's businesses, industries and agriculture to focus on process improvements that can save both money and water. The final focus will be on residential water use, where MWD will work with water agencies and energy utilities to better promote the choices that consumers have for water-efficient products like faucets, shower heads and high-efficiency clothes washers (MWD, 2012).

MWD's incentive programs aimed at residential, commercial and industrial water users make a key contribution to the region's conservation achievements. The rebate program is credited with water savings of 156,000 acre-feet annually. Funding provided by MWD to member agencies and retail water agencies for locally-administered conservation programs included rebates for turf removal projects, toilet distribution and replacement programs, high-efficiency clothes washer rebate programs and residential water audits (MWD, 2012).

3.5.5.1 Residential Programs

MWD's residential conservation consists of the following programs:

- SoCal Water$mart: A region-wide program to help offset the purchase of water-efficient devices. MWD issued 54,000 rebates for residential fixtures in fiscal year 2008/09, resulting in approximately 2.3 thousand acre-feet of water to be saved annually.
- Save Water, Save A Buck: This program extends rebates to multi-family dwellings. More than 40,000 rebates were issued fiscal year 2008/09 for high-efficiency toilets and washers for multi-family units.
- Member Agency Residential Programs: member and retail agencies also implement local water conservation programs within their respective service areas and receive

[18] Annual Progress Report to the California State Legislature, Metropolitan Water District; February, 2012.

MWD incentives for qualified retrofits and other water-saving actions. Typical projects include toilet replacements, locally administered clothes washer rebate programs, and residential water audits.

MWD has provided incentives on a variety of water efficient devices for the residential sector, including: 1) high-efficiency clothes washers; 2) high-efficiency toilets and ultra-low toilets; 3) irrigation evaluations and residential surveys; 4) rotating nozzles for sprinklers; 5) weather-based irrigation controllers; and, 6) synthetic turf.

3.5.5.2 Commercial, Industrial and Institutional Programs

MWD's commercial industrial and institutional conservation consists of three major programs:

- Save Water, Save-A-Buck Program: The Save-A-Buck program had its largest year in fiscal year 2008/09, providing rebates for approximately 145,000 device retrofits.
- Water Savings Performance Program: This program allows large-scale water users to customize conservation projects and receive incentives for five years of water savings for capital water-use efficiency improvements.
- Member Agency Commercial Programs: Member and retail agencies also implement local commercial water conservation programs using MWD incentives.

A fourth program, the Public Sector Demonstration Program also resulted in water savings. From August 2007 through 2008, MWD offered a one-time program to provide up-front funding to increase water use efficiency in public buildings and landscapes within its service area. Participants included various special districts, school districts, state colleges and universities, municipalities, counties, and other government agencies.

- Enhanced incentives were provided to replace high water-use equipment including toilets, urinals, and irrigation controllers. Program incentives were often sufficient to cover the total cost of the equipment.
- Pay-for-performance incentives were also offered to reduce landscape irrigation water use by at least 10 percent through behavioral modifications.
- MWD' s programs provide rebates for water-saving plumbing fixtures, landscaping equipment, food-service equipment, cleaning equipment, HVAC (heating, ventilating, air conditioning) and medical equipment.

LADWP implements public outreach and school education programs to encourage conservation ethics; seasonal water rates that are approximately 20 percent greater during the summer high use period; and free water conservation kits. In addition, LADWP implemented Mandatory Water Conservation measures in 2009, which are still in effect today. Mandatory Water Conservation restricts outdoor watering and prohibits certain uses of water such as prohibiting customers from hosing down driveways and sidewalks, requiring all leaks to be fixed, and requiring customers to use hoses fitted with shut-off nozzles. As a result of these conservation efforts by LADWP, the water demand for Los Angeles is about the same as it was 25 years ago, despite a population increase of more than one million people. LADWP projects an additional savings of at least 50,000 acre-feet per year by 2030 through additional water conservation programs. The Central Basin Municipal Water District and the WBMWD recently completed water conservation master plans to coordinate and prioritize conservation efforts and identify enforcement protocols (DWR, 2010).

OCWD implements several water use efficiency programs in the Santa Ana Planning Area, including a hotel/motel water conservation program, an annual Children's Water Festival, a Water Heroes program, and water saving tips and tools. Eastern Municipal Water District has a strategic goal to reduce per capita water use and has several programs to replace existing inefficient water devices and encourage water efficiency in new development. Inland Empire Utilities Agency provides multiple rebate programs, including turf removal and water efficient fixtures, and has established the Inland Empire Landscape Alliance to promote the use of water efficiency landscaping by its cities and retail agencies. Western Municipal Water District operates the preeminent water conservation demonstration center in the southland, Landscapes Southern California Style, which has been educating the public about water efficient planting and irrigation for over 15 years (DWR, 2010).

3.5.6 Water Quality

Water quality is a key issue in the South Coast region. Population and economic growth not only affect water demand, but add contamination challenges from increases in wastewater and industrial discharges, urban runoff, agricultural chemical usage, livestock operations, and seawater intrusion. Urban and agricultural runoff can contribute to local surface water sediment from disturbed areas; oil, grease, and toxic chemicals from automobiles; nutrients and pesticides from turf and crop management; viruses and bacteria from failing septic systems and animal waste; road salts; and heavy metals. Three areas that are receiving intense interest are nonpoint source pollution control, salinity management, and emerging contaminants (DWR, 2010).

Three Regional Water Quality Control Boards (Regional Water Boards) have jurisdiction in the South Coast: Los Angeles (Region 4), Santa Ana (Region 8), and San Diego (Region 9). Each Regional Water Board identifies impaired water bodies, establishes priorities for the protection of water quality, issues waste discharge requirements, and takes appropriate enforcement actions within in its jurisdiction. Specific water quality issues within the South Coast include beach closures, contaminated sediments, agricultural discharges, salinity management, and port and harbor discharges. Outside the region, high salinity levels and perchlorate contamination contribute to degraded Colorado River supplies, while seawater intrusion and agricultural drainage threaten SWP supplies (DWR, 2010).

3.5.6.1 Non-Point Source Pollution Control

All non-point source pollution is currently regulated through either the NPDES Permitting Program or the Coastal Non-point Pollution Control Program. The Regional Water Boards issue municipal, industrial, and construction NPDES permits with the goal of reducing or eliminating the discharge of pollutants into the storm water conveyance system. The coastal program requires the USEPA and National Oceanic and Atmospheric Administration to develop and implement enforceable BMPs to control non-point source pollution in coastal waters. Further, the Los Angeles Regional Water Board has adopted conditional waivers for discharges from irrigated agricultural lands, which require farmers to measure and control discharges from their property (DWR, 2010).

South Coast agencies have recently begun to implement Low Impact Development (LID) as a way of improving water quality through sustainable urban runoff management. LID practices include: bioretention and rain gardens, rooftop gardens, vegetated swales and buffers, roof disconnection, rain barrels and cisterns, permeable pavers, soil amendments, impervious surface reduction, and pollution prevention. The Los Angeles and San Diego Regional Water Boards have both incorporated LID language into Standard Urban Storm Water Mitigation Plan requirements for municipal NPDES permits (DWR, 2010).

3.5.6.2 Salinity Management

Surface and groundwater salinity is an ongoing challenge for South Coast water supply agencies. Higher levels of treatment are needed following long-range import of water supplies, as total dissolved solids (TDS) levels are increased during conveyance. Salinity sources in local supplies include concentration from agricultural irrigation, seawater intrusion, discharge of treated wastewater, and recycled water. MWD depends on blending the higher salinity CRA supply at Parker Dam with the lower salinity SWP supply to maintain 500 milligrams per liter (mg/L) TDS or lower. Further, seawater intrusion and agricultural drainage threatens to increase the salinity of SWP supplies. Reduced surface water quality would require additional or upgraded demineralization facilities. Increased salinity also reduces the life of plumbing fixtures and consequently increases replacement costs to customers (DWR, 2010).

Groundwater quality has also been degraded by a long history of groundwater overdrafting and subsequent seawater intrusion. The OCWD, WRD, and Los Angeles County Department of Public Works (LACDPW) operate groundwater injection programs to form hydraulic barriers that protect aquifers from seawater intrusion. Brackish groundwater treatment occurs throughout the Santa Clara and Santa Ana planning areas. Various local agencies have developed salinity and nutrient management plans to reduce salt loading. For example, the Chino Basin Watermaster developed an Optimum Basin Management Plan (Chino Basin Watermaster, 1999) to develop the maximum yield of the basin while protecting water quality. Further development of groundwater recharge programs within the South Coast may exacerbate groundwater salinity and require additional technological advances in desalination (DWR, 2010).

3.5.6.3 Potential Contaminants

Chemical and microbial constituents that have not historically been considered as contaminants are increasingly present in the environment due to municipal, agricultural, and industrial wastewater sources and pathways. Established and emerging contaminants of concern to the region's drinking water supplies include pharmaceuticals and personal care products; disinfection byproducts; those associated with the production of rocket fuel such as perchlorate and nitrosodimethylamine; those that occur naturally such as arsenic; those associated with industrial processes such as hexavalent chromium and MTBE. Wastewater treatment plants are not currently designed to remove these emerging contaminants (DWR, 2010).

3.5.6.4 Planning Area Impairments

Water quality issues within the MWD Los Angeles planning areas (Los Angeles Regional Water Board) stem from a range of sources, including industrial and municipal operations, flow diversion, channelization, introduction of non-native species, sand and gravel operations, natural oil seeps, dredging, spills from ships, transient camps, and illegal dumping. Over time, these practices have resulted in the bioaccumulation of toxic compounds in fish and other aquatic life, instream toxicity, eutrophication, beach closures, and a number of Clean Water Act §303 (d) listings. Water bodies within this planning area have been listed for metals, pesticides, nitrates, trash, salinity, and pH. The Regional Water Board is developing TMDLs for nutrients, pathogens, trash, toxic organic compounds, and metals (DWR, 2010).

Key issues within the Santa Ana Planning Area (Santa Ana Regional Water Board) include: nitrogen/TDS due to flow diversion; nitrogen/TDS associated with past agricultural activities and dairies in the Chino Basin; and pathogen issues from urbanization impacting river and coastal beaches, and past contamination of groundwater basins from perchlorate which is related to rocket fuel disposal and fertilizer use. Water bodies within this planning area typically have nutrient issues, including organic enrichment, low dissolved oxygen, and algal blooms. These are particular problems in Big Bear Lake and Lake Elsinore. Water quality issues also include pathogens, metals, and toxic organic compounds in the lower watershed due to urbanization and agricultural activities. TMDLs have been developed throughout the Santa Ana River and San Jacinto River watersheds for nutrients and pathogens. Along the Newport coast, TMDLs are in place for metals, nutrients, pathogens, pesticides/priority organics, and siltation (DWR, 2010).

The Chino Basin maintains a large concentration of dairy operations along with livestock. Runoff from the dairies contributes nitrates, salts, and microorganisms to both surface water and groundwater. Since 1972, the Santa Ana Regional Water Board has issued waste discharge requirements to the dairies in this basin. Groundwater quality in this basin is integrally related to the surface water quality downstream in the Santa Ana River, which in turn serves as a source for groundwater recharge in Orange County.

3.5.7 Wastewater Treatment

The CWA requires wastewater treatment facilities discharging to waters of the U.S. to provide a minimum level of treatment commonly referred to as tertiary treatment. Modern wastewater treatment facilities consist of staged processes with the specific treatment systems authorized through NPDES permits. Primary treatment generally consists of initial screening and clarifying. Primary clarifiers are large pools where solids in wastewater are allowed to settle out over a period of hours. The clarified water is pumped into secondary clarifiers and the screenings and solids are collected, processed through large digesters to break down organic contents, dried and pressed, and either disposed of in landfills or used for beneficial agricultural applications. Secondary clarifiers repeat the process of the primary clarifiers further, refining the effluent.

Other means of secondary treatment include flocculation (adding chemicals to precipitate solids removal) and aeration (adding oxygen to accelerate breakdown of dissolved constituents). Tertiary treatment may consist of filtration, disinfection, and reverse osmosis technologies. Chemicals are added to the wastewater during the primary and secondary treatment processes to accelerate the removal of solids and to reduce odors. Hydrogen peroxide can be added to reduce odors and ferric chloride can be used to remove solids. Polymers are added to secondary effluent as flocculate. Chlorine is often added to eliminate pathogens during final treatment and sulfur dioxide is often added to remove the residual chlorine. Methane produced by the treatment processes can be used as fuel for the plant's engines and electricity needs. Recycled water must receive a minimum of tertiary treatment in compliance with DHS regulations. Water used to recharge potable groundwater supplies generally receives reverse osmosis and microfiltration prior to reuse. Microfiltration technologies have improved substantially in recent years and have become more affordable. As levels of treatment increase, greater volumes of solids and condensed brines are produced. These by-products of water treatment are disposed of in landfills or discharged to local receiving waters.

Wastewater flows and capacities of major treatment facilities are shown in Table 3.5-5. Much of the urbanized areas of Los Angeles and Orange Counties are serviced by three agencies that operate large publicly owned treatment works (POTWs): the City of Los Angeles Bureau of Sanitation's Hyperion Treatment Plant in El Segundo, the City of Los Angeles Bureau of Sanitation's Terminal Island facility in San Pedro, the Los Angeles County Sanitation District's (LACSD) Joint Water Pollution Control Plant (JWPCP) in Carson, and the Orange County Sanitation District's (OCSD) treatment plants in Huntington Beach and Fountain Valley. These facilities handle more than 70 percent of the wastewater generated in the entire SCAG region (SCAG, 2008).

In addition to these large facilities, medium sized POTWs (greater than 10 mgd) and small treatment plants (less than 10 mgd) service smaller communities in Ventura County, southern Orange County, and in the inland regions. Many of these treatment systems recycle their effluent through local landscape irrigation and groundwater recharge projects. Other treatment systems discharge to local creeks on a seasonal basis, effectively matching the natural conditions of ephemeral and intermittent stream habitats (SCAG, 2012).

Many rural communities utilize individually owned and operated septic tanks rather than centralized treatment plants. The RWQCB generally delegates oversight of septic systems to local authorities. However, water discharge requirements are generally required for multiple-dwelling units and in areas where groundwater is used for drinking water. These water discharge requirements are only issued to properties greater than one acre and are not required for properties greater than five acres in size (SCAG, 2012).

TABLE 3.5-5
Wastewater Flow and Capacity within the SCAQMD

WASTEWATER AGENCY	CURRENT FLOW (MGD)	CAPACITY FLOW (MGD)
Los Angeles County		
Los Angeles County Sanitation Districts		
Joint Water Pollution Control Plant	406.1	590.2
Lancaster Water Reclamation Plant	12.0	16.0
Palmdale Water Reclamation Plant	8.0	15.0
Santa Clarita Water Reclamation Plant	20.0	28.6
City of Los Angeles	554.5	580.0
Las Virgenes Municipal Water District	9.5	16.0
City of Burbank	9.0	9.0
Orange County		
Orange County Sanitation District	221.0	699.0
Irvine Ranch Water District	12.3	23.5
South Orange County Wastewater Authority	26.5	37.7
El Toto Water District	5.4	6.0
Riverside County		
Eastern Municipal Water District	37.3	59.0
City of Riverside	36.0	40.0
Coachella Valley Water District	18.0	31.0
San Bernardino County		
Inland Empire Utilities Agency	60.0	84.0
City of San Bernardino	25.5	33.0
Victor Valley Wastewater Reclamation Authority	12.5	14.5
City of Redlands	6.0	9.5
Total	**1,479.6**	**2,292**

SUBCHAPTER 3.6

SOLID AND HAZARDOUS WASTE

Regulatory Background

Solid Waste Management

Hazardous Waste Management

3.6 SOLID AND HAZARDOUS WASTE

This subchapter describes existing regulatory setting relative to solid and hazardous waste within the SCAQMD.

3.6.1 Regulatory Background

The Regulatory Background is divided into two sections: Solid Waste and Hazardous Waste.

3.6.1.1 Solid Waste

Federal

The USEPA is the primary federal agency charged with protecting human health and with safeguarding the natural environment: air, water, and land. The USEPA works to develop and enforce regulations that implement environmental laws enacted by Congress. The USEPA is also responsible for researching and setting national standards for a variety of environmental programs, and delegates to states and tribes the responsibility for issuing permits and for monitoring and enforcing compliance. Since 1970, Congress has enacted numerous environmental laws including RCRA, CERCLA, and TSCA. 40 CFR Part 258, Subpart D of RCRA establishes minimum location standards for siting municipal solid waste landfills. Because California laws and regulations governing the approval of solid waste landfills meet the requirements of 40 CFR Part 258, Subpart D, the USEPA delegated the enforcement responsibility to the State of California.

State

With regard to solid non-hazardous wastes, the California Integrated Waste Management Act of 1989 (AB 939), as amended, requires every city and county in the state to prepare a Source Reduction and Recycling Element (SRRE) with its Solid Waste Management Plan that identifies how each jurisdiction will meet the mandatory state waste diversion goals of 25 percent by the year 1995, and 50 percent by the year 2000. SB 2202 mandates that jurisdictions continue 50 percent diversion on and after January 1, 2000. The purpose of AB 939 is to facilitate the reduction, recycling, and re-use of solid waste to the greatest extent possible. Penalties for non-compliance with the goals and timelines set forth within AB 939 can be severe, since the bill imposes fines of up to $10,000 per day on cities and counties not meeting these recycling and planning goals (SCAG, 2012). AB 939 has recognized that landfills and transformation facilities are necessary components of any integrated solid waste management system and an essential component of the waste management hierarchy. AB 939 establishes a hierarchy of waste management practices in the following order and priority: 1) source reduction; 2) recycling and composting; and, 3) environmentally safe transformation/land disposal.

CalRecycle (formerly known as the California Integrated Waste Management Board) has numerous responsibilities in implementing the federal and state regulations summarized above. CalRecycle is the state agency responsible for permitting, enforcing and monitoring solid waste landfills, transfer stations, material recovery facilities (MRFs), and composting facilities within California. Permitted facilities are issued Solid Waste Facility Permits

(SWFPs) by CalRecycle. CalRecycle also certifies and appoints Local Enforcement Agencies (LEAs), county or city agencies which monitor and enforce compliance with the provisions of SWFPs. CalRecycle is also responsible for monitoring implementation of AB 939 by the cities and counties. In addition to these responsibilities, CalRecycle also manages the Recycled-Content Materials Marketing Program to encourage the use of specific recycled-content products in road applications, public works projects and landscaping. These products include recycled aggregate, tire-derived aggregate, rubberized asphalt concrete, and organic materials.

AB 939 requires that each county in the state of California prepare a Countywide Integrated Waste Management Plan (CIWMP). The CIWMP is a countywide planning document that describes the programs to be implemented in unincorporated and incorporated areas of the county that will effectively manage solid waste, and promote and implement the hierarchy of CalRecycle. The CIWMPs consists of a Summary Plan, a SRRE, a Household Hazardous Waste Element, a Non-Disposal Facility Element, and a Countywide Siting Element.

<u>Local</u>

A Summary Plan is a solid waste planning document required by Public Resources Code §41751, in which counties or regional agencies provide an overview of significant waste management problems faced by the jurisdiction, along with specific steps to be taken, independently and in concert with cities within their boundaries (SCAG, 2012).

The SRRE consists of the following components: waste characterization, source reduction, recycling, composting, solid waste facility capacity, education and public information, funding, special waste and integration. Each city and county is required to prepare, adopt, and submit an SRRE to CalRecycle that includes a program for management of solid waste generated within the respective local jurisdiction. The SRREs must include an implementation schedule for the proposed implementation of source reduction, recycling, and composting programs. In addition, the plan identifies the amount of landfill and transformation capacity that will be needed for solid waste which cannot be reduced, recycled, or composted (SCAG, 2012).

Each city and county is required to prepare, adopt and submit to CalRecycle a Household Hazardous Waste Element which identifies a program for the safe collection, recycling, treatment, and disposal of hazardous wastes that are generated by households. The Household Hazardous Waste Element specifies how household hazardous wastes generated within the jurisdiction must be collected, treated, and disposed. An adequate Household Hazardous Waste Element contains the following components: Evaluation of alternatives, program selection, funding, implementation schedule and education and public information (SCAG, 2012).

Each city and county is required to prepare, adopt and submit to CalRecycle, a Non-Disposal Facility Element which includes a description of new facilities and expansion of existing facilities, and all solid waste facility expansions (except disposal and transformation facilities) that recover for reuse at least five percent of the total volume. The Non-Disposal Facility Elements are to be consistent with the implementation of a local jurisdiction's

SRRE. Each jurisdiction must also describe transfer stations located within and outside of the jurisdiction, which recover less than five percent of the material received (SCAG, 2012).

Counties are required to prepare a Countywide Siting Element that describes areas that may be used for developing new disposal facilities. The element also provides an estimate of the total permitted disposal capacity needed for a 15-year period if counties determine that their existing disposal capacity will be exhausted within 15 years or if additional capacity is desired (Public Resources Code §§41700 - 41721.5) (SCAG, 2012).

Each county in the SCAG region has created a CIWMP in accordance with AB 939. Below is a brief description of the recent updates to these plans by county.

Los Angeles County

Los Angeles County is revising its Summary Plan and Siting Element to reflect changes in the county's policies and goals, including promotion of conversion technologies, formation of the Los Angeles Regional Agency, update of countywide jurisdiction assistance programs to meet diversion goals, expansion of existing disposal facilities, and development of additional non-disposal facilities for the use of out-of-county disposal facilities (SCAG, 2012).

Los Angeles County's 2009 Annual Report details the revision process, assesses remaining permitted capacity for the mandated 15-year planning horizon, and outlines seven disposal capacity scenarios, two of which project sufficient capacity to meet future demand through the use of conversion technologies and out-of-county disposal facilities. The Annual Report outlines county solid waste management challenges, including a projected shortfall of permitted disposal capacity in the county, insufficient markets for recovered materials, and steps to promote and develop conversion technologies (SCAG, 2012).

Orange County

Orange County completed the first review of its CIWMP in April 2003. It found sufficient disposal capacity for the 15-year planning horizon, but identified other challenges, including the lack of an operational materials recovery facility in the southern portion of the county, changes in records management to comply with the Disposal Recovery System, and determination of accurate base year data (SCAG, 2012).

In addition to the CIWMP, Orange County's Integrated Waste Management Department has initiated a long-term strategic planning project, the Regional Landfill Options for Orange County, which assesses the solid waste disposal needs of Orange County for the next 40 years. The 2007 Strategic Plan Update for this planning project summarizes progress to maximize capacity at existing landfills, assess alternative technologies and potential out-of-county disposal sites, and expand the Frank R. Bowerman and Olinda Alpha landfills (SCAG, 2012).

Riverside County

Riverside County's CIWMP was approved in 1996, and its 2010 Annual Report found the original plan remained applicable, so no comprehensive update is planned. The Non-Disposal Facility Elements was updated in 2009 and includes plans for four possible solid waste material recovery and transfer facilities; two of which would include household hazardous waste disposal facilities. The Non-Disposal Facility Elements also includes an additional proposed solid waste material recovery facility with capacity for household hazardous waste disposal and one composting facility. The 2008 Five Year Review Report for the CIWMP concluded that the most effective allocation of available resources is to continue to utilize the existing CIWMP as a planning tool augmented by annual reports, and that a revision of the CIWMP is not warranted (SCAG, 2012).

San Bernardino County

San Bernardino County's CIWMP five-year review report was completed in 2007. The report reflects updates to the county's goals and policies, changes to its disposal facilities, and assesses disposal capacity for the mandated 15-year planning horizon. Updated policies include programs to help jurisdictions reach diversion goals, such as additional recycling and composting programs and the development of regional material recovery facilities. The 2007 review found that based on the remaining permitted refuse capacity and projected refuse generation for disposal, the landfills within the county have approximately 26 years of capacity (SCAG, 2012).

Regional Water Quality Control Boards (RWQCB)

New or expanded landfills must submit Reports of Waste Discharge to RWQCBs prior to landfill operations. In conjunction with CalRecycle's approval of SWFPs, RWQCBs issue Waste Discharge Orders which regulate the liner, leachate control and removal, and groundwater monitoring systems at Class III landfills (SCAG, 2012).

South Coast Air Quality Management District (SCAQMD)

The SCAQMD regulates emissions from landfills. Landfill owners/operators must obtain permits to construct and operate landfill flares, cogeneration facilities or other facilities used to combust landfill gas. Owner/operators also are subject to the provisions of SCAQMD Rule 1150.1 - Control of Gaseous Emissions from Landfills. SCAQMD Rule 1150.1 requires the submittal of a compliance plan for implementation of a landfill gas control system, periodic ambient monitoring of surface emissions and the installation of probes to detect the lateral migration of landfill gas (SCAG, 2012).

3.6.1.2 Hazardous Waste

Federal

Hazardous material, as defined in 40 CFR Part 261.20 and 22 CCR Article 9, is required to be disposed of in Class I landfills. California has enacted strict legislation for regulating Class I landfills. The California Health and Safety Code requires Class I landfills to be equipped with liners, a leachate collection and removal system, and a ground water monitoring system.

