		TOTAL	**114 to 117 SCRs** **7 to 8 LoTOx™ with WGSs** **1 LoTOx™ without WGS** **3 UltraCat DGSs**

* Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs.

^ Since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74.

Several components with regard to reducing NOx emissions by installing new or modifying existing NOx controls as part of implementing the proposed project may affect the use, storage and transport of hazards and hazardous materials during operational-related activities. Thus, the routine transport of hazardous materials, use, and disposal of hazardous materials may increase as a result of implementing the proposed project.

The key effects of implementing the proposed project and the determination of which aspects involve hazards and hazardous materials focus on: 1) the anticipated increase of substances used to operate the new or modified NOx controls; and, 2) the increased capture of hazardous substances as part of the overall NOx reduction effort. Table 4.4-2 contains a summary of the substances that may be used, stored and transported as part of implementing the proposed project.

Table 4.4-2
Substances Used by NOx Control Technologies

Sector	Equipment/Source Category	Potential NOx Control Devices	Proposed Substances To Be Used/Increased for NOx Control
Refinery	FCCUs	1. SCRs 2. LoTOx™ with WGSs 3. LoTOx™ without WGS	1. NH3 and fresh catalyst 2. NaOH and fresh catalyst 3. Oxygen
Refinery	Refinery Process Heaters and Boilers	SCRs	NH3 and fresh catalyst
Refinery	Refinery Gas Turbines	SCRs	NH3 and fresh catalyst
Refinery	SRU/TGUs	1. LoTOx™ with WGSs 2. SCRs	1. Soda Ash 2. NH3 and fresh catalyst
Refinery	Petroleum Coke Calciner	1. LoTOx™ with WGS 2. UltraCat DGS	1. NaOH and fresh catalyst 2. NH3 and Hydrated Lime – Ca(OH)2
Non-Refinery	Container Glass Melting Furnaces	1. SCR 2. UltraCat DGS	1. NH3 and fresh catalyst 2. Hydrated Lime – Ca(OH)2 and fresh catalyst
Non-Refinery	Sodium Silicate Furnaces	1. SCR 2. UltraCat DGS	1. NH3 and fresh catalyst 2. NH3 and fresh catalyst
Non-Refinery	Metal Heat Treating Furnaces	SCRs	NH3 and fresh catalyst
Non-Refinery	ICEs (Non-Refinery/Non-Power Plant)	SCRs	NH3 and fresh catalyst
Non-Refinery	Turbines (Non-Refinery/Non-Power Plant)	SCRs	NH3 and fresh catalyst

Hazard Safety Regulations

Notwithstanding implementation of the proposed project, operators of each affected facility must comply or continue to comply with various regulations, including Occupational Safety and Health Administration (OSHA) regulations (29 Code of Federal Regulations (CFR) Part 1910) that require the preparation of a fire prevention plan, and 20 CFR Part 1910 and CCR Title 8 that require prevention programs to protect workers who handle toxic, flammable, reactive, or explosive materials. In addition, §112 (r) of the CAA Amendments of 1990 [42 United States Code (USC) 7401 et. seq.] and Article 2, Chapter 6.95 of the California HSC require facilities that handle listed regulated substances to develop Risk Management Programs (RMPs) to prevent accidental releases of these substances. If any of the affected facilities has already prepared an RMP, it may need to be revised to incorporate any changes that may be associated with the proposed project. The Hazardous Materials Transportation Act is the federal legislation that regulates transportation of hazardous materials.

A number of physical or chemical properties may cause a substance to be hazardous. With respect to determining whether any material identified in Table 4.4-5 is hazardous, each Material Safety Data Sheet (MSDS) has also been consulted for the National Fire Protection Association (NFPA) 704 hazard rating system (i.e. NFPA 704). NFPA 704 is a "standard (that) provides a readily recognized, easily understood system for identifying specific hazards and their severity using spatial, visual, and numerical methods to describe in simple terms the relative hazards of a material. It addresses the health, flammability, instability, and related hazards that may be presented as short-term, acute exposures that are most likely to occur as a result of fire, spill, or similar emergency[1]." In addition, the hazard ratings per NFPA 704 are used by emergency personnel to quickly and easily identify the risks posed by nearby hazardous materials in order to help determine what, if any, specialty equipment should be used, procedures followed, or precautions taken during the first moments of an emergency response. The scale is divided into four color-coded categories, with blue indicating level of health hazard, red indicating the flammability hazard, yellow indicating the chemical reactivity, and white containing special codes for unique hazards such as corrosivity and radioactivity. Each hazard category is rated on a scale from 0 (no hazard; normal substance) to 4 (extreme risk). Table 4.4-3 summarizes what the codes mean for each hazards category.

It is expected that the operators of affected facilities will comply with all applicable design codes and regulations, conform to NFPA standards, and conform to policies and procedures concerning leak detection containment and fire protection. Therefore, no significant adverse offsite hazard impacts are expected as explained in the following sections.

[1] National Fire Protection Association, FAQ for Standard 704. http://www.nfpa.org/faq.asp?categoryID=928&cookie%5Ftest=1#23057

Table 4.4-3

NFPA 704 Hazards Rating Codes

Hazard Rating Code	Health (Blue)	Flammability (Red)	Reactivity (Yellow)	Special (White)
4 = Extreme	Very short exposure could cause death or major residual injury (extreme hazard)	Will rapidly or completely vaporize at normal atmospheric pressure and temperature, or is readily dispersed in air and will burn readily. Flash point below 73°F.	Readily capable of detonation or explosive decomposition at normal temperatures and pressures.	**~~W~~** = Reacts with water in an unusual or dangerous manner.
3 = High	Short exposure could cause serious temporary or moderate residual injury	Liquids and solids that can be ignited under almost all ambient temperature conditions. Flash point between 73°F and 100°F.	Capable of detonation or explosive decomposition but requires a strong initiating source, must be heated under confinement before initiation, reacts explosively with water, or will detonate if severely shocked.	**OXY** = Oxidizer
2 = Moderate	Intense or continued but not chronic exposure could cause temporary incapacitation or possible residual injury.	Must be moderately heated or exposed to relatively high ambient temperature before ignition can occur. Flash point between 100°F and 200°F.	Undergoes violent chemical change at elevated temperatures and pressures, reacts violently with water, or may form explosive mixtures with water.	**SA** = Simple asphyxiant gas (includes nitrogen, helium, neon, argon, krypton and xenon).
1 = Slight	Exposure would cause irritation with only minor residual injury.	Must be heated before ignition can occur. Flash point over 200°F.	Normally stable, but can become unstable at elevated temperatures and pressures	
0 = Insignificant	Poses no health hazard, no precautions necessary	Will not burn	Normally stable, even under fire exposure conditions, and is not reactive with water.	

Hazard Impacts on Water Quality

A spill of any hazardous material that is used and stored at any of the affected facilities could occur under upset conditions such as an earthquake, tank rupture, or tank overflow. Spills could also occur from corrosion of containers, piping and process equipment; and leaks from seals or gaskets at pumps and flanges. A major earthquake would be a potential cause of a large spill. Other causes could include human or mechanical error. Construction of the vessels and foundations in accordance with the Uniform Building Code Zone 4 requirements helps structures to resist major earthquakes without collapse, but may result in some structural and non-structural damage following a major earthquake. Any facility with storage tanks on-site is currently required to have emergency spill containment equipment and would implement spill control measures in the event of an earthquake. Storage tanks typically have secondary containment such as a berm which would be capable of containing 110 percent of the contents of the storage tanks. Therefore, should a rupture occur, the contents of the tank would be collected within the containment system and pumped to an appropriate storage tank.

Spills at the affected facilities would generally be collected within containment areas. Large spills outside of containment areas at the affected facilities are expected to be captured by the process water system where they could be collected and controlled. Spilled material would be collected and pumped to an appropriate tank or sent off-site if the materials cannot be used on-site. Because of the containment system design, spills are not expected to migrate from the spill site and as such, potential adverse water quality hazard impacts are considered to be less than significant.

Project Specific Impacts

The following discussion describes the hazards profile for each substance involved with proposed NOx control equipment.

Caustic

For any operator that chooses to install a WGS for a FCCU, hazardous materials may be needed to operate the WGSs depending on the source category and additional solid waste is expected to be generated. Caustic is a key ingredient needed for the operation of a WGS. While there are several types of caustic solutions that can be used in WGS operations, caustic made from sodium hydroxide (NaOH) is the most commonly used for WGSs for FCCUs and it is considered an acutely hazardous substance. Located on the MSDS for NaOH (50 percent by weight), the hazards ratings are as follows: health is rated 3 (highly hazardous), flammability is rated 0 (none) and reactivity is rated 1 (slightly hazardous).

For WGSs that may be installed to control NOx from SRU/TGUs, the caustic used in the WGS is made from soda ash, instead of NaOH. Soda ash is the common name for sodium carbonate (Na2CO3), a non-toxic, non-cancerous, and non-hazardous substance. Located on the MSDS for Na2CO3, the hazards ratings are as follows: health is rated 2 (moderate), flammability is rated 0 (none) and reactivity is rated 0 (none). Soda ash has a NFPA health rating 2 because it corrosive and may be harmful if inhaled and may cause skin irritation and workers handling soda ash will need to take the necessary precautions when dealing with this substance. Thus, less than significant increases in hazards associated with the use, storage, or transportation relative to the deliveries of soda ash is expected.

As previously analyzed in Subchapter 4.2 in the air quality discussion, for "worst-case" operations, 5.84 tons per day of NaOH (50 percent solution, by weight) is estimated to be needed to operate three WGSs at three refineries. In addition, even though the refineries may already use NaOH elsewhere in their facilities, for the purpose of conducting a "worst-case" construction analysis, one 10,000 gallon storage tank for caustic solution was assumed to be constructed for every WGS installed.

As previously summarized in Table 4.2-22 in Subchapter 4.2, for each refinery that was projected to increase the use in the acutely hazardous substance NaOH, the filling loss and the working loss of each NaOH tank was calculated, added together, and that sum was compared to the most stringent Rule 1401 Screening Emission Level for NaOH (0.004 pounds per hour at the nearest receptor distance of 25 meters). None of the total hourly loss projections exceeded the acute screening level for NaOH for any of the affected facilities. Because the screening level for NaOH was not exceeded for any of the affected facilities, no significant hazards and hazardous materials impacts with respect to NaOH uses are expected from the proposed project. NaOH is not classified as a carcinogen, so a cancer risk analysis was not performed.

It is expected that the affected facilities will receive NaOH from a local supplier located in the greater Los Angeles area. Deliveries of NaOH (50 percent by weight) would be made by tanker truck via public roads. The maximum capacity of a NaOH tanker truck is approximately 6,000 gallons.

The projected consumption and the annual deliveries of NaOH are summarized in Tables 4.4-4. To accommodate the increased demand in NaOH, there will be an increase in truck deliveries to supply NaOH to the facilities that need it. Table 4.4-4 also summarizes the annual and peak daily truck deliveries needed to supply NaOH. Based on the volume of NaOH solution (50 percent by weight) needed, the calculations assume that one 10,000 gallon capacity storage tank will be installed at each affected facility for NaOH storage. The amount of annual deliveries is based on the assumption that one delivery truck can hold 6,000 gallons per truck load. While the number of annual NaOH deliveries will vary based on each facility's needs, the peak daily truck deliveries would be one truck per day per facility. Based on the annual deliveries estimates, each facility is not expected to exceed the peak of one delivery per day per facility. However, the "worst-case" assumption for a peak daily delivery frequency from a supplier would be to deliver 10,000 gallons of NaOH to two facilities to fill two new NaOH tanks on the same day. Regulations for the transport of hazardous materials by public highway are described in 49 CFR §§ 173 and 177.

Table 4.4-4
Summary of NaOH Deliveries

Refinery ID	Daily Increase in NaOH Demand (tons/day)	Annual Increase in NaOH Demand (tons/year)	Peak Daily NaOH Deliveries (truck trips/day)	Annual NaOH Deliveries [1] (truck trips/year)
2	3.37	1,228	1	32
4	0.45	164	1	5
9	2.02	737	1	19
Total	**5.84**	**2,129**	**3**	**56**

[1] Annual NaOH deliveries are calculated based on one delivery truck holding 6,000 gallons per truck load. For example, for Refinery 4: 164 tons/yr NaOH x 2,000 lbs/ ton = 328,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 25,685 gal/year x 1 truck/6,000 gallons = 4.28 trucks/year (rounded up to 5 to be conservative).

Both the refineries currently receive NaOH from local suppliers located in the greater Los Angeles area. As is currently the case with existing NaOH deliveries, deliveries of additional NaOH would be made to each facility by tanker truck via public roads. NaOH is typically delivered in 6,000 gallon trucks, so the proposed project would not introduce any new transportation hazards for NaOH.

The onsite storage and handling of NaOH creates the possibility of an accidental spill and release of NaOH. However, because NaOH has such a low vapor pressure (6.33 mm Hg at 40 ^{o}C or 104 ^{o}F) when compared to water (55.3 mm Hg at 40 ^{o}C or 104 ^{o}F) at the same temperature, any spill of NaOH would not be expected to evaporate faster than water. Thus, any spill of NaOH would be expected to stay in liquid form and would not likely exceed the ERPG-2 vapor concentration of five milligrams per cubic meter for NaOH. Further, operators at each affected facility who construct a new NaOH storage tank will need to build a containment berm large enough to hold 110 percent of the tank capacity in the event of an accidental release due to tank rupture. Thus, any spill of NaOH would not be expected to migrate beyond the boundaries of the berm on-site. Thus, any spill of NaOH is not expected to present a potential offsite public and sensitive receptor exposure. Lastly, since NaOH is not a flammable compound, other types of heat-related hazard impacts such as fires, explosions, boiling liquid – expanding vapor explosion (BLEVE) are not expected to occur and, therefore, will not be evaluated as part of this hazards analysis.

In conclusion, the hazards and hazardous materials impacts due to the use, tank rupture and the accidental release of NaOH will be less than significant for the proposed project.

Hydrated Lime

For any operation that chooses to install an Ultracat DGSs, a dry calcium- and sodium-based alkaline powdered sorbent can be used to absorb NOx from the flue (outlet) gas stream. The sorbent expected to be used in the Ultracat DGSs for the coke calciner and the container glass melting furnaces will be hydrated lime, also known as calcium hydroxide (Ca(OH)2). Approximately 2.7 tons per day of hydrated lime may be needed as part of operating two UltraCat DGSs at two facilities (one refinery and one non-refinery facilities). Note that the third UltraCat DGS is assumed to only use ammonia because an evaluation of the sodium silicate furnaces exhaust shows that the use of hydrated lime would not be effective for reducing NOx emissions.

Calcium carbonate is a non-toxic, non-cancerous, and non-hazardous substance. The NFPA has not assigned a rating for calcium carbonate. The solid waste by-products that may be generated from this process would also not be considered hazardous waste. Because calcium carbonate is not considered to be hazardous, no increase in transportation hazards relative to the deliveries of calcium carbonate or the hauling of calcium carbonate waste is expected. In conclusion, the hazards and hazardous materials impacts due to the use of hydrated lime and the recycling or disposal of its solid, non-hazardous waste by-product is expected to be less than significant for the proposed project.