The HMTA is the federal legislation regulating the trucks that transport hazardous wastes. The primary regulatory authorities are the USDOT, the FHWA, and the FRA. The HMTA requires that carriers report accidental releases of hazardous materials to the USDOT at the earliest practicable moment (49 CFR Part 171, Subpart C).

RCRA gives the USEPA the authority to control hazardous waste from the "cradle-to-grave." This includes the generation, transportation, treatment, storage, and disposal of hazardous waste by "large-quantity generators" (1,000 kilograms/month or more). Under RCRA regulations, hazardous wastes must be tracked from the time of generation to the point of disposal. At a minimum, each generator of hazardous waste must register and obtain a hazardous waste activity identification number. If hazardous wastes are stored for more than 90 days or treated or disposed at a facility, any treatment, storage, or disposal unit must be permitted under RCRA. Additionally, all hazardous waste transporters are required to be permitted and must have an identification number. RCRA allows individual states to develop their own program for the regulation of hazardous waste as long as it is at least as stringent as RCRA. In California, the USEPA has delegated RCRA enforcement to the State of California.

<u>State</u>

Authority for the statewide administration and enforcement of RCRA rests with CalEPA's DTSC. While the DTSC has primary responsibility in the state for regulating the generation, transfer, storage and disposal of hazardous materials, DTSC may further delegate enforcement authority to local jurisdictions. In addition, the DTSC is responsible and/or provides oversight for contamination cleanup, and administers state-wide hazardous waste reduction programs. DTSC operates programs to accomplish the following: 1) deal with the aftermath of improper hazardous waste management by overseeing site cleanups; 2) prevent releases of hazardous waste by ensuring that those who generate, handle, transport, store, and dispose of wastes do so properly; and, 3) evaluate soil, water, and air samples taken at sites. The DTSC conducts annual inspections of hazardous waste facilities. Other inspections can occur on an as-needed basis.

Caltrans sets standards for trucks transporting hazardous wastes in California. The regulations are enforced by the CHP. Trucks transporting hazardous wastes are required to maintain a hazardous waste manifest. The manifest is required to describe the contents of the material within the truck so that wastes can readily be identified in the event of a spill.

The storage of hazardous materials in USTs is regulated by CalEPA's SWRCB, which has delegated authority to the RWQCB and, typically at the local level, to the local fire department.

The Hazardous Waste Control Act (HWCA) created a statewide hazardous waste management program, which is similar to but more stringent than the federal RCRA program. The HWCA is implemented by regulations in CCR Title 26 which describes the following required aspects for the proper management of hazardous waste: identification and classification; generation and transportation; design and permitting of recycling, treatment, storage, and disposal facilities; treatment standards; operation of facilities and staff training; and closure of facilities and liability requirements. These regulations list more than 800 materials that may be hazardous and establish criteria for identifying, packaging, and disposing of such waste. Under the HWCA and CCR Title 26, the generator of hazardous waste must complete a manifest that accompanies the waste from generator to transporter to the ultimate disposal location. Copies of the manifest must be filed with DTSC.

The Unified Program required the administrative consolidation of six hazardous materials and waste programs (Program Elements) under one agency, a CUPA. The Program Elements consolidated under the Unified Program are: Hazardous Waste Generator and On-site Hazardous Waste Treatment Programs (also known as Tiered Permitting); Aboveground Petroleum Storage Tank SPCC; Hazardous Materials Release Response Plans and Inventory Program (also known as the Hazardous Materials Accidental Release Plan); UST Program; and Uniform Fire Code Plans and Inventory Requirements. The Unified Program is intended to provide relief to businesses complying with the overlapping and sometimes conflicting requirements of formerly independently managed programs. The Unified Program is implemented at the local government level by CUPAs. Most CUPAs have been established as a function of a local environmental health or fire department. Some CUPAs have contractual agreements with another local agency, a participating agency, which implements one or more Program Elements in coordination with the CUPA.

The Hazardous Waste Source Reduction and Management Review Act of 1989 requires generators of 12,000 kilograms per year of typical operational hazardous waste to conduct an evaluation of their waste streams every four years and to select and implement viable source reduction alternatives. This Act does not apply to non-typical hazardous waste such as asbestos and polychlorinated biphenyls.

Local

Fire departments and other agencies in the district have a variety of local laws that regulate reporting, storage and handling of hazardous materials and wastes. There are no hazardous waste disposal sites within the jurisdiction of the district. Hazardous waste generated at area facilities, which is not reused on-site, or recycled offsite, is disposed of at a licensed in-state hazardous waste disposal facility. Two such facilities are the Chemical Waste Management (CWM) Kettleman Hills facility in King’s County, and the Clean Harbors facility in Buttonwillow (Kern County). Kettleman Hills has an estimated 15.65 million cubic yard capacity. Buttonwillow receives approximately 960 tons of hazardous waste per day and has an approximate remaining capacity of approximately nine million cubic yards.

3.6.2 Solid Waste Management

Permit requirements, capacity, and surrounding land use are three of the dominant factors limiting the operations and life of landfills. Landfills are permitted by the local enforcement agencies with concurrence from CalRecycle. Local agencies establish the maximum amount of solid waste which can be received by a landfill each day and the operational life of a landfill. Landfills are operated by both public and private entities. Landfills in the district are also subject to requirements of the SCAQMD as they pertain to gas collection systems, dust and nuisance impacts.

Landfills throughout the region typically operate between five and seven days per week. Landfill operators weigh arriving and departing deliveries to determine the quantity of solid waste delivered. At landfills that do not have scales, the landfill operator estimates the quantity of solid waste delivered (e.g., using aerial photography). Landfill disposal fees are determined by local agencies based on the quantity and type of waste delivered.

Over the past thirteen years, disposal tonnage has decreased significantly in the district as the emphasis on recycling to meet the requirements of AB 939 has served to divert tonnage from landfills and conserve landfill capacity. Table 3.6-1 shows data from CalRecycle regarding the number of tons disposed in 2014 (the most recent year for which information is available), for each county within the jurisdiction of the district.

TABLE 3.6-1
Solid Waste Disposed in 2014 by County

County	**Solid Waste Disposed** (tons)
Los Angeles	2,380,812
Orange	2,176,246
Riverside	1,747,442
San Bernardino	808,658
Total	**7,113,158**

Source: 2014 Landfill Summary Tonnage Report, CalRecycle, 2015
Http://www.calrecycle.ca.gov/SWFacilities/Landfills/Tonnages

In viewing facilities on a county-by-county basis, it is important to note that landfills in one county may import waste generated elsewhere. Currently, Orange County offers capacity to out-of-county waste at a “tipping fee” low enough to attract waste from Los Angeles and San Bernardino Counties. In Riverside County, the El Sobrante Landfill is licensed to accept up to 10,000 tons of waste per day from Riverside, Los Angeles, Orange, San Diego, and San Bernardino counties (SCAG, 2012).

Since the enactment of AB 939 in 1989, local governments have implemented recycling programs on a widespread basis, making efforts to meet the 25 percent and 50 percent diversion mandates of AB 939. Statewide, CalRecycle reports that diversion increased from 10 percent in 1989 to 42 percent in 2000 and to 48 percent in 2002. As of 2008, the counties in the SCAG region had met their disposal target rates for waste diversion (SCAG, 2012).

A total of 31 Class III active landfills and two transformation facilities are located within the district with a total capacity of 107,933 tons per day and 3,240 tons per day[1], respectively (see Tables 3.6-2 and 3.6-3). The status of landfills within each county in the district is described in Tables 3.6-6 through 3.6-9.

TABLE 3.6-2

Number and Capacity of Class III Landfills by County

3.6.2.1 Los Angeles County

The Los Angeles Countywide Siting Element addresses landfill disposal. The purpose of the Countywide Siting Element is to provide a planning mechanism to address the solid waste disposal capacity needed by the 88 cities in Los Angeles County and the unincorporated communities for each year of the 15-year planning period through a combination of existing facilities, expansion of existing facilities, planned facilities, and other strategies.

In 2012, residents and businesses in the county disposed of 8.7 million tons of solid waste at Class III landfills and transformation facilities located in and out of the county (see Tables 3.6-4 and 3.6-5). In addition, the amount of inert waste disposed at permitted inert waste landfills totaled 89,000 tons (LACDPW, 2013).

1 This represents the sum of the permitted capacities of the Southeast Resource Recovery Facility at 2,240 tons per day and the Commerce Refuse-To-Energy Facility at 1,000 tons per day. http://www.calrecycle.ca.gov/SWFacilities/Directory/19-AK-0083/Detail/; http://www.calrecycle.ca.gov/SWFacilities/Directory/19-AA-0506/Detail.

Waste Generation

The LACDPW conducted a survey requesting landfill operators in the county to provide updates to their estimated remaining disposal capacity based on permitted disposal levels and years of remaining operation. Based on the results of the survey, the total remaining permitted Class III landfill capacity in the county is estimated at 129 million tons (see Table 3.6-6).

TABLE 3.6-6
Los Angeles County Landfill Status as of 2012

Solid Waste Facilities	Total Annual Disposal in 2012	Average Daily Disposal in 2012	Remaining Permitted Capacity		Estimated Year of Closure
	(million tons)	(tons per day)	(million tons)	(million cubic yards)

Source: LACDPW, 2013
(a) Currently only accepting inert waste.

Because of community resistance to the extension of operating permits for existing facilities and to the opening of new landfills in the county, and the dwindling capacity of those landfills with operating permit time left, the exact date on which landfill capacity within the county will be exceeded is uncertain. Landfill remaining life based on Solid Waste Facility

Permits in the county ranges from one year at one facility, to as many as 41 years at another (LACDPW, 2013).

The LACDPW has reviewed the county's ability to meet daily disposal demands under different scenarios (e.g., landfill expansions, alternative technologies, waste-by-rail systems, and reduction/recycling). Under some of the scenarios, the county will have a difficult time meeting future disposal demands. In order to ensure disposal capacity to meet the county needs, jurisdictions in Los Angeles County must continue to pursue all of the following strategies: 1) expand existing landfills; 2) study, promote, and develop conversion technologies; 3) expand transfer and processing infrastructure; 4) develop a waste-by-rail system; and, 5) maximize waste reduction and recycling.

3.6.2.2 Orange County

Orange County currently has three active Class III landfills. They include the following: Prima Deshecha, Frank R. Bowerman and Olinda Alpha. The Prima Deshecha Landfill has a permitted capacity of 4,000 tons per day and an expected closure date of 2067. The Frank R. Bowerman Landfill has a maximum capacity of 11,500 tons per day, and an expected closure date of 2053. The Olinda Alpha Landfill has a permitted capacity of 8,000 tons per day. The current permit expiration of the Olinda Alpha Landfill is 2021 (see Table 3.6-7).

TABLE 3.6-7
Orange County Landfill Status

Landfill	**Total Annual Disposal in 2012** (tons)	**Permitted** (tons/day)	**Remaining Permitted Capacity** (cubic yards)	**Estimated Year of Closure**
Frank R. Bowerman	1,395,735	11,500	205,000,000	2053
Olinda Alpha	1,728,854	8,000	38,578,383	2021
Prima Deshecha	397,536	4,000	87,384,799	2067
Total	**3,522,125**	**23,500**	**330,963,182**	**--**

Source: CalRecycle, 2012

CalRecycle is responsible for ensuring that the county's waste is disposed of in a way that protects public health, safety and the environment. Long-range strategic planning is necessary to ensure that waste generated by the county is safely disposed of and that the county's future disposal needs are met. The Regional Landfill Options for Orange County (RELOOC) program was created for this reason. RELOOC is a 40-year strategic plan being prepared by the CIWMD. The purpose of RELOOC is to evaluate options for solid waste disposal for Orange County citizens. The plan was last updated in September 2007 (RELOOC, 2007)

Orange County cities and unincorporated areas have completed, adopted and implemented a Countywide Integrated Waste Management Plan. Orange County cities and unincorporated areas have residential curbside recycling programs in place.

3.6.2.3 Riverside County

Riverside County has six active sanitary landfills with a total capacity of 23,914 tons per day. Each of these landfills is located within the unincorporated area of the county and is classified as Class III. El Sobrante Landfill is a privately operated landfill open to the public. The six major sites have closure dates projected from 2021 to 2087. The projected date of closure for each landfill is tentative and could be affected by engineering, environmental, and waste flow issues (see Table 3.6-8).

TABLE 3.6-8
Riverside County Landfill Status

Landfill	**Total Annual Disposal in 2010** (tons)	**Permitted** (tons/day)	**Remaining Permitted Capacity** (cubic yards)	**Estimated Year of Closure**

3.6.2.4 San Bernardino County

The County of San Bernardino Solid Waste Management Division (SWMD) is responsible for the operation and management of the County of San Bernardino's solid waste disposal system which consists of five regional landfills and nine transfer stations.

San Bernardino County has six active public landfills within the district’s boundaries with a combined permitted capacity of 18,129 tons per day. Mid-Valley/Fontana Landfill is estimated to reach final capacity by the end of 2033, San Timoteo by 2016, Victorville by 2047, Barstow by 2071, Landers by 2018, California Street by 2042 and Colton Landfill by 2017 (see Table 3.6-9).

TABLE 3.6-9
San Bernardino County Landfill Status

Landfill	**Total Annual Disposal in 2010** (tons)	**Permitted** (tons/day)	**Remaining Permitted Capacity** (cubic yards)	**Estimated Year of Closure**

3.6.3 Hazardous Waste Management

Hazardous material, as defined in 40 CFR Part 261.20 and 22 CCR Article 9, is disposed of in Class I landfills. California has enacted strict legislation for regulating Class I landfills. The California Health and Safety Code requires Class I landfills to be equipped with liners, a leachate collection and removal system, and a ground water monitoring system.

There are no hazardous waste disposal sites within the jurisdiction of the SCAQMD. Hazardous waste generated at area facilities, which is not reused on-site, or recycled off-site, is disposed of at a licensed in-state hazardous waste disposal facility. Two such facilities are the CWM Kettleman Hills facility in King's County, and the Clean Harbors facility in Buttonwillow (Kern County).

The Kettleman Hills landfill is operating close to capacity. The DTSC has approved CWM's application to modify its RCRA permit at Kettleman Hills to allow for the expansion of its hazardous waste landfill, Unit B-18, by 14 acres and about 4.9 million cubic yards. CWM has also applied to the USEPA to both renew and modify its existing permits to allow for the expansion of the landfill. The expansion would provide another 12-14 years of life. Kettleman Hills landfill is permitted to dispose of or treat and store hazardous waste from all over California. The facility accepts almost all solid, semi-solid, and liquid hazardous waste. However, Kettleman Hills landfill is not permitted to accept biological agents or infectious wastes, regulated radioactive materials, or compressed gases and explosives.

Buttonwillow receives approximately 900 tons of hazardous waste per day. Buttonwillow has a maximum permitted throughput of 10,500 tons per day. The expectant life of the Buttonwillow Landfill is approximately 25 years.

Hazardous waste also can be transported to permitted facilities outside of California. The nearest out-of-state landfills are U.S. Ecology, Inc., located in Beatty, Nevada; Laidlaw Environmental Services located in Lake Point, Utah; Envirosafe Services, in Grandview, Idaho; CWM in

Carlyss, Louisiana, and Waste Control Specialists in Andrews, Texas. Incineration is provided at Laidlaw Environmental Services, Inc., located in Deer Park, Texas.

In 2013, less than 2.30 million tons of hazardous waste were generated in the four counties that comprise the district, and about two million tons of hazardous waste were generated in California (see Table 3.6-10). These amounts are increased from the totals of 2011 by approximately 99, 46, 81, and 2 percent respectively. The most common types of hazardous waste generated in the district include waste oil, inorganic solid waste, contaminated soils, organic solids, asbestos-containing waste, and unspecified oil-containing wastes. Because of the population and economic base in southern California, a large portion of hazardous waste is generated within the district. Not all wastes are disposed of in a hazardous waste facility or incinerator. Many of the wastes generated, including waste oil, are recycled within the Basin.

TABLE 3.6-10
Hazardous Waste Generation by County – 2013
(tons per year)

Waste Name	Los Angeles	Orange	Riverside	San Bernardino	Four County Total	Statewide Total
Waste & Mixed Oil	237,814	11,596	6,177	37,960	293,547	511,503
Inorganic Solid Waste	78,875	23,260	1,611	13,801	117,547	376,237

(--) Not on list of top twenty waste totals generated in the county.
(a) Smaller than restricted levels.
(b) The data for this waste code is as reported in the California Hazardous Waste Tracking System database; however, one or more of the data entries for this waste category appear to be in error.

SUBCHAPTER 3.7

TRANSPORTATION AND TRAFFIC

Transportation Regulatory Framework

Existing Traffic Setting

3.7 TRANSPORTATION AND TRAFFIC

The proposed project may have direct or indirect traffic impacts associated with implementation of control strategies proposed by the Port(s). Traffic concerns are related to modifications to the existing transportation system that may generate significant impacts. This subchapter describes the current transportation system in southern California.

3.7.1 Transportation Regulatory Framework

3.7.1.1 Federal Regulatory Framework

Transportation Equity Act for the 21st Century

The Transportation Equity Act for the 21st Century (TEA-21), signed into law in 1998, provides the regulatory framework at the federal level for transportation planning in urban areas. This legislation requires that Metropolitan Planning Organizations (MPO) prepare long-range transportation plans. In federally designated air quality nonattainment and maintenance areas, the long-range transportation plan is to be updated every three years. The state of California has additional regulations for the preparation of long-range transportation plans. Otherwise, because transportation and traffic are generally local activities, there are no other federal regulations that are pertinent to the proposed project.

3.7.1.2 State Regulatory Framework

California Department of Transportation (Caltrans)

Traffic management in the state of California is guided by policies and standards set at the state level, primarily by the California Department of Transportation (Caltrans). Caltrans is an executive department within California responsible for highway, bridge, and rail transportation planning, construction, and maintenance. Its purpose is to improve mobility across the state. Caltrans manages the state highway system (which includes the California Freeway and Expressway System) and is actively involved with public transportation systems throughout the state. For administrative purposes, Caltrans has divided the state of California into 12 districts supervised by district offices. In southern California, District 7 covers Los Angeles and Ventura counties, District 12 covers Orange County, and District 8 covers Riverside and San Bernardino counties.

Caltrans, in conjunction with the California Highway Patrol (CHP), has created Transportation Management Centers (TMCs) to rapidly detect and respond to roadway incidents, while managing the resulting traffic congestion. With the help of intelligent transportation system technologies, such as electronic sensors in the pavement, freeway call boxes, video cameras, ramp meter sensors, earthquake monitors, motorist cellular calls, and commercial traffic reports, as well as Caltrans highway crews, 911 calls and officers on patrol, each TMC provides coordinated transportation management for general commutes, special events and incidents affecting traffic. The TMCs are operated within each Caltrans district.

<u>CARB Truck and Bus Regulation</u>

CARB adopted the Truck and Bus Regulation in December 2008 to reduce PM and NOx emissions from existing diesel vehicles operating throughout California. This regulation applies to nearly all diesel fueled trucks and buses with a gross vehicle weight rating (GVWR) greater than 14,000 pounds that are privately or federally owned and for privately and publicly owned school buses. This regulation requires all trucks and buses to have 2010 model year engines by 2023. As of January 1, 2012, heavier trucks would be required to meet the engine model year phase-in schedule and fleets that comply with the schedule would install the best available PM filter on 1996 model year and newer engines and would replace the vehicle eight years later. Trucks with 1995 model year and older engines would be replaced starting 2015. Replacements with a 2010 model year or newer engines meet the final requirements, but fleets could also replace with used trucks that would have a future compliance date on the schedule. In addition, fleets that report and use the phase-in option for heavier trucks, could take advantage of credits to delay requirements for other heavier trucks in the fleet until 2017 for the following:

- PM filters installed before July 2011;
- Early purchase of cleaner engines before 2012 (originally equipped with PM filters) ;
- Reducing the number of trucks since 2006; and,
- Adding fuel-efficient hybrids or alternative fueled engines to the fleet.

As part of the analysis of the phase-in option, CARB's projections at the time the Truck and Bus Regulation was adopted estimated the number of plug-in hybrid vehicles, battery electric vehicles, and fuel cell vehicles that will be driving on district roadways will substantially increase between year 2013 and year 2025, as shown in Table 3.7-1.

TABLE 3.7-1

CARB's Projected Populations of Near-Zero and Zero Emission Vehicles in the SCAQMD

Year	Plug-In Hybrid Vehicle (PHEV)	Battery Electric Vehicle (BEV)	Fuel Cell Vehicle (FCV)	Total
2013	15,088	7,196	771	23,055
2014	22,626	7,476	1,058	31,160
2015	33,217	9,725	2,204	45,146
2016	44,442	12,114	3,420	59,976
2017	55,708	14,496	4,635	74,839
2018	79,608	19,778	5,825	105,211
2019	108,615	30,754	8,398	147,767
2020	142,290	46,129	12,837	201,256
2021	178,827	64,365	19,049	262,241
2022	219,896	84,998	27,745	332,639
2023	265,310	108,206	38,839	412,355

3.7.1.3 Regional Regulatory Framework – Congestion Management Programs (CMPs)

In order to meet federal certification requirements, county Congestion Management Agencies (CMAs) have worked together to develop a congestion management process for the southern California area. In southern California, the Congestion Management System (CMS) is comprised of the combined activities of the Regional Transportation Plan (RTP), the CMP and the Regional Transportation Improvement Program (RTIP).

Under California law, CMPs are prepared and maintained by the CMAs. The Los Angeles County Metropolitan Transportation Authority (Metro), Orange County Transportation Authority (OCTA), Riverside County Transportation Commission (RCTC), and San Bernardino Associated Governments (SANBAG) are the designated CMAs of each county and are subject to State requirements.

In addition to the SCAG RTP and RTIP, the key elements of the federal Congestion Management Process are addressed through the counties' CMPs. Because the magnitude of congestion and degree of urbanization differ among the counties, each CMP differs in form and local procedure. By state law, all CMPs are required to perform the monitoring and management functions summarized in the following bullet points, which also fulfill the federal CMP requirements:

- Highway Performance: The monitoring of the performance of an identified highway system as conducted by each CMA allows each county to track how their system, and its individual components, is performing against established standards, and how performance changes over time.
- Multi-Modal Performance: Each CMP contains an element to evaluate the performance of other transportation modes including transit.
- Transportation Demand Management: Each CMP contains a Transportation Demand Management (TDM) component geared at reducing travel demand and promoting alternative transportation methods.
- Land Use Programs and Analysis: Each CMP incorporates a program for analyzing the effects of local land use decisions on the regional transportation system.
- Capital Improvement Program: Using data and performance measures developed through the activities identified above, each CMP develops a Capital Improvement Program (CIP) which is the first step in developing the RTIP. Under state law, projects funded through the RTIP must first be contained in the county CIP.
- Deficiency Planning: The CMP contains provisions for "deficiency plans" to address unacceptable levels of congestion. Deficiency plans can be developed for specific problem areas or on a system-wide basis. Projects implemented through the deficiency plans must, by statute, have both mobility and air quality benefits. In many cases, the deficiency plans capture the benefits of transportation improvements that occur outside the county TIPs and RTIP such as non-traditional strategies and/or non-regionally significant projects.

- The regional transportation planning process and the county congestion management process should be compatible with one another. To ensure consistency, SCAG and the CMAs have developed the Regional Consistency and Compatibility Criteria for CMPs. Information on the CMP activities and resulting data are updated on a biennial basis by each CMA and supplied to SCAG and air quality management districts.

3.7.1.4 Local Regulatory Framework – General Plans

Under state planning law, every city and county must adopt a General Plan that sets forth the goals, policies and implementation measures for future growth and development. General plans must include seven elements, among which is a circulation element. The circulation element must describe the existing transportation network and describes all planned future transportation improvements. Many local transportation elements, or their implementing ordinances, include criteria for measuring the functionality of current and future roadways, typically through a level-of-service (LOS) measurement system, a volume-to-capacity (VC) ratio, or other such approaches.

3.7.1.5 Transportation-related Policies in California

<u>METRANS Transportation Center</u>

The METRANS Transportation Center, a joint partnership between the University of Southern California and California State University Long Beach, is a University Transportation Center that was established in 1998 under the TEA-21 as a policy advocacy organization to foster independent, high quality research to solve the nation's transportation problems. The mission of METRANS is to "solve transportation problems of large metropolitan regions through interdisciplinary research, education and outreach." METRANS conducts research in several areas relating to transportation, including safety, security, and vulnerability. In addition to performing research, one of the primary goals of METRANS is to disseminate the research information, as well as, best practices and technology to the professional community.

<u>Intelligent Transportation System</u>

One way to incorporate safety and security into transportation planning is through greater collaboration between transportation planning and operations. An Intelligent Transportation System (ITS) is one method of establishing this collaborative relationship by creating an ITS Architecture. An ITS Architecture is a framework for ensuring institutional agreement and technical integration of technologies for the implementation of projects or groups of projects under an ITS strategy. ITS projects were originally designed to increase transportation efficiency and to enhance the safety, security and emergency response capabilities of the region.