Ammonia

Ammonia (NH3,) though not a carcinogen, is a chronic and acutely hazardous material. Located on the MSDS for NH3 (19 percent by weight), the hazards ratings are as follows: health is rated 3 (highly hazardous), flammability is rated 1 (slight) and reactivity is rated 0 (none). Therefore, an increase in the use of ammonia in response to the proposed project may increase the current existing risk setting associated with deliveries (i.e., truck and road accidents) and onsite or offsite spills for each of the facilities that currently use or will begin to use ammonia. Exposure to a toxic gas cloud is the potential hazard associated with this type of control equipment. A toxic gas cloud is the release of a volatile chemical such as anhydrous ammonia that could form a cloud and migrate off-site, thus exposing individuals. Anhydrous ammonia is heavier than air such that when released into the atmosphere, would form a cloud at ground level rather than be dispersed "Worst-case" conditions tend to arise when very low wind speeds coincide with the accidental release, which can allow the chemicals to accumulate rather than disperse.

Though there are facilities that may be affected by the proposed project and that are currently permitted to use anhydrous ammonia, for new construction, however, current SCAQMD policy no longer allows the use of anhydrous ammonia. To minimize the hazards associated with using ammonia for air pollution control technology, it is the permitting policy of the SCAQMD to require the use of 19 percent by volume aqueous ammonia in air pollution control equipment for the following reasons: 1) 19 percent aqueous ammonia does not travel as a dense gas like anhydrous ammonia; and 2) 19 percent aqueous ammonia is not on any acutely hazardous material lists unlike anhydrous ammonia or aqueous ammonia at higher percentages. As such, SCAQMD staff does not issue permits for the use of anhydrous ammonia or aqueous ammonia in concentrations higher than 19 percent by volume for use in SCR systems. As a result, this analysis focuses on the use of 19 percent by volume aqueous ammonia. Thus, because aqueous ammonia (at 19 percent by weight) would be required for any permits issued for the installation of air pollution control equipment that utilize ammonia, no new hazards from toxic clouds are expected to be associated with the proposed project.

In addition, the shipping, handling, storage, and disposal of hazardous materials inherently poses a certain risk of a release to the environment. Thus, the routine transport of hazardous materials, use, and disposal of hazardous materials may increase as a result of implementing the proposed project. Further, if the control option chosen by each affected facility is to install control technology that utilizes ammonia, such as SCR or a DGS, the proposed project may alter the transportation modes for feedstock and products to/from the existing facilities such as aqueous ammonia and catalyst.

The analysis of hazard impacts can rely on information from past similar projects (i.e., installing new, or retrofitting existing equipment with NOx control technology that utilizes ammonia to comply with SCAQMD rules and regulations and installation of associated ammonia storage tanks) where the SCAQMD was the lead agency responsible for preparing an environmental analysis pursuant to CEQA. To the extent that future projects to install NOx control technology that utilizes ammonia and associated ammonia storage equipment conform to the ammonia hazard analysis in this PEA, no further hazard analysis may be necessary. If site-specific characteristics are involved with future projects to install NOx control equipment that utilize ammonia that are outside the scope of this analysis, a further ammonia hazards analysis may be warranted.

The maximum capacity of an ammonia tanker truck is approximately 7,000 gallons. Based on, the "worst-case" assumption for delivery frequency from a supplier would be to deliver

If all 117 SCRs are installed at all 20 facilities and one Ultracat DGS is installed at one facility, approximately 39.5 tons per day (equivalent to approximately 10,284 gallons per day) of aqueous ammonia (at 19 percent concentration) would be needed to operate the equipment. It is expected that the affected facilities will receive ammonia from a local ammonia supplier located in the greater Los Angeles area. Deliveries of aqueous ammonia would be made by tanker truck via public roads. Since one ammonia delivery truck can deliver up to 7,000 gallons per visit, based on the peak daily total volume of ammonia that would be needed, two trucks would be needed on a peak day. However, because the deliveries are spread across 20 facilities, the analysis conservatively assumes that 28 tankers carrying up to 7,000 gallons per truck would visit all 20 facilities on a peak day. Because the size of the aqueous ammonia storage tanks varies from 600 gallons to 11,000 gallons and the amount needed on a daily basis per facility will also vary, the actual amount of aqueous ammonia delivered per facility on a peak day will vary. The onsite storage capacity and the projections for future ammonia use and storage are estimated in Appendix E.

The accidental release of ammonia from a delivery and use is a localized event (i.e., the release of ammonia would only affect the receptors that are within the zone of the toxic endpoint). The accidental release from a delivery would also be temporally limited in the fact that deliveries are not likely to be made at the same time in the same area. Based on these limitations, it is assumed that an accidental release would be limited to a single delivery or single facility at a time. In addition, it is unlikely that an accidental release from both a delivery truck and the stationary storage tank would result in more than the amount evaluated in the catastrophic release of the storage tank because the level of ammonia in the storage tanks would be low or else the delivery trip would not be necessary.

Ammonia Transportation Release Scenario:
To analyze the effects of aqueous ammonia as a result of an accidental release due to tank rupture, a Consequence Analysis using the EPA RMP*Comp (Version 1.07) is typically performed. Aqueous ammonia trucks have a capacity of 7,000 gallons. EPA's RMP*Comp was used to estimate the zone of impact from a worst-case release. Although it is SCAQMD policy to reduce potential hazards associated with ammonia by requiring a permit condition that limits the aqueous ammonia concentration to 19 percent, the EPA model only has the capability of evaluating the hazard potential of 20 percent aqueous ammonia. Therefore, the potential adverse impacts from aqueous ammonia were evaluated based on 20 percent aqueous ammonia. Based on the worst-case defaults, the toxic endpoint from a delivery truck would be 0.4 miles.

A hazard analysis is dependent on knowing the exact location of the spill (e.g., meteorological conditions, location of the receptor, et cetera, a site-specific hazard analysis is difficult to conduct without this information. Since SCAQMD staff does not currently know the exact location of ammonia storage tanks that would be installed in the future, to estimate a worst-case analysis, the RMP*COMP worst-case assumptions were used:

Location of tank~~s~~: Stand alone tanks (i.e., not within a building)

Quantity Released: 7,000 gallons of aqueous ammonia

Liquid Temperature at the time of the spill: 77 degrees Fahrenheit

Mitigation Measures: None

Topography: Urban surroundings with many obstacles in the immediate area

Toxic Endpoint: 0.14 milligrams per liter (basis: ERPG-2)

Wind Speed: 1.5 meters per second (3.4 miles per hour)

Air Temperature: 77 degrees Fahrenheit

The estimated distance to the toxic endpoint from a worst-case delivery truck release is 0.4 miles or 2,112 feet. Since sensitive receptors are expected to be found within 0.4 miles from roadways, the hazards and hazardous materials impacts due to-a delivery truck accident will be potentially significant. Therefore, the proposed project has the potential to generate significant adverse hazard impacts during transportation as a result of the potential for accidental releases of delivered aqueous ammonia.

Ammonia Tank Rupture Scenario 1 (Non-Refinery Sector):
Based on engineering estimates and discussion with control technology vendors, it was estimated that the largest aqueous ammonia tank that would be installed at a non-refinery facility would be 5,000 gallons. All ammonia tanks are required to be installed within berms that hold 110 percent of the contents of the tank. EPA's RMP*Comp was used to estimate the zone of impact from a worst-case release. Although it is SCAQMD policy to reduce potential hazards associated with ammonia by requiring a permit condition that limits the aqueous ammonia concentration to 19 percent, the EPA model only has the capability of evaluating the hazard potential of 20 percent aqueous ammonia. Therefore, the potential adverse impacts from aqueous ammonia were evaluated based on the 20 percent aqueous ammonia. Further, since it is assumed that an aqueous ammonia tank servicing one or more SCR systems would need to be relatively near to the existing equipment, the toxic endpoint for aqueous ammonia from a worst-case failure of a storage tank would significantly adversely affect the sensitive receptors within 0.1 mile of the existing equipment.

A hazard analysis is dependent on knowing the exact location of the hazard within the site (e.g., location of the ammonia storage tank(s)), meteorological conditions, location of the receptor, et cetera, a site-specific hazard analysis is difficult to conduct without this information. Since SCAQMD staff does not currently know the exact location of ammonia storage tanks that would be installed in the future, to estimate a worst-case analysis, the RMP*COMP worst-case assumptions were used:

Location of tanks: Stand alone tanks not within a building

Quantity Released: 5,500 gallons of aqueous ammonia will be spilled into a berm (the total of one 5,000 gallon tanks plus 10 percent to account for a rupture during filling)

Liquid Temperature at the time of the spill: 77 degrees Fahrenheit

Mitigation Measures: Release into an open berm, in direct contact with outside air

Topography: Urban surroundings with many obstacles in the immediate area

Toxic Endpoint: 0.14 milligrams per liter (basis: ERPG-2)

Wind Speed: 1.5 meters per second (3.4 miles per hour)

Air Temperature: 77 degrees Fahrenheit

The estimated distance to the toxic endpoint from the facility is 0.1 miles or 528 feet. There are no schools or other sensitive receptors located within 0.1 miles of any of the non-refinery facilities. Thus, the hazards and hazardous materials impacts due to tank rupture for non-refinery facilities will be less than significant. Therefore, the proposed project does not have the potential to generate significant adverse hazard impacts as a result of the potential for accidental releases of aqueous ammonia.

Ammonia Tank Rupture Scenario 2 (Refinery Sector):
Based on engineering estimates and discussion with control technology vendors, it was estimated that the largest aqueous ammonia tank that would be installed at a refinery facility would be 11,000 gallons. Although it is SCAQMD policy to reduce potential hazards associated with ammonia by requiring a permit condition that limits the aqueous ammonia concentration to 19 percent, the EPA model only has the capability of evaluating the hazard potential of 20 percent aqueous ammonia. Therefore, the potential adverse impacts from aqueous ammonia were evaluated based on the 20 percent aqueous ammonia. Further, since it is assumed that an aqueous ammonia tank servicing one or more SCR systems would need to be relatively near to the existing equipment, the toxic endpoint for aqueous ammonia from a worst-case failure of a storage tank would significantly adversely affect the sensitive receptors within 0.1 mile of the existing equipment.

A hazard analysis is dependent on knowing the exact location of the hazard within the site (e.g., location of the ammonia storage tank(s)), meteorological conditions, location of the receptor, et cetera, a site-specific hazard analysis is difficult to conduct without this information. Since SCAQMD staff does not currently know the exact location of ammonia storage tanks that would be installed in the future, to estimate a worst-case analysis, the RMP*COMP worst-case assumptions were used:

Location of tanks: Stand alone tanks not within a building

Quantity Released: 12,100 gallons of aqueous ammonia will be spilled into a berm (the total of one 11,000 gallon tanks plus 10 percent to account for a rupture during filling)

Release Rate: 11.7 pounds per minute

Liquid Temperature at the time of the spill: 77 degrees Fahrenheit

Mitigation Measures: Release into an open berm, in direct contact with outside air

Topography: Urban surroundings with many obstacles in the immediate area

Toxic Endpoint: 0.14 milligrams per liter (basis: ERPG-2)

Wind Speed: 1.5 meters per second (3.4 miles per hour)

Air Temperature: 77 degrees Fahrenheit

The estimated distance to the toxic endpoint from any refinery facility is 0.1 miles or 528 feet. Since there are no sensitive receptors within 0.1 miles from any refinery facility, the hazards and hazardous materials impacts due to tank rupture will not be potentially significant. Therefore, for the affected refinery facilities, the proposed project does not have the potential to generate significant adverse hazard impacts as a result of the potential for accidental releases of aqueous ammonia for refinery facilities.

<u>Oxygen</u>

One facility (Refinery 7) is assumed to need an ozone generator which requires a regular supply of oxygen to operate a LoTOx™ unit that may be installed to work with an existing WGS that services the FCCU. Approximately 7,950 pounds of oxygen will be needed on peak day. The analysis assumes that one oxygen delivery truck on a peak day and 44 oxygen delivery trucks in one year will be needed.

Oxygen is an odorless, colorless, nonflammable gas that is stored in tanks or cylinders at high pressure. Oxygen is a non-toxic, non-cancerous, and non-hazardous substance. While no NFPA ratings have been assigned for health, flammability, or reactivity, the NFPA has assigned a special rating to oxygen, OXY, because it is considered an oxidizer that vigorously accelerates combustion. For example, some materials which are noncombustible in air will burn in the presence of an oxygen enriched atmosphere (greater than 23%). In addition, fire resistant clothing may burn and offer no protection in oxygen rich atmospheres. Oxygen may form explosive compounds when exposed to combustible materials or oil, grease, and other hydrocarbon materials. Pressure in a container can build up due to heat and it may rupture if pressure relief devices should fail to function. Upon exposure to intense heat or flame cylinder will vent rapidly and/or rupture violently. Most storage tanks and cylinders are designed to vent contents when exposed to elevated temperatures. Thus, because oxygen is not considered to be hazardous, no increase in hazards associated with the use, storage, or transportation relative to the deliveries of oxygen is expected.

<u>Solid Waste</u>

If the proposed project is implemented, additional solid waste may be generated, depending on the type of NOx control equipment employed. Tables 4.4-5 and 4.4-6 summarize the potential increased amount of solid waste expected to be generated for the refinery and non-refinery sector.

Table 4.4-5

Potential Increase in Solid Waste at Refinery Facilities

Refinery ID	**Proposed Increase in Amount of Solids Collected Due to New NOx Controls** (tons/day)	**Is the proposed increase in Solid Waste Hazardous?**	**Solid Waste will be trucked to:**

11	0	NO	Not Applicable
Total	**1.2**		

* Solid waste would only be generated if the operator of non-refinery Facility 8 chooses to install an Ultracat system. However, if the operator of non-refinery Facility 8 chooses to install SCR technology, in lieu of the Ultracat system, then no solid waste would be generated.

Thus, because the solid waste that may be generated from the proposed project is not considered to be hazardous, less than significant hazards and hazardous waste impacts associated with the use, storage, or transportation relative to the hauling of solid waste are expected.

Fresh and Spent Catalyst

Commercial catalysts used in SCRs are comprised of a base material of titanium dioxide (TiO2) that is coated with either tungsten trioxide (WO3), molybdic anhydride (MoO3), vanadium pentoxide (V2O5), or iron oxide (Fe2O3). SCR catalysts are replaced approximately one every five years. The key hazards associated with the proposed project are the crushing of the spent catalyst and transporting it for disposal or recycling. Recycling of catalyst means hauling the spent catalyst to a cement plant located outside of the District for use in manufacturing cement.

With respect to hazards and hazardous materials, there will be an increase in the frequency of truck transportation trips to remove the spent catalyst as hazardous materials or hazardous waste from each affected facility. However, facilities that have existing catalyst-based operations currently recycle the catalysts blocks, in lieu of disposal. Moreover, due to the heavy metal content and relatively high cost of catalysts, recycling can be more lucrative than disposal. Thus, facilities that have existing SCR units and choose to employ additional SCR equipment, in most cases already recycle the spent catalyst and subsequently may continue to do so with any additional catalyst that may be needed..

Although recycling may be the more popular (and potentially lucrative) consideration, it is possible that facilities may choose to dispose of the spent catalyst in a landfill. The composition and type of the catalyst will determine the type of landfill that would be eligible to handle the disposal. For example, catalysts with a metal structure would be considered a metal waste, like copper pipes, and not a hazardous waste. Therefore, metal structure catalysts would not be a regulated waste requiring disposal in a Class I landfill, unless it is friable or brittle. As ceramic-based catalysts contain a fiber-binding material, they are not considered friable or brittle and, thus, would not be a regulated waste requiring disposal in a Class I landfill. Furthermore, typical catalyst materials are not considered to be water soluble, which also means they would not require disposal in a Class I landfill. In both cases, spent catalyst would not require disposal in a Class I landfill.

A number of physical or chemical properties may cause a substance to be hazardous, including toxicity (health), flammability, reactivity, and any other specific hazard such as corrosivity or radioactivity. Based on a hazard rating from 0 to 4 (0 = no hazard; 4 = extreme hazard) located on the Material Safety Data Sheet (MSDS) the hazard rating for silica/alumina catalyst, for example, health is rated 1 (slightly hazardous), flammability is rated 0 (none) and reactivity is rated 0 (none). However, if nickel is deposited on the catalyst, the hazard rating is 2 for health (moderately toxic), 4 (extreme fire hazard) for flammability, 1 for reactivity (slightly hazardous if heated or exposed to water). The particular composition of the catalyst used in the SCR units, combined with the metals content of the flue gas will determine the hazard rating and whether the spent catalyst is considered a hazardous material or hazardous waste. This distinction is important because a spent catalyst that qualifies as a hazardous material could be still be recycled (e.g., to be reused by another industry such as manufacturing Portland cement). However, for any spent catalyst that is considered hazardous waste, if it is not recycled, then it must be disposed of in a landfill that can accept hazardous waste.

Based on the aforementioned information, it is likely that spent catalysts would be considered a "designated waste," which is characterized as a non-hazardous waste consisting of, or containing pollutants that, under ambient environmental conditions, could be released at concentrations in excess of applicable water objectives, or which could cause degradation of the waters of the state (California Code of Regulations, Title 23, Chapter 3 Subparagraph 2522(a)(1)). Depending on its actual waste designation, spent catalysts would likely be disposed of in a Class II landfill or a Class III landfill that is fitted with liners. Based on the remaining permitted Class III landfill capacity data for each county as provided in Subchapter 3.6 – Solid and Hazardous Waste, Table 3.6-2, the total remaining permitted Class III landfill capacity in Los Angeles, Orange, Riverside, and San Bernardino counties is 107,933 tons per day.

Proximity to Schools

Of the facilities that may install NOx control equipment, none of the facilities in either the refinery sector or non-refinery sector are located within one-quarter mile of an existing or proposed school. Therefore, no potential for adversely significant impacts from hazardous emissions onsite or the handling of acutely hazardous materials, substances and wastes on sensitive receptors is expected from the proposed project.

Summary

Table 4.4-7 summarizes the substances that may be involved in the various processes at the affected facilities.

Table 4.4-7
Substances that May Be Affected By The Proposed Project

Substance	Potential Overall Increase, Decrease, or No Change from Existing Setting?	Contains TAC(s) per SCAQMD Rule 1401?	Hazardous per CalARP?	NFPA Rating: Health (Blue)	NFPA Rating: Flammability (Red)	NFPA Rating: Reactivity (Yellow)	NFPA Rating: Special (White)
Hydrated Lime - Ca(OH)2	Increase	No	No	N/A	N/A	N/A	N/A
NaOH Caustic (50% by weight)	Increase	Yes, Acute (non-cancer)	Yes	3	0	1	None
Soda Ash Caustic (sodium carbonate)	Increase	No	No	2	0	0	None
NH3 (19% by weight)	Increase	Yes, Chronic & Acute (non-cancer)	Yes	3	1	0	None
Oxygen	Increase	No	No	0	0	0	Oxy
Solid Waste	Increase	No	No	N/A	N/A	N/A	N/A
Fresh Catalyst	Increase	No	No	N/A	N/A	N/A	N/A
Spent Catalyst	Increase	No	No	N/A	N/A	N/A	N/A

NFPA Hazard Code Key: 4 = Extreme; 3 = High; 2 = Moderate; 1 = Slight; 0 = Insignificant; N/A = NFPA hazard is not assigned.

Some of the substances listed are considered hazardous while others are not. Of the substances listed in this table, the only net increase in the use of a hazardous material will be for NaOH and ammonia. The effects of the potential increased use of NaOH and ammonia have been previously analyzed in the "Caustic" and "Ammonia" discussions, respectively. For the remaining substances identified, there will be no change in hazards from the existing setting. Thus, none of the changes to the existing setting is expected to result in a significant adverse impact for hazards and hazardous materials.

Project-Specific Impacts – Conclusion

Based on the preceding description of hazards and hazardous materials impacts, the proposed project is expected to generate significant adverse hazards and hazardous materials impacts for ammonia deliveries and less than significant hazards and hazardous materials impacts for ammonia use and storage. For the substances other than ammonia listed in Table 4.4-8, the proposed project is expected to generate less than significant hazards and hazardous materials impacts. To the extent that future projects to install new or modify existing NOx controls conform with the hazard analysis in this PEA, no further hazard analysis may be necessary. However, if site-specific characteristics are involved with future projects that are outside the scope of this analysis, further hazards analysis may be warranted.

Project-Specific Mitigation: The analysis concluded that the hazards and hazardous materials impacts from implementing the proposed project are considered to be adverse for ammonia deliveries. Therefore, mitigation measures are required. However, no feasible mitigation measures have been identified, over and above the extensive safety regulations that currently apply to delivery trucks that haul ammonia.

The analysis also concluded that the hazards and hazardous materials impacts from implementing the proposed project are considered to be less than significant for ammonia use and storage. Finally, for the substances other than ammonia listed in Table 4.4-8, analysis concluded that the proposed project is expected to generate less than significant hazards and hazardous materials impacts. Therefore, mitigation measures are not required.

Remaining Impacts After Mitigation: The hazards and hazardous materials analysis concluded that potential hazards and hazardous materials impacts for ammonia deliveries would be significant such that mitigation measures are required. However, because there are no feasible mitigation measures, over and above the extensive safety regulations that currently apply to delivery trucks that haul ammonia, to reduce ammonia transportation impacts to less than significant, the hazards and hazardous materials impacts for the ammonia deliveries remain significant.

For ammonia use and storage and for the other substances listed in Table 4.4-8, the hazards and hazardous materials analysis concluded that potential hazards and hazardous materials impacts would be less than significant, such that no mitigation measures are required. Thus, the hazards and hazardous materials impacts for these substances remain less than significant.

4.4.4 Cumulative Hazards and Hazardous Materials Impacts

Because the project-specific hazards and hazardous materials impacts for ammonia deliveries would potentially create significant impacts, they are considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, generate significant adverse cumulative hazards and hazardous materials impacts.

For ammonia use and storage and for the other substances listed in Table 4.4-8, the project-specific hazards and hazardous materials impacts do not exceed any applicable significance thresholds; thus, they are not considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, do not generate significant adverse cumulative hazards and hazardous materials impacts.

4.4.5 Cumulative Mitigation Measures

Because the project-specific hazards and hazardous materials impacts are considered to be cumulatively considerable for ammonia deliveries, cumulative mitigation measures for hazards and hazardous materials impacts for ammonia deliveries are required. However, since no feasible mitigation measures have been identified, over and above the extensive safety regulations that currently apply to delivery trucks that haul ammonia, no feasible cumulative mitigation measures for ammonia deliveries have been identified.

For ammonia use and storage and for the other substances listed in Table 4.4-8, because the project-specific hazards and hazardous materials impacts are not considered to be cumulatively considerable, no cumulative mitigation measures for hazards and hazardous materials impacts for ammonia use and storage and for the other substances listed in Table 4.4-8 are required.

SUBCHAPTER 4.5

HYDROLOGY AND WATER QUALITY

Introduction

Significance Criteria

Potential Hydrology and Water Quality Impacts and Mitigation Measures

Cumulative Hydrology and Water Quality Impacts

Cumulative Mitigation Measures

4.5 HYDROLOGY AND WATER QUALITY

The proposed amended regulation will require facilities to collectively lower their emissions, thus improving air quality in the long term in order to meet the project's objectives. However, the installation of air pollution control equipment as a result of implementing the proposed project could potentially result in adverse hydrology and water quality impacts. The hydrology and water quality analysis in this PEA identifies the net effect of hydrology and water quality from implementing the proposed project.

4.5.1 Introduction

As previously summarized in Table 4.0-2, the proposed project is expected to result in the installation of the following new NOx air pollution control equipment for the top NOx emission equipment/source categories. The equipment/source categories are divided into two sectors: refinery and non-refinery. There are nine facilities in the refinery sector and 11 facilities in the non-refinery sector. For both sectors, individual facilities were evaluated to determine the number and type of NOx control devices that may be installed as a result of implementing the proposed project. The different types of control devices include SCR, LoTOx^{TM} with or without a WGS, and catalyst impregnated filters with an UltraCat DGS. Reducing NOx emissions from the affected facilities will provide an air quality benefit in the near- and long-term. Direct air quality impacts from the proposed project are expected to result in a reduction of NOx at the affected facilities, which will provide air quality and human health benefits to the public. However, installing new or modifying existing air pollution control equipment is expected to have potentially adverse hydrology and water quality impacts. The analysis of these impacts can be found in Section 4.5.3. Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs. Further, since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74. Thus, the analysis in this PEA for the refinery sector is conservative as it overestimates the potential adverse hydrology and water quality impacts. Refer to Appendix E for the calculations used to estimate adverse hydrology and water quality impacts during construction and operation.

4.5.2 Significance Criteria

Potential impacts on water resources will be considered significant if any of the following criteria apply:

Water Demand:

- The existing water supply does not have the capacity to meet the increased demands of the project, or the project would use more than 262,820 gallons per day of potable water.
- The project increases demand for total water by more than five million gallons per day.

Water Quality:

- The project will cause degradation or depletion of ground water resources substantially affecting current or future uses.

- The project will cause the degradation of surface water substantially affecting current or future uses.
- The project will result in a violation of National Pollutant Discharge Elimination System (NPDES) permit requirements.
- The capacities of existing or proposed wastewater treatment facilities and the sanitary sewer system are not sufficient to meet the needs of the project.
- The project results in substantial increases in the area of impervious surfaces, such that interference with groundwater recharge efforts occurs.
- The project results in alterations to the course or flow of floodwaters.

4.5.3 Potential Hydrology and Water Quality Impacts and Mitigation Measures

Table 4.5-1 summarizes the estimated number of NOx emission control devices per sector and per equipment/source category. The different types of control devices include Selective Catalytic Reduction (SCR), a proprietary Low Temperature Oxidation technology (LoTOx^{TM}) with or without a Wet Gas Scrubber (WGS), and catalyst impregnated filters with a Dry Gas Scrubber (UltraCat DGS).). In total, the proposed project is expected to result in the installation of the following new NOx air pollution control equipment: up to 117 SCRs, eight LoTOx^{TM} with WGSs, one LoTOx^{TM} without WGS, and three UltraCat DGSs.

Table 4.5-1
Estimated Number of NOx Control Devices Per Sector and Equipment/Source Category

Sector	Equipment/Source Category	Number of Affected Facilities	Estimated Number of Control Devices
Refinery	Fluid Catalytic Cracking Units (FCCUs)	5	2 SCRs 2 LoTOx^{TM} with WGSs* 1 LoTOx^{TM} without WGS
Refinery	Refinery Process Heaters and Boilers	8	74 SCRs^
Refinery	Refinery Gas Turbines	5	7 SCRs
Refinery	Sulfur Recovery Unit / Tail Gas Units (SRU/TGUs)	5	5 LoTOx^{TM} with WGSs 1 SCR
Refinery	Petroleum Coke Calciner	1	1 LoTOx^{TM} with WGS or 1 UltraCat with DGS
Non-Refinery	Container Glass Melting Furnaces	1	2 SCRs or 1 UltraCat with DGS
Non-Refinery	Sodium Silicate Furnaces	1	1 SCR or 1 UltraCat with DGS
Non-Refinery	Metal Heat Treating Furnaces	1	1 SCR
Non-Refinery	Internal Combustion Engines (Non-Refinery/Non-Power Plant)	3	16 SCRs
Non-Refinery	Turbines (Non-Refinery/Non-Power Plant)	7	13 SCRs and 1 SCR replacement
		TOTAL	**114 to 117 SCRs** **7 to 8 LoTOx^{TM} with WGSs** **1 LoTOx^{TM} without WGS** **3 UltraCat DGSs**

* Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs.

^ Since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74.

4.5.3.1 Hydrology and Water Quality Impacts During Construction

Implementation of the proposed project could potentially result in construction activities at 20 NOx RECLAIM facilities, which are complex, well-established and mostly paved, industrial facilities. The physical changes that are expected from implementing the proposed project focus on the installation of new or the modification of existing control equipment for the following stationary sources of NOx: 1) FCCUs; 2) refinery boilers and heaters; 3) refinery gas turbines; 4) SRU/TGUs; 5) non-refinery/non-power plant gas turbines; 6) non-refinery sodium silicate furnaces; 7) non-refinery/non-power plant ICEs; 8) container glass melting furnaces; 9) coke calcining; and, 10) metal heat treating furnaces. As previously summarized in Table 4.3-1, the proposed project is expected to result in the installation of the following new NOx air pollution control equipment: up to 117 SCRs, eight LoTOx^{TM} with WGSs, one LoTOx^{TM} without WGS, and three UltraCat DGSs.

During installation or modification of add-on air pollution control devices, adverse hydrology and water quality impacts may occur during construction due to the need for water for dust suppression. Depending on the proposed location within each facility's boundaries for the siting of any new control equipment that may be installed as a result of implementing the proposed project, construction activities such as digging, earthmoving, grading, slab pouring, or paving could occur if the proposed site for the new equipment is not suitable in its present form (e.g., graded with a foundation slab). Tables 4.5-2 and 4.5-3 contain a summary of the estimates of plot space needed per facility for the refinery and non-refinery sectors, respectively. Table 4.5-4 contains a summary of the estimates of plot space needed for all 20 facilities.

Based on the consultant's surveys of the affected facilities, if all affected facilities conduct site preparation activities, the total amount of disturbed area for all of the 20 facilities combined is estimated to be 102,495 square feet (2.35 acres). For a worst-case analysis, all affected facilities are assumed to conduct overlapping site preparation activities, though as a practical matter, not much overlap of site preparation activities would be expected since there are several years from when the first and last NOx RTC shave occurs (e.g., between 2016 and 2022). Further, depending on the scale, site preparation typically can take anywhere from two days to one month. Therefore, it is unlikely that all affected facilities will do site preparation both in the same month of the same year. The largest parcel of land to be potentially disturbed at any one facility could occur at Refinery 5 and is approximately 24,943 square feet which represents almost 25 percent of the total area to be disturbed.