Because the successful operation of ITS projects usually depends on multiple agencies and the systems they operate, a framework made up of multiple ITS Architectures, has been developed at the state, regional, and local levels to help achieve cooperation, coordination and communication amongst participants in the most cost-effective manner. For example, at the state level, the California ITS Architecture and System Plan addresses those services that are managed at a state level or are interregional in nature. Project sponsors are responsible for ensuring that their projects maintain consistency with the regional architectures, regardless of which architecture applies, as a requirement for federally funded projects.

At the regional level, a Regional ITS Architecture provides a framework to address multi-county issues including those projects, programs, and services that require connectivity across county boundaries or are deployed at a multi-county level for ITS planning that promotes interoperability and communication across jurisdictional boundaries. Projects developed under a regional framework extend the usefulness of any single project by making information easily accessible for operators and users of the system. For example, the southern California ITS Regional Architecture is a Regional ITS Architecture that was developed specifically for all counties in the southern California area in order to document the ITS Architecture covering the region.

Local components to the ITS Architecture exist for Los Angeles County, Orange County, Riverside County, and San Bernardino County.

3.7.2 Existing Traffic Setting

The southern California transportation system is a complex intermodal network designed to carry both people and goods that consists of roads, highways, public transit, paratransit, bus, rail, airports, seaports, and intermodal terminals. The regional highway system consists of an interconnected network of local streets, arterial streets, freeways, carpool lanes and toll roads. This highway network allows for the operation of private automobiles, carpools, private and public buses, and trucks. Active transportation modes, such as bicycles and pedestrians share many of these facilities. The regional public transit system includes local shuttles, municipal and area-wide public bus operations, rail transit operations, regional commuter rail services, and interregional passenger rail service. The freight railroad network includes an extensive system of private railroads and several publicly owned freight rail lines serving industrial cargo and goods. The airport system consists of commercial, general, and military aviation facilities serving passenger, freight, business, recreational, and defense needs. The region's seaports support substantial international and interregional freight movement and tourist travel. Intermodal terminals consisting of freight processing facilities, which transfer, store, and distribute goods. The transportation system supports the region's economic needs, as well as the demand for personal travel.

Transit use is growing in southern California. As of 2009, transit agencies in the southern California area reported 747.3 million boardings (SCAG, 2012). This represents growth of nearly 20 percent in the decades between 2000 and 2010, but only four percent growth in per capita trips due to population growth. Metrolink and Metro Rail (Los Angeles County) have seen ridership growth of six percent to eight percent per year.

3.7.2.1 Transportation Planning

Numerous agencies are responsible for transportation planning and investment decisions within the southern California area. SCAG helps integrate the transportation-planning activities in the region to ensure a balanced, multimodal plan that meets regional as well as county, subregional, and local goals.

Table 3.7-2 identifies local and state agencies that participate in the development of RTP. Seven major entities and agencies are involved including SCAG as the designated Metropolitan Planning Organization, the County Transportation Commissions, Subregional Councils of Governments, local and county governments, transit and transportation owners, operators and implementing agencies, resource/regulating agencies and other private non-profit organizations, interest groups and tribal nations.

TABLE 3.7-2

Stakeholders in Transportation Planning in the Southern California Area

COUNTY TRANSPORTATION COMMISSIONS
Los Angeles County Metropolitan Transportation Authority (Metro)
Orange County Transportation Authority (OCTA)
Riverside County Transportation Commission (RCTC)
SUBREGIONAL COUNCILS OF GOVERNMENTS
Southern California Association of Governments (SCAG)
San Bernardino Associated Governments (SANBAG)
City of Los Angeles
North Los Angeles County
Orange County Council of Governments
San Fernando Council of Governments
San Gabriel Valley Council of Governments
Western Riverside County Council of Governments
Westside Cities Council of Governments
OTHERS
Caltrans
Airport Authorities
Port Authorities
Transportation Corridor Agencies
Transit/Rail Operators

Each of the four counties within the jurisdiction of the SCAQMD has a Transportation Commission or Authority. These agencies are charged with countywide transportation planning activities, allocation of locally generated transportation revenues, and in some cases operation of transit services. In addition, there are many subregional Councils of Government within the southern California area. A Council of Governments is a group of cities and communities geographically clustered and sometimes comprises an entire county (e.g., Orange County), which work together to identify, prioritize, and seek transportation funding for needed investments in their respective service areas.

3.7.2.2 Existing Circulation System

Commute Patterns and Travel Characteristics

The existing transportation network serving the southern California area supports the movement of people and goods. On a typical weekday in the four-county region, including those portions of the county not located within the jurisdiction of the SCAQMD, the transportation network supports approximately 420 million vehicle miles of travel (VMT) and 12 million vehicle hours of travel (VHT). Of these totals, over half occur in Los Angeles County and less in Orange County, San Bernardino County, and Riverside County, respectively. Detailed summaries of the existing VMT and VHT for these areas are presented in Table 3.7-3 and Table 3.7-4, respectively.

TABLE 3.7-3
Summary of Existing Daily Vehicle Miles

County	Vehicle Miles of Travel (VMT)					
	AM Peak Period		PM Peak Period		Daily	
	Miles	% of Region	Miles	% of Region	Miles	% of Region
Los Angeles	46,321,000	54%	74,635,000	54%	224,312,000	54%
Orange	15,589,000	18%	24,793,000	18%	75,224,000	18%
Riverside	12,099,000	14%	18,817,000	14%	60,494,000	14%
San Bernardino	12,242,000	14%	18,944,000	14%	61,010,000	14%

TABLE 3.7-4
Summary of Existing Daily Vehicle Hours of Travel

County	Vehicle Hours of Travel (VHT)					
	AM Peak Period		PM Peak Period		Daily	
	Hours	% of Region	Hours	% of Region	Hours	% of Region
Los Angeles	1,627,000	60%	3,181,000	62%	7,428,000	60%
Orange	474,000	17%	879,000	17%	2,171,000	17%
Riverside	320,000	12%	542,000	11%	1,469,000	12%
San Bernardino	307,000	11%	512,000	10%	1,416,000	11%
Total	**2,728,000**	**100%**	**5,114,000**	**100%**	**12,484,000**	**100%**

Source: SCAG, 2012. Data presented are for the entire county and not limited to the portion of the county located within the jurisdiction of the SCAQMD.

Much of the existing travel in the southern California area takes place during periods of congestion, particularly during the morning (e.g., from 6:00 a.m.to 9:00 a.m.) and evening peak periods (e.g., from 3:00 p.m. to 7:00 p.m.). Congestion can be quantified as the amount of travel that takes place in delay (vehicle hours of delay or VHD), and alternately, as the percentage of all travel time that occurs in delay (defined as the travel time spent on the highway due to congestion, which is the difference between VHT at free-flow speeds and VHT at congested speeds). Table 3.7-5 presents the existing travel delays and percent of regional VHT in delay by county on freeways and arterials. As shown in Table 3.7-5, regional travel time in delay represents approximately 25 percent of all daily, 30 percent of all AM peak period, and 38 percent of all PM peak period travel times. Also as shown in Table 3.7-5, a substantial portion of AM peak period travel in each county takes place in delay, ranging from a low of 21 percent in San Bernardino County to a high of 34 percent in Los Angeles County.

TABLE 3.7-5
Summary of Existing Vehicle Hours of Delay

County	Vehicle Hours of Delay			% of Travel in Delay		
	AM Peak Period	AM Peak Period	Daily	AM Peak Period	AM Peak Period	Daily
Los Angeles	554,000	1,387,000	2,204,000	34%	44%	4%
Orange	128,000	313,000	493,000	27%	36%	23%
Riverside	78,000	158,000	263,000	24%	29%	18%
San Bernardino	64,000	125,000	205,000	21%	24%	14%
Total	**824,000**	**1,983,000**	**3,165,000**	**30%**	**38%**	**25%**

Source: SCAG, 2012. Data presented are for the entire county and not limited to the portion of the county located within the jurisdiction of the SCAQMD.

As shown in Table 3.7-6. the average vehicle home-to-work trip duration in each county is generally similar while a greater range of average work distances is found in the different counties of the region (e.g., from a low of 13 miles in Orange County to a high of 18 miles in San Bernardino and Riverside counties). Home-to-work trip duration and distance are both greater for the inland counties of Riverside and San Bernardino, reflecting regional housing and employment distribution patterns.

TABLE 3.7-6
Summary of Existing Vehicle Work Trip Length

County	Average Home to Work Trip Distance (miles)	Average Home to Work Duration (minutes)	
	Vehicle Trips (AM Only)	Vehicle Trips (AM Only)	Transit Trips (AM Only)
Los Angeles	14	26	69
Orange	13	21	78
Riverside	18	29	95
San Bernardino	18	29	116

Source: SCAG 2012-2035 RTP/SCS Program Draft EIR.
Data presented are for the entire county and not limited to the portion of the county located within the jurisdiction of the SCAQMD.

Based on average accident rates provided by Caltrans, transportation-related fatalities occur at an overall rate of 0.83 fatalities per 100 million vehicle miles traveled, taking into account the varying accident rates on different facility types (freeway, arterials) and travel modes (bus transit, rail transit) (SCAG, 2012). These specific accident rates and the resulting estimate of region-wide accidents are detailed in Table 3.7-7.

TABLE 3.7-7
Total Vehicle Fatalities

County	Fatalities (2009)	Fatalities per 100 Million Vehicle Miles Traveled	Annual Vehicle Miles Traveled per 100 Million
Los Angeles	589	0.76	778
Orange	154	0.59	261
Riverside	219	1.04	210
San Bernardino	236	1.11	212

Source: SCAG 2012-2035 RTP/SCS Program Draft EIR.
Data presented are for the entire county and not limited to the portion of the county located within the jurisdiction of the SCAQMD.

A summary of home-to-work trip characteristics by county is presented in Table 3.7-8. Vehicles with single passenger occupancy are still the most common form of transportation for home to work trips, accounting for 76 percent of the trips in Los Angeles County, 81 percent of the trips in Orange County, and 82 percent of the trips in Riverside and San Bernardino County. Public transit in all forms (including school buses) carries approximately 2.4 percent of all trips in the southern California area. Of these, the greatest number of travelers is carried by buses, with lesser patronage on Metro Rail, paratransit, commuter rail and other forms of public transit services. Work trips made via public transit account for about 6.1 percent of all home-to-work trips in the area.

TABLE 3.7-8
Existing Travel Mode Split (% of County Total)

County	Person Trip Type	Drive Alone	2 Person Carpool	3 Person Carpool	Auto Passenger Trip	Transit	Non-Motorized	Total
Los Angeles	Home-Work/Univ	76%	3.4%	1.5%	7.1%	9.1%	3%	100%
	All Daily Trips	43%	8%	6.5%	24%	3.5%	14%	100%
Orange	Home-Work/Univ	81%	3.7%	1.5%	7.4%	3.4%	3%	100%
	All Daily Trips	46%	8.3%	6.8%	26%	1.4%	12%	100%
Riverside	Home-Work/Univ	82%	3.7%	1.8%	8%	1.5%	3.1%	100%
	All Daily Trips	42%	8.3%	7.3%	27%	0.72%	15%	100%

Regional Freeway, Highway and Arterial System

The regional freeway and highway system as shown in Figure 3.7-1 is the primary means of person and freight movement for the region. This system provides for direct automobile, bus and truck access to employment, services and goods. The network of freeways and State highways serves as the backbone of the system offering very high capacity limited-access travel and serving as the primary heavy duty truck route system.

Major freeways that transverse Los Angeles County in a generally north/south direction include the San Diego Freeway (I-405), the Golden State Freeway (I-5), the Hollywood Freeway (I-101), Pasadena Freeway (I-110), the Long Beach Freeway (I-710), and the San Gabriel Freeway I-605). Major freeways that transverse Los Angeles County in a generally east/west direction include the Santa Monica Freeway (I-10), Century Freeway (I-105), Foothill Freeway (I-210), Ronald Reagan Freeway (I-118), Pomona Freeway (I-60), and Riverside Freeway (I-91).

Major freeways that transverse Orange County in a generally north/south direction include I-405, I-5, the Orange Freeway (I-57), and the Newport Freeway (I-55), as well as toll roads located in the south-eastern portion of the County (I-241 and 261). Major freeways that transverse Orange County in a generally east/west direction include the I-91, Garden Grove Freeway (I-22), and Corona Del Mar Freeway (I-73).

Major freeways that transverse Riverside County in a generally north/south direction include the Chino Valley Freeway (I-71), Ontario Freeway (I-15), and Escondido Freeway (I-215). Major freeways that transverse Riverside County in a generally east/west direction include the I-91, I-60, and I-10.

Major freeways that transverse San Bernardino County in a generally north/south direction include the Ontario Freeway (I-15), and I-215. Major freeways that transverse San Bernardino County in a generally east/west direction include the Needles Freeway (I-40) (outside of the air Basin).

The components of the regional highway and freeway system are summarized in Table 3.7-9.

TABLE 3.7-9

Existing Regional Freeway Route Miles and Lane Miles by County

County	Freeway Route Miles	Freeway Lane Miles
Los Angeles	637	4,583
Orange	167	1,294
Riverside	309	1,722
San Bernardino	471	2,512
Total	**1,584**	**10,111**

Source: SCAG, 2012.
Data presented are for the entire county and not limited to the portion of the county located within the jurisdiction of the SCAQMD.

Regional High Occupancy Vehicle System and Park & Ride System

The regional high occupancy vehicle (HOV) system consists of exclusive lanes on freeways and arterials, as well as bus ways and exclusive rights-of-way dedicated to the use of HOVs. It includes lanes on freeways, ramps and freeway-to-freeway connectors. The regional HOV system is designed to maximize the person-carrying capacity of the freeway system through the encouragement of shared-ride travel modes. HOV lanes operate at a minimum occupancy threshold of either two or three persons. Many include on-line and off-line park and ride facilities, and several HOV lanes are full "transitways" including on-line and offline stations for buses to board passengers. The current system is described in Table 3.7-10.

TABLE 3.7-10

Existing Regional Freeway HOV Total Lane Miles by County

County	HOV Total Lane Miles
Los Angeles	479
Orange	241
Riverside	83
San Bernardino	105

Source: SCAG, 2012.
Data presented is for the entire county and not limited to the portion of the county located within the jurisdiction of the SCAQMD.

Park and ride facilities are generally located at the urban fringe along heavily-traveled freeway and transit corridors and support shared-ride trips, either by transit, by carpool or vanpool. Most rail transit stations have park and ride lots nearby. There are currently 168 park and ride facilities in the southern California area, including Metrolink station parking lots. These park and ride facilities are distributed amongst the four county areas as follows: 106 in Los Angeles County, 20 in Orange County, 25 in Riverside County, and 17 in San Bernardino County.

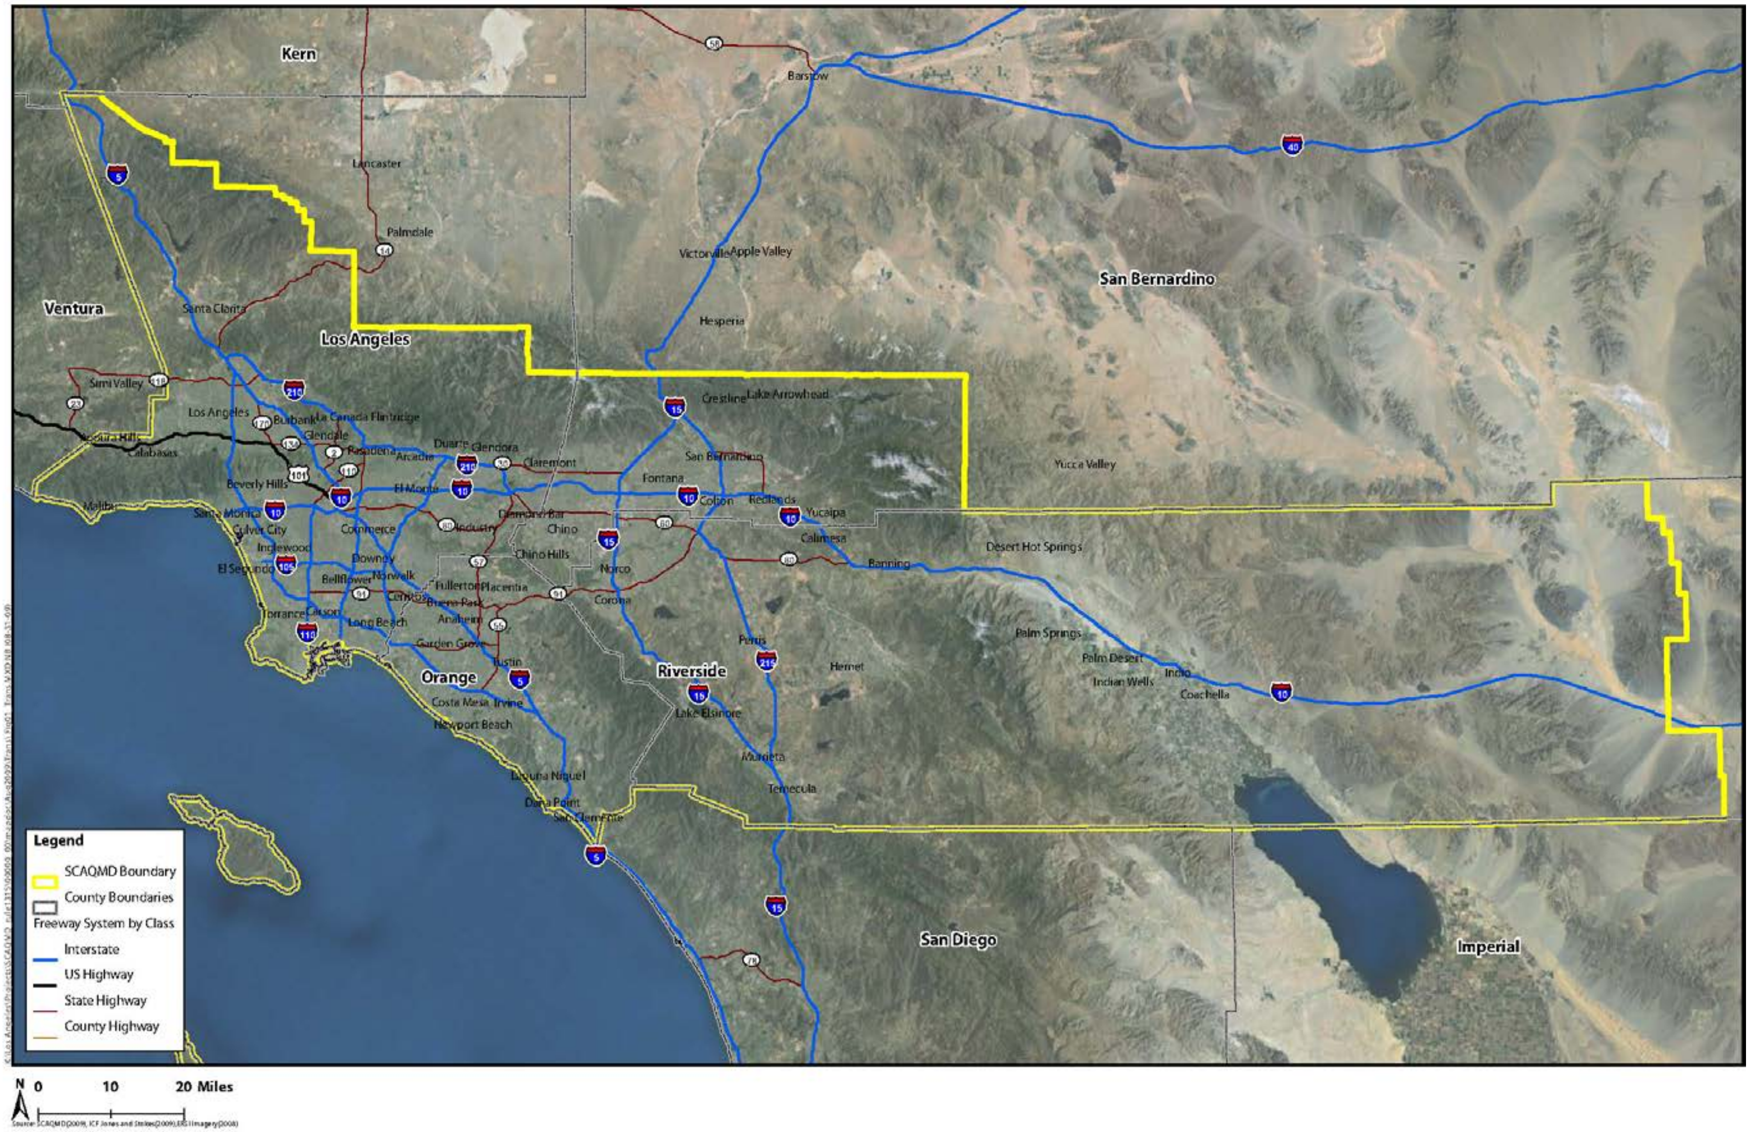

FIGURE 3.7-1
Major Freeway Routes within SCAQMD

Arterial Street System

The local street system provides access for local businesses and residents. Arterials account for over 80 percent of the total road network and carry a high percentage of total traffic. In many cases arterials serve as alternate parallel routes to congested freeway corridors. Peak period congestion on the arterial street system occurs generally in the vicinity of activity centers, at bottleneck intersections and near many freeway interchanges. The region's arterial street system is described in terms of number of miles in Table 3.7-11.

TABLE 3.7-11
Existing Regional Arterial Route Miles and Lane Miles by County

Data presented are for the entire county and not limited to the portion of the county located within the jurisdiction of the SCAQMD.

3.7.2.3 Goods Movement

Wholesale and retail trade, transportation, and manufacturing support over 3.3 million jobs in the region according to statistics provided by the California Employment Development Department. Goods movement includes trucking, rail freight, air cargo, marine cargo, and both domestic and international freight, the latter entering the country via the seaports, airports, and the international border with Mexico. Additionally, many cargo movements are intermodal (e.g., sea to truck, sea to rail, air to truck, or truck to rail). The goods movement system includes not only highways, railroads, sea lanes, and airways, but also intermodal terminals, truck terminals, railyards, warehousing, freight consolidation/de-consolidation terminals, freight forwarding, package express, customs inspection stations, truck stops, and truck queuing areas.

Railroads

The southern California area is served by two main line commercial freight railroads (e.g., BNSF and UP). These railroads link southern California with other regions in California and the remainder of the United States, as well as Mexico and Canada either directly or via their connections with other railroads. They also provide freight rail service within

California. In 2011, railroads moved approximately 150 million tons of cargo throughout California (SCAG, 2012). These railroads perform specific local functions and serve as feeder lines to the trunk line railroads for moving goods to and from southern California.

The two main line railroads also maintain and serve major facilities in the southern California area. Intermodal facilities in Commerce (BNSF-Hobart), East Los Angeles (UP), San Bernardino (BNSF), and Carson near the San Pedro Bay Ports (UP-ICTF), the Los Angeles Transportation Center (UP-LATC), and the UP-City of Industry yards serve on-dock rail capacity at the Port of Los Angeles (UP/BNSF) and Port of Long Beach (UP/BNSF).

BNSF and UP are both seeking approvals for new or expanded intermodal container facilities to help manage the estimated increase in container movements through the ports. BNSF is seeking approvals for the Southern California International Gateway (SCIG) facility, a new intermodal facility in the City of Los Angeles about four miles north of the Ports of Long Beach and Los Angeles and adjacent to the Alameda Corridor (LAHD, 2011). UP is seeking approvals to expand its existing Intermodal Container Transfer Facility (ICTF) near the City of Carson, adjacent to the Alameda Corridor (ICTF JPA, 2009)

All of the major rail freight corridors in the region have some degree of grade separation, but most still have a substantial number of at-grade crossings on major streets with high volumes of vehicular traffic. These crossings cause both safety and reliability problems for the railroads and for those in motor vehicles at the affected crossings. Trespassing on railroad rights-of-way by pedestrians is another safety issue affecting both freight and commuter railroads. As an example, the Colton Crossing, is an at-grade railroad crossing located south of I-10 between Rancho Avenue and Mount Vernon Avenue in the City of Colton, where BNSF's San Bernardino Line crosses UP's Alhambra/Yuma Lines. In 2008, the Colton Crossing saw on average 110 freight trains per day.

The southern California area is also served by two short line or switching railroads:

- The Pacific Harbor Line (formerly the Harbor Belt Railroad) handles all rail coordination involving the Port of Los Angeles and Port of Long Beach, including dispatching and local switching in the harbor area.
- Los Angeles Junction Railway Company, owned by BNSF, provides switching service in the Vernon area for both the BNSF and UP.

Another key component of the regional rail network is the Alameda Corridor, a 20-mile, four-lane freight rail expressway that began operations in April 2002. In 2010, approximately 14,177 intermodal trains transited the Alameda Corridor, an approximate increase of 8.6 percent since 2009 (SCAG, 2012).

Marine Ports

Southern California is served by three major deep-water seaports (e.g., Port of Los Angeles, Port of Long Beach, and Port of Hueneme). However, the Port of Hueneme is not within the jurisdiction of the SCAQMD. The Port of Los Angeles and Port of Long Beach handle trade from Asia and North America, and are served by the two major railroads (e.g., BNSF and UP), as well as numerous trucking companies in southern California. The Port of Hueneme handles primarily automobile and agricultural products. Both the Port of Los Angeles and the Port of Long Beach are full service ports with facilities for containers, autos and various bulk cargoes. With an extensive landside transportation network, these three ports moved more than 310 million metric tons of cargo in 2010 (SCAG, 2012).