Instead of installing new equipment, there are a few facility operators that may choose to modify or replace their existing NOx control equipment. In these cases, site preparation activities are not expected because the existing foundation and the existing equipment are expected to be reused in their current location and current plot space. Therefore, no water for dust suppression purposes is expected to be needed for these facilities for any construction upgrades to existing NOx control equipment.

Table 4.5-2
Potential Plot Space Needed For Proposed NOx Control Technologies at Refinery Facilities

Refinery ID	Potential NOx Control per Equipment/Source Category	Plot Space Needed for Proposed Controls (square feet)
1	SRU/TGU: 1 LoTOx™ with WGS Gas Turbine: 1 SCR Boilers/Heaters: 14 SCRs 15 NH3 Storage Tanks	3,953 + 0 + 2,464 + 6,000 + **12,417**

	TOTAL	**12,272**

Table 4.5-4
Total Plot Space Needed By All 20 Facilities

Sector	Plot Space Needed for Proposed Controls (square feet)	Total Acreage
9 Refineries	93,927	2.16
11 Non-Refineries	12,272	0.28
TOTAL	**106,199**	**2.44**

The amount of plot spaced needed per facility directly correlates to how much soil may be disturbed and how much water may be needed for dust suppression during construction. To comply with the dust suppression requirements in SCAQMD Rule 403 – Fugitive Dust, during site preparation activities, some water is expected to be used. For example, one water truck per affected facility may be needed for dust suppression activities during the initial site preparation/earth moving portion of the proposed project. One water truck can hold approximately 6,000 gallons for dust control and it can be refilled over the course of the day if more than 6,000 gallons is needed. To minimize fugitive dust, a minimum of watering two times per day is required. However, on windy days, it may be necessary to conduct a third water application.

At a peak watering rate of three applications per day, Table 4.5-5 shows that the peak amount of water that could be used for site preparation/dust suppression is 12,501 gallons per day if all 20 facilities were under construction and disturbing the soil at the same time. The calculations in Table 4.5-5 assume watering three times per day during construction, with 1/16 inch depth of water applied per visit, and 451 gallons of water applied per cubic foot of disturbed area.

Table 4.5-5

Total Amount of Water Needed By All 20 Facilities For Dust Suppression

Sector	**Water Needed for Dust Suppression** (gallons/day)
9 Refineries	10,674
11 Non-Refineries	1,377
TOTAL	**12,501**

The potential increase in water use for the facilities that may need to conduct watering for dust suppression activities is below the SCAQMD's significance thresholds of five million gallons per day of total water (e.g., potable, recycled, and groundwater) and 262,820 gallons per day of potable water. It is important to note that due to the need to quickly construct a proper foundation for the proposed control equipment, earth moving activities during site preparation are expected to be of a short duration lasting from two to three days to no longer than one month per facility. As such, the corresponding dust control activities are also not expected to last longer than one month per facility. Further, water used for dust suppression does not have to be of potable quality, but can be recycled water. Nonetheless, the amount of water that may be used on a daily basis for dust suppression activities during construction is less than significant.

Once constructed, but prior to operation, additional water is expected to be used to hydrostatically (pressure) test all storage tanks and pipelines to ensure each structure's integrity and wastewater may be created during the testing. Pressure testing or hydrotesting is typically a one-time event, unless a leak is found. Similar to dust suppression, water used for pressure testing does not have to be of potable quality, but can be recycled water. In addition, water used during hydrotesting can be sent somewhere else within a facility for future re-use. For example, in the Final Negative Declaration for the Phillips 66 Los

Angeles Refinery Carson Plant – Crude Oil Storage Capacity Project[1], water used during hydrotesting of the crude storage tank was later sent to hydrotest another smaller tank being built as part of the project. Afterwards, the water from the hydrotesting was transferred to a fire water tank that supplies process water to the refinery so that no water was wasted as a result of hydrotesting.

Tables 4.5-6 and 4.5-7 contain a summary of the number of NH3 storage tanks that may be constructed at each facility, the number of tanks that may have overlapping construction activities per facility, and the amount of water that may be needed to hydrotest each tank for the refinery and non-refinery sectors, respectively. Table 4.5-8 contains a summary of the peak water demand for hydrotesting one tank per facility at all 20 facilities in one day as well as the total amount of water needed for hydrotesting the entire project.

Table 4.5-6

Total Amount of Water Needed for Hydrotesting Storage Tanks at Refinery Facilities

10	2	2,000	2	4,000	4,000
11	1	10,000	1	10,000	10,000
TOTAL	**15**		**15**	**34,724**	**34,724**

Table 4.5-8
Total Amount of Water Needed By All 20 Facilities For Hydrotesting

Sector	**Peak Daily Water Needed for Hydrotesting** (gallons/day)	**Total Water Needed for Hydrotesting Entire Project** (gallons/project)
9 Refineries	319,000	924,000
11 Non-Refineries	34,724	34,724
TOTAL	**353,724**	**958,724**

As shown in Table 4.5-7, the potential increase in water use for all 20 facilities conducting hydrotesting activities in one day is greater than the SCAQMD’s significance threshold of 262,820 gallons per day of potable water. Thus, the amount of potable water that may be used on a daily basis for hydrotesting activities post-construction but prior to operation is potentially significant, primarily due to the refinery sector. However, the potential increase in water use for all 20 facilities conducting hydrotesting activities for the entire project is below the SCAQMD’s significance threshold of five million gallons per day of total water. Thus, the amount of total water that may be used for hydrotesting activities post-construction but prior to operation for the entire project is less than significant.

Construction Water Quality

Any wastewater generated from hydrotesting or pressure testing is expected to flow to each affected facility's wastewater treatment or collection system and recycled or discharged after treatment with process wastewater. Thus, wastewater generation from pressure testing activities is not expected to affect groundwater quality. Further, the volume of wastewater that will be generated from pressure testing is equivalent to the amount of water needed for hydrotesting, as shown in Table 4.5-8. Relative to the potential increases in wastewater generation during operation over the long-term as shown in Table 4.5 10, the volume of wastewater that will be generated during hydrotesting on the short-term is expected to be minimal and within the capacity of each facility's wastewater treatment and collection systems.

Further, because the total amount of disturbed area for all of the facilities combined is estimated to be 106,199 square feet (2.44 acres) with the peak amount of area to be disturbed at Refinery 5 at 27,418 square feet (0.63 acre), the proposed construction activities will disturb less than one acre at all 20 facilities. This means that a NPDES General Permit for Storm Water Discharges Associated with Construction Activity, also referred to as a Storm Water Construction Permit, would not be required for any of the affected facilities. Because the proposed project is expected to disturb substantially less than one acre per facility, on-site collection of storm water in each facility's storm water collection system is expected to be about the same as the amount currently collected.

Therefore, less than significant impacts are expected from wastewater generation or storm water during construction or during hydrotesting post-construction.

Construction Conclusion

Construction Dust Suppression: Less than significant adverse water demand and wastewater impacts are expected during construction of the proposed project.

Hydrotesting Post-Construction: Significant adverse water demand impacts from hydrotesting are expected. Less than significant impacts are expected from wastewater generation or storm water from hydrotesting.

4.5.3.2 Mitigation of Construction Hydrology and Water Quality Impacts

Construction Dust Suppression: Less than significant adverse impacts associated with hydrology (water demand) and water quality are expected from the proposed project during construction, so no mitigation measures during construction are required.

Hydrotesting Post-Construction – Water Demand: Significant adverse water demand impacts from hydrotesting are expected, so mitigation measures during hydrotesting are required. For any facility that installs NOx control equipment that also requires the installation of support equipment, such as a storage tank or other equipment, to be installed and hydrotested as part of the proposed project, SCAQMD staff, pursuant to mitigation measures, will require~~s~~ that the facility operators utilize both current supplies and future supplies of recycled water in accordance with the California Water Code, and if available, pursuant to the HRRWP or other recycled water pipeline, if available, to conduct hydrotesting~~ of the storage tank~~. Alternately, facility operators may substitute the use of purchased recycled water with non-potable water such as treated process water (e.g., cooling tower blowdown water, etc.) that is temporarily re-routed or diverted from elsewhere within the facility. Based on the preceding discussion, the following water demand mitigation measures during hydrotesting will apply to the proposed project:

HWQ-1 When support equipment such as a storage tank or other equipment is installed to support operations of installed NOx control equipment and hydrotesting is required prior to ~~its~~ operation, the facility operator is required to use, in lieu of potable water, recycled water or other non-potable process water temporarily diverted from elsewhere within the facility, if available, to satisfy the water demand for hydrotesting.

HWQ-2 For hydrotesting purposes, i~~I~~n the event that recycled water cannot be delivered to the affected facility and diverted non-potable process water is not used, the facility operator is required to submit two ~~a~~ written declarations with each ~~the~~ application for a Permit to Construct for the NOx control equipment and any support equipment such as ~~the~~ storage tank or other equipment that requires hydrotesting, one to be signed by an official of the water purveyor indicating the reason(s) why recycled water cannot be delivered ~~supplied~~ to the project and one from a high-ranking officer at the facility indicating the reason(s) and the supporting evidence that explains why the non-potable process water cannot be diverted to the project from elsewhere within the facility.

Hydrotesting Post-Construction – Water Quality: Less than significant impacts are expected from wastewater generation or storm water from hydrotesting, so no water quality mitigation measures are required during hydrotesting.

4.5.3.3 Remaining Construction Hydrology and Water Quality Impacts After Mitigation

Construction Dust Suppression: The hydrology and water quality analysis concluded that potential hydrology (water demand) and water quality impacts during construction would be less than significant, so no mitigation measures are required during construction. Thus, hydrology and water quality impacts during construction remain less than significant.

Hydrotesting Post-Construction – Water Demand: The hydrology analysis concluded that potential water demand impacts during hydrotesting would be significant, so mitigation measures are required during hydrotesting. The water demand analysis during hydrotesting shows that the potential increase in potable water use cannot be fully satisfied ~~supplied~~ either with all ~~potable water or with a combination of~~ recycled water or ~~and~~ a combination of non-potable water such as process water and recycled water, since some potable water may still be required for certain facilities. The use of non-potable water such as recycled water and diverted process water can help substantially reduce the water demand impacts to a less than significant level if facility operators that have access to recycled water or diverted non-potable process water are required to use recycled water, if available, or diverted non-potable process water. For example, Refineries 1, 5 and 6 currently have access to recycled water and Refineries 4 and 9 may have future access to recycled water (see Subsection 4.5.3.4 for a more detailed discussion). Further, the use of other non-potable process water temporarily diverted from elsewhere within the facility is another option that can help substantially reduce the potable water demand impacts to a less than significant level if facility operators that have a way to divert non-potable process water to a location within the facility where hydrotesting will be conducted. For example, for the Phillips 66 Los Angeles Refinery Carson Plant – Crude Oil Storage Capacity Project, water for conducting hydrotesting was satisfied with non-potable groundwater that was temporarily diverted from the fire water tank[2]. In addition, the reuse of hydrotest water, whether the source is recycled water or other non-potable water, for multiple tanks, for example, for other uses within each facility can also help substantially reduce~~d~~ the water demand impacts to a less than significant level. However, because there is no absolute guarantee at the time of this writing that ~~future supplies of potable water or~~ recycled water or other non-potable will be available to all of the affected facilities, the analysis conservatively assumes that potable water may be needed. Therefore, the proposed project will remain significant after mitigation for water demand during hydrotesting.

Hydrotesting Post-Construction – Water Quality: Since less than significant impacts are expected from wastewater generation or storm water from hydrotesting, no water quality mitigation measures are required during hydrotesting. Thus, water quality impacts during hydrotesting remain less than significant.

4.5.3.4 Hydrology and Water Quality Impacts During Operation

Of the technologies proposed as BARCT for NOx control, only WGSs utilize water and generate wastewater as part of their day-to-day operations. For this reason, only WGS technology was identified as having the potential to generate adverse hydrology and water quality operational impacts. The potential adverse affects on hydrology (water demand) and wastewater will be the focus of the evaluation in this subchapter. The analysis shows that WGS technology may be installed for two FCCUs, five SRU/TGUs, and one coke calciner for the refinery sector. However, for the non-refinery sector, WGS technology was not identified as BARCT for the affected equipment. Table 4.5-9 summarizes the estimated number of WGSs that may be installed for each ~~the~~ refinery, the amount of increased water demand, and the amount of increased wastewater to be generated as a result of implementing the proposed project.

[2] SCAQMD, Final Negative Declaration for: Phillips 66 Los Angeles Refinery Carson Plant – Crude Oil Storage Capacity Project, SCH No. 2013091029, December 12, 2014, p. 2-57. http://www.aqmd.gov/docs/default-source/ceqa/documents/permit-projects/2014/phillips-66-fnd.pdf?sfvrsn=2

Table 4.5-9
Estimated Number of WGSs to be Installed for the Refinery Sector and Associated Water Use/Wastewater Generation

Refinery ID	Potential NOx Control per Equipment/Source Category	Potential Increase in Operational Water Demand (gal/day)	Potential Increase in Wastewater Generation (gal/day)
1	SRU/TGU: 1 LoTOx™ with WGS	70,000	13,973
2	Coke Calciner: 1 LoTOx™ with WGS	40,896	16,992
4	FCCU: 1 LoTOx™ with WGS	49,315	21,918
5	SRU/TGU: 2 LoTOx™ with 2 WGSs	219,178	98,630
6	SRU/TGU: 1 LoTOx™ with WGSs	109,589	49,315
8	SRU/TGU: 1 LoTOx™ with WGS	70,000	13,973
9	FCCU: 1 LoTOx™ with WGS	43,836	21,918
	TOTAL	**602,814**	**236,719**

<u>Water Demand</u>
As summarized in Table 4.5-10, each affected refinery provided its water demand baseline and these water usage rates were compared to each facility's estimated potential increase in water demand that may result from implementing the proposed project. The peak percentage increase from baseline levels when compared to the proposed project was approximately 3.70 percent (Refinery 2) but most of the affected facilities have a potential increase in water demand from less than one to two percent above each facility's baseline. The overall increase in water demand for is 1.31 percent above the total water use baseline for all of the affected refineries combined.

Table 4.5-10
Potential Increases in Operational Water Demand per Affected Refinery

Refinery ID	Proposed Control Technology That Utilizes Water	Potential Increase in Water Use (MMgal/day)	Current Facility Water Use (MMgal/day)	Percentage Increase Above Baseline
1	SRU/TGU: 1 LoTOx™ with WGS	0.07	12.5	0.56%
2	Coke Calciner: 1 LoTOx™ with WGS	0.04	1.08	3.70%
4	FCCU: 1 LoTOx™ with WGS	0.05	5.76	0.87%
5	SRU/TGU: 2 LoTOx™ with 2 WGSs	0.21	10.75	1.95%
6	SRU/TGU: 1 LoTOx™ with WGSs	0.11	10.32	1.07%
8	SRU/TGU: 1 LoTOx™ with WGS	0.07	2.88	2.43%
9	FCCU: 1 LoTOx™ with WGS	0.04	2.5	1.60%
	TOTAL*	**0.60**	**45.79**	**1.31%**

*Total adjusted due to rounding

It is important to note that operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the installation of WGS technology along with the corresponding increased water demand and wastewater generation projections that were originally contemplated for one of the two FCCUs (e.g., Refineries 4 and 9) identified in Tables 4.5-9 and 4.5-10 are no longer expected to occur. Thus, the potential increase in operational water demand is expected to be less. To protect the identity of the refinery in this document, the revised potential increase in operational water demand will be presented as a range, from 553,499 gallons per day to 558,978 gallons per day, instead of 602,814 gallons per day as shown in Table 4.5-9.