The Port of Los Angeles and Port of Long Beach dominate the container trade in the Americas by shipping and receiving more than 11.8 million twenty-foot Equivalent Units (TEUs) of containers in 2009. Together, these two ports rank third in the world, behind Rotterdam and Hong Kong, as the busiest maritime ports (SCAG, 2012).

3.7.2.4 Public Transit, Bicycle or Pedestrian Facilities

Public Transit

In southern California public transit service is comprised of local and express buses, transit ways, Rapid Bus, and urban rail, including subway and light rail, principally centered in the core of Los Angeles County. Transit service is provided by approximately 67 separate public agencies. Twelve of these agencies provide 91 percent of the existing public bus transit service. Local service is supplemented by municipal lines and shuttle services. Private bus companies provide additional regional service.

Transit ridership was approximately 708 million in 2010 in southern California (SCAG, 2012). The largest provider of public transit service in Los Angeles County is the Metro, which provides bus service and an urban light rail system and subway. In 2010, the Metro system experienced approximately 41.9 million average monthly boardings (SCAG, 2010).

The largest provider of public transit service in Orange County is OCTA, which operates 77 bus local and express routes and approximately 62,000 bus stops located throughout the urbanized portions of Orange County. In 2010, the OCTA system experienced approximately 4.8 million average monthly boardings (SCAG, 2010).

The largest provider of public transit service in Riverside County is the Riverside Transit Agency, which operates 231 buses on approximately 43 local and express routes. In 2010, the system experienced approximately 950,000 average monthly boardings (SCAG, 2010).

The largest provider of public transit service in San Bernardino County is Omnitrans, which operates 277 buses over approximately 27 routes. In 2010, the system experienced approximately 1.3 million average monthly boardings (SCAG, 2010).

Metro Rail System

Within the district, the Los Angeles County Metropolitan Transit Authority (Metro) provides urban rail transit service on six lines within Los Angeles County. The Blue Line extends from Long Beach to the 7th Street Metro Center in downtown Los Angeles. The Red Line connects Union Station with North Hollywood via the Metro Center, the Gold Line connects Union Station with Pasadena, and the Green Line extends from Redondo

Beach to Norwalk. The Purple Line connects Koreatown in the mid-Wilshire District to Union Station. The Metro Expo Line connects the 7th Street Metro Center in downtown Los Angeles to Culver City. Other Metro operated urban transit systems include the Orange Line which connects with the northern terminus of the Red Line in North Hollywood and serves much of the northwestern portion of Los Angeles County, and the Eastside Gold Line Extension, which provides rail transit service to East Los Angeles. The Metro Rail system has a total of 87 route miles that serve a total of 80 stations. Ridership on the system is about 303,000 boardings per day (SCAG, 2012)

Regional Commuter Rail

Metrolink is a commuter rail service that is governed and operated by the Southern California Regional Rail Authority (SCRRA), a joint powers authority that consists of the following county agencies tasked with reducing highway congestion and improving mobility throughout southern California: 1) Los Angeles County Metropolitan Transportation Authority (Metro); 2) Orange County Transportation Authority (OCTA); 3) Riverside County Transportation Commission; 4) San Bernardino Associated Governments (SanBAG); and, 5) Ventura County Transportation Commission. Metrolink serves as the link between six Southern California counties by providing commuters seamless transportation connectivity options. Metrolink currently operates seven routes including five from downtown Los Angeles to Ventura, Lancaster, San Bernardino, Riverside and Oceanside; one from San Bernardino to Oceanside; and one from Riverside via Fullerton or City of Industry to downtown Los Angeles. The system operates about 144 trains on weekdays, 40 trains on Saturdays, and 26 trains on Sundays to 55 stations on 512 miles of track. Average weekday ridership is approximately 40,544 passengers (SCAG, 2012).

Amtrak provides regional and inter-regional service from San Diego to San Luis Obispo along the Pacific Surfliner corridor. Amtrak also operates four interstate routes within the region that on average have one daily trip.

Bicycle and Pedestrian Facilities

Biking and walking tend to play a bigger role in densely-populated, mixed land use areas of the region. However, in 2009, less than four percent of commuters within the SCAG region, of which the district is a subset, traveled to work via biking or walking (0.7 percent bicycled and 2.5 percent walked)[1]. Current transit infrastructures provide 97 percent of residents in the SCAG region with access to transit via bicycle and 86 percent access to transit by walking.

The region's bikeways include Class I bikeways, which are shared-use paths that are also used by pedestrians. Class II bikeways are striped lanes in streets, and Class III bikeways are signed routes. Nearly 4,615 miles of Class I and II bikeways exist throughout the region, as well as mountain bike trails. The City of Los Angeles alone has more than 216 miles of

1 SCAG. 2012. 2012 – 2035 Regional Transportation Plan/Sustainable Communities Strategy, adopted April 2012, p. 53. http://rtpscs.scag.ca.gov/Documents/2012/final/f2012RTPSCS.pdf

Class I and II bikeways. In addition, local jurisdictions in the region have proposed an additional 4,980 miles of bikeways (SCAG, 2012).

Pedestrian access at and near public transit, in most major commercial areas, and many residential areas is facilitated by sidewalks, a number of pedestrian malls, and in some cases local jogging and pedestrian trails or paths.

4.0 POTENTIAL ENVIRONMENTAL IMPACTS AND MITIGATION MEASURES

The CEQA Guidelines require environmental documents to identify significant environmental effects that may result from a proposed project [CEQA Guidelines §15126.2(a)]. Direct and indirect significant effects of a project on the environment should be identified and described, with consideration given to both short- and long-term impacts. The discussion of environmental impacts may include, but is not limited to: the resources involved; physical changes; alterations of ecological systems; health and safety problems caused by physical changes; and other aspects of the resource base, including water, scenic quality, and public services. If significant adverse environmental impacts are identified, the CEQA Guidelines require a discussion of measures that could either avoid or substantially reduce any adverse environmental impacts to the greatest extent feasible [CEQA Guidelines §15126.4].

CEQA Guidelines indicate that the degree of specificity required in a CEQA document depends on the type of project being proposed [CEQA Guidelines §15146]. The detail of the environmental analysis for certain types of projects cannot be as great as for others. For example, the environmental document for projects, such as the adoption or amendment of a comprehensive zoning ordinance or a local general plan, should focus on the secondary effects that can be expected to follow from the adoption or amendment, but the analysis need not be as detailed as the analysis of the specific construction projects that might follow. As a result, this PEA analyzes impacts on a regional level and impacts on the level of individual industries or individual facilities only where feasible.

The categories of environmental impacts to be studied in a CEQA document are established by CEQA [Public Resources Code, §21000 et seq.], and the CEQA Guidelines, as promulgated by the State of California Secretary of Resources. Under the CEQA Guidelines, there are 17 environmental topic areas in which potential adverse impacts from a project are evaluated. Projects are evaluated against the environmental categories in an Environmental Checklist and those environmental categories that may be adversely affected by the proposed project are further analyzed in the appropriate CEQA document.

The proposed project is based on reducing NOx RTC holdings from certain NOx RECLAIM RTC holders. The likely possibility is that the affected source categories will reduce actual NOx emissions via physical modifications to a wide variety of equipment by installing new air pollution control equipment or modifying existing air pollution control equipment. Because of the number of potentially affected equipment units, these physical changes, while reducing NOx emissions, may cause potentially significant adverse secondary impacts. Pursuant to CEQA, an Initial Study, including an environmental checklist, was prepared for this project (see Appendix F). Of the 17 potential environmental impact categories, the following seven topic areas were identified in the NOP/IS as being potentially adversely affected by the proposed project: aesthetics; air quality and GHG emissions; energy; hazards and hazardous materials; hydrology and water quality; solid and hazardous waste; and, transportation and traffic. Eight comment letters were received relative to the NOP/IS. These comment letters and responses to the comments can be found in Appendix G of this document.

The seven environmental impact areas that were identified as potentially significant in the NOP/IS are further evaluated in detail in this PEA. The environmental impact analysis for each environmental topic incorporates a "worst-case" approach. This approach entails the premise that whenever the analysis requires that assumptions be made, assumptions that result in the greatest adverse impacts are typically chosen. This method ensures that all potential effects of the proposed project are documented for the decision-makers and the public. Accordingly, the following analyses use a conservative "worst-case" approach for analyzing the potentially significant adverse environmental impacts associated with the implementation of the proposed project.

The proposed project consists of applying a "shave" to holders of the top 90 percent of NOx RTCs (e.g., refineries, power plants, and other large RTC holders). The amount of the shave is weighted by a BARCT reduction contribution to achieve an overall reduction of 14 tons of NOx per day from current total RTC holdings (starting with the facility holding the most RTCs and proceeding to include 90 percent of the RTCs) by 2022 according to the following implementation schedule as summarized in Table 4.0-1:

Table 4.0-1
Implementation Schedule for NOx RTC Reductions

Implementation Year	Amount of NOx RTC Reductions (tons/day)
2016	4
2018	2
2019	2
2020	2
2021	2
2022	2
TOTAL	**14**

The NOx RTC shave will apply to 56 ~~65~~ facilities. In addition, the RTC shave will apply to RTC investors, but they will be treated as 1 company. The RTC shave will apply to refineries, certain non-major facilities, and all power plants. The shave is distributed as follows:

- 66~~67~~% shave for 9 refineries and investors (treated as one facility)
- 49~~47~~% shave for 21 electricity generating facilities (EGFs) ~~30~~ power plants
- 49~~47~~% shave for 26 non-major facilities
- 0% shave for 219 ~~210~~ remaining facilities

Note that for the remaining 219 ~~210~~ facilities, no NOx RTC shave is proposed because no new BARCT was identified for the types of equipment and source categories at these facilities.

SCAQMD staff is proposing BARCT levels that will be applicable to the refinery sector (e.g., FCCUs, refinery process heaters and boilers, refinery gas turbines, petroleum coke calciner, and SRU/TGUs) and the non-refinery sector (e.g., container glass melting furnaces, sodium silicate furnaces, metal heat treating furnaces, non-refinery/non-power plant gas turbines, ICEs, and cement kilns). On an equipment/process basis, Table 4.0-2 summarizes the potential control technologies that will be considered as part of the BARCT analysis for the proposed project.

Table 4.0-2

BARCT Control Technology Options for Top NOx Emitting Equipment/Processes

Equipment/Process	BARCT Control Technology To Be Analyzed in PEA
FCCUs	1. SCR 2. LoTOx™ with WGS
Refinery Process Heaters and Boilers	SCR
Refinery Gas Turbines	SCR
SRU/TGUs	1. LoTOx™ with WGS 2. SCR
Petroleum Coke Calciner	1. UltraCat DGS 2. LoTOx™ with WGS
Portland Cement Kilns	None[1]
Container Glass Melting Furnaces	1. SCR 2. UltraCat DGS
Sodium Silicate Furnaces	1. SCR 2. UltraCat DGS (without sorbent)
Metal Heat Treating Furnaces	SCR
ICEs (Non-Refinery/Non-Power Plant)	SCR

Key: SCR = Selective Catalytic Reduction; WGS = Wet Gas Scrubber; DGS = Dry Gas Scrubber

Of the 56 ~~65~~ facilities that would be subject to a shave of the NOx RTC holdings , the BARCT analysis found that it would be both feasible and cost-effective for operators of 20 facilities to install new control equipment or modify existing control equipment in response to the proposed NOx RTC shave for facilities which operate with current SCAQMD permits. Of the 20 facilities, 11 facilities belong to the non-refinery sector and 9 facilities belong to the refinery sector. Thus, the proposed project may result in the installation and operation of new or ~~the~~ modified~~cation of~~ existing NOx emission control equipment for 20 of these industrial equipment and processes (e.g., 9 facilities from the refinery sector and 11 facilities from the non-refinery sector). Accordingly, the analyses in the following subchapters for each environmental topic area focus on the potential environmental impacts that may occur as a result of installing and operating new or modified~~ying~~ existing NOx emission control equipment at these 20 facilities.

[1] Because of CPCC's current permitting status for their Portland cement kilns (e.g., the permits were surrendered), CPCC operators will not be able to retrofit the Portland cement kilns with air pollution control equipment in response to the proposed project without first dealing with the permitting issues for the cement kilns. Thus, the installation of control technology and the secondary adverse environmental impacts that may be associated with such control technology is not a reasonably foreseeable consequence for CPCC under the present circumstances. Further, there are no other facilities in SCAQMD's jurisdiction that operate Portland cement kilns. Thus, this PEA does not contain an environmental analysis of the control technologies that were originally contemplated in the NOP/IS for the CPCC facility.

At the time the Draft PEA was released for the public review and comment period (from August 14, 2015 to October 6, 2015), the analysis was based on the version of the rules that was presented at the July 22, 2015 Public Workshop. Subsequent to release of the Draft PEA, modifications were made to the proposed project and some of the revisions were made in response to verbal and written comments received. Most of the subsequent revisions that are identified in strikeout/underlined text in Chapter 2 of this PEA are administrative in nature and thus, would not create any environmental impacts. However, there are two key revisions proposed which SCAQMD staff has received comments suggesting that their environmental effects, if any, be addressed in the PEA, as follows: 1) revisions have been made to the proposed project that would include amending Rule 2001 – Applicability, to allow electricity generating facilities (EGFs) to exit or opt out of the RECLAIM program provided that certain criteria are met (see the project description in Chapter 2 which describes the proposed amendments to Rule 2001); and 2) revisions have been made to Rule 2002 that would require facilities to surrender RTCs if the facility undergoes a complete shutdown or if equipment that represents more than 25 percent of facility emissions is shutdown.

Option for EGF Opt Out: Under the proposed amendments to Rule 2001, an EGF, excluding cogeneration plants, would be allowed to exit the RECLAIM program, provided that at least 99 percent of the facility's NOx emissions for the most recent three full compliance years are from equipment that meets current BACT or BARCT for NOx. This stringent criteria was deliberately crafted to ensure that the emissions from EGFs operating under a RECLAIM permit would not change if these EGF facilities opt out of RECLAIM and instead, operate under a command-and-control permit. In addition, if an EGF decides to opt out from RECLAIM, it would need to surrender a pre-defined amount of NOx RTCs to be retired from the NOx RTC market. For EGFs with existing permits issued prior to the inception date of the RECLAIM program, the amount to be surrendered would be equivalent to the amount of NOx RTCs initially allocated to the facility upon entry into RECLAIM as adjusted by the 2005 and proposed shaves; for other EGFs with all permits issued on or after the RECLAIM inception date, the amount would be equivalent to the quantity required to be held by the facility pursuant to Rule 2005 – New Source Review. The requirement to surrender RTCs will prevent other facilities within the RECLAIM program from using RTCs from EGFs and emitting more NOx. In addition, once an EGF is under command-and-control, the EGF will no longer have the ability to purchase RTCs in the event their emissions increase above their RTC holdings. Instead, they would be subject to a facility-wide emission limit based on their surrendered RTCs. In addition, any future increases in emissions would be subject to the emissions offset and all other requirements pursuant to Regulation XIII – New Source Review.

Actual emissions for EGFs fluctuate relative to the potential to emit (PTE), and this would remain true whether the EGF operates under a RECLAIM permit or under a command-and-control permit. However, without having the flexibility of purchasing RTCs that was afforded to EGFs under a RECLAIM permit, an EGF operating under a command-and-control permit would be limited to having emissions operate at or below the permitted level. For these reasons, SCAQMD staff believes there would be no substantial change in actual or PTE emissions from the existing setting (e.g., an EGF operating under a RECLAIM permit) when compared to the proposed project which would allow an EGF to exit RECLAIM and operate pursuant to a command-and-control permit.

Surrender RTCs for Complete Facility Closures or Equipment Shutdowns: Since the adoption of RECLAIM, facilities which planned to shut down were not restricted from selling off their RTCs prior to facility closures. RTCs resulting from shutdowns are not subject to the best available control technology (BACT) discount that applies to non-RECLAIM sources and are not based on the emissions from the last two years of operation.

As a consequence, staff estimated that large amounts of RTCs that are in the market can be traced to the sale of RTCs from facilities that have, or are planning to, shut down. As shown in Table 2 of the Socioeconomic Report, facility shutdowns amounted to 2.62 tpd of actual NOx emission reductions between 2006 and 2012, which was just less than two-thirds of the 4 tpd actual total NOx emission reductions over the same period. However, NOx RTCs that were previously held by these shutdown facilities were never removed from the market, thus exerting a downward pressure on the RTC market prices. This, in turn, had the effect of dis-incentivizing some of the the remaining NOx RECLAIM facilities from installing cost-effective control equipment or making other changes at their facilities.

Under Proposed Amended Rule 2002, any facility that permanently shuts down some or all equipment with emissions greater than or equal to 25 percent of the facility emissions for any quarter within the previous two compliance years would need to surrender NOx RTCs to be retired from the market. By reducing the amount of available RTCs on the market, facilities that remain in the RECLAIM program would be induced to reduce NOx emissions by installing new or modifying existing air pollution control equipment instead of purchasing RTCs. The analysis of installing new or modifying existing air pollution control equipment is already addressed in this PEA.

Thus, after careful review of the proposed revisions, SCAQMD staff believes the inclusion of an EGF opt out option and requiring facilities undergoing a shutdown to surrender RTCS would not constitute: 1) significant new information; 2) a substantial increase in the severity of an environmental impact; 3) provide new information of substantial importance relative to the draft document; or, 4) create new, avoidable significant effects. As a result, these revisions do not require recirculation of the document pursuant to CEQA Guidelines §15073.5 and §15088.5.

SUBCHAPTER 4.1

AESTHETICS

Introduction

Significance Criteria

Potential Aesthetics Impacts and Mitigation Measures

Cumulative Aesthetic Impacts

Cumulative Mitigation Measures

4.1 AESTHETICS

The proposed amended regulation will require facilities to collectively lower their emissions, thus improving air quality in the long term in order to meet the project's objectives. However, the installation of air pollution control equipment as a result of implementing the proposed project could potentially result in aesthetics impacts. The aesthetic impact analysis in this ~~Draft~~ Final PEA identifies the net effect on aesthetic resources from implementing the proposed project.

4.1.1 Introduction

As previously summarized in Table 4.0-2, the proposed project is expected to result in the installation of new or the modification of existing NOx air pollution control equipment for the top NOx emission equipment/source categories. The equipment/source categories are divided into two sectors: refinery and non-refinery. There are nine facilities in the refinery sector and 11 facilities in the non-refinery sector. For both sectors, individual facilities were evaluated to determine the number and type of NOx control devices that may be installed as a result of implementing the proposed project. Reducing NOx emissions from the affected facilities will provide an air quality benefit in the near- and long-term. Direct air quality impacts from the proposed project are expected to result in a reduction of NOx emissions at the affected facilities, once operational, which will provide air quality and human health benefits to the public. However, the NOP/IS identified potentially adverse aesthetics impacts from installing new or modifying existing air pollution control equipment and committed to analyzing in the PEA whether these activities would substantially degrade the existing visual character or quality of the site and its surroundings. Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs. Further, since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74. Thus, the analysis in this PEA for the refinery sector is conservative as it overestimates the potential adverse aesthetics impacts. The analysis of these impacts can be found in Section 4.1.3.

4.1.2 Significance Criteria

The proposed project impacts on aesthetics will be considered significant if:

- The project will block views from a scenic highway or corridor.
- The project will adversely affect the visual continuity of the surrounding area.
- The impacts on light and glare will be considered significant if the project adds lighting which would add glare to residential areas or sensitive receptors.

4.1.3 Potential Aesthetics Impacts and Mitigation Measures

Table 4.1-1 summarizes the estimated number of NOx emission control devices per sector and per equipment/source category. The different types of control devices include Selective Catalytic Reduction (SCR), a proprietary Low Temperature Oxidation technology (LoTOx™)

with or without a Wet Gas Scrubber (WGS), and catalyst impregnated filters with a Dry Gas Scrubber (UltraCat DGS). In total, the proposed project is expected to result in the installation of the following new NOx air pollution control equipment: up to 117 SCRs, eight LoTOx™ with WGSs, one LoTOx™ without WGS, and three UltraCat DGSs.

Table 4.1-1
Estimated Number of NOx Control Devices Per Sector and Equipment/Source Category

Sector	Equipment/Source Category	Number of Affected Facilities	Estimated Number of Control Devices
Refinery	Fluid Catalytic Cracking Units (FCCUs)	5	2 SCRs 2 LoTOx™ with WGSs* 1 LoTOx™ without WGS
Refinery	Refinery Process Heaters and Boilers	8	74 SCRs^
Refinery	Refinery Gas Turbines	5	7 SCRs
Refinery	Sulfur Recovery Unit / Tail Gas Units (SRU/TGUs)	5	5 LoTOx™ with WGSs 1 SCR
Refinery	Petroleum Coke Calciner	1	1 LoTOx™ with WGS or 1 UltraCat with DGS
Non-Refinery	Container Glass Melting Furnaces	1	2 SCRs or 1 UltraCat with DGS
Non-Refinery	Sodium Silicate Furnaces	1	1 SCR or 1 UltraCat with DGS
Non-Refinery	Metal Heat Treating Furnaces	1	1 SCR
Non-Refinery	Internal Combustion Engines (Non-Refinery/Non-Power Plant)	3	16 SCRs
Non-Refinery	Turbines (Non-Refinery/Non-Power Plant)	7	13 SCRs and 1 SCR replacement
		TOTAL	**114 to 117 SCRs** **7 to 8 LoTOx™ with WGSs** **1 LoTOx™ without WGS** **0 to 3 UltraCat DGSs**

* Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs.

^ Since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74.

4.1.3.1 Potential Aesthetics Impacts During Construction

Implementation of the proposed project could potentially result in construction activities at 20 NOx RECLAIM facilities, which are complex industrial facilities. The physical changes that are expected focus on the installation of new or the modification of existing control equipment for the following stationary sources of NOx: 1) FCCUs; 2) refinery boilers and heaters; 3) refinery gas turbines; 4) SRU/TGUs; 5) non-refinery/non-power plant gas turbines; 6) non-refinery sodium silicate furnaces; 7) non-refinery/non-power plant ICEs; 8) container glass melting furnaces; 9) coke calcining; and, 10) metal heat treating furnaces.

Due to the large size profiles of the affected equipment involved, the construction activities that may be associated with installing new or modifying existing NOx control equipment are expected to require the use of heavy-duty construction equipment, such as cranes, tractor/loader/backhoes, forklifts, et cetera. The use of cranes, in particular, because of their height when fully extended, may be visible to the surrounding areas and temporarily change the skyline of the affected facilities, depending on where they are located within each facility's property. Except for the use of cranes, the majority of the construction equipment is expected to be low in height and not substantially visible to the surrounding area due to existing fencing along the property lines and existing structures currently within the facilities that would buffer the views of the construction activities.

Because each affected facility is located in heavy industrial areas, the construction equipment is not expected to be substantially discernable from what exists on-site for routine operations and maintenance activities. Further, the construction activities are not expected to adversely impact views and aesthetics resources since most of the heavy equipment and activities are expected to occur within the confines of each existing facility and are expected to introduce only minor visual changes to areas outside each facility, if at all, depending on the location of the construction activities within the facility.

Lastly, the construction activities are expected to be temporary in nature and will cease following completion of the equipment installation or modifications. All construction equipment will be removed following completion of the proposed project. For these reasons, the construction activities are not expected to substantially degrade the existing visual character or quality of each affected site and the surroundings of each affected site. Thus, adverse visual continuity aesthetics impacts during construction are expected to be less than significant.

4.1.3.2 Aesthetics Mitigation During Construction

Less than significant adverse impacts associated with aesthetics are expected from the proposed project during construction, so no mitigation measures are required.

4.1.3.3 Remaining Aesthetics Impacts During Construction After Mitigation

The aesthetics analysis concluded that potential aesthetics impacts during construction would be less than significant, no mitigation measures were required. Thus, aesthetics impacts during construction remain less than significant.

4.1.3.4 Potential Aesthetics Impacts During Operation

Of the technologies proposed as BARCT for NOx control, only WGS technology was identified as having the potential to generate adverse aesthetic operational impacts. WGS technology is potentially BARCT for two FCCUs, five SRU/TGUs and one coke calciner.

SCRs, Ultracat DGSs, and LoTOx^{TM} technology without a WGS, if installed (or modified) and operated, would be expected to blend in with the existing industrial profile at the affected facilities because the heights of these units are typically smaller when compared to neighboring existing equipment onsite at a refinery and their associated stack heights would be about the same or shorter than existing stacks within the affected facilities. However, operation of one WGS is expected to generate a substantial, continuous steam plume that is white in appearance. A steam plume is generated as the result of using water to reduce particulate emissions in the WGS, and consists of water vapor and clean, but warm flue gas in the exit stream of the scrubber. As a result of atmospheric changes in temperature and humidity, the vapor plume is expected to be smaller on warm, dry days and larger on cool, damp days. Under certain atmospheric conditions, the steam plume from a WGS could extend as much as 1,500 feet in length from a relatively high flue gas stack at approximately 200 feet above grade. As the vapor travels away from the stack, the plume will eventually evaporate and become clear.

As a point of comparison, other equipment operating at these industrial facilities routinely generate steam plumes on a similar scale as part of their day-to-day operations (e.g., cooling towers, cogeneration plants, etc.). In addition, the refineries, which operate the FCCUs, SRU/TGUs, and coke calciner, are located near the Ports of Los Angeles and Long Beach whose facilities, such as the Harbor Cogeneration Plant and the Long Beach SERRF, routinely generate multiple steam plumes.

The Philips 66 Refinery in Wilmington recently installed a WGS to reduce NOx and PM10 emissions from their FCCU. The potential adverse aesthetics impacts were analyzed for this project in the Final Environmental Impact Report for the ConocoPhillips Los Angeles Refinery PM10 and NOx Reduction Projects[1]. The aesthetics analysis acknowledged that while the steam plume from the WGS would be visible, it was not expected to adversely affect the visual continuity of the surrounding area and none of the significance criteria were expected to be exceeded.

Further, in 2010, a similar aesthetics analysis relative to multiple WGSs and their associated steam plumes was also conducted in the Final Program Environmental Assessment prepared for the amendments to the SOx RECLAIM program[2]. This analysis in the SOx RECLAIM Final PEA also came to the same less than significant aesthetics impact conclusion as the Final EIR for the ConocoPhillips Los Angeles Refinery PM10 and NOx Reduction Projects, except that the SOx RECLAIM Final PEA assumed that up to as many as 11 WGSs could be installed.

For these reasons, if any WGS is installed as part of the proposed project at any of the affected facilities and even if all eight WGSs are installed, each steam plume, though visible, would not be expected to significantly adversely affect the visual continuity of the surrounding area of each affected facility because no scenic highways or corridors exist within the areas of the refineries. Further, the visual continuity of the surrounding area is

[2] SCAQMD, Final Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), SCH No. 2009061088, SCAQMD No. 06182009BAR, certified November 5, 2010. http://www.aqmd.gov/docs/default-source/ceqa/documents/aqmd-projects/2010/final-program-environmental-assessment-for-proposed-amended-regulation-xx.pdf?sfvrsn=4

not expected to be adversely impacted because each WGS, if constructed, will be built within the confines of industrial areas and would be visually consistent with the profiles of the existing affected facilities. Thus, even if each WGS could be visible, depending on the location within each property boundary, the aesthetic significance criteria would not be exceeded.

Overall, the aesthetics impacts are expected to be less than significant during operation for the proposed project.

4.1.3.5 Aesthetics Mitigation During Operation

Less than significant adverse impacts associated with aesthetics are expected from the proposed project during operation, so no mitigation measures are required.

4.1.3.6 Remaining Aesthetics Impacts During Operation After Mitigation

The aesthetics analysis concluded that potential aesthetics impacts during operation would be less than significant, no mitigation measures were required. Thus, aesthetics impacts during operation remain less than significant.

4.1.4 Cumulative Aesthetic Impacts

Because the project-specific aesthetic impacts do not exceed any applicable significance thresholds either during construction or operation, they are not considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, do not generate significant adverse cumulative aesthetics impacts.

4.1.5 Cumulative Mitigation Measures

Because the project-specific aesthetic impacts during construction and operation are not considered to be cumulatively considerable, no cumulative mitigation measures are required.

AIR QUALITY AND GREENHOUSE GASES

Introduction

Significance Criteria

Potential Air Quality Impacts and Mitigation Measures

Cumulative Air Quality Impacts

Cumulative Mitigation Measures

Greenhouse Gas Impacts

Greenhouse Gas Mitigation Measures

4.2 AIR QUALITY AND GREENHOUSE GASES

The proposed amended regulation will require facilities to collectively lower their emissions, thus improving air quality in the long term in order to meet the project's objectives. However, the installation of air pollution control equipment as a result of implementing the proposed project could potentially result in air quality and greenhouse gas (GHG) impacts. The air quality and GHG analysis in this PEA identifies the net effect of air quality and GHG impacts from implementing the proposed project.

4.2.1 Introduction

As previously summarized in Table 4.0-2, the proposed project is expected to result in the installation of the following new NOx air pollution control equipment for the top NOx emission equipment/source categories. The equipment/source categories are divided into two sectors: refinery and non-refinery. There are nine facilities in the refinery sector and 11 facilities in the non-refinery sector. For both sectors, individual facilities were evaluated to determine the number and type of NOx control devices that may be installed as a result of implementing the proposed project. Reducing NOx emissions from the affected facilities will provide an air quality benefit in the near- and long-term. Direct air quality impacts from the proposed project are expected to result in a reduction of NOx at the affected facilities, which will provide air quality and human health benefits to the public. However, installing new or modifying existing air pollution control equipment is expected to have potentially adverse air quality and GHG impacts.

The environmental analysis assumes that installation of NOx control technologies for the affected sources will reduce NOx emissions overall, but construction activities associated with both the installation of new control devices and the modification of existing control devices will create secondary air quality impacts (e.g., emissions), which can adversely affect local and regional air quality. A project may generate emissions both during the period of its construction and through ongoing daily operations. During installation or modification of add-on air pollution control devices, emissions may be generated by onsite construction equipment and by offsite vehicles used for worker commuting. After construction activities are completed, emissions may be generated by the operation of the add-on air pollution control devices (as GHGs) and offsite vehicles used for delivering fresh materials needed for operations (e.g., chemicals, fresh catalyst, etc.) and hauling away solid waste for disposal or recycling (e.g., spent catalyst). The analysis of these impacts can be found in Section 4.2.3. Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs. Further, since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74. Thus, the analysis in this PEA for the refinery sector is conservative as it overestimates the potential adverse air quality and GHG impacts. Refer to Appendix E for the calculations used to estimate secondary construction- and operational-related air quality impacts.

4.2.2 Significance Criteria

To determine whether air quality and GHG impacts from adopting and implementing the proposed project are significant, impacts will be evaluated and compared to the following criteria. If impacts exceed any of the significance thresholds in Table 4.2-2, they will be considered significant. All feasible mitigation measures will be identified in Section 4.2.3 and implemented to reduce significant impacts to the maximum extent feasible. The SCAQMD makes significance determinations for construction impacts based on the maximum or peak daily emissions during the construction period, which provides a "worst-case" analysis of the construction emissions. Similarly, significance determinations for operational emissions are based on the maximum or peak daily allowable emissions during the operational phase.

The proposed project will have significant adverse air quality impacts if any one of the thresholds in Table 4.2-2 are equaled or exceeded.

4.2.3 Potential Air Quality Impacts and Mitigation Measures

Table 4.2-1 summarizes the estimated number of NOx emission control devices per sector and per equipment/source category. The different types of control devices include Selective Catalytic Reduction (SCR), a proprietary Low Temperature Oxidation technology (LoTOx™) with or without a Wet Gas Scrubber (WGS), and catalyst impregnated filters with a Dry Gas Scrubber (UltraCat DGS). In total, the proposed project is expected to result in the installation of the following new NOx air pollution control equipment: up to 117 SCRs, eight LoTOx™ with WGSs, one LoTOx™ without WGS, and three UltraCat DGSs.

Table 4.2-1
Estimated Number of NOx Control Devices Per Sector and Equipment/Source Category

Sector	Equipment/Source Category	Number of Affected Facilities	Estimated Number of Control Devices
Refinery	Fluid Catalytic Cracking Units (FCCUs)	5	2 SCRs 2 LoTOx™ with WGSs* 1 LoTOx™ without WGS
Refinery	Refinery Process Heaters and Boilers	8	74 SCRs^
Refinery	Refinery Gas Turbines	5	7 SCRs
Refinery	Sulfur Recovery Unit / Tail Gas Units (SRU/TGUs)	5	5 LoTOx™ with WGSs 1 SCR
Refinery	Petroleum Coke Calciner	1	1 LoTOx™ with WGS or 1 UltraCat with DGS
Non-Refinery	Container Glass Melting Furnaces	1	2 SCRs or 1 UltraCat with DGS
Non-Refinery	Sodium Silicate Furnaces	1	1 SCR or 1 UltraCat with DGS
Non-Refinery	Metal Heat Treating Furnaces	1	1 SCR
Non-Refinery	Internal Combustion Engines (Non-Refinery/Non-Power Plant)	3	16 SCRs
Non-Refinery	Turbines (Non-Refinery/Non-Power Plant)	7	13 SCRs and 1 SCR replacement
		TOTAL	**114 to 117 SCRs** **7 to 8 LoTOx™ with WGSs** **1 LoTOx™ without WGS** **3 UltraCat DGSs**

* Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs.

^ Since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74.

4.2.3.1 Construction Analysis

Construction-related emissions can be distinguished as either onsite or offsite. Onsite emissions generated during construction principally consist of exhaust emissions (NOx, SOx, CO, VOC, PM2.5 and PM10) from heavy-duty construction equipment operation, fugitive dust (primarily as PM10) from disturbed soil, and VOC emissions from asphaltic paving and painting. Offsite emissions during the construction phase normally consist of exhaust emissions and entrained paved road dust (primarily as PM10) from worker commute trips, material delivery trips, and haul truck material trips to and from the construction site. In general, limited construction emissions from site preparation activities, which may include earthmoving/grading, are anticipated because the sites, typically, have already been graded and paved. Further, operators at each affected facility who construct NOx control equipment that utilize chemicals as part of the NOx control equipment operations, such as a new ammonia or caustic storage tank, may also need to build a containment berm large enough to hold 110 percent of the tank capacity in the event of an accidental release, pursuant to U.S. EPA's spill prevention control and countermeasure regulations.

The space limitations within each affected facility have been evaluated and each facility was determined to have sufficient space to install new NOx control equipment or modify existing NOx control equipment. However, because installation of larger NOx air pollution control equipment such as a new scrubber (WGS or DGS), may need to occupy the space of previous equipment, demolition activities were assumed to occur prior to the equipment installation to remove any existing equipment or structures (as applicable), remove the old piping and electrical connections, and break up the old foundation with a demolition hammer. For these reasons, digging, earthmoving, grading, slab pouring, or paving activities are anticipated and were analyzed.

The type of construction-related activities attributable to installing new NOx control equipment or modifying existing NOx control equipment would consist predominantly of deliveries of steel, piping, wiring, chemicals, catalysts, and other materials, and would also involve maneuvering the materials within the site via a variety of off-road and on-road equipment such as a crane, forklift et cetera or haul truck, respectively. If a new foundation is not needed, to establish footings or structure supports, some concrete cutting and digging may be necessary in order to re-pour new footings prior to building above the existing foundation.

Non-Refinery Facilities

Of the 275 facilities subject to the NOx RECLAIM Rules, there are currently 206 facilities that belong to the non-refinery sector. SCAQMD staff conducted an analysis of the potential feasibility and cost-effectiveness of adding controls to reduce NOx from all of these facilities. This analysis found that it would be both feasible and cost-effective for only 11 non-refinery facilities to install air pollution controls. However, for all other non-refinery facilities, because of the lack of feasible of cost-effective controls, operators of the remaining non-refinery facilities will comply with their NOx shave through the purchase of RTCs which will have no environmental impact.

In 2011, the 11 non-refinery facilities emitted approximately 2.82 tons per day or 14 percent of the total NOx emitted from facilities in the RECLAIM program. These facilities include the following equipment/source categories: container glass melting furnaces, glass melting furnace facilities, sodium silicate furnaces, metal heat treating furnaces, stationary ICEs and non-power plant stationary gas turbines. As stated previously, under the proposed project, operators of these facilities could potentially install SCR technology or UltraCat filtration units to reduce NOx emissions. For the purpose of conducting a worst-case analysis, 34 SCR units and one UltraCat filtration unit are assumed to be installed at the 11 non-refinery affected facilities. It is possible that another UltraCat filtration unit may also be installed instead of one of the 34 SCR units.

Ammonia or urea is necessary to operate SCR and UltraCat filtration technology, and tanks to store these chemicals would also need to be installed. The size of each ammonia tank needed to operate the SCR units and one UltraCat filtration unit have been estimated to range between 600 and 10,000 gallons in capacity. If a second UltraCat filtration unit is installed in lieu of one of the 34 SCR units, two 300 gallon ammonia portable totes instead of one ammonia storage tank would be needed[3]. Also, since an adsorbent would be needed to operate the second UltraCat unit, a 5,000-cubic foot hydrated lime silo would be needed. Because the non-refinery affected facilities are existing facilities, it was assumed that no more than one acre of area would need to be disturbed at a single facility at a given time. Construction was assumed to consist of four phases: 1) demolition; 2) site preparation; 3) paving; and, 4) building of the emission control units along with supporting devices and structures. A list of the construction equipment expected to be needed for each construction phase at a single non-refinery affected facility is presented in Table 4.2-3 below.

It is important to note that six of the non-refinery affected facilities have space restrictions that could limit mobility throughout the facility, and these same six facilities could potentially install more than one SCR unit. As such, the analysis assumes that the same amount of construction equipment would be used at these facilities, but that the construction duration would be extended over a longer period of time.

Construction emissions associated with installing air pollution control equipment at each of the 11 non-refinery facilities were estimated using the California Emission Estimator Model (CalEEMod). To allow for enough lead time needed to procure contracts and order equipment, construction is expected to begin in 2016 and, depending on the facility, construction could last over a year. Table 4.2-4 presents the peak daily emissions from construction activities to install control equipment at one facility. To conduct a conservative analysis, overlapping construction activities were assumed to occur at all 11 of the non-refinery facilities. Table 4.2-5 presents the peak daily emissions if construction occurs simultaneously at all 11 non-refinery facilities.

[3] For a worst-case analysis, the impacts from a second UltraCat unit have been included in the calculations.

Refinery Facilities

There are nine refinery facilities subject to the NOx RECLAIM rules whose operators may choose to install NOx air pollution control equipment in response to the proposed project. These facilities include the following equipment/source categories: FCCUs, SRU/TGUs, coke calciner, refinery boilers and heaters, and refinery gas turbines. As summarized in Table 4.2-6, several types of NOx control technology may be installed on the various equipment/source categories operating at the nine affected refinery sector facilities.

Table 4.2-6

Estimated Number of NOx Control Devices to be Installed at 9 Refinery Facilities

Sector	Equipment/Source Category	Number of Affected Facilities*	Estimated Number of NOx Control Devices
Refinery	FCCUs	5	2 SCRs 2 LoTOx™ with WGSs* 1 LoTOx™ without WGS
Refinery	Refinery Process Heaters and Boilers	8	74 SCRs^
Refinery	Refinery Gas Turbines	5	7 SCRs
Refinery	SRU/TGUs	5	5 LoTOx™ with WGSs 1 SCR
Refinery	Petroleum Coke Calciner	1	1 LoTOx™ with WGS or 1 UltraCat with DGS
		TOTAL	**84 SCRs** **8 LoTOx™ with WGSs** **1 LoTOx™ without WGS** **1 UltraCat DGS**

~~*~~ Note: While the total number of affected facilities for the refinery sector is nine, there is an overlap for all of the equipment/source categories except the petroleum coke calciner.

* Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs.

^ Since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74.

The overall objective of the proposed project is to reduce NOx emissions. However, in consideration of the complexity involved with operating FCCUs, SRU/TGUs, refinery boilers/heaters, coke calciners, and gas turbines, the equipment operators utilize a combination of various emission control equipment and techniques to control not only NOx, but other pollutants such as SOx, CO, PM10, PM2.5, and ammonia slip, as applicable, while maintaining overall efficiency. As there is no way to fully predict on a case-by-case basis what each facility operator will do to comply with the proposed project, the estimates in this CEQA analysis are based on the estimates provided in the ~~Preliminary~~ Draft Staff Report (which are based on information reported by the refineries in the survey and information from the control device manufacturers as well as the consultant reports prepared for each affected facility) combined with the assumptions applied in the previous CEQA documents which analyzed similar equipment in both the 2005 amendments to NOx RECLAIM and the 2010 amendments to SOx RECLAIM. Further, if a particular technology was identified as having a cost that exceeds $50,000 per ton, this CEQA analysis assumed that the facility operator would not install this type of air pollution control technology in response to the project.

For the purpose of conducting a worst-case analysis, 84 SCR units, eight LoTOx^{TM} with WGSs, one LoTOx^{TM} without a WGS, and one UltraCat DGS are assumed to be installed at the nine refinery sector facilities. In order to operate SCR and UltraCat technology, ammonia is necessary and, as such, tanks to store ammonia would also need to be installed. The size of each ammonia tank needed to operate the SCR units and one UltraCat filtration unit have been estimated to range between 2,000 and 11,000 gallons in capacity. The UltraCat filtration unit that was analyzed for the coke calciner would also need to utilize hydrated lime (Ca(OH)2) as an adsorbent. Further, three LoTOx^{TM} with WGSs for two FCCUs and one coke calciner may need to utilize sodium hydroxide (NaOH) to capture emissions. As such, tanks to store the hydrated lime and sodium hydroxide would also need to be installed.

Because the amount of plot space that may be needed to install one or more NOx control devices at any of the affected facilities would not exceed one acre, no more than one acre of area would need to be disturbed at a single facility at a given time. Construction was assumed to consist of two phases: 1) demolition; and 2) construction to install the air pollution control devices units along with supporting devices and structures. In addition, for facilities that will need to install tanks to store ammonia or sodium hydroxide, a site preparation phase was also included to account for building a containment berm as part of installing a storage tank.

A list of the anticipated construction equipment needed to install one SCR for either a refinery boiler/heater or refinery gas turbine at one refinery facility is presented in Table 4.2-7. A list of the anticipated construction equipment needed to install one SCR for one FCCU is presented in Table 4.2-8. Finally, a list of the anticipated construction equipment needed to install one scrubber, either WGS or DGS, for one refinery facility is presented in Table 4.2-9.

There are multiple source categories with multiple approaches to reducing NOx at the refinery facilities. With so many possibilities or permutations of how operators of the refinery could achieve actual NOx reductions, there is no way to predict what each facility operator will actually do. For this reason, the analysis illustrates the worst-case effects of applying the various NOx control technologies to each affected refinery facility. As a result, the construction emissions were calculated for each of the nine refineries.

From a construction point of view, the installation of a NOx control technology at a refinery is a complex process. For example, if a facility operator chooses to install NOx control equipment, time will be needed for pre-construction/advance planning activities such as engineering analysis of the affected equipment, engineering design of the potential control equipment, contracting with a vendor, securing financing, ordering and purchasing the equipment, obtaining permits and clearances, and scheduling contractors and workers. The amount of lead time can vary from six months (e.g., for a SCR for refinery/boiler heater or gas turbine) to up to 18 months for a scrubber (either a WGS or DGS).

Then to physically build the equipment, an additional six to 18 months would be needed. For example, six months would be needed to construct one SCR for one refinery boiler/ heater or gas turbine, 12 months would be needed to construct a SCR for a FCCU, and up to 18 months would be needed to construct a scrubber (either a WGS or DGS) for a FCCU or SRU/TGU. Where the new equipment will be sited will determine if any demolition activities would be required. For this analysis for a scrubber installation, to be conservative, one month of demolition activities is assumed to occur at each affected facility and an additional 17 months is assumed for site preparation, assembly and installation of the unit and ancillary support equipment, preparation of the affected unit for a turnaround/shutdown, and tying-in the new scrubber to the affected equipment.

For any facility operator that plans to undergo construction to install NOx control equipment, and prior to receiving any permit to construct from the SCAQMD, a site-specific CEQA analysis in addition to this PEA may also be necessary depending on how much construction (i.e., demolition, site grading, etc.) would be involved and if the analysis varies from the assumptions in this document. For these reasons, the timing of constructing all of the possible NOx controls equipment is conservatively estimated to overlap for each refinery facility, at the earliest in 2016 because of the lead time that will be needed for most of types of NOx control projects contemplated in this PEA. This means that any on-road or off-road emission factors applied to calculate construction and operational impacts will conservatively be for equipment fleet year 2016 even though it is likely that all of the refinery facilities would begin construction activities well after 2016. While the NOx shave begins in 2016 with a four ton per year reduction in RECLAIM Trading Credits (RTCs), the available NOx RTCs continue to be reduced in two ton increments until 2022. In addition, the decision when construction would commence between 2016 and 2022 for refinery facilities in particular is also dependent upon the turnaround schedule of the affected equipment. Once construction of the control equipment is completed, it will need to be "tied-in" to the main equipment prior to start-up which typically occurs during a scheduled turnaround period.

To conduct a conservative "worst-case" analysis, this document examines the possibility that the facility operators will install NOx control equipment, including but not limited to exhaust stacks, cooling units, injection support equipment for catalyst, caustic, or sorbents including the associated storage vessels, associated piping designs, pumps, plus other ancillary equipment, as applicable. As a practical matter, construction activities that are anticipated to occur as a result of implementing the proposed project would likely occur prior to a scheduled maintenance (e.g., turnaround) of the affected unit.

Typically construction projects have staggered construction schedules which take into account design and engineering, ordering, purchasing and delivery of equipment, permitting and environmental review, the availability of construction crews, budgeting, and any other construction projects on site. However, due to wide range of construction time necessary to build the various types of NOx control equipment, the construction activities at other affected facilities could overlap. However, because of widely varying turnaround schedules of affected equipment within any given facility and based on past construction projects involving major construction equipment where the SCAQMD was the lead agency, the analysis in this PEA includes a conservative assumption that all of the refineries will have overlapping construction activities occurring in one year. However, since having all facilities construct all NOx controls within the first year is unlikely, for demonstrative purposes, the analysis also includes an analysis of the overlapping impacts spread out over a five- and seven-year period.

Table 4.2-10 presents the peak daily emissions from construction activities to install control equipment at each of the nine refinery facilities. To conduct a conservative analysis, overlapping construction activities were assumed to occur at all nine of the refinery facilities. Table 4.2-11 presents the peak daily emissions if construction spanning a five year period between 2016 and 2020 occurs at all nine refinery facilities. Finally, Table 4.2-12 presents the peak daily emissions if construction spanning a seven-year period between 2016 and 2022 occurs at all nine refinery facilities.

Combined Construction Emissions From Non-Refinery and Refinery Facilities

As explained previously, due to the inability to predict if and when each operator of a non-refinery and a refinery facility alike would choose to install control equipment as a consequence to implementing the proposed project, the analysis conservatively assumes that construction activities within each of the non-refinery facilities and refinery facilities could overlap beginning in 2016.

Table 4.2-13 presents the peak daily emissions from construction activities to install control equipment at all 20 facilities (e.g., 11 non-refinery facilities plus 9 refinery facilities) and conservatively assumes that the overlapping construction activities will occur in the same year. However, since the operators of refinery facilities will need sufficient time to conduct advanced planning and financing for their capital improvement projects, it is likely that only minimal, if any, construction activities would occur at any refinery facilities during 2016. To account for the construction fluctuations that may occur, Tables 4.2-14 and 4.2-15 presents the peak daily emissions if construction occurs at all 20 facilities and spans a five year period between 2016 and 2020 and a seven-~~-~~year period between 2016 and 2022, respectively.

For the simultaneous construction of NOx control equipment at non-refinery and refinery facilities for construction all in the same year or for construction spread out over five years, the calculations show the total daily construction emissions exceed the SCAQMD's CEQA air quality significance thresholds for NOx, VOCs, CO, PM10, and PM2.5. For the simultaneous construction of NOx control equipment at non-refinery and refinery facilities for construction spread out over seven years, the calculations show the total daily construction emissions exceed the SCAQMD's CEQA air quality significance thresholds for NOx, PM10 (unmitigated), and PM2.5 (unmitigated and mitigated). Appendix E contains the spreadsheets with the results, assumptions, and methodologies used by the SCAQMD staff for this analysis.

With regard to odors, currently, for all diesel-fueled construction equipment and vehicles, the diesel fuel is required to have a low sulfur content (e.g., 15 ppm by weight or less) in accordance with SCAQMD Rule 431.2 – Sulfur Content of Liquid Fuels. Because the operation of the construction equipment for both non-refinery and refinery facilities will occur within the confines of existing affected facilities, sufficient dispersion of diesel emissions over distance generally occurs such that odors associated with diesel emissions may not be discernable to offsite receptors, depending on the location of the equipment and its distance relative to the nearest offsite receptor. Further, construction worker vehicles and delivery trucks onsite as a part of construction activities will not be allowed to idle longer than five minutes per any one location in accordance with the CARB idling regulation, so odors from these vehicles would not be expected. Thus, the proposed project is not expected to create significant adverse objectionable odors during construction. Since no significant impacts were identified for this issue, no mitigation measures for odors are necessary or required.

4.2.3.2 Construction Mitigation

The VOC, NOx, CO, PM10, and PM2.5 emissions for construction occurring in the same year and for construction spread out over five years exceed the applicable significance thresholds during construction. The NOx, PM10, and PM2.5 emissions for construction spread out over seven years also exceed the applicable significance thresholds during construction. As a result, the proposed project is expected to have significant adverse construction air quality impacts. If significant adverse environmental impacts are identified in a CEQA document, the CEQA document shall describe feasible measures that could minimize the significant adverse impacts (CEQA Guidelines §15126.4). Mitigation measures focus on the construction emissions of VOC, NOx, CO, PM10 and PM2.5 emissions. Therefore, feasible mitigation measures to reduce emissions associated with construction activities at the affected facilities are necessary to control emissions from heavy construction equipment and worker travel.