As explained in Subchapter 3.5 – Hydrology and Water Quality, Governor Brown proclaimed a State of Emergency for California due to unprecedented drought conditions. New laws went into effect to begin regulating groundwater by adding restrictions on pumping in some areas to prevent aquifers from dwindling and wells from running dry. Water districts, in response to the drought, have also taken actions throughout the state such as: 1) asking for voluntary reductions; 2) imposing mandatory restrictions or declaring a local emergency; 3) imposing agricultural rationing; 4) imposing drought rates, surcharges and fines; 5) limiting new development and requiring water efficient landscaping; 6) implementing a conservation campaign; 7) stopping water pumping from various streams; and, 8) adjusting water contract allocations. In addition, water shortages have prompted cities to begin infrastructure improvements to secure future water supplies.

Because of the drought and the uncertainty of future water supplies, it was ~~is~~ not clear at the~~is~~ time of the release of the Draft PEA whether water suppliers would be able to accommodate the additional operational water demand if the proposed project goes forward, especially if potable water or groundwater would be relied upon to supply the water demand. Subsequently, SCAQMD staff has been able to verify that projected water deliveries of potable water and recycled water to industrial sources will be able to supply the potential water demand needs of the proposed project. As part of making a determination if water supplies will be sufficient for the proposed project, the availability of recycled water is an important factor. Of the ~~seven~~ affected refineries, three facilities (e.g., Refineries ~~Facilities~~ 1, 5, and 6) currently access recycled water from the Harbor Refineries Recycled Water Pipeline (HRRWP) which is maintained by the Los Angeles Department of Water and Power (LADWP), in conjunction with the West Basin Municipal Water District (WBMWD). The LADWP/WBMWD currently provides 35 million gallons per day (MMgal/day) of recycled water to its customers, which include Refineries 1, 5, and 6. The WBMWD is also in the process of expanding its Hyperion Pump Station to accommodate a throughput of 70 MMgal/day of source water which would result in about 55 to 60 MMgal/day of saleable recycled water if, and when needed to accommodate any increased need by their customers[3]. Thus, s~~S~~hould operators of these three facilities commit to utilizing recycled water in lieu of potable water to satisfy the water demand for the NOx control equipment, then the LADWP/WBMWD would be able to supply the additional water (e.g., 398,767 gallons per day or approximately 71 ~~66~~ percent of the projected water demand).

[3] Personal communications with Joe Walters, West Basin Municipal Water District, August 3, 2015 and November 4, 2015.

At the time of writing the~~is~~ Draft PEA, SCAQMD was ~~has~~ not ~~been~~ able to confirm whether three refineries (e.g., Refineries ~~Facilities~~ 4, 8 and 9) have connected to the HRRWP to access its supply of recycled water. To date, none of these refineries have connected to the HRRWP. However, Refinery 4 is in the process of finalizing an agreement with WBMWD to acquire 2,240 acre-feet/year (AF/yr)[4] of recycled water (equivalent to two MMgal/day) to replace its current potable water use with recycled water by 2018. In addition, Refineries 4, 8, and 9 are currently in talks with the LADWP and WBMWD to negotiate options for replacing as much as 11,100 AF/yr (equivalent to approximately 9.9 MMgal/day) of current potable water use with recycled water instead via the HRRWP[5]. Thus, if Refineries 4, 8 and 9 need additional recycled water in response to this proposed project, the LADWP/WBMWD has the capacity to provide additional recycled water as necessary[2].

Table 4.5-11 identifies each refinery's suppliers of purchased potable and recycled at the wholesale and retail level.

Table 4.5-11
Purchased Water Suppliers per Affected Refinery

Refinery ID	**Purchased Water Supplier**
1 and 8	CWS (retailer); WBMWD (wholesaler)
2	LBWD
4 and 9	LADWP (retailer); MWD (wholesaler)
5	City of El Segundo (retailer); WBMWD (wholesaler)
6	City of Torrance (retailer); WBMWD (recycled wholesaler)

Key:
CWS = California Water Service
WBMWD = West Basin Municipal Water District
LBWD = Long Beach Water Department
LADWP = Los Angeles Department of Water and Power
MWD = Metropolitan Water District

A 2010 Urban Water Management Plan (UWMP) is required to be adopted by July 1, 2011 (California Water Code §10608.20) for each urban water supplier to demonstrate the availability of current and projected water supplies. Tables 4.5-12 through 4.5-18 summarize the water delivery projections for the various suppliers to the refinery facilities that have a projected increase in water demand.

According to the 2010 UWMPs for the California Water Service (CWS) and the West Basin Municipal Water District (WBMWD) that were prepared in accordance with the California Water Code §10608.20 and as summarized in Tables 4.5-12 and 4.5-13, the potable water delivery projections to their industrial customers show a long-term projected increase in potable water supply with a slight tapering in supply occurring between years 2025 and 2035 that will be offset by increased deliveries of recycled water instead. These two water suppliers provide water to Refineries 1 and 8. Based on the short- and long-term growth projections for potable and recycled water supplies for the CWS and WBMWD, SCAQMD staff believes that the potential increased water demand of 140,000 gallons per day (equivalent to approximately 157 AF/yr) for Refineries 1 and 8 can be accommodated with either potable or recycled water.

[2] Metropolitan Water District of Southern California, 2010 Regional Urban Water Management Plan, November 2010, Table 2-7, p. 2-13. http://mwdh2o.com/PDF_About_Your_Water/2.4.2_Regional_Urban_Water_Management_Plan.pdf

According to the 2010 UWMPs for the Los Angeles Department of Water and Power (LADWP) and the Metropolitan Water District (MWD) that were prepared in accordance with the California Water Code §10608.20 and as summarized in Tables 4.5-14 and 4.5-15, the potable and recycled water delivery projections to their municipal and industrial customers show a gradual increase in supply occurring between years 2010 and 2035. These two water suppliers provide water to Refineries 4 and 9. As explained earlier, because one of these two refineries has plans to shut down its FCCU, only one of the two WGSs contemplated for the two FCCUs is now projected to occur. Thus, only the water demand for one of the two refineries is also expected to occur (e.g., either 43,836 gallons per day or 49,315 gallons per day). Based on the short- and long-term projections for potable and recycled water supplies for the LADWP and MWD, SCAQMD staff believes that the potential increased water demand of either 43,836 gallons per day or 49,315 gallons per day (equivalent to approximately 49 AF/year to 55 AF/yr) for either Refinery 4 or 9 can be accommodated with either potable or recycled water.

N/A = data not available
[1] City of El Segundo, 2010 Urban Water Management Plan, Tables 3.2.3 through 3.2.6, pp. 3-11 to 3-12. http://www.elsegundo.org/civicax/filebank/blobdload.aspx?BlobID=14356
[2] City of El Segundo, 2010 Urban Water Management Plan, Table 3.2.8, p. 3-13. http://www.elsegundo.org/civicax/filebank/blobdload.aspx?BlobID=14356

According to the 2010 UWMPs for the WBMWD and the City of El Segundo that were prepared in accordance with the California Water Code §10608.20 and as summarized in Tables 4.5-13 and 4.5-16, the City of El Segundo's potable water delivery projections to their industrial customers show a gradual tapering in potable water supply occurring between years 2015 and 2030 that will be offset by deliveries of recycled water instead. However, the WBMWD's potable and recycled water delivery projections show an increase over the same timeframe (gradual for potable water, substantial increase for recycled water). These two water suppliers provide water to Refinery 5, which currently receives recycled water. Based on the short- and long-term projections for potable and recycled water supplies for the WBMWD and the City of El Segundo, SCAQMD staff believes that the potential increased water demand of 219,178 gallons per day (equivalent to approximately 246 AF/year) can be accommodated with either potable or recycled water.

* The pot able water data is for all customers, not just industrial sources.

1 City of Torrance, 2010 Urban Water Management Plan, July 2011, Table 2.6, page 2-10. http://www.water.ca.gov/urbanwatermanagement/2010uwmps/Torrance,%20City%20of/00%20Final%20Torrance%202010%20UWMP_07-28-11.pdf

2 City of Torrance, 2010 Urban Water Management Plan, July 2011, Tables 2.5 and 2.6, page 2-10. http://www.water.ca.gov/urbanwatermanagement/2010uwmps/Torrance,%20City%20of/00%20Final%20Torrance%202010%20UWMP_07-28-11.pdf

According to the 2010 UWMPs for the WBMWD and the City of Torrance that were prepared in accordance with the California Water Code §10608.20 and as summarized in Tables 4.5-13 and 4.5-17, the City of Torrance's potable water delivery projections to their industrial customers show an increase in potable and recycled water supply when compared to deliveries in 2010. The WBMWD's potable and recycled water delivery projections also show an increase over the same timeframe (gradual for potable water, substantial increase for recycled water). These two water suppliers provide water to Refinery 6, which currently receives recycled water. Based on the short- and long-term projections for potable and recycled water supplies for the WBMWD and the City of Torrance, SCAQMD staff believes that the potential increased water demand of either 109,589 gallons per day (equivalent to approximately 123 AF/year) can be accommodated with either potable or recycled water.

[2] Long Beach Water Department, 2010 Urban Water Management Plan, September 2011, Attachment B, Tables 23 and 24, page 9. http://www.water.ca.gov/urbanwatermanagement/2010uwmps/Long%20Beach%20Water%20Department/Attach_B.pdf

~~Further, Facility~~ Refinery 2 is not located near the HRRWP nor any other recycled water pipeline so it is unlikely that Refinery ~~Facility~~ 2 would be able to obtain recycled water should facility operators choose to install a WGS and instead, would need to satisfy the water demand with potable water. According to the Long Beach Water Department's (LBWD's) 2010 UWMP that was prepared in accordance with the California Water Code §10608.20, the potable water delivery projections to their industrial and commercial customers show a long-term projected increase in potable water supply with a slight tapering occurring in years 2030 and 2035 to reflect offsetting by increased deliveries of recycled water to other customers currently being supplied by LBWD with potable water. Based on LBWD's short- and long-term projections for potable and recycled water supplies, SCAQMD staff believes that the potential increased water demand of 40,896 gallons per day for Refinery 2 can be accommodated.

In addition, it is important to keep in mind that operators of Refinery 2 have two different types of control equipment options available for consideration. As summarized in the Tables 1-2 and 1-3 for the petroleum coke calciner source category, the BARCT NOx levels of 10 ppmv corrected for 3% oxygen can be achieved with either a WGS which uses water, or a DGS, which does not. While the analysis in this subchapter considers the technology with the worst-case impacts to water demand and water quality, for Refinery 2, installing WGS technology is not their only option. Should operators choose to install a DGS, instead of a WGS, then no water would be needed.

Thus, while the amount of water demand that would be needed to operate NOx control equipment would be 398,767 gallons per day at Refineries 1, 5 and 6 and the amount of water demand at Refineries ~~Facilities~~ 2, 4, 8, and 9 would be in the range of 113,836 gallons per day to 160,211 ~~204,047~~ gallons per day, which collectively is greater ~~less~~ than the significance threshold of 262,820 gallons per day of potable water ~~and~~ but less than the significance threshold of five million gallons per day of total water (e.g., potable, recycled, and groundwater), in consideration that Refineries 1, 5 and 6 have a high potential to use recycled water because of their current access and in light of the negotiations for recycled water at Refineries 4, 8, and 9, potable water only may be needed for a future project occurring at Refinery 2, or not at all if operators of Refinery 2 choose to install a DGS instead of a WGS. ~~it is not known at this time whether~~ In any case, the previous analysis shows that the water purveyors would be able to supply potable water to ~~for these facilities~~ Refinery 2 and to Refineries 1, 4, 5, 6, 8 and 9, if needed. Thus, using an abundance of caution, because the peak daily water demand for the proposed project exceeds the potable water threshold of 262,820 gallons per day and because ~~SCAQMD staff is unable verify whether the peak daily water demand can be satisfied with~~ recycled water is not currently available at ~~for any of the~~ R~~r~~efineries 4, 8 and 9, and no contractual commitments to increase recycled water demand above the existing recycled water baseline for ~~including~~ the three refineries that already have access to recycled water (e.g., Refineries 1, 5 and 6) have been finalized, the analysis conservatively concludeds that significant adverse impacts associated with water demand are expected from the proposed project during operation.

Water Quality

As summarized in Table 4.5-19~~11~~, each affected facility provided their wastewater discharge limits and these limits were compared to each facility's estimated potential increase in wastewater that may result from implementing the proposed project. The peak percentage increase from baseline levels when compared to the proposed project was approximately nine~~12~~ percent (Refinery 2~~9~~). An increase of 25 percent above discharge permit limits would trigger a permit revision and would be considered a significant adverse wastewater impact. Since all of the affected facilities have been shown to have a potential wastewater increase less than 25 percent, no modifications to any existing wastewater discharge permits are anticipated as a result of the proposed project. Thus, the operational impacts of the proposed project on each affected facility's wastewater discharge and the Industrial Wastewater Discharge Permit are expected to be less than significant.

Table 4.5-19~~11~~
Potential Increases in Wastewater Generation per Affected Refinery

Refinery ID	Proposed Control Technology that Generates Wastewater	Potential Increase in Wastewater Generation (MMgal/day)	Wastewater Permit Discharge Limit[1] (MMgal/day)	Percentage Increase Above Discharge Limit	Greater than 25% Increase? (Exceeds CEQA Significance Threshold?)
1	SRU/TGU: 1 LoTOx™ with WGS	0.01	8.8	0.16%	NO
2	Coke Calciner: 1 LoTOx™ with WGS	0.02	0.18	9.44%	NO
4	FCCU: 1 LoTOx™ with WGS	0.02	1.1	1.99%	NO
5	SRU/TGU: 2 LoTOx™ with 2 WGSs	0.10	7.5	1.31%	NO
6	SRU/TGU: 1 LoTOx™ with WGSs	0.05	15	0.33%	NO
8	SRU/TGU: 1 LoTOx™ with WGS	0.01	2.88	0.49%	NO
9	FCCU: 1 LoTOx™ with WGS	0.02	1.08 ~~0.18~~	2.16 ~~12.18~~%	NO
	TOTAL[2]	**0.24**	**36.54 ~~35.64~~**	**0.66~~7~~%**	

[1] Wastewater limits were obtained from each facility's wastewater permit(s). For any facility that has multiple discharge limits (i.e. dry weather, wet weather, etc.), the most conservative limit will be used for the purposes of this comparison.
[2] Total adjusted due to rounding

It is important to note that operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the installation of WGS technology along with the corresponding increased wastewater generation projections that were originally contemplated for one of the two FCCUs (e.g., Refineries 4 and 9) identified in Tables 4.5-9 and 4.5-10 are no longer expected to occur. Thus, the potential increase in operational wastewater generation is expected to be less. To protect the identity of the refinery in this document, the revised potential increase in operational wastewater generation will be reduced from 236,719 gallons per day to 214,801 gallons per day instead. Nonetheless, this reduction in operational wastewater generation will lessen the impacts further than what was analyzed at the time the Draft PEA was released for public review and comment.