The following construction mitigation measures are required for each of the affected facilities whose operators choose to install NOx control equipment. If, at the time when each facility-specific project is proposed in response to the proposed project, SCAQMD staff will conduct a CEQA evaluation of the facility-specific project and determine if the project is covered by the analysis in this PEA. In addition, these mitigation measures will be included in a mitigation monitoring plan as part of issuing SCAQMD permits to construct for the facility-specific project. The mitigation measures will be enforceable by SCAQMD personnel.

<u>On-Road Mobile Sources</u>

AQ-1 Develop a Construction Emission Management Plan for each affected facility to minimize emissions from vehicles including, but not limited to: consolidating truck deliveries; scheduling deliveries to avoid peak hour traffic conditions; describing truck routing; describing deliveries including logging delivery times; describing entry/exit points; identifying locations of parking; identifying construction schedule; and prohibiting truck idling in excess of five consecutive minutes or another time-frame as allowed by the California Code of Regulations, Title 13 §2485 - CARB's Airborne Toxic Control Measure to Limit Diesel-Fueled Commercial Motor Vehicle Idling. The Construction Emission Management Plan shall be submitted to SCAQMD CEQA for approval prior to the start of construction. At a minimum the Construction Emission Management Plan would include the following types of mitigation measures.

<u>Off-Road Mobile Sources:</u>

AQ-2 Maintain construction equipment tuned to manufacturer's recommended specifications that optimize emissions without nullifying engine warranties.

AQ-3 The project proponent shall survey and document the proposed project's construction areas and identify all construction areas that are served by electricity. This documentation shall be provided as part of the Construction Emissions Management Plan.

AQ-4 For all construction areas that are demonstrated to be served by electricity, use electricity for on-site mobile equipment instead of diesel equipment to the extent feasible. For example, electric welders should be used in lieu of diesel or gasoline-fueled welders and onsite electricity should be used in lieu of temporary power generators. If electricity is not available, use alternative fuels where feasible.

AQ-5 ~~Construction equipment shall incorporate, where feasible, emissions-reducing technology such as hybrid drives and specific fuel economy standards~~

~~AQ-6~~ All off-road diesel-powered construction equipment greater than 50 hp shall meet Tier-4 off-road emission standards at a minimum. In addition, if not already supplied with a factory-equipped diesel particulate filter, all construction equipment shall be outfitted with Best Available Control Technology (BACT) devices certified by CARB. Any emissions control device used by the contractor shall achieve emissions reductions that are no less than what could be achieved by a Level 3 diesel emissions control strategy for a similarly sized engine as defined by CARB regulations. Construction equipment shall incorporate, where feasible, emissions-reducing technology such as hybrid drives and specific fuel economy standards. In the event that any equipment required under this mitigation measure is not available, the project proponent shall provide documentation in the Construction Emissions Management Plan or associated subsequent status reports as information becomes available.

AQ-6~~7~~ Suspend use of all construction activities that generate air pollutant emissions during first stage smog alerts as defined in SCAQMD Rule 701.

If, at the time when each facility-specific project is proposed in response to the proposed project, that improved emission reduction technologies become available for on- and off-road construction equipment, as part of the CEQA evaluation for the facility-specific project, the construction mitigation measures will be updated accordingly.

4.2.3.3 Remaining Construction Impacts After Mitigation

The air quality analysis concluded that significant adverse construction air quality impacts could be created by the proposed project because future construction activities, either for construction occurring in the same year or over a five year period, indicate that emissions from NOx, VOC, CO, PM10, and PM2.5 would exceed the SCAQMD's applicable significance thresholds for the respective pollutants. The air quality analysis also concluded that significant adverse construction air quality impacts could be created by the proposed project because future construction activities occurring over a seven-~~–~~year period indicate that emissions from NOx, PM10, and PM2.5 would exceed the SCAQMD's applicable significance thresholds for the respective pollutants.

Since it is expected that construction activities may occur as a consequence of implementing the proposed project, construction air quality impacts were concluded to be significant. In spite of implementing the above mitigation measures, construction air quality impacts would likely remain significant. Thus, because the proposed project overall has the potential to generate significant adverse air quality impacts for construction, even after applying mitigation, a Statement of Findings and a Statement of Overriding Considerations will be prepared for the Governing Board's consideration and approval prior to the public hearing for the proposed project.

4.2.3.4 Operation Analysis

Implementation of the proposed project is expected to result in direct air quality benefits from the reduction of 14 tons per day of NOx RTCs by 2022. Because of the RECLAIM market system, the actual reduction in NOx emissions each year may be less than the reduction in RTC holdings imposed by the project. However, emissions may be generated by the operation of the add-on air pollution control devices (as GHGs) due to increased electricity and water use, increased wastewater disposal, and amortized GHG emissions from construction. In addition, emissions of criteria pollutants and GHGs may be generated from offsite vehicles used for delivering fresh materials needed for operations (e.g., chemicals, fresh catalyst, etc.) and for hauling away solid waste for disposal or recycling (e.g., spent catalyst). Finally, since SCR technology utilizes ammonia, a Toxic Air Contaminant (TAC), some emissions of ammonia slip are expected for operation of SCR units.

Non-Refinery Facilities

The operation of each air pollution control device that may be installed at the 11 non-refinery facilities is not expected to generate criteria pollutant emissions but rather to lessen the amount of NOx generated by the existing equipment/emission sources. However, secondary criteria pollutant emissions are expected to be generated as part of operation activities associated with operating and maintaining the air pollution control equipment after it is installed. In particular, the following activities may be sources of secondary criteria pollutant emissions during operation: 1) vehicle trips via heavy-duty truck for periodic ammonia/urea deliveries for each SCR and Ultracat filtration unit installed; 2) vehicle trips via heavy-duty truck for periodic deliveries of absorbent, catalyst, and replacement filters as well as solid waste hauling of spent filters for each Ultracat filtration unit installed. A summary of these heavy-duty truck trips are presented in Table 4.2-16.

Table 4.2-16

Heavy-Duty Truck Trips at 11 Non-Refinery Facilities

Heavy-Duty Truck Trips	NH3/Urea Delivery Trips[1]	Adsorbent Delivery Trips [1,2]	Solid Waste Haul Trips[1]	Filter Waste Haul Trips[1]	Catalyst Delivery Trips[3]	Total Trips
Annual	437	5	11	1	11	465
Peak Daily	11	1	1	1	11	25

[1] Peak daily trips assumed one ammonia/urea delivery occurs at each non-refinery facility and adsorbent, solid waste and filter waste haul trips occurs on the same day.

[2] Adsorbent, solid waste and filter waste based on vendor estimates for SOx portion of Ultracat system.

[3] Only five catalyst delivery trips are expected because catalysts are replaced every two to three years.

Secondary operational emissions from the 11 non-refinery facilities were estimated using EMFAC2011 emission factors. In addition to heavy-duty truck trips, that analysis assumes that one medium-duty round-trip for control system maintenance personnel may be needed for each of the 11 non-refinery facilities. Based on the locations of disposal sites and ammonia suppliers relative to the locations of the affected facilities, default truck trip distances were assumed to be 80 miles round-trip, except that truck trip distances to deliver ammonia were assumed to be 100 miles round-trip.

As analyzed in Subchapter 4.3 (Energy), the add-on air pollution control devices anticipated to be installed pursuant to the proposed project will require electricity to operate. A total increase in energy demand of 45,344 kWh/day (or 45.3 MWh/day) for 11 non-refinery facilities (see Table 4.3-8 in Subchapter 4.3 – Energy) is estimated, thus requiring an increase in electricity generation from the electric generating utility local to the affected facility due to the proposed project. Because affected facilities are located throughout the SCAQMD jurisdiction, it is not possible to determine which specific utility will be impacted. However, utilities typically operate either combined cycle turbines (*assembly of heat engines that work in tandem from the same source of heat*) or simple cycle turbines (*one power cycle with no provision for waste heat recovery*). Because they are less efficient, the simple cycle turbine has higher emission factors so tend to generate higher criteria pollutant emissions. Thus, for a "worst-case" impact scenario and due to the unknown source of electricity generation, the simple cycle turbine emission factors (provided in the footnote to Table 4.2-17) are used to estimate criteria pollutant impact from operation of the air pollution control devices.

Secondary operational emissions from the non-refinery affected facilities are presented in Table 4.2-17.

Table 4.2-17
Peak Daily Operational Emissions from 11 Non-Refinery Facilities

Source	**No of Trips**	**Distance** (round trip miles/day)	**VOC** (lb/day)	**CO** (lb/day)	**NOx** (lb/day)	**SOx** (lb/day)	**PM10** (lb/day)	**PM2.5** (lb/day)

Medium-Duty Truck	11	80	0.29	1.40	8.58	0.02	0.37	0.23
Electric Generation[4]	--	--	0.91	3.63	4.08	--	2.72	2.69
		TOTAL	**2**	**9**	**37**	**0.07**	**5**	**4**
		Significance Threshold	55	550	55	150	150	55
		Exceed Significance?	**NO**	**NO**	**NO**	**NO**	**NO**	**NO**

As explained in Chapter 2 of this PEA, SCR and Ultracat filtration systems reduce NOx emissions by using ammonia, which is a toxic air contaminant (TAC). Unreacted ammonia emissions generated from these units are referred to as ammonia slip. Ammonia slip is limited to five parts per million (ppm) by permit condition. Based on the June 2015 Staff Report for SCAQMD Rule 1401.1 – Requirements for New and Relocated Facilities Near Schools, and SCAQMD Rule 1402 – Control of Toxic Air Contaminants from Existing Sources, the concentration at a receptor located 25 meters from a stack would be much less than one percent of the concentration at the release from the exit of the stack. Thus, the

4 Simple Cycle Turbine Emission Factors: NOx (0.09 lbs/MWh); CO (0.08 lbs/MWh); VOC (0.02 lbs/MWh); PM10 (0.06 lbs/MWh) - *Example Calculation*: NOx: 0.09 lbs/MWh x 45.3 MWh = 4.08 lbs

peak concentration of ammonia at a receptor located 25 meters from a stack is calculated by assuming a dispersion of one percent. While ammonia does not have an OEHHA approved cancer potency value, it does have non-carcinogenic chronic (200 µg/m^3) and acute (3,200 µg/m^3) reference exposure levels (RELs). Table 4.2-18 summarizes the calculated non-carcinogenic chronic and acute hazard indices for ammonia and compared these values to the respective significance thresholds; both were shown to be less than significant.

Table 4.2-18

Health Risk from the Non-Refinery Facilities Using Ammonia

Ammonia Slip Concentration at the Exit of the Stack (ppm)	**Peak Concentration at a Receptor 25 m from the Stack** (µg/m^3)	**Acute REL** (µg/m^3)	**Chronic REL** (µg/m^3)	**Acute Hazard Index**	**Chronic Hazard Index**
5	35	3,200	200	**0.01**	**0.17**
		Significance Threshold		**1.0**	**1.0**
		Exceed Significance?		**NO**	**NO**

Even if multiple SCRs are installed at one non-refinery facility, the locations of all the stacks would not be situated in the same place within the affected facility's property. As such, even with multiple SCR installations, the acute and chronic hazard indices would not be expected exceed the significance threshold.

The peak number of heavy-duty truck trips that may occur at one non-refinery facility (Facility 8) in one year is 149. Heavy-duty trucks are prohibited from idling for more than five minutes at any one location, but they can move to multiple locations and idle at each location for up to five minutes. Thus, for a conservative analysis, the analysis assumes that the trucks may idle for up to a total of 15 minutes per trip. Therefore, a peak of approximately 37 hours of idling may occur at one facility in one year. The CARB emission factor for an idling heavy-duty truck is 1.67 grams per hour of diesel particulate matter. Therefore, 6.88×10^{-5} ton of diesel particulate exhaust per year would be generated per year at an affected non-refinery facility. Based on the Tier II methodology described in the SCAQMD Risk Assessment Procedures for Rules 1401, 1401.1 and 212, Version 8.0 dated June 5, 2015, 6.88×10^{-5} ton of diesel particulate exhaust per year would generate a health risk of 1.5 in one million, which is less than the significance threshold of an increased probability of 10 cancer cases in one million.

<u>Refinery Facilities</u>

The operation of each air pollution control device that may be installed at the nine refinery facilities is also not expected to generate criteria pollutant emissions but rather to lessen the amount of NOx generated by the existing equipment/emission sources. However, as with the analysis for the non-refinery facilities, secondary criteria pollutant emissions are expected to be generated as part of operation activities associated with operating and maintaining the air pollution control equipment after it is installed. In particular, the following activities may be sources of secondary criteria pollutant emissions during operation: 1) vehicle trips via heavy-duty truck for periodic deliveries of ammonia for each

SCR installed, NaOH for three LoTOx™ WGSs installed, hydrated lime for two Ultracat DGSs installed, and oxygen for every LoTOx™ unit installed; 2) vehicle trips via heavy-duty truck for periodic deliveries of catalyst and replacement filters as well as solid waste hauling of spent filters for each SCR unit installed; and 3) via heavy-duty truck hauling solid waste generated by each scrubber (WGS and DGS) installed. A summary of these heavy-duty truck trips are presented in Table 4.2-19.

Table 4.2-19

Heavy-Duty Operational Truck Trips at 9 Refinery Facilities

	Number of Heavy-Duty Truck Trips								
	NH3[1]	**NaOH[1]**	**Hydrated Lime[1]**	**Soda Ash[1]**	**Oxygen [1]**	**Fresh Catalyst[2]**	**Solid Waste[1]**	**Spent Catalyst[2]**	**TOTAL**
Annual	498	56	26	21	44	49	96	49	839
Peak Daily	17	3	1	4	1	16	7	16	65

[1] Peak daily trips assumed one heavy-duty truck trip occurs at each refinery facility for each chemical delivery or waste/spent catalyst haul trip.

[2] SCR fresh catalyst delivery trips are expected when the SCR is first built and then replaced every five years. Similarly, spent catalyst waste is also generated every five years.

Secondary operational emissions from the nine refinery facilities were estimated using EMFAC2011 emission factors. Based on the locations of disposal sites and chemical suppliers relative to the locations of the affected refineries, default round-trip truck distances were assumed to be: 1) 200 miles for solid waste hauling; 2) 50 miles for soda ash deliveries; 3) 100 miles for ammonia deliveries; 4) 100 miles for fresh catalyst deliveries; 5) 100 miles for spent catalyst hauling; 6) 66.2 miles for hydrated lime deliveries; 7) 50 miles for NaOH deliveries; and, 8) 50 miles for oxygen deliveries.

As previously discussed for non-refinery facilities, Subchapter 4.3 (Energy) analyzed potential energy demand from the operation of add-on air pollution control devices anticipated to be installed pursuant to the proposed project. A total increase in energy demand for 9 refinery facilities is 168,170 kWh/day (or 168.2 MWh/day) (see Table 4.3-7 in Subchapter 4.3 – Energy), thus requiring an increase in electricity generation from the local power plants servicing the affected facilities due to the proposed project. Because affected facilities are located throughout the SCAQMD jurisdiction, it is not possible to determine which specific utility will be impacted. Similar to the calculations conducted for the non-refinery facilities (see Table 4.2-17), the simple cycle turbine emission factors (see footnote for Table 4.2-20) are used to estimate criteria pollutant impact from the operation of the air pollution control devices at the 9 refinery facilities because simple cycle turbine emission factors are higher than combined cycle turbine emission factors. By doing so, the air quality analysis is based on a "worst-case" impact scenario.

Secondary operational emissions from the refinery affected facilities are presented in Table 4.2-20.

Table 4.2-20
Peak Daily Operational Emissions from 9 Refinery Facilities

Vehicle Type	**No of Trips**	**Distance** (round trip miles/day)	**VOC** (lb/day)	**CO** (lb/day)	**NOx** (lb/day)	**SOx** (lb/day)	**PM10** (lb/day)	**PM2.5** (lb/day)
Heavy-Duty Truck	65	8,166	11.86	53.12	138.04	0.33	6.93	5.69
Electric Generation[5]	--	--	3.36	13.45	15.14	--	10.09	9.89
		TOTAL	**15**	**67**	**153**	**0**	**17**	**16**
		Significance Threshold	55	550	55	150	150	55
		Exceed Significance?	**NO**	**NO**	**YES**	**NO**	**NO**	**NO**

Emission sources associated with the operational-related activities as a result of implementing the proposed project may emit toxic air contaminants (TACs). For example, as explained in Chapter 2 of this PEA, SCR and Ultracat filtration systems reduce NOx emissions by using ammonia, which is a TAC. Unreacted ammonia emissions generated from these units are referred to as ammonia slip. Ammonia slip is limited to five parts per million (ppm) by permit condition. Based on the June 2015 Staff Report for SCAQMD Rule 1401.1 – Requirements for New and Relocated Facilities Near Schools, and SCAQMD Rule 1402 – Control of Toxic Air Contaminants from Existing Sources, the concentration at a receptor located 25 meters from a stack would be much less than one percent of the concentration at the release from the exit of the stack. Thus, the peak concentration of ammonia at a receptor located 25 meters from a stack is calculated by assuming a dispersion of one percent. While ammonia does not have an OEHHA approved cancer potency value, it does have non-carcinogenic chronic (200 $\mu g/m^3$) and acute (3,200 $\mu g/m^3$) reference exposure levels (RELs). Table 4.2-21 summarizes the calculated non-carcinogenic chronic and acute hazard indices for ammonia and compared these values to the respective significance thresholds; both were shown to be less than significant.

Table 4.2-21
Health Risk from Refinery Facilities Using Ammonia

Ammonia Slip Concentration at the Exit of the Stack (ppm)	**Peak Concentration at a Receptor 25 m from the Stack** ($\mu g/m^3$)	**Acute REL** ($\mu g/m^3$)	**Chronic REL** ($\mu g/m^3$)	**Acute Hazard Index**	**Chronic Hazard Index**
5	35	3,200	200	**0.01**	**0.2**
		Significance Threshold		**1.0**	**1.0**
		Exceed Significance?		**NO**	**NO**

[5] Simple Cycle Turbine Emission Factors: NOx (0.09 lbs/MWh); CO (0.08 lbs/MWh); VOC (0.02 lbs/MWh); PM10 (0.06 lbs/MWh) - *Example Calculation*: NOx: 0.09 lbs/MWh x 168.2 MWh = 15.14 lbs

Even if multiple SCRs are installed at one refinery facility, the locations of all the stacks would not be situated in the same place within the affected facility's property. As such, even with multiple SCR installations, the acute and chronic hazard indices would not be expected exceed the significance threshold.

In addition, diesel particulate matter from the exhaust of diesel-fueled heavy duty trucks is also a TAC. The analysis estimates that a peak of 147 heavy-duty truck trips may occur at a single facility in one year (e.g., at Facility 6). Heavy-duty trucks are expected to idle for up to 15 minutes per trip. Therefore, up to 37 hours of idling may occur at a single facility. The CARB emission factor for an idling heavy-duty truck is 1.67 grams per hour of diesel particulate matter. Therefore, a peak of 6.78×10^{-5} ton of diesel particulate exhaust per year would be generated at one refinery facility. Based on the Tier II methodology described in the SCAQMD Risk Assessment Procedures for Rules 1401, 1401.1 and 212, Version 8.0 dated June 5, 2015, 6.78×10^{-5} ton of diesel particulate exhaust per year would generate a health risk of 1.5 in one million, which is less than the significance threshold of an increased probability of 10 cancer cases in one million.

Lastly, caustic may be used in the operation of three WGSs. With the potential for the installation of eight WGSs that utilize caustic, a maximum of eight caustic storage tanks may be installed. There are several types of caustic solutions that can be used in WGS operations, but sodium hydroxide (NaOH) is the most commonly used. Due to facility-specific information about their respective processes, three facilities are estimated to install three WGSs (one each) that utilize NaOH. NaOH is a TAC that is a non-cancerous but acutely hazardous substance. For "worst-case" operations, 5.84 tons per day of NaOH (50 percent solution, by weight) is estimated to be needed to operate three WGSs. Again, due to facility-specific information about their respective processes, the remaining five of the eight facilities that were assumed to install WGSs were projected to have an increased demand in caustic that is made of sodium carbonate (Na2CO3) which is commonly known as soda ash, a non-toxic, non-cancerous, and non-hazardous substance.

Even though the facilities that may be affected by the proposed project may already use NaOH elsewhere in their facilities, for the purpose of conducting a "worst-case" construction analysis, one 10,000 gallon storage tank for caustic solution was assumed to be constructed for each WGS installed. Thus, for three WGSs, three 10,000 gallon NaOH storage tanks was assumed to be constructed. As summarized in Table 4.2-22, for each facility that was projected to increase the use in the acutely hazardous substance NaOH, the filling loss and the working loss of each NaOH tank were calculated, added together, and that sum was compared to the most stringent Rule 1401 Screening Emission Level for NaOH (0.004 pounds per hour at the nearest receptor distance of 25 meters).

Table 4.2-22
Summary of Filling and Working Losses for NaOH Storage Tanks

Facility ID	Projected Increase in NaOH Demand (tons/day)	A: Hourly NaOH (as PM10) Filling Loss (lb/hr)	B: Hourly NaOH (as PM10) Working Loss (lb/hr)	A + B = Total Hourly NaOH (as PM10) Losses (lb/hr)	NaOH Acute Screening Level at 25 meters (lb/hr)	Do Total Hourly Losses Exceed Acute Screening Level For NaOH? (Yes/No)	Significant?
2	3.37	7.60E-04	2.28E-03	3.04E-03	4.00E-03	NO	NO
4	0.45	1.01E-04	3.04E-04	4.06E-04	4.00E-03	NO	NO
9	2.02	4.57E-04	1.37E-03	1.83E-03	4.00E-03	NO	NO
Total	**5.84**						

None of the total hourly loss projections exceeded the acute screening level for NaOH for any of the affected facilities. It is important to note that the toxics analysis is a localized analysis and because of the distances between the affected facility locations, the NaOH emission impacts would not overlap. Thus, because the screening level for NaOH was not exceeded for either of the affected facilities, no significant air quality operational impacts with respect to the use of NaOH are expected from the proposed project. NaOH is not classified as a carcinogen, so a cancer risk analysis was not performed.

Combined Operation Emissions From Both Non Refinery and Refinery Facilities

Table 4.2-23 presents the peak daily emissions from operating control equipment at all 20 facilities (e.g., 11 non-refinery facilities plus nine refinery facilities) at full build out.

Table 4.2-23
Peak Daily Overlapping Non-Refinery and Refinery Emissions
from Operating Various NOx Control Equipment in Same Year

Operation Activity	**VOC** (lb/day)	**CO** (lb/day)	**NOx** (lb/day)	**SOx** (lb/day)	**PM10** (lb/day)	**PM2.5** (lb/day)

TOTAL	**17**	**75**	**-17,350 ~~17,390~~**	**0.4**	**22**	**19**
Significance Threshold	55	550	55	150	150	55
Exceed Significance?	**NO**	**NO**	**NO**	**NO**	**NO**	**NO**

* A negative number denotes an emission *reduction* (or benefit to air quality)

The calculations show the total daily operation emissions due to delivery and haul trips and electricity generation exceed the SCAQMD's CEQA air quality significance threshold of 55 pounds of NOx per day. However, because there will be an overall reduction in NOx emissions of 8.77~~8.79~~ tons per day (or ~~17,580~~ 17,540 pounds ~~lbs~~ per day) during the operational phase due to the operation of NOx air pollution control equipment, the net NOx emissions impact will result in an overall reduction in NOx emissions creating an air quality benefit. Appendix E contains the spreadsheets with the results, assumptions, and methodologies used by the SCAQMD staff for this analysis.

With regard to odors currently, for all diesel-fueled vehicles that may be utilized during operation activities at both non-refinery and refinery facilities, the diesel fuel is required to have a low sulfur content (e.g., 15 ppm by weight or less) in accordance with SCAQMD Rule 431.2 – Sulfur Content of Liquid Fuels. Because the deliveries of supplies and the removal of solid waste for both non-refinery and refinery facilities will occur within the confines of existing affected facilities, sufficient dispersion of diesel emissions over distance generally occurs such that odors associated with diesel emissions may be discernable to offsite receptors, depending on the location of the equipment and its distance relative to the nearest offsite receptor. Further, the use of diesel-fueled trucks as part of operation activities will not be allowed to idle longer than fifteen minutes at the affected facilities once onsite, so odors from these vehicles would not be expected. Thus, the proposed project is not expected to create significant adverse objectionable odors during operation. Since no significant impacts were identified for this issue, no mitigation measures are necessary or required.

4.2.3.5 Operation Mitigation

The analysis indicates that there will be an overall reduction in NOx emissions during the operational phase of the proposed project. Further, no other pollutant emissions exceed the applicable significance thresholds during operation for the proposed project. Thus, because there are no significant adverse air quality impacts with the operational phase of the proposed project, no air quality mitigation measures are required.