No changes to each affected facility's storm water collection systems are expected because the physical changes that will occur at a facility will be associated with existing units (i.e., to install new control equipment on existing equipment or upgrading existing control equipment) and these changes will not affect existing storm water collection systems. Further, typically most of the areas likely to be affected by the proposed project are currently paved and are expected to remain paved. Any new units constructed will be curbed and the existing units will remain curbed to contain any runoff. Any runoff occurring will continue to be handled by each affected facility's wastewater system and sent to an on-site wastewater treatment system prior to discharge. The surface water runoff is expected to be handled with each facility's current wastewater collection or treatment system. Storm water runoff will be collected and discharged in accordance with each facility's discharge permit terms and conditions.

Operation Conclusion

In summary, significant adverse water demand impacts and less than significant water quality impact are expected during operation of the proposed project.

4.5.3.5 Mitigation of Operation Hydrology and Water Quality Impacts

The proposed project is expected to have significant adverse water demand impacts during operation. If significant adverse environmental impacts are identified in a CEQA document, the CEQA document shall describe feasible measures that could minimize the significant adverse impacts (CEQA Guidelines §15126.4). The following mitigation measures will apply to any facility whose operator chooses to install NOx control equipment that utilizes water for its operation. If, at the time when each facility-specific project is proposed in response to the proposed project, SCAQMD staff will conduct a CEQA evaluation of the facility-specific project and determine if the project is covered by the analysis in this PEA. In addition, these mitigation measures will be included in a mitigation monitoring plan as part of issuing SCAQMD permits to construct for the facility-specific project. The mitigation measures will be enforceable by SCAQMD personnel.

Water Demand: Potentially significant adverse impacts associated with operational water demand are expected from the proposed project during operation. Thus, mitigation measures for water demand are required. For any facility that installs a WGS as part of the proposed project, SCAQMD staff requires, pursuant to mitigation measures, that the facility operators utilize both current supplies and future supplies of recycled water in accordance with the California Water Code, and if available, pursuant to the HRRWP or other recycled water pipeline, if available, for operation of a WGS. Based on the preceding discussion, the following water demand mitigation measures will apply to the proposed project:

HWQ-3 When NOx control equipment is installed and water is required for its operation, the facility operator is required to use recycled water, if available, to satisfy the water demand for the NOx control equipment.

HWQ-4 In the event that recycled water cannot be delivered to the affected facility, the facility operator is required to submit a written declaration with the application for a Permit to Construct for the NOx control equipment, to be signed by an official of the water purveyor indicating the reason(s) why recycled water cannot be delivered ~~supplied~~ to the project.

Water Quality: Less than significant adverse impacts associated with operational water quality are expected from the proposed project during operation, so no mitigation measures during operation are required.

4.5.3.6 Remaining Operation Hydrology and Water Quality Impacts After Mitigation

Water Demand: The water demand analysis shows that the potential increase in potable water use can~~not~~ be fully satisfied ~~supplied~~ either with all potable water or with a combination of recycled water and potable water, since some potable water may still be required for certain facilities. The use of recycled water can help substantially reduce the water demand impacts to a less than significant level if facility operators that have access to recycled water are required to use recycled water, if available. However, there is no absolute guarantee at the time of this writing that future supplies of ~~potable water or~~

recycled water can actually be delivered ~~will be available~~ to all of the affected facilities. Therefore, the proposed project will remain significant after mitigation for water demand.

Water Quality: The water quality analysis concluded that potential water quality impacts during operation would be less than significant, so no mitigation measures are required. Thus, water quality impacts during operation remain less than significant.

4.5.4 Cumulative Hydrology and Water Quality Impacts

Water Demand: Even though the analysis shows that there is a sufficient supply of both potable and recycled water available, b~~B~~ecause the project-specific water demand impacts have been concluded to be significant due to the uncertainty of the ability for some facilities to receive recycled water ~~supplies for some of the affected facilities~~ and in consideration of California's on-going drought, it could be argued that the potential water demand impacts from implementing the proposed project is cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1). Therefore, the proposed project is expected to generate significant adverse cumulative water demand impacts.

Water Quality: Because the project-specific water quality impacts do not exceed any applicable significance thresholds, they are not considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, do not generate significant adverse cumulative water quality impacts.

4.5.5 Cumulative Mitigation Measures

Water Demand: Because the project-specific water demand impacts during hydrotesting and during operation are considered to be cumulatively considerable, cumulative mitigation measures are required. Thus, the following cumulative water demand mitigation measures will apply to any facility whose operator chooses to install NOx control equipment that utilizes water for its operation. If, at the time when each facility-specific project is proposed in response to the proposed project, SCAQMD staff will conduct a CEQA evaluation of the facility-specific project and determine if the project is covered by the analysis in this PEA. In addition, these mitigation measures will be included in a mitigation monitoring plan as part of issuing SCAQMD permits to construct for the facility-specific project. The mitigation measures will be enforceable by SCAQMD personnel.

HWQ-1 When support equipment such as a storage tank is installed to support operations of installed NOx control equipment and hydrotesting is required prior to ~~its~~ operation, the facility operator is required to use, in lieu of potable water, recycled water or other non-potable process water temporarily diverted from elsewhere within the facility, if available, to satisfy the water demand for hydrotesting.

HWQ-2 For hydrotesting purposes, i~~I~~n the event that recycled water cannot be delivered to the affected facility and diverted non-potable process water is not used,, the facility operator is required to submit two ~~a~~ written declarations with the application for a Permit to Construct for the NOx control equipment and any support equipment such as a storage tank or other equipment that requires hydrotesting, one to be signed by an official of the water purveyor indicating the reason(s) why recycled water cannot be delivered ~~supplied~~ to the project and one from a high-ranking officer at the facility indicating the reason(s) and the supporting evidence that explains why the non-potable process water cannot be diverted to the project from elsewhere within the facility.

HWQ-3 When NOx control equipment is installed and water is required for its operation, the facility operator is required to use recycled water, if available, to satisfy the water demand for the NOx control equipment.

HWQ-4 In the event that recycled water cannot be delivered to the affected facility, the facility operator is required to submit a written declaration with the application for a Permit to Construct for the NOx control equipment, to be signed by an official of the water purveyor indicating the reason(s) why recycled water cannot be delivered ~~supplied~~ to the project.

Water Quality: Because the project-specific water quality impacts during construction and operation are not considered to be cumulatively considerable, no cumulative mitigation measures are required.

SUBCHAPTER 4.6

SOLID AND HAZARDOUS WASTE

Introduction

Significance Criteria

Potential Solid and Hazardous Waste Impacts and Mitigation Measures

Cumulative Solid and Hazardous Waste Impacts

Cumulative Mitigation Measures

4.6 SOLID AND HAZARDOUS WASTE

The proposed amended regulation will require facilities to collectively lower their emissions, thus improving air quality in the long term in order to meet the project's objectives. However, the installation of air pollution control equipment as a result of implementing the proposed project could potentially result in adverse solid and hazardous waste impacts. The solid and hazardous waste analysis in this PEA identifies the net effect of solid and hazardous waste from implementing the proposed project.

4.6.1 Introduction

As previously summarized in Table 4.0-2, the proposed project is expected to result in the installation of the following new NOx air pollution control equipment for the top NOx emission equipment/source categories. The equipment/source categories are divided into two sectors: refinery and non-refinery. There are nine facilities in the refinery sector and 11 facilities in the non-refinery sector. For both sectors, individual facilities were evaluated to determine the number and type of NOx control devices that may be installed as a result of implementing the proposed project. The different types of control devices include SCR, LoTOx^{TM} with or without a WGS, and catalyst impregnated filters with an UltraCat DGS. Reducing NOx emissions from the affected facilities will provide an air quality benefit in the near- and long-term. Direct air quality impacts from the proposed project are expected to result in a reduction of NOx at the affected facilities, which will provide air quality and human health benefits to the public. However, installing new or modifying existing air pollution control equipment is expected to have potentially adverse solid and hazardous waste impacts. The analysis of these impacts can be found in Section 4.6.3. Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs. Further, since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74. Thus, the analysis in this PEA for the refinery sector is conservative as it overestimates the potential adverse solid and hazardous waste impacts. Refer to Appendix E for the calculations used to estimate the amount of solid and hazardous waste that may be generated during construction and operation of the proposed project.

4.6.2 Significance Criteria

The proposed project impacts on solid and hazardous waste will be considered significant if the following occurs:

- The generation and disposal of hazardous and non-hazardous waste exceeds the capacity of designated landfills.

4.6.3 Potential Solid and Hazardous Waste Impacts and Mitigation Measures

4.6.3.1 Potential Solid and Hazardous Waste Impacts During Construction

Construction activities associated with installing NOx control equipment such as demolition and site preparation/grading/excavating could generate solid waste as result of implementing the proposed project. Demolition activities could generate demolition waste while site preparation, grading, and excavating could uncover contaminated soils since the facilities affected by the proposed project are located in existing industrial areas. Excavated soil, which may be contaminated, will need to be characterized, treated, and disposed of offsite in accordance with applicable regulations. Where appropriate, the soil will be recycled if it is considered or classified as non-hazardous waste or it can be disposed of at a landfill that accepts non-hazardous waste. Otherwise, the material will need to be disposed of at a hazardous waste facility. (Potential soil contamination is addressed in the NOP/IS (see Appendix F of this PEA), in the Hazards/Hazardous Materials discussion in Section VIII. d. and was concluded to have less than significant impacts.)

Solid or hazardous wastes generated from construction-related activities at the 20 affected facilities would consist primarily of materials from the demolition of existing air pollution control equipment (if applicable) and construction associated with installing new air pollution control equipment or modifying existing air pollution control equipment. Construction-related waste can be disposed of either at a Class II (industrial) or Class III (municipal) landfill. Any equipment that is removed during demolition may be dismantled and metals may be sold as scrap. Class II landfills may accept designated and nonhazardous wastes and Class III landfills may accept nonhazardous wastes. However, there are no Class II landfills within the SCAQMD's jurisdiction. There are 31 Class III active landfills and two transformation facilities located within the district with a total capacity of 107,933 tons per day and 3,240 tons per day, respectively (see Subchapter 3.6, Tables 3.6-2 and 3.6-3)[1]. While the actual amount of construction debris that may be generated from installing new or modifying existing NOx control equipment at 20 facilities cannot be calculated, the amount of debris generated would not be expected to exceed the designated capacity of these landfills. For this reason, the construction impacts of the proposed project on waste treatment/disposal facilities are expected to be less than significant.

4.6.3.2 Mitigation of Solid and Hazardous Waste Impacts During Construction

Less than significant adverse impacts associated with solids and hazardous wastes are expected from the proposed project during construction, so no mitigation measures are required.

4.6.3.3 Remaining Solid and Hazardous Waste Impacts During Construction After Mitigation

The solids and hazardous wastes analysis concluded that potential solids and hazardous wastes impacts during construction would be less than significant, no mitigation measures were required. Thus, solids and hazardous wastes impacts during construction remain less than significant.

[1] 2012 Annual Report, Los Angeles County Countywide Integrated Waste Management Plan, Appendix E-2 Table 1 (LACDPW, 2013).

4.6.3.4 Potential Solid and Hazardous Waste Impacts During Operation

If the proposed project is implemented, solid waste may also be generated from the operation of the new NOx air pollution control equipment at both the refinery and non-refinery facilities, depending on the type of NOx control equipment employed. Tables 4.6-1 and 4.6-2 summarize the potential increased amount of solid waste expected to be generated for the refinery and non-refinery sector, respectively.

Table 4.6-1
Potential Increase in Solid Waste at Refinery Facilities

* Solid waste would only be generated if the operator of non-refinery Facility 8 chooses to install an Ultracat system. However, if the operator of non-refinery Facility 8 chooses to install SCR technology, in lieu of the Ultracat system, then no solid waste would be generated.

In addition, if the proposed project is implemented, waste from spent catalyst may also be generated every five years from the operation of SCR technology at both the refinery and non-refinery facilities. For both solid waste and spent catalyst waste, it is possible that some, if not all, of the 20 affected facilities will address any increase in waste through their existing waste minimization plans. For example, some of the affected facilities in both the refinery and non-refinery sectors currently have existing catalyst-based operations and the spent catalysts are either regenerated, reclaimed or recycled, in lieu of disposal. Moreover, due to the heavy metal content and its relatively high cost, catalyst recycling can be a lucrative choice. Depending on operating conditions, it is expected that for any new SCR system installed, the spent catalysts would also be reclaimed and recycled, though it is possible that spent catalysts could be disposed of. The composition of the catalyst will determine in which type of landfill a catalyst would be disposed.

A catalyst with a metal structure would not normally be considered a hazardous waste. Instead, it would be considered a metal waste, like copper pipes, and, therefore, would not be a regulated waste requiring disposal in a Class I landfill unless it is friable or brittle. Ceramic-based catalysts are not considered friable or brittle because they typically include a fiber binding material in the catalyst material. In both cases, spent catalyst would not require disposal in a Class I landfill. Furthermore, typical catalyst materials are not considered to be water soluble, which also means they would not require disposal in a Class I landfill.

Based on the preceding discussion, it is likely that spent catalysts would be considered a "designated waste," which is characterized as a non-hazardous waste consisting of, or containing pollutants that, under ambient environmental conditions, could be released at concentrations in excess of applicable water objectives, or which could cause degradation of the waters of the state (California Code of Regulations, Title 23, Chapter 3 Subparagraph 2522(a)(1)). Depending on its actual waste designation, spent catalysts would likely be disposed of in a Class III landfill that is fitted with liners.

Disposal of spent catalyst would typically involve crushing the material and encasing it in concrete prior to disposal. Since it is expected that most spent catalysts will be recycled and regenerated, it is anticipated that there will be sufficient landfill capacity in the district to accommodate disposal of any spent catalyst materials. Thus, the potential increase of solid waste generated by the air pollution control equipment operated at the 20 affected facilities that are expected to install NOx control equipment as a result implementing the proposed project may not necessarily be disposed of and, therefore, is not expected to exceed the capacity of designated landfills available to each affected facility.

As summarized in Table 4.6-1, the projected solid waste data obtained by the consultant from each affected refinery facility also indicated that approximately six tons per day of solid waste may be generated by the NOx air pollution control equipment. However, because the solid waste that may be generated at the refinery facilities is expected to be a commodity, it is also not expected to be disposed of in a landfill. Instead, the additional solid waste that may be generated from the refinery facilities will be sent to a cement plant located outside of SCAQMD's jurisdiction for recycling. In any case, even if the entire amount of solid waste that may be generated by the refinery facilities as a result of the proposed project is sent to a landfill, the amount would not exceed the capacity of these designated landfills. For this reason, the operational impacts from the refinery facilities on waste treatment/disposal facilities are expected to be less than significant.

For the non-refinery facilities, potential solid waste generation data is summarized in As summarized in Table 4.6-1, and shows that only one non-refinery facility, Facility 8, could potentially generate solid waste (approximately 1.2 tons per day) if an Ultracat system is installed. However, if operators of Facility 8 choose to install SCR technology, in lieu of an Ultracat system, then no solid waste would be generated from the SCR technology and only spent catalyst waste would be generated once every five years. Operators of Facility 8 have indicated that solid waste that may be generated from the Ultracat system could either be sent to a cement plant for recycling or to a Class III landfill. As such, the relatively small amount of solid waste that may be generated from the non-refinery sector would not exceed the capacity of the designated landfills. Thus, the operational impacts from the one non-refinery facility on waste treatment/disposal facilities are also expected to be less than significant.

Further, implementing the proposed project is not expected to hinder in any way any affected facility's ability to comply with existing federal, state, and local regulations related to solid and hazardous wastes. Based upon these considerations, the overall operational impacts of the proposed project on waste treatment/disposal facilities due to solid waste that may be generated from both refinery and non-refinery facilities are expected to be less than significant.

4.6.3.5 Mitigation of Operational Solid and Hazardous Waste Impacts

Less than significant adverse impacts associated with solids and hazardous wastes are expected from the proposed project during operation, so no mitigation measures are required.

4.6.3.6 Remaining Operational Solid and Hazardous Waste Impacts After Mitigation

The solids and hazardous wastes analysis concluded that potential solids and hazardous wastes impacts during operation would be less than significant, no mitigation measures were required. Thus, solids and hazardous wastes impacts during operation remain less than significant.

4.6.4 Cumulative Solid and Hazardous Waste Impacts

Because the project-specific solid and hazardous waste impacts do not exceed any applicable significance thresholds, they are not considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, do not generate significant adverse cumulative solid and hazardous waste impacts.

4.6.5 Cumulative Mitigation Measures

Because the project-specific solid and hazardous waste impacts during construction and operation are not considered to be cumulatively considerable, no cumulative mitigation measures are required.

SUBCHAPTER 4.7

TRANSPORTATION AND TRAFFIC

Introduction

Significance Criteria

Potential Transportation and Traffic Impacts and Mitigation Measures

Cumulative Transportation and Traffic Impacts

Cumulative Mitigation Measures

4.7 TRANSPORTATION AND TRAFFIC

The proposed amended regulation will require facilities to collectively lower their emissions, thus improving air quality in the long term in order to meet the project's objectives. However, the installation of air pollution control equipment as a result of implementing the proposed project could potentially result in transportation and traffic impacts. The transportation and traffic analysis in this PEA identifies the net effect of transportation and traffic impacts from implementing the proposed project.

4.7.1 Introduction

As previously summarized in Table 4.0-2, the proposed project is expected to result in the installation of the following new NOx air pollution control equipment for the top NOx emission equipment/source categories. The equipment/source categories are divided into two sectors: refinery and non-refinery. There are nine facilities in the refinery sector and 11 facilities in the non-refinery sector. For both sectors, individual facilities were evaluated to determine the number and type of NOx control devices that may be installed as a result of implementing the proposed project. Reducing NOx emissions from the affected facilities will provide an air quality benefit in the near- and long-term. Direct air quality impacts from the proposed project are expected to result in a reduction of NOx at the affected facilities, which will provide air quality and human health benefits to the public. However, installing new or modifying existing air pollution control equipment is expected to have potentially adverse transportation and traffic impacts.

The environmental analysis assumes that installation of NOx control technologies for the affected sources will reduce NOx emissions overall, but construction activities associated with both the installation of new control devices and the modification of existing control devices will create adverse transportation and traffic impacts. A project generates adverse transportation and traffic impacts both during the period of its construction and through ongoing daily operations. During installation or modification of add-on air pollution control devices, transportation and traffic impacts may be generated by delivering onsite construction equipment and by offsite vehicles used for worker commuting. After construction activities are completed, transportation and traffic impacts may be generated by maintenance activities associated with the operation of the add-on air pollution control devices such as offsite vehicles used for delivering fresh materials needed for operations (e.g., chemicals, fresh catalyst, etc.) and hauling away solid waste for disposal or recycling (e.g., spent catalyst). The analysis of these impacts can be found in Section 4.7.3. Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs. Further, since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74. Thus, the analysis in this PEA for the refinery sector is conservative as it overestimates the potential adverse transportation and traffic impacts. Refer to Appendix E for the calculations used to estimate secondary construction- and operational-related transportation and traffic impacts.

4.7.2 Significance Criteria

Impacts on transportation and traffic will be considered significant if any of the following criteria apply:

- Peak period levels on major arterials are disrupted to a point where level of service (LOS) is reduced to D, E or F for more than one month.
- An intersection's volume to capacity ratio increase by 0.02 (two percent) or more when the LOS is already D, E or F.
- A major roadway is closed to all through traffic, and no alternate route is available.
- The project conflicts with applicable policies, plans or programs establishing measures of effectiveness, thereby decreasing the performance or safety of any mode of transportation.
- There is an increase in traffic that is substantial in relation to the existing traffic load and capacity of the street system.
- The demand for parking facilities is substantially increased.
- Water borne, rail car or air traffic is substantially altered.
- Traffic hazards to motor vehicles, bicyclists or pedestrians are substantially increased.
- The need for more than 350 employees
- An increase in heavy-duty transport truck traffic to and/or from the facility by more than 350 truck round trips per day
- Increase customer traffic by more than 700 visits per day.

4.7.3 Potential Transportation and Traffic Impacts and Mitigation Measures

Table 4.7-1 summarizes the estimated number of NOx emission control devices per sector and per equipment/source category. The different types of control devices include Selective Catalytic Reduction (SCR), a proprietary Low Temperature Oxidation technology (LoTOx^{TM}) with or without a Wet Gas Scrubber (WGS), and catalyst impregnated filters with a Dry Gas Scrubber (UltraCat DGS). In total, the proposed project is expected to result in the installation of the following new NOx air pollution control equipment: up to 117 SCRs, eight LoTOx^{TM} with WGSs, one LoTOx^{TM} without WGS, and three UltraCat DGSs.

Table 4.7-1

Estimated Number of NOx Control Devices Per Sector and Equipment/Source Category

Sector	Equipment/Source Category	Number of Affected Facilities	Estimated Number of Control Devices
Refinery	Fluid Catalytic Cracking Units (FCCUs)	5	2 SCRs 2 LoTOx^{TM} with WGSs* 1 LoTOx^{TM} without WGS
Refinery	Refinery Process Heaters and Boilers	8	74 SCRs^
Refinery	Refinery Gas Turbines	5	7 SCRs
Refinery	Sulfur Recovery Unit / Tail Gas Units (SRU/TGUs)	5	5 LoTOx^{TM} with WGSs 1 SCR
Refinery	Petroleum Coke Calciner	1	1 LoTOx^{TM} with WGS or 1 UltraCat with DGS
Non-Refinery	Container Glass Melting Furnaces	1	2 SCRs or 1 UltraCat with DGS
Non-Refinery	Sodium Silicate Furnaces	1	1 SCR or 1 UltraCat with DGS
Non-Refinery	Metal Heat Treating Furnaces	1	1 SCR
Non-Refinery	Internal Combustion Engines (Non-Refinery/Non-Power Plant)	3	16 SCRs
Non-Refinery	Turbines (Non-Refinery/Non-Power Plant)	7	13 SCRs and 1 SCR replacement
		TOTAL	**114 to 117 SCRs** **7 to 8 LoTOx^{TM} with WGSs** **1 LoTOx^{TM} without WGS** **3 UltraCat DGSs**

* Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs.

^ Since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74.

4.7.3.1 Construction Analysis

Construction activities resulting from implementing the proposed project may generate a temporary increase in traffic in the areas of each affected facility associated with construction workers, construction equipment, and the delivery of construction materials. However, the proposed project is not expected to cause a significant increase in traffic relative to the existing traffic load and capacity of the street systems surrounding the affected facilities. Also, the proposed project is not expected to exceed, either individually or cumulatively, the current LOS of the areas surrounding the affected facilities during construction as explained in the following discussion.

Table 4.7-2 summarizes the number of construction workers and delivery/haul trips that may be needed to install the various NOx control equipment during construction for both the refinery and non-refinery sectors.

Table 4.7-2
Estimated Number of Worker Trips and Delivery/Haul Trips Needed During Construction of NOx Control Devices in a Peak Day

Sector	Equipment/Source Category	Type of NOx Control Technology	Peak Daily Construction Workers Trips Needed Per NOx Control	Peak Daily Delivery/ Haul Trips Needed
Refinery	FCCUs	1. SCR 2. LoTOx™ with WGS 3. LoTOx™ without WGS	1. 140 2. 175 3. 20	1. 10 2. 10 3. 10
Refinery	Refinery Process Heaters and Boilers	SCR	20	10
Refinery	Refinery Gas Turbines	SCR	20	10
Refinery	SRU/TGUs	1. LoTOx™ with WGS 2. SCR	1. 175 2. 140	1. 10 2. 10
Refinery	Petroleum Coke Calciner	1. LoTOx™ with WGS 2. UltraCat DGS	1. 175 2. 175	1. 10 2. 10
Non-Refinery	Container Glass Melting Furnaces	1. SCR 2. UltraCat DGS	1. 18 2. 175	1. 5 2. 10
Non-Refinery	Sodium Silicate Furnaces	1. SCR 2. UltraCat DGS	1. 18 2. 175	1. 5 2. 10
Non-Refinery	Metal Heat Treating Furnaces	SCR	18	5
Non-Refinery	ICEs (Non-Refinery/Non-Power Plant)	SCRs	18	5
Non-Refinery	Turbines (Non-Refinery/Non-Power Plant)	SCR	18	5

There are multiple source categories with multiple approaches to reducing NOx at the refinery facilities. With so many possibilities or permutations of how operators of the refinery could achieve actual NOx reductions, there is no way to predict what each facility operator will actually do. For this reason, the analysis illustrates the worst-case effects of applying the various NOx control technologies to each affected facility.

From a construction point of view, the installation of a NOx control technology at a facility is a rather complex process. For example, if a facility operator chooses to install NOx control equipment, time will be needed for pre-construction/advance planning activities such as engineering analysis of the affected equipment, engineering design of the potential control equipment, contracting with a vendor, securing financing, ordering and purchasing the equipment, obtaining permits and clearances, and lining up contractors and workers. The amount of lead time can vary from six months (e.g., for a SCR for refinery/boiler heater or gas turbine) to up to 18 months for a scrubber (either a WGS or DGS).

Then to physically build the equipment, an additional six to 18 months would be needed. For example, six months would be needed to construct one SCR for one refinery boiler/ heater or gas turbine, 12 months would be needed to construct a SCR for a FCCU, and up to 18 months would be needed to construct a scrubber (either a WGS or DGS) for a FCCU or SRU/TGU. Where the new equipment will be sited will determine if any demolition activities would be required. For this analysis, scrubber installation would have the most impacts relative to the number of construction workers and delivery/haul trips needed. Thus, to be conservative, to construct one WGS, one month of demolition activities is assumed to occur at each affected facility and an additional 17 months is assumed for site preparation, assembly and installation of the unit and ancillary support equipment, preparation of the affected unit for a turnaround/shutdown, and tying-in the new scrubber to the affected equipment. As a practical matter, construction activities that are anticipated to occur as a result of implementing the proposed project would likely occur prior to a scheduled maintenance (e.g., turnaround) of the affected unit.

Typically construction projects have staggered construction schedules which take into account design and engineering, ordering, purchasing and delivery of equipment, permitting and environmental review, the availability of construction crews, budgeting, and any other construction projects on site. However, due to wide range of construction time necessary to build the various types of NOx control equipment, the construction activities at other affected facilities could overlap. However, because of widely varying turnaround schedules of affected equipment within any given facility and based on past construction projects involving major construction equipment where the SCAQMD was the lead agency, the air quality analysis in Subchapter 4.2 of this PEA includes a conservative assumption that all of the refineries will have overlapping construction activities occurring in one year. However, since having all facilities construct all NOx controls within the first year is unlikely, for demonstrative purposes, the air quality analysis also includes an analysis of the overlapping construction impacts spread out over a five- and seven-year period.

However, for conducting a worst-case transportation and traffic analysis, the significance criteria is on a per facility basis because the facilities are not located close enough together to have large amounts of overlapping traffic. Of the 20 facilities that may install NOx control equipment as a result of the proposed project, Refinery 5 represents the worst-case for construction activities because it has the most equipment/source categories identified as potential candidates for installing NOx control equipment. Based on conversations with operators at Refinery 5, from a construction worker point of view, the turnaround schedule for the FCCU and SRU/TGUs could overlap but both SRU/TGUs would not be shut-down at the same time. Thus, the analysis assumes that construction overlap of the two SRU/TGUs prior to when the turnarounds would not be expected to occur. For the purpose of conducting a worst-case analysis, construction of one SCR for the FCCU and construction for one LoTOx^{TM} system with one WGS scrubber is assumed to overlap. Further, Refinery 5 is projected to retrofit three gas turbines and 12 boilers and heaters with SCR, for a total of 15 units. Peak SCR construction for refinery boilers, heaters and gas turbines was based on a one-third overlap or five SCRs being installed at one time.

Table 4.7-3 summarizes the number of construction workers and delivery/haul trips that may be needed to install the various NOx control equipment during construction at Refinery 5 on a peak day.

Table 4.7-3

Estimated Number of Worker Trips and Delivery/Haul Trips Needed During Construction of NOx Control Devices in a Peak Day For Refinery 5

Affected Equipment/Source Category at Refinery 5	Type of NOx Control Technology	Overlap of Construction for NOx Controls on a Peak Day	Peak Daily Construction Workers Trips Needed Per NOx Control	Peak Daily Delivery/ Haul Trips Needed
1 FCCU	1 SCR	1 SCR	140	10
2 SRU/TGUs	2 LoTOx™ with WGS	1 LoTOx™ with 1 WGS	175	10
1 SRU/TGU	1 SCR	0	0	0
3 Gas Turbines*	3 SCR	1	20	10
12 Boilers/Heaters *	12 SCRs	4	80	40
		TOTAL	**415**	**70**
		Significance Threshold?	700	350
		Significant?	**NO**	**NO**

* While Refinery 5 could install a total of 15 new SCRs for their boilers/heaters/gas turbines, peak construction is based on a 1/3rd overlap of 5 SCRs at one time.

As shown in Table 4.7-3, the peak daily increase in construction workers at a peak facility (Refinery 5) is 415 the peak daily increase in delivery and haul trips utilizing a heavy-duty is 70. Both of these values are less than their respective significance thresholds.

Even if all 415 construction workers drive alone (which represents an average vehicle ridership equal to 1.0), it is unlikely that these vehicle trips would substantially affect the LOS at any intersection because the trips will be somewhat dispersed over a large area. Therefore, the peak daily work force is not expected to significantly increase as a result of the proposed project.

Therefore, the peak daily work force during construction is not expected to significantly increase as a result of the proposed project. Further, the peak daily number of heavy-duty truck trips during construction is also not expected to significantly increase as a result of the proposed project.