4.2.3.6 Remaining Operation Impacts After Mitigation

The air quality analysis concluded that potential operational air quality impacts would be less than significant, no mitigation measures were required, so operational air quality impacts remain less than significant.

4.2.4 Cumulative Air Quality Impacts

In general, the preceding analysis concluded that air quality impacts from construction activities would be significant from implementing the proposed project because the SCAQMD's significance thresholds for construction will be exceeded before mitigation for VOC, NOx, CO, PM10, and PM2.5. After mitigation, VOC, NOx, CO, PM10, and PM2.5emissions will also exceed the SCAQMD's significance thresholds for construction. Thus, the air quality impacts due to construction are considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, generate significant adverse cumulative air quality impacts. It should be noted, however, that the air quality analysis is a conservative, "worst-case" analysis so the actual construction impacts are not expected to be as great as estimated here. Further, the construction activities are temporary when compared to the permanent projected long-term emission reductions of NOx as a result of the proposed project.

The analysis also indicates that, in addition to the overall reduction in NOx emissions, the proposed project will result in less than significant increases of VOC, CO, NOx, PM10 and PM2.5 emissions during the operational phase of the proposed project. Because operational emissions do not exceed the project-specific air quality significance thresholds, which also serve as the cumulative significance thresholds, they are not considered to be cumulatively considerable (CEQA Guidelines §15064 (h)(1)). Further, the amount of emission reductions to be achieved by the proposed project for NOx will, at the very least, meet the emission reduction projections and commitments made in the AQMP. Even though the proposed project will cause a temporary and significant adverse increase in air emissions during the construction phase and less than significant increases in air emissions during the operation phase, the temporary net increase in construction emissions combined with the total permanent emission reductions projected overall during operation would not interfere with the air quality progress and attainment demonstration projected in the AQMP. Further, based on regional modeling analyses performed for the 2012 AQMP, implementing control measures contained in the 2012 AQMP, in addition to the air quality benefits of the existing rules, is anticipated to bring the District into attainment with all national and most state ambient air quality standards by the year 2023. Therefore, cumulative operational air quality impacts from the proposed project, previous amendments and all other AQMP control measures considered together, are not expected to be significant because implementation of all AQMP control measures is expected to result in net emission reductions and overall air quality improvement. This determination is consistent with the conclusion in the 2012 AQMP Final Program EIR that cumulative air quality impacts from all AQMP control measures are not expected to be significant (SCAQMD, 2012). Therefore, there will be no significant cumulative adverse operational air quality impacts from implementing the proposed project.

Though the proposed project involves combustion processes which could generate GHG emissions such as CO2, CH4, and N2O, the proposed project does not affect equipment or operations that have the potential to emit other GHGs such as SF6, HFCs or PFCs. Relative to GHGs, implementing the proposed project is expected to increase GHG emissions that exceed the SCAQMD's GHG significance threshold for industrial sources. In addition, implementing the proposed project is expected to generate significant adverse cumulative GHG air quality impacts. The GHG analysis for the proposed project can be found in the Section 4.2.6 – Greenhouse Gas Impacts.

4.2.5 Cumulative Mitigation Measures

The analysis indicates that, in addition to the overall reduction in NOx emissions, the proposed project will result in less than significant increases of VOC, CO, NOx, PM10 and PM2.5 emissions during the operational phase of the proposed project. However, no pollutant emissions exceed the applicable significance thresholds during operation for the proposed project. Thus, there are no adverse significant cumulative air quality impacts with the operational phase of the proposed project and as such, no cumulative mitigation measures for operation are required.

The analysis also indicates that the VOC, NOx, CO, PM10, and PM2.5 emissions will exceed the applicable significance thresholds during construction. As a result, the proposed project is expected to have significant cumulative adverse construction air quality impacts. Mitigation measures that focus on the VOC, NOx, CO, PM10, and PM2.5 emissions that may be generated during construction are required to minimize the significant air quality impacts associated with construction activities. Therefore, feasible mitigation measures to reduce emissions associated with construction activities at the affected facilities are necessary to control emissions from heavy construction equipment and worker travel. While the mitigation measures may reduce emissions associated with construction activities at the affected facilities to the maximum extent feasible, none will avoid the significant impact or reduce the impact to less than significant.

The following construction mitigation measures are required for each of the affected facilities whose operators choose to install NOx control equipment. If, at the time when each facility-specific project is proposed in response to the proposed project, SCAQMD staff will conduct a CEQA evaluation of the facility-specific project and determine if the project is covered by the analysis in this PEA. In addition, these mitigation measures will be included in a mitigation monitoring plan as part of issuing SCAQMD permits to construct for the facility-specific project. The mitigation measures will be enforceable by SCAQMD personnel.

<u>On-Road Mobile Sources</u>

AQ-1 Develop a Construction Emission Management Plan for each affected facility to minimize emissions from vehicles including, but not limited to: consolidating truck deliveries; scheduling deliveries to avoid peak hour traffic conditions; describing truck routing; describing deliveries including logging delivery times; describing entry/exit points; identifying locations of parking; identifying construction schedule; and prohibiting truck idling in excess of five consecutive minutes or another time-frame as allowed by the California Code of Regulations, Title 13 §2485 - CARB's Airborne Toxic Control Measure to Limit Diesel-Fueled Commercial Motor Vehicle Idling. The Construction Emission Management Plan shall be submitted to SCAQMD CEQA for approval prior to the start of construction. At a minimum the Construction Emission Management Plan would include the following types of mitigation measures.

<u>Off-Road Mobile Sources:</u>

AQ-2 Maintain construction equipment tuned to manufacturer's recommended specifications that optimize emissions without nullifying engine warranties.

AQ-3 The project proponent shall survey and document the proposed project's construction areas and identify all construction areas that are served by electricity. This documentation shall be provided as part of the Construction Emissions Management Plan.

AQ-4 For all construction areas that are demonstrated to be served by electricity, use electricity for on-site mobile equipment instead of diesel equipment to the extent feasible. For example, electric welders should be used in lieu of diesel or gasoline-fueled welders and onsite electricity should be used in lieu of temporary power generators. If electricity is not available, use alternative fuels where feasible.

AQ-5 ~~Construction equipment shall incorporate, where feasible, emissions-reducing technology such as hybrid drives and specific fuel economy standards~~

~~AQ-6~~ All off-road diesel-powered construction equipment greater than 50 hp shall meet Tier-4 off-road emission standards at a minimum. In addition, if not already supplied with a factory-equipped diesel particulate filter, all construction equipment shall be outfitted with Best Available Control Technology (BACT) devices certified by CARB. Any emissions control device used by the contractor shall achieve emissions reductions that are no less than what could be achieved by a Level 3 diesel emissions control strategy for a similarly sized engine as defined by CARB regulations. Construction equipment shall incorporate, where feasible, emissions-reducing technology such as hybrid drives and specific fuel economy standards. In the event that any equipment required under this mitigation measure is not available, the project proponent shall provide documentation in the Construction Emissions Management Plan or associated subsequent status reports as information becomes available.

AQ-6~~7~~ Suspend use of all construction activities that generate air pollutant emissions during first stage smog alerts.

If, at the time when each facility-specific project is proposed in response to the proposed project, that improved emission reduction technologies become available for on- and off-road construction equipment, as part of the CEQA evaluation for the facility-specific project, the construction mitigation measures will be updated accordingly.

4.2.6 Greenhouse Gas Impacts

Significant changes in global climate patterns have recently been associated with global warming, an average increase in the temperature of the atmosphere near the Earth's surface, attributed to accumulation of GHG emissions in the atmosphere. GHGs trap heat in the atmosphere, which in turn heats the surface of the Earth. Some GHGs occur naturally and are emitted to the atmosphere through natural processes, while others are created and emitted solely through human activities. The emission of GHGs through the combustion of fossil fuels (i.e., fuels containing carbon) in conjunction with other human activities, appears to be closely associated with global warming. State law defines GHG to include the following: carbon dioxide (CO2), methane (CH4), nitrous oxide (N2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF6) (HSC §38505(g)). The most common GHG that results from human activity is CO2, followed by CH4 and N2O.

Traditionally, GHGs and other global warming pollutants are perceived as solely global in their impacts and that increasing emissions anywhere in the world contributes to climate change anywhere in the world. A study conducted on the health impacts of CO2 "domes" that form over urban areas cause increases in local temperatures and local criteria pollutants, which have adverse health effects[6].

The analysis of GHGs is a different analysis than the analysis of criteria pollutants for the following reasons. For criteria pollutants, the significance thresholds are based on daily emissions because attainment or non-attainment is primarily based on daily exceedances of applicable ambient air quality standards. Further, several ambient air quality standards are based on relatively short-term exposure effects on human health (e.g., one-hour and eight-hour standards). Since the half-life of CO2 is approximately 100 years, for example, the effects of GHGs occur over a longer term which means they affect the global climate over a relatively long time frame. As a result, the SCAQMD's current position is to evaluate the effects of GHGs over a longer timeframe than a single day (i.e., annual emissions). GHG emissions are typically considered to be cumulative impacts because they contribute to global climate effects. GHG emission impacts from implementing the proposed project were calculated at the project-specific level during construction and operation. For example, installation of NOx control equipment has the potential to increase the use of electricity, fuel, and water and the generation of wastewater which will in turn increase CO2 emissions.

The SCAQMD convened a "Greenhouse Gas CEQA Significance Threshold Working Group" to consider a variety of benchmarks and potential significance thresholds to evaluate GHG impacts. On December 5, 2008, the SCAQMD adopted an interim CEQA GHG Significance Threshold for projects where SCAQMD is the lead agency (SCAQMD, 2008). This interim threshold is set at 10,000 metric tons of CO2 equivalent emissions (MTCO2eq) per year. The SCAQMD prepared a "Draft Guidance Document – Interim CEQA GHG Significance Thresholds" that outlined the approved tiered approach to determine GHG significance of projects (SCAQMD, 2008, pg. 3-10). The first two tiers involve: 1) exempting the project because of potential reductions of GHG emissions allowed under CEQA; and, 2) demonstrating that the project's GHG emissions are consistent with a local general plan. Tier 3 proposes a limit of 10,000 MTCO2eq per year as the incremental increase representing a significance threshold for projects where SCAQMD is the lead agency (SCAQMD, 2008, pg. 3-11). Tier 4 (performance standards) is yet to be developed. Tier 5 allows offsets that would reduce the GHG impacts to below the Tier 3 brightline threshold. Projects with incremental increases below this threshold will not be cumulatively considerable.

As indicated in Chapter 3, combustion processes generate GHG emissions in addition to criteria pollutants. The following analysis mainly focuses on directly emitted CO2 because this is the primary GHG pollutant emitted during the combustion process and is the GHG pollutant for which emission factors are most readily available. CO2 emissions were estimated using emission factors from CARB's EMFAC2011 and OFFROAD2011 models and USEPA's AP-42.

[6] Jacobsen, Mark Z. "Enhancement of Local Air Pollution by Urban CO2 Domes," Environmental Science and Technology, as describe in Stanford University press release on March 16, 2010 available at: http://news.stanford.edu/news/2010/march/urban-carbon-domes-031610.html.

In addition, CH4 and N20 emissions were also estimated and are included in the overall GHG calculations. No other GHGs are expected to be emitted because the proposed project does not affect equipment or operations that have the potential to emit other GHGs such as SF6, HFCs or PFCs.

Installation of NOx control equipment as part of implementing the proposed project is expected to generate construction-related CO2 emissions. In addition, based on the type and size of equipment affected by the proposed project, CO2 emissions from the operation of the NOx control equipment are likely to increase from current levels due to using electricity, fuel and water and generating more wastewater. The proposed project will also result in an increase of GHG operational emissions produced from additional truck hauling and deliveries necessary to accommodate the additional solid waste generation and increased use of chemicals and supplies.

For the purposes of addressing the potential GHG impacts of the proposed project, the overall impacts of CO2e emissions from the project were estimated and evaluated from the earliest possible initial implementation of the proposed project with construction beginning in 2016. Once the proposed project is fully implemented, the potential NOx emission reductions would continue through the end of the useful life of the equipment. The analysis estimated CO2e emissions from all sources subject to the proposed project (construction and operation) from the beginning of the proposed project (2016) to the end of the project (2022). The beginning of the proposed project was assumed to be no sooner than 2016, since installing NOx control equipment takes considerable advance planning and engineering. Full implementation of the proposed project is expected to occur by the end of 2022 when the entire 14 tons per day of the NOx RTC shave is completed such that any installed or modified NOx controls could be constructed and operational by this final date. Thus, once construction is complete and the equipment is operational, CO2e emissions will remain constant.

GHG emissions from the 11 non-refinery and nine refinery facilities were quantified by applying the same assumptions used to quantify the criteria pollutant emissions. The only exception is that the construction GHG emissions were amortized over a 30-year project life in accordance with the guidance provided in the Interim CEQA GHG Significance Threshold for Stationary Sources, Rules and Plans[7] that was adopted by the SCAQMD Governing Board in December 2008.

For the non-refinery facilities, approximately 325 amortized[8] metric tons per year (MT/year) of GHGs (as carbon dioxide equivalent emissions or CO2e) would be generated from construction-related activities that may occur at the affected non-refinery facilities in response to implementing the proposed project. Similarly, approximately 77 MT/year of GHG emissions would be generated from operation-related activities (e.g., truck trips) that may occur at the non-refinery facilities in response to implementing the proposed project. The generation of electricity needed to operate the air pollution control devices is calculated based on the assumption a simple

[7] Interim CEQA GHG Significance Threshold for Stationary Sources, Rules and Plans, http://www.aqmd.gov/docs/default-source/ceqa/handbook/greenhouse-gases-(ghg)-ceqa-significance-thresholds/ghgattachmente.pdf?sfvrsn=2

[8] To amortize GHGs from temporary construction activities over a 30-year period (*est. life of the project/ equipment*), the amount of CO2e emissions during construction are calculated and then divided by 30.

cycle turbine is increasing operation to fulfill additional demand. Simple cycle turbines have higher emission factors than combined cycle turbines so the results are more "worst case." Based on the energy needs from non-refinery facilities at 45.3 MWh/day (see Table 4.3-8 in Subchapter 4.3 – Energy), the GHG emissions from electric generation is 7,866 MT/year[9]. It should be noted that unlike refinery facilities, the control equipment at non-refinery facilities do not generate water demand or wastewater, thus are not included in the GHG calculations.

In total, 8,268 MT/year of GHG emissions would be generated by construction and operation activities at the 11 non-refinery facilities, should these facility operators choose to install NOx control technology in response to the proposed project. The total amount of GHG emissions that may be generated from operation activities at all affected non-refinery facilities is less than the GHG significance threshold of 10,000 MT/year.

In addition, for the nine refinery facilities, approximately 1,373 amortized MT/year of GHGs as CO2e would be generated from construction-related activities that may occur at the affected refinery facilities in response to implementing the proposed project. Similarly, approximately 194 MT/year of GHG emissions would be generated from operation-related activities (e.g., truck trips) that may occur at the refinery facilities in response to implementing the proposed project. Further, because WGSs utilize water and generate wastewater during operation, GHG emissions may be created from the increased use of water and the increased generation of wastewater from WGS operation activities. As such, approximately 813 MT/yr of CO2e from increased water use and 319 MT/year of CO2e from increased wastewater generation would be expected if WGSs are installed and operated as a result of implementing the proposed project. Lastly, because operation of all of the NOx control technologies require electricity, approximately 30,818 MT/year of CO2e may be generated if all refinery facilities install NOx control equipment. In total, 33,517 MT/year of CO2e emissions would be generated by construction and operation activities occurring at the nine refinery facilities, should these facility operators choose to install NOx control technology in response to the proposed project. The total amount of GHG emissions that may be generated from operation activities at refinery facilities is greater than the GHG significance threshold of 10,000 MT/year and thus, would be considered a significant adverse GHG emissions impact.

Table 4.2-24 summarizes the unmitigated CO2e impacts from both construction activities and operation activities per refinery facility.

[9] Simple cycle turbine GHG emission factor: 1,049 lbs/MWhr
Calculation: 1,049 lbs/MWhr x 45.3 MWhr/day x 365 days/year ÷ 2,205 MT/lbs = 7,866 MT/year

Table 4.2-24

[1] 1 metric ton = 2,205 pounds
[2] GHGs from temporary construction activities are amortized over 30 years.

It is important to note that none of the affected facilities individually exceed the industrial GHG significance threshold of 10,000 MT/day. However, the GHG emissions from the refinery sector exceed the threshold and therefore, the proposed project is considered to have adverse significant GHG impacts for the refinery sector.

After combining the GHG emissions from the non-refinery and refinery sectors, in total, 41,785 MT/year of CO2e emissions would be generated by construction and operation activities occurring at all 11 of the non-refinery facilities and nine refinery facilities, should these facility operators choose to install NOx control technology in response to the proposed project. Thus, the overall GHG emissions from combining both sectors exceed the GHG significance threshold and therefore, the proposed project is considered to have significant adverse GHG impacts.

Because the proposed project is expected to generate construction-related CO2 emissions, and the operational phase of the proposed project is also expected to generate additional GHG emissions, adverse significant GHG cumulative impacts from the proposed project are expected. If significant adverse environmental impacts are identified in a CEQA document, the CEQA document shall describe feasible measures that could minimize the significant adverse impacts (CEQA Guidelines §15126.4). Mitigation measures focus on the GHG emissions. Therefore, feasible mitigation measures to reduce GHG emissions at the affected facilities are necessary.

4.2.7 Greenhouse Gas Mitigation Measures

If the proposed project is implemented, the analysis indicates that there will be a significant increase in GHG emissions. Because adverse significant GHG impacts are expected from the proposed project, feasible GHG mitigation measures are required. While none of the affected facilities individually exceed the industrial GHG significance threshold of 10,000 MT/day, individual facilities may be able to offset their increases in GHG emissions through CARB's AB 32 cap-and-trade program. Cap-and-trade is a market-based regulation that is designed to reduce GHGs from multiple sources by setting a firm limit or cap on GHGs and minimize the compliance costs of achieving AB 32 goals. The cap will decline approximately three percent each year from 2015 to 2020. Every year, facilities in the cap-and-trade program turn in allowances and offsets for 30 percent of previous year's GHG emissions. Also, for each compliance period, facilities in the cap-and-trade program turn in allowances and a limited number of offsets to cover the remainder of emissions in that compliance period. Finally, if the compliance deadline is missed or there is a shortfall, four allowances must be provided for every ton of emissions that was not covered in time. All nine refineries and 10 out of the 11 non-refinery facilities that may be affected by the proposed project are in the CARB's AB 32 cap-and-trade program for GHGs, so their GHG emissions, including any individual facility increases from the proposed project would be covered under that program.

For the one facility that is not in CARB's AB 52 cap-and-trade program (e.g., Facility 9), GHG emissions could potentially be mitigated through purchasing reductions via SCAQMD Regulation XXVII – Climate Change, which created the SoCal Climate Solutions Exchange. The SoCal Climate Solutions Exchange is a voluntary program where facilities in the district can undertake projects to voluntarily reduce GHG emissions in advance of any regulatory requirement. GHG mitigation measures for industrial sources are under development but there are some existing GHG reducing protocols that have been approved or adopted by various organizations and some of these are already used in the SCAQMD's SoCal Climate Solutions Exchange. In order to participate in the exchange, the GHG reductions need to be real, additional (surplus), quantifiable, verifiable, permanent over a specific time, and enforceable. These early reductions can be helpful to facilities that would need offsets for GHG mitigation.

In addition, the California Climate Action Registry (CCAR) is currently developing the following protocols: 1) bus rapid transit; 2) blended cement; 3) tidal wetland sequestration (farms converting to wetlands). CCAR is also evaluating several categories for potential protocol development, including waste diversion, local government operations, boiler efficiency; and truck stop electrification. CCAR has been asked to look at other areas, such as waste water biogas, natural gas pipelines, agricultural soil sequestration, and CO2 capture and storage, and those will be evaluated in the future.

In addition, the California Air Pollution Control Officers Association (CAPCOA) has suggested that lead agencies develop a "Green List of Projects" (Green List) to be consistent with and achieve the goals of AB 32 and to encourage projects that can provide overall GHG emission reduction benefits. Of the Green List projects, especially in consideration that compliance with the proposed project could result in the installation of water-intensive scrubbers, recycled water projects and the utilization of recycled water seem to be among the most direct ways to mitigate GHG emissions for the proposed project. Specifically, the energy it would take to treat and convey reclaimed water to a facility (e.g., 1,200 kWh/MMgallons[10]) is approximately 10 times less than the amount of energy it would take for potable water (e.g., 12,700 kWh/MMgallons[11]) to be supplied, conveyed and distributed. Thus, for each facility that will have future access to recycled water and uses reclaimed wastewater to satisfy the water demands for the proposed project and in turn, mitigate CO2eq emissions, less GHG emissions would be generated for the operational water use/conveyance and operational wastewater generation portions of the proposed project.

Based on the preceding discussion, the following mitigation measures will apply to any facility whose operator chooses to install NOx control equipment that utilizes water for its operation. If, at the time when each facility-specific project is proposed in response to the proposed project, SCAQMD staff will conduct a CEQA evaluation of the facility-specific project and determine if the project is covered by the analysis in this PEA. In addition, these mitigation measures will be included in a mitigation monitoring plan as part of issuing SCAQMD permits to construct for the facility-specific project. The mitigation measures will be enforceable by SCAQMD personnel.

GHG-1 When NOx control equipment is installed and water is required for its operation, the facility operator is required to use recycled water, if available, to satisfy the water demand for the NOx control equipment.

GHG-2 In the event that recycled water cannot be delivered to the affected facility, the facility operator is required ~~to use their best efforts~~ to submit a written declaration with the application for a Permit to Construct for the NOx control equipment, to be signed by an official of the water purveyor indicating the reason(s) why recycled water cannot be supplied to the project.

Tables 4.2-25 summarizes the mitigated CO2e impacts from both construction activities and operation activities per refinery facility and shows that if mitigation for water and wastewater is applied to Refineries 1, 5 and 6 should they utilize recycled water, a savings of GHG emissions of 685 MT/year may occur. It is important to note that none of the NOx control equipment contemplated for the non-refinery sector utilize water or would generate wastewater. Thus, utilizing recycled water to mitigate GHG emissions from the proposed project would only apply to certain refinery facilities whose operators choose to install NOx control equipment that utilize water (e.g., WGSs).

[1] 1 metric ton = 2,205 pounds
[2] GHGs from temporary construction activities are amortized over 30 years.

As demonstrated in Tables 4.2-24 and 4.2-25, none of the affected refinery facilities individually exceed the GHG industrial significance threshold of 10,000 MT/yr before or after mitigation. However, the GHG emissions from the project as a whole exceed the GHG threshold both before and after mitigation. Therefore, the proposed project is considered to have adverse significant GHG impacts after mitigation. Because the proposed project is expected to generate construction-related CO2e emissions, and the operational phase of the proposed project is also expected to generate additional GHG emissions, cumulative GHG adverse impacts after mitigation from the proposed project are considered significant.

While there may be additional measures that could eventually be imposed upon sources with potential increases in GHG emissions, CARB is adopting measures pursuant to AB 32 that would require the maximum technically feasible and cost-effective GHG emission reductions from most of the industry categories affected by the proposed project. CEQA Guidelines §15364 defines "feasible" as "capable of being accomplished in a successful manner within a reasonable period of time…" For example, CARB has adopted a Low Carbon Fuel Standard for motor vehicle fuels. In October 2010, CARB has also adopted a GHG reduction cap and trade program that will apply to projects that will need to receive permits, including any projects that may occur as a result of amending the NOx RECLAIM program. CARB GHG reduction measures are required to "achieve the maximum technologically feasible and cost-effective greenhouse gas reductions from sources or categories of sources" (Health and Safety Code §38560). CARB has published two scoping plans, as required by Health and Safety Code §38561, that identifies additional measures CARB intends to adopt that will reduce GHG emissions. The scoping plan is required to identify measures that will achieve "the maximum feasible and cost-effective reductions of greenhouse gas emissions by 2020." (Health and Safety Code §38561 (b)).

All CARB GHG measures are required to meet the "maximum feasible and cost-effective" reductions test. This test is equally as stringent as the CEQA definition of "feasible." Given that CARB has been working on this statutory mandate for several years, and has an entire office and staff devoted to GHG rulemaking, it would not be feasible for SCAQMD staff to develop generally applicable GHG reduction measures that go beyond CARB measures. Thus, application of CARB rules will require the maximum feasible GHG reductions for existing sources.

EPA has stated that because there is no national ambient air quality standard for CO2, or any of the other primary GHGs, and EPA does not plan to promulgate any, the "nonattainment" NSR program that applies to criteria pollutants will not apply to GHGs[12]. However, for a NSR program that applies to attainment pollutants, prevention of significant deterioration (PSD) will also apply. PSD applies to any "major stationary source" of pollutants subject to regulation under the federal CAA. Accordingly, because EPA has promulgated its GHG reduction rules for motor vehicles, GHGs is a pollutant that is subject to regulation under the federal Clean Air Act. EPA has issued its interpretation that GHGs become regulated pollutants as of the time the motor vehicle rule becomes effective (i.e., January 2011). SCAQMD staff concluded at the time that it would not be feasible to begin requiring GHG BACT prior to January 2011, because it would be necessary to amend the agency's rules in order to do so.

EPA promulgated its GHG PSD rule requiring several "steps." In Step 1, which began on January 2, 2011, only facilities that would already be subject to Title V or PSD would be subject to GHG requirements under these programs. In addition, a facility modification would only trigger PSD for GHGs if the modification resulted in an increase of 75,000 MT/yr CO2eq. Therefore, SCAQMD began requiring GHG BACT for sources already subject to PSD and having a GHG increase of 75,000 MT/yr or more, effective January 2, 2011. In Step 2, which occurred between ~~began on~~ July 1, 2011 and June 30, 2013, facilities with a potential to emit 100,000 MT/yr CO2eq or more would be subject to Title V and PSD, regardless of whether they would otherwise be subject to these programs as a result of emissions of other pollutants. Therefore, effective July 1, 2011, SCAQMD started requiring GHG BACT for all new and modified facilities having the potential to emit 100,000 MT/yr CO2eq and having an increase of at least 75,000 MT/yr CO2eq. For the third phase, Step 3, of the GHG Tailoring Rule, effective August 13, 2012, EPA retained the GHG permitting thresholds that were established in Steps 1 and 2 of the GHG Tailoring Rule[13]. Recently, the U.S. Supreme Court held that EPA was limited to Step 1.

At the local level, SCAQMD adopted Rule 1714 – Prevention of Significant Deterioration for Greenhouse Gases, implementing PSD requirements for GHGs. SCAQMD interprets its Rule 1714 to be consistent with the U.S. Supreme Court decision.

---

[12] "Prevention of Significant Deterioration and Title V Greenhouse Gas Tailoring Rule; Proposed Rule" ("Tailoring Rule Proposal") 74 FR 55292, 55297 (October 27, 2009).

[13] Environmental Protection Agency, Prevention of Significant Deterioration and Title V Greenhouse Gas Tailoring Rule Step 3 and GHG Plantwide Applicability Limits, Final Rule. 77 FR 41051–41075 (July 12, 2012).

Although the definition of federal BACT for PSD sources is somewhat different from the definition of BACT that SCAQMD uses for nonattainment NSR, this definition is still at least as stringent as the CEQA definition of feasible. Pursuant to federal CAA §169(3) (42 U.S.C. §7479(3)), the term "best available control technology" means in pertinent part "an emission limitation based on the maximum degree of reduction of each pollutant subject to regulation under this chapter emitted from or which results from any major emitting facility, which the permitting authority, on a case-by-case basis, taking into account energy, environmental, and economic impacts and other costs, determines is achievable for such facility through application of production processes and available methods, systems, and techniques, including fuel cleaning, clean fuels, or treatment or innovative fuel combustion techniques for control of each such pollutant." Therefore, GHG BACT is at least as stringent as CEQA's definition of feasible mitigation, which similarly allows consideration of economic, technological and environmental factors. Thus, application of BACT will require the maximum feasible reductions of GHGs at new or modified sources, which would otherwise be subject to PSD. Because the potential GHG increases at each affected facility are individually well below EPA's initial thresholds, GHG BACT would not be required for any of the individual facilities making facility modifications to comply with the proposed project.

Further, in light of the uncertainty associated with the effects of the proposed project on individual facilities whose operators have not submitted any applications for permits to construct as a result of the proposed project, the adoption and implementation of feasible mitigation beyond the requirement of using recycled water when available will not feasibly reduce significant air quality and climate change impacts to a less-than-significant level, because it would not be feasible for the SCAQMD to attempt to develop and impose additional GHG mitigation measures for the myriad of source categories that may be affected by the proposed project. Accordingly, the project-level and cumulative impacts identified as significant in this chapter cannot feasibly be mitigated to a less-than-significant level and remain significant and unavoidable.

SUBCHAPTER 4.3

ENERGY

Introduction

Significance Criteria

Potential Energy Impacts and Mitigation Measures

Cumulative Energy Impacts

Cumulative Mitigation Measures

4.3 ENERGY

The proposed amended regulation will require facilities to collectively lower their emissions, thus improving air quality in the long term in order to meet the project's objectives. However, the installation of air pollution control equipment as a result of implementing the proposed project could potentially result in energy impacts. The energy impact analysis in this PEA identifies the net effect on energy resources from implementing the proposed project.

4.3.1 Introduction

As previously summarized in Table 4.0-2, the proposed project is expected to result in the installation of new or the modification of existing NOx air pollution control equipment for the top NOx emission equipment/source categories. The equipment/source categories are divided into two sectors: refinery and non-refinery. There are nine facilities in the refinery sector and 11 facilities in the non-refinery sector. For both sectors, individual facilities were evaluated to determine the number and type of NOx control devices that may be installed as a result of implementing the proposed project. Reducing NOx emissions from the affected facilities will provide an air quality benefit in the near- and long-term. Direct air quality impacts from the proposed project are expected to result in a reduction of NOx at the affected facilities, which will provide air quality and human health benefits to the public. However, installing new or modifying existing air pollution control equipment is expected to have potentially adverse energy impacts.

The environmental analysis assumes that installation of NOx control technologies for the affected sources will reduce NOx emissions overall, but activities associated with both the installation of new control devices and the modification of existing control devices will create adverse energy impacts both during the period of its construction and through ongoing daily operations. During installation or modification of add-on air pollution control devices, energy impacts may be generated from the need for diesel fuel to operate onsite construction equipment and heavy-duty vehicles and for gasoline to operate offsite vehicles used for worker commuting. After construction activities are completed, increased use of electricity needed to operate the NOx air pollution control devices and diesel fuel needed to operate offsite vehicles used for delivering fresh materials needed for operations (e.g., supplies, chemicals, fresh catalyst, etc.) and hauling away solid waste for disposal or recycling (e.g., spent catalyst). No increased use of natural gas is expected because the NOx air pollution control devices identified in Table 4.0-2 do not utilize natural gas. The analysis of these impacts can be found in Section 4.3.3. Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs. Further, since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74. Thus, the analysis in this PEA for the refinery sector is conservative as it overestimates the potential adverse energy impacts. Refer to Appendix E for the calculations used to estimate adverse energy impacts during construction and operation.

4.3.2 Significance Criteria

Impacts to energy resources will be considered significant if any of the following criteria are met:

- The project conflicts with adopted energy conservation plans or standards.
- The project results in substantial depletion of existing energy resource supplies.
- An increase in demand for utilities impacts the current capacities of the electric and natural gas utilities.
- The project uses non-renewable resources in a wasteful and/or inefficient manner.

4.3.3 Potential Energy Impacts and Mitigation Measures

Table 4.3-1 summarizes the estimated number of NOx emission control devices per sector and per equipment/source category. The different types of control devices include Selective Catalytic Reduction (SCR), a proprietary Low Temperature Oxidation technology (LoTOx™) with or without a Wet Gas Scrubber (WGS), and catalyst impregnated filters with a Dry Gas Scrubber (UltraCat DGS). In total, the proposed project is expected to result in the installation of the following new NOx air pollution control equipment: up to 117 SCRs, eight LoTOx™ with WGSs, one LoTOx™ without WGS, and three UltraCat DGSs.

Table 4.3-1
Estimated Number of NOx Control Devices Per Sector and Equipment/Source Category

Sector	Equipment/Source Category	Number of Affected Facilities	Estimated Number of Control Devices
Refinery	Fluid Catalytic Cracking Units (FCCUs)	5	2 SCRs 2 LoTOx™ with WGSs* 1 LoTOx™ without WGS
Refinery	Refinery Process Heaters and Boilers	8	74 SCRs^
Refinery	Refinery Gas Turbines	5	7 SCRs
Refinery	Sulfur Recovery Unit / Tail Gas Units (SRU/TGUs)	5	5 LoTOx™ with WGSs 1 SCR
Refinery	Petroleum Coke Calciner	1	1 LoTOx™ with WGS or 1 UltraCat with DGS
Non-Refinery	Container Glass Melting Furnaces	1	2 SCRs or 1 UltraCat with DGS
Non-Refinery	Sodium Silicate Furnaces	1	1 SCR or 1 UltraCat with DGS
Non-Refinery	Metal Heat Treating Furnaces	1	1 SCR
Non-Refinery	Internal Combustion Engines (Non-Refinery/Non-Power Plant)	3	16 SCRs
Non-Refinery	Turbines (Non-Refinery/Non-Power Plant)	7	13 SCRs and 1 SCR replacement
		TOTAL	**114 to 117 SCRs** **7 to 8 LoTOx™ with WGSs** **1 LoTOx™ without WGS** **0 to 3 UltraCat DGSs**

* Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs.

^ Since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74.

4.3.3.1 Energy Impacts During Construction

Implementation of the proposed project could potentially result in construction activities at 20 NOx RECLAIM facilities, which are complex industrial facilities. The physical changes that are expected focus on the installation of new or the modification of existing control equipment for the following stationary sources of NOx: 1) FCCUs; 2) refinery boilers and heaters; 3) refinery gas turbines; 4) SRU/TGUs; 5) non-refinery/non-power plant gas turbines; 6) non-refinery sodium silicate furnaces; 7) non-refinery/non-power plant ICEs; 8) container glass melting furnaces; 9) coke calcining; and, 10) metal heat treating furnaces. As previously summarized in Table 4.3-1, the proposed project is expected to result in the installation of the following new NOx air pollution control equipment: up to 117 SCRs, eight LoTOx™ with WGSs, one LoTOx™ without WGS, and three UltraCat DGSs.

During installation or modification of add-on air pollution control devices, adverse energy impacts (e.g., increased demand in energy) may occur during construction due to the need for: 1) diesel fuel to operate onsite construction equipment that cannot utilize or access electricity; 2) diesel fuel to operate heavy-duty and medium-duty vehicles for delivering supplies and hauling waste during construction; and, 3) gasoline to operate offsite vehicles used for worker commuting. Tables 4.3-2 and 4.3-3 summarize the how much diesel fuel and gasoline will be need to construct an assortment of NOx control technologies (including the vehicles for deliveries, hauling and construction workers) at the 20 facilities for the refinery and non-refinery sectors, respectively. Table 4.3-4 summarizes the how much diesel fuel and gasoline will be needed to construct all NOx control equipment at all 20 facilities combined.

To determine whether a project would cause a substantial depletion of existing energy resource supplies for diesel fuel and gasoline, the SCAQMD determines significance for increased fuel use by comparing the potential increases in diesel fuel and gasoline to one percent of supply for each fuel type. As shown in Table 4.3-4, the increased use of diesel fuel and gasoline during construction would not exceed the significance threshold of one percent of supply. As such, these projected increased usages of diesel fuel and gasoline would not create any significant effects on local or regional energy supplies and on requirements for additional energy. Further, these projected increased usages of diesel fuel and gasoline would not create any significant effects on peak and base period demands on the availability of diesel fuel and gasoline.

As part of the installing or modifying existing air pollution control equipment, electricity could be utilized to operate certain construction equipment in lieu of diesel, such as welders, if access to electricity is available. (In fact, utilizing electricity for welders, in lieu of diesel welders is encouraged and required as part of mitigation for air quality construction emissions.) Any additional electricity that may be needed as part of implementing the proposed project is typically supplied by each affected facility's local electrical utility and if applicable, supplemented by the facility's own cogeneration unit.

http://energyalmanac.ca.gov/gasoline/retail_fuel_outlet_survey/retail_gasoline_sales_by_county.html

[b] SCAQMD's Energy Threshold for both types of fuel used is 1% of Fuel Supply.

However, because it is unknown whether electricity would be available to operate construction equipment, any electricity consumption that may occur during construction as a substitute for operating some diesel fueled construction equipment cannot be quantified.

Nonetheless, the amount of electricity that may be needed for this purpose is expected to be minimal because most of the construction activities will be supplied with diesel-powered construction equipment and each affected facility should have enough electricity supplies to provide power to the limited number of electric construction equipment that may be utilized under these circumstances.

Since the proposed project would not exceed the SCAQMD's energy threshold of one percent of supply for electricity usage during construction, implementation of the proposed project is expected to have less than significant energy impacts during construction. Further, any temporary usage of electricity during construction would not be expected to result in the need for new or substantially altered power utility systems. In addition, any temporary usage of electricity that may occur would not be expected to create any significant effects on local or regional electricity supplies or on requirements for additional electricity. Lastly, any temporary usage of electricity that may occur would not be expected to create any significant effects on peak and base period demands for electricity.

4.3.3.2 Mitigation of Construction Energy Impacts

Less than significant adverse impacts associated with energy (e.g., diesel fuel, gasoline, and electricity) are expected from the proposed project during construction, so no mitigation measures during construction are required.

4.3.3.3 Remaining Construction Energy Impacts After Mitigation

The energy analysis concluded that potential energy impacts during construction would be less than significant, so no mitigation measures are required. Thus, energy impacts during construction remain less than significant.

4.3.3.4 Energy Impacts During Operation

After the add-on air pollution control devices are installed and operating, adverse energy impacts (e.g., increased demand in energy) may occur during operation due to the need for: 1) electricity to operate the air pollution control devices; and, 2) diesel fuel to operate heavy-duty and medium-duty vehicles for delivering supplies and hauling waste during operation.

Tables 4.3-5 and 4.3-6 summarize the electricity sources and local utility service providers for the 20 affected facilities belonging to the refinery and non-refinery sectors, respectively.

Energy information as it relates to operational activities was derived as part of the air quality analysis in Subchapter 4.2 and the calculations are shown in Appendix E of this PEA. If the potential NOx controls are installed and operated, Tables 4.3-7 and 4.3-8 summarize the estimated impacts on operational electricity use on a per facility per sector basis, respectively.

Table 4.3-7
Potential Operational Energy Use Per Refinery Facility

Refinery ID	Affected Equipment/ Source Category and Potential NOx Control Equipment	Potential Increased Electricity Demand (kWh/day)	Potential Increased Instantaneous Electricity Demand (MW)
1	SRU/TGU: 1 LoTOx™ with WGS Gas Turbine: 1 SCR Boilers/Heaters: 5 SCRs	41,307	1.72

	TOTAL	**168,170**	**7.01**

In addition, as part of operation for three WGSs at Refineries 2, 4 and 9, NaOH caustic soda solution is required and approximately 2.47 tons per day would be needed. NaOH is produced locally by several chemical processing companies and as such, is locally available for transport. Further, it is likely that the existing local caustic manufacturers can handle the proposed increase in caustic for the entire project. To accommodate the estimated increase in caustic demand, the chemical processing companies may need to increase production, which, in turn, will use more electricity. It takes approximately 2,500 kWh to produce one metric ton of NaOH. Thus, the approximate amount of additional electricity that may be needed to produce additional caustic to meet the needs for these three refineries is approximately 13,235 kWh/day, calculated as follows:

<u>Electricity Needed to Manufacture Caustic Soda Solution:</u>

$$\frac{5.84 \text{ tons NaOH}}{\text{Day}} \times \frac{2{,}000 \text{ lbs}}{\text{Ton}} \times \frac{1 \text{ metric ton}}{2{,}205 \text{ lbs}} \times \frac{2{,}500 \text{ kWh}}{1 \text{ metric ton of NaOH produced}} = \mathbf{13{,}235\ kWh/day}$$

The overall electricity needed during operation activities for the refinery sector as summarized in Tables 4.3-7 include the amount of electricity that may be needed to produce additional NaOH.

Table 4.3-8

To determine whether a project would cause an increased demand for electricity beyond the current capacities of the electric utilities, the SCAQMD determines significance for increased energy by comparing the potential increases in electricity demand to one percent of supply. Table 4.3-9 summarizes the how much electricity will be needed to construct all NOx control equipment at all 20 facilities combined. To determine if the operational energy use is significant, the total for electricity was compared to the threshold electricity supply as shown in Table 4.3-9.

Table 4.3-9
Total Projected Operational Electricity Demand By All 20 Facilities

Sector	Total Projected Electricity Demand	
	Daily (kwh/day)	Instantaneous (MW)
9 Refineries	168,170	7.01
11 Non-Refineries	45,344	1.89
TOTAL	**213,514**	**8.90**
Threshold Fuel Supply[a]	320,000,000 kWh	13,333 MW
% of Supply	0.07%	0.07%
Significant (Yes/No)[b]	**NO**	**NO**

[a] 2013 Electricity Use in GWh (Aggregated, includes self generation and renewables), for Los Angeles, Orange, Riverside and San Bernardino Counties, California Energy Commission .
[b] SCAQMD's Energy Threshold for electricity is 1% of Supply.

As shown in Table 4.3-9, the increased use of electricity during operation would not exceed the significance threshold of one percent of supply. Since the proposed project would not exceed the SCAQMD’s energy threshold of one percent of supply for electricity usage, implementation of the proposed project is expected to have less than significant energy impacts during operation. Further, any usage of electricity during operation would not be expected to result in the need for new or substantially altered power utility systems. In addition, any operational increases in electricity usage that may occur would not be expected to create any significant effects on local or regional electricity supplies or on requirements for additional electricity. Lastly, any increased operational usage of electricity that may occur would not be expected to create any significant effects on peak and base period demands for electricity.

During operation of the projected add-on air pollution control devices, adverse energy impacts (e.g., increased demand in energy) may also occur during operation due to the need for diesel fuel to operate heavy-duty and medium-duty vehicles for delivering supplies and hauling waste. For example, for refinery facilities, heavy-duty truck trips would be needed to deliver chemicals such as ammonia, sodium hydroxide, oxygen, lime, soda ash, and fresh catalyst and to haul away solid waste that may be generated and spent catalyst. Similarly, for non-refinery facilities, medium-duty and heavy-duty truck trips would be needed to deliver chemicals such as ammonia, urea, hydrated lime, and fresh catalyst and to haul away solid waste and filter waste that may be generated and spent catalyst.

Tables 4.3-10 and 4.3-11 summarize the how much diesel fuel and gasoline will be needed for support activities (fuel needed for the vehicles for deliveries and waste hauling) associated with the operation of an assortment of NOx control technologies at the 20 facilities for the refinery and non-refinery sectors, respectively.

	TOTAL	**610**	**12,090**

To determine whether a project would cause a substantial depletion of existing energy resource supplies for diesel fuel, the SCAQMD determines significance for increased diesel fuel use by comparing the potential increases in diesel fuel needed to one percent of supply. Table 4.3-12 summarizes the how much diesel fuel will be needed to operate all NOx control equipment at all 20 facilities combined. To determine if the operational energy use is significant, the total for diesel fuel use was compared to the threshold fuel supply as shown in Table 4.3-12.

Table 4.3-12
Total Projected Operational Diesel Fuel Use By All 20 Facilities

Sector	Total Projected Diesel Fuel Use	
	Daily (gal/day)	**Annual (gal/yr)**
9 Refineries	1,670	21,241
11 Non-Refineries	610	12,090
TOTAL	**2,280**	**33,331**
Threshold Fuel Supply[a]	4,347,945	1,587,000,000
% of Fuel Supply	0.05%	0.002%
Significant (Yes/No)[b]	**NO**	**NO**

[a] 2012 California Retail Sales by County; California Energy Commission http://energyalmanac.ca.gov/gasoline/retail_fuel_outlet_survey/retail_diesel_sales_by_county.html

[b] SCAQMD's Energy Threshold for both types of fuel used is 1% of Fuel Supply.

As shown in Table 4.3-12, the increased use of diesel fuel during operation would not exceed the significance threshold of one percent of supply. Since the proposed project would not exceed the SCAQMD's energy threshold of one percent of supply for diesel fuel usage, implementation of the proposed project is expected to have less than significant energy impacts during operation. As such, the projected increased usage of diesel fuel would not create any significant effects on local or regional energy supplies and on requirements for additional energy. Further, the projected increased usage of diesel fuel would not create any significant effects on peak and base period demands on the availability of diesel fuel.

4.3.3.5 Mitigation of Operational Energy Impacts

Less than significant adverse impacts associated with energy (e.g., increased usage in electricity, diesel fuel, and gasoline) are expected from the proposed project during operation, so no mitigation measures are required.

4.3.3.6 Remaining Operational Energy Impacts After Mitigation

The energy analysis concluded that potential energy impacts during operation would be less than significant, no mitigation measures were required. Thus, energy impacts during operation remain less than significant.

4.3.4 Cumulative Energy Impacts

Because the project-specific energy impacts do not exceed any applicable significance thresholds, they are not considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, do not generate significant adverse cumulative energy impacts.

4.3.5 Cumulative Mitigation Measures

Because the project-specific energy impacts during construction and operation are not considered to be cumulatively considerable, no cumulative mitigation measures are required.

SUBCHAPTER 4.4

HAZARDS AND HAZARDOUS MATERIALS

Introduction

Significance Criteria

Potential Hazards and Hazardous Materials Impacts and Mitigation Measures

Cumulative Hazards and Hazardous Materials Impacts

Cumulative Mitigation Measures

4.4 HAZARDS AND HAZARDOUS MATERIALS

The proposed amended regulation will require facilities to collectively lower their emissions, thus improving air quality in the long term in order to meet the project's objectives. However, the installation of air pollution control equipment as a result of implementing the proposed project could potentially result in hazards and hazardous materials impacts. The hazards and hazardous materials impact analysis in this PEA identifies the net effect on hazards and hazardous materials from implementing the proposed project.

The potential for hazards exist in the production, use, storage, and transportation of hazardous materials. For the purposes of this PEA, the term "hazardous materials" refers to both hazardous materials and hazardous wastes. In general, hazards can occur due to natural events, such as earthquake, and non-natural events, such as mechanical failure or human error. The risk associated with each affected facility is defined by the probability of an event and the consequence (or hazards) should the event occur.

Hazardous materials may be found at industrial production and processing facilities. Some facilities produce hazardous materials as their end product, while others use such materials as an input to their production process. Hazardous materials are stored at facilities that produce such materials and at facilities where hazardous materials are a part of the production process. Specifically, storage refers to the bulk handling of hazardous materials before and after they are transported to the general geographical area of use. Currently, hazardous materials are transported throughout the district via all modes of transportation including rail, highway, water, air, and pipeline. Hazard concerns are related to the potential for fires, explosions or the release of hazardous materials/substances in the event of an accident or upset conditions.

4.4.1 Introduction

The NOP/IS (see Appendix F) determined that the proposed project has the potential to generate significant adverse hazards and hazardous materials impacts. The hazard and hazardous materials impacts associated with the operation of the proposed project are potentially significant and the impacts are evaluated in this subchapter.

As previously summarized in Table 4.0-2, the proposed project is expected to result in the installation of new or the modification of existing NOx air pollution control equipment for the top NOx emission equipment/source categories. The equipment/source categories are divided into two sectors: refinery and non-refinery. There are nine facilities in the refinery sector and 11 facilities in the non-refinery sector. For both sectors, individual facilities were evaluated to determine the number and type of NOx control devices that may be installed as a result of implementing the proposed project. Reducing NOx emissions from the affected facilities will provide an air quality benefit in the near- and long-term. Direct air quality impacts from the proposed project are expected to result in a reduction of NOx at the affected facilities, which will provide air quality and human health benefits to the public. However, installing new or modifying existing air pollution control equipment is expected to have potentially adverse hazards and hazardous materials impacts. Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs. Further, since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74. Thus, the analysis in this PEA for the refinery sector is conservative as it overestimates the potential adverse hazards and hazardous materials impacts.

4.4.2 Significance Criteria

Impacts associated with hazards will be considered significant if any of the following occur:

- Non-compliance with any applicable design code or regulation.
- Non-conformance to National Fire Protection Association standards.
- Non-conformance to regulations or generally accepted industry practices related to operating policy and procedures concerning the design, construction, security, leak detection, spill containment or fire protection.
- Exposure to hazardous chemicals in concentrations equal to or greater than the Emergency Response Planning Guideline (ERPG) 2 levels.

4.4.3 Potential Hazards and Hazardous Materials Impacts and Mitigation Measures

Table 4.4-1 summarizes the estimated number of NOx emission control devices per sector and per equipment/source category. The different types of control devices include Selective Catalytic Reduction (SCR), a proprietary Low Temperature Oxidation technology (LoTOx™) with or without a Wet Gas Scrubber (WGS), and catalyst impregnated filters with a Dry Gas Scrubber (UltraCat DGS). In total, the proposed project is expected to result in the installation of the following new NOx air pollution control equipment: up to 117 SCRs, eight LoTOx™ with WGSs, one LoTOx™ without WGS, and three UltraCat DGSs.

Table 4.4-1
Estimated Number of NOx Control Devices Per Sector and Equipment/Source Category

Sector	Equipment/Source Category	Number of Affected Facilities	Estimated Number of Control Devices
Refinery	Fluid Catalytic Cracking Units (FCCUs)	5	2 SCRs 2 LoTOx™ with WGSs* 1 LoTOx™ without WGS
Refinery	Refinery Process Heaters and Boilers	8	74 SCRs^
Refinery	Refinery Gas Turbines	5	7 SCRs
Refinery	Sulfur Recovery Unit / Tail Gas Units (SRU/TGUs)	5	5 LoTOx™ with WGSs 1 SCR
Refinery	Petroleum Coke Calciner	1	1 LoTOx™ with WGS or 1 UltraCat with DGS