Further, the conclusion of no significant transportation impacts based on the workforce is consistent with the transportation analyses in the CEQA documents prepared for six refineries in accordance with the CARB Phase III Reformulated Gasoline requirements[1]. Specifically, the number of construction workers for each of the six projects ranged from approximately 200 to 700 daily construction worker trips and each of these projects was concluded to have no significant transportation impacts.

4.7.3.3 Mitigation of Transportation and Traffic Impacts During Construction

Less than significant adverse impacts associated with transportation and traffic impacts are expected from the proposed project during construction, so no mitigation measures during construction are required.

4.7.3.6 Remaining Construction Transportation and Traffic Impacts After Mitigation

The transportation and traffic analysis concluded that potential transportation and traffic impacts during construction would be adverse, but less than significant, so mitigation measures during construction are not required. Thus, transportation and traffic impacts during construction remain less than significant.

4.7.3.4 Operation Analysis

Non-Refinery Facilities

The following activities may be sources of transportation and traffic impacts during operation of NOx control equipment at 11 non-refinery facilities: 1) vehicle trips via heavy-duty truck for periodic ammonia/urea deliveries for each SCR and Ultracat filtration unit installed; 2) vehicle trips via heavy-duty truck for periodic deliveries of hydrated lime, catalyst, and replacement filters as well as solid waste hauling of spent filters for each Ultracat system installed. In addition to heavy-duty truck trips, the analysis assumes that one medium-duty round-trip for control system maintenance personnel may be needed for each of the 11 non-refinery facilities. A summary of these heavy-duty truck trips are presented in Table 4.7-4.

Table 4.7-4

Operational Truck Trips at 11 Non-Refinery Facilities

Truck Trips	NH3/Urea Delivery Trips[1]	Hydrated Lime Delivery Trips [1,2]	Solid Waste Haul Trips[1]	Filter Waste Haul Trips[1]	Catalyst Delivery Trips[3]	Control System Maintenance Trips[4]	Total Trips
Annual	437	5	11	1	11	11	476
Peak Daily	11	1	1	1	11	1	26

[1] Peak daily trips assumed one ammonia/urea delivery occurs at each non-refinery facility and adsorbent, solid waste and filter waste haul trips occurs on the same day.
[2] Adsorbent, solid waste and filter waste based on vendor estimates for SOx portion of Ultracat system.
[3] Only five catalyst delivery trips are expected because catalysts are replaced every two to three years.
[4] A medium-duty truck is assumed for control system maintenance.

Refinery Facilities

The following activities may be sources of transportation and traffic impacts during operation of NOx control equipment at 9 refinery facilities: 1) vehicle trips via heavy-duty truck for periodic deliveries of ammonia for each SCR installed, NaOH for two LoTOx^{TM} WGSs installed, soda ash for two LoTOx^{TM} WGSs installed, hydrated lime for the Ultracat DGS installed, and oxygen for every LoTOx^{TM} unit installed; 2) vehicle trips via heavy-duty truck for periodic deliveries of catalyst and replacement filters as well as solid waste hauling of spent filters for each SCR unit installed; and 3) via heavy-duty truck hauling solid waste generated by each scrubber (WGS and DGS) installed. A summary of these heavy-duty truck trips are presented in Table 4.7-5.

Table 4.7-5

Heavy-Duty Operational Truck Trips at 9 Refinery Facilities

	Number of Heavy-Duty Truck Trips								
	NH3[1]	NaOH[1]	Hydrated Lime[1]	Soda Ash[1]	Oxygen [1]	Fresh Catalyst[2]	Solid Waste[1]	Spent Catalyst[2]	TOTAL
Annual	498	56	26	21	44	49	96	49	839
Peak Daily	17	3	1	4	1	16	7	16	65

[1] Peak daily trips assumed one heavy-duty truck trip occurs at each refinery facility for each chemical delivery or waste/spent catalyst haul trip.
[2] SCR fresh catalyst delivery trips are expected when the SCR is first built and then replaced every five years. Similarly, spent catalyst waste is also generated every five years.

As shown in Table 4.7-6, the amount of truck trips associated with the proposed project if all 20 facilities install NOx control equipment is 91 round trips in a peak day and 1,315 in one year.

Table 4.7-6
Operational Truck Trips at 20 Affected Facilities

Sector	Peak Daily Truck Trips	Annual Truck Trips
9 Refineries	65	839
11 Non-Refineries	26	476
TOTAL	**91**	**1,315**

Since the increase in transport truck traffic to and/or from each of the 20 affected facilities and from all 20 affected facilities combined is not greater than 350 truck round trips per day, less than significant transportation impacts are expected from implementation of the proposed project during operation. Further, taking into consideration the “worst-case” delivery and hauling transportation schedule, delivery and hauling trips associated with the proposed project are not expected to exceed, either individually or cumulatively, the current LOS of the areas surrounding the affected facilities during operations. Thus, the projected increase of traffic due to operational activities is expected to be minimal and thus, the traffic impacts are expected to be less than significant for the proposed project.

4.7.3.5 Mitigation of Transportation and Traffic Impacts During Operation

Less than significant adverse impacts associated with transportation and traffic impacts are expected from the proposed project during operation, so no mitigation measures are required.

4.7.3.6 Remaining Operational Transportation and Traffic Impacts After Mitigation

The transportation and traffic analysis concluded that potential transportation and traffic impacts during operation would be adverse, but less than significant, so mitigation measures are not required. Thus, transportation and traffic impacts during operation remain less than significant.

4.7.4 Cumulative Transportation and Traffic Impacts

Because the project-specific transportation and traffic impacts do not exceed any applicable significance thresholds during construction and operation, they are not considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, do not generate significant adverse cumulative transportation and traffic impacts.

4.7.5 Cumulative Mitigation Measures

Because the project-specific transportation and traffic impacts during construction and operation are not considered to be cumulatively considerable, no cumulative mitigation measures are required.

SUBCHAPTER 4.8

OTHER CEQA TOPICS

Potential Environmental Impacts Found Not to be Significant

Significant Environmental Effects Which Cannot Be Avoided

Potential Growth-Inducing Impacts

Relationship Between Short-Term Uses and Long-Term Productivity

4.8 OTHER CEQA TOPICS

4.8.1 Potential Environmental Impacts Found Not to be Significant

While all the environmental topics required to be analyzed under CEQA were reviewed to determine if the proposed project would create significant impacts, the screening analysis in the NOP/IS concluded that the following environmental areas would not be significantly adversely affected by the proposed project: agriculture and forestry resources, biological resources, cultural resources, geology and soils, land use and planning, mineral resources, noise, population and housing, public services, and recreation. Eight comment letters were received from the public relative to the NOP/IS. The comment letters and responses to individual comments are included in Appendix G of this document. No comment letters were received that identified other potentially significant adverse impacts from the proposed project.

In addition, subsequent to the release of the NOP/IS, the requirements of California Assembly Bill (AB 52) went into effect on July 1, 2015. AB 52 is promulgated in Public Resources Code §21080.3.1 (d) and requires a formal notification to all California Native American Tribes about lead agency projects that would require the preparation of a CEQA document. While the Office of Planning and Rule (OPR) has until July 1, 2016 to finalize the implementation guidance for this requirement, the SCAQMD is required to comply with AB 52 in the interim.

The Native American Heritage Commission (NAHC) has provided interim guidance to SCAQMD staff recommending that notifications to California Native American Tribes should occur at the same time the SCAQMD releases a CEQA document for public review and comment. The SCAQMD currently follows the State Clearinghouse (SCH) procedures for distributing all CEQA documents to reviewing agencies and the NAHC was specifically designated as a reviewing agency at the time the NOP/IS was released for public review and comment. Of the eight comment letters that were received relative to the NOP/IS, none were from the NAHC. In addition to following the SCH procedures for soliciting agency review of CEQA documents, SCAQMD staff also sent a copy of the NOP for this project to an interested party contact list, which included over 100 contacts for Native American Tribes. Again, no comment letters from any contacts on the Native American Tribes list were received relative to the NOP/IS.

Since the NOP/IS was released for public review and comment prior to July 1, 2015, the Cultural Resources checklist, significance criteria, and discussion that was originally published in the NOP/IS did not reflect the requirements of AB 52. As such, the Cultural Resources checklist, significance criteria, and discussion have been updated in this PEA to specifically address Native American cultural resources in accordance with the requirements of AB 52. However, the conclusion of "No Impact" for all questions under this topic area remains unchanged. Further, SCAQMD staff ~~will continue to~~ followed the same procedures for designating the NAHC as a reviewing agency and for notifying all of the Native American Tribes contained in SCAQMD's interested party database as to the availability of the Draft PEA for public review and comment.

The following is a brief discussion of each environmental topic area found not to be significant in the NOP/IS:

Agriculture and Forestry Resources

Land use, including agriculture- and forest-related uses, and other planning considerations are determined by local governments. While implementation of the proposed project may cause air pollution control equipment to be installed and operated on existing equipment to control NOx emissions, these activities will occur at established NOx RECLAIM facilities which are located on previously developed land in primarily industrial areas and are not located in the vicinity of agricultural or forest areas.

Further, no new construction of buildings or other structures is expected that would require conversion of farmland to non-agricultural use or conflict with zoning for agricultural uses or a Williamson Act contract. Further, because the proposed project does not require construction or operation activities within an area designated as forest land, implementation of the proposed project is not expected to conflict with any forest land zoning codes or convert forest land to non-forest uses. Similarly, there is nothing in the proposed project that would affect or conflict with existing land use plans, policies, or regulations or require conversion of farmland to non-agricultural uses or forest land to non-forest uses. Thus, no agricultural land use or planning requirements will be altered by the proposed project.

Finally, in the event the proposed project is implemented, the installation of NOx control equipment will ensure that projected NOx emission reductions will occur and that air quality in the region will improve. Thus, assuring that these air quality improvements occur could provide benefits to agricultural and forest land resources by reducing the adverse oxidation impacts of ozone on plants and animals located in the Basin. Accordingly, these impact issues will not be further analyzed in the ~~Draft~~ Final PEA.

Based upon these considerations, significant agricultural and forestry resources impacts are not expected from implementing the proposed project, and thus, this topic was not further analyzed in the ~~Draft~~ Final PEA. Since no significant agriculture and forestry resources impacts were identified for any of the issues, no mitigation measures are necessary or required.

Biological Resources

The proposed project would only affect units operating at the top NOx emitting facilities in the NOx RECLAIM program. These facilities have locations scattered throughout the District. All of the affected units operating at existing facilities are located primarily in developed industrial areas, which have already been greatly disturbed and paved. These areas currently do not support riparian habitat, federally protected wetlands, or migratory corridors. Additionally, special status plants, animals, or natural communities are not expected to be found within close proximity to the affected sites within the facilities. Therefore, the proposed project would have no direct or indirect impacts that could adversely affect plant or animal species or the habitats on which they rely in the SCAQMD's jurisdiction. The current and expected future land use development to accommodate population growth is primarily due to economic considerations or local government planning decisions. A conclusion in the Final Program EIR for the 2012 AQMP was that population growth in the region would have greater adverse effects on plant species and wildlife dispersal or migration corridors in the basin than SCAQMD regulatory activities, (e.g., air quality control measures or regulations). In addition, by reducing air pollutants, biological resources will benefit. Moreover, the current and expected future land use development to accommodate population growth is primarily due to economic considerations or local government planning decisions.

Further, the proposed project is not envisioned to conflict with local policies or ordinances protecting biological resources or local, regional, or state conservation plans. Land use and other planning considerations are determined by local governments and no land use or planning requirements will be altered by the proposed project. Additionally, the proposed project will not conflict with any adopted Habitat Conservation Plan, Natural Community Conservation Plan, or any other relevant habitat conservation plan, and would not create divisions in any existing communities because all activities associated with complying with the proposed project will occur at existing industrial facilities.

Based upon these considerations, significant biological resources impacts are not expected from implementing the proposed project, and thus, this topic was not further analyzed in the ~~Draft~~ Final PEA. Since no significant biological resources impacts were identified for any of the issues, no mitigation measures are necessary or required.

Cultural Resources

Subsequent to release of the NOP/IS, modifications were made to the environmental checklist, significance criteria, and discussion of Cultural Resources impacts in response to the requirements in AB 52 to consider the proposed project's potential effects on Cultural Native American Tribe resources. To facilitate identification of what updates have been made to the environmental checklist, significance criteria, and discussion of Cultural Resources impacts in response to the requirements in AB 52 to consider Cultural Native American Tribe impacts, the Cultural Resources portion of the NOP/IS checklist has been repeated in this PEA. The updates are included as underlined text. However, even with the additional information, the overall conclusion of "No Impact" for this topic area remains unchanged.

		Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
V.	**CULTURAL RESOURCES.** Would the project:				
a)	Cause a substantial adverse change in the significance of a historical resource as defined in §15064.5?	☐	☐	☐	☑
b)	Cause a substantial adverse change in the significance of an archaeological resource as defined in §15064.5?	☐	☐	☐	☑
c)	Directly or indirectly destroy a unique paleontological resource, site, or feature?	☐	☐	☐	☑
d)	Disturb any human remains, including those interred outside formal cemeteries?	☐	☐	☐	☑
e)	<u>Cause a substantial adverse change in the significance of a tribal cultural resource as defined in Public Resources Code §21074?</u>	☐	☐	☐	☑

Significance Criteria

Impacts to cultural resources will be considered significant if:

- The project results in the disturbance of a significant prehistoric or historic archaeological site or a property of historic or cultural significance, <u>or tribal cultural significance</u> to a community or ethnic or social group <u>or a California Native American tribe</u>.
- Unique paleontological resources or objects with cultural value to a California Native American tribe are present that could be disturbed by construction of the proposed project.
- The project would disturb human remains.

Discussion

V. a) No Impact. There are existing laws in place that are designed to protect and mitigate potential impacts to cultural resources. Since construction-related activities associated with the implementation of the proposed project are expected to be confined within the existing footprint of the affected facilities that have been fully developed and paved, no impacts to historical resources are expected to occur as a result of implementing the proposed project. Accordingly, this impact issue will not be further analyzed in the Draft PEA.

V. b), c), & d) No Impact. Installing or modifying add-on controls and other associated equipment to comply with the proposed project may require disturbance of previously disturbed areas at the affected existing industrial facilities. However, since construction-related activities are expected to be confined within the existing footprint of the affected facilities that have been fully developed and paved, the proposed project is not expected to require physical changes to the environment, which may disturb paleontological or archaeological resources. Furthermore, it is envisioned that these areas are already either devoid of significant cultural resources or whose cultural resources have been previously disturbed. Therefore, the proposed project has no potential to cause a substantial adverse change to a historical or archaeological resource, directly or indirectly destroy a unique paleontological resource or site or unique geologic feature, or disturb any human remains, including those interred outside a formal cemeteries. The proposed project is, therefore, not anticipated to result in any activities or promote any programs that could have a significant adverse impact on cultural resources in the District. Accordingly, these impact issues will not be further analyzed in the Draft PEA.

V. e) No Impact. The proposed project is not expected to require physical changes to a site, feature, place, cultural landscape, sacred place or object with cultural value to a California Native American Tribe. Furthermore, the proposed project is not expected to result in a physical change to a resource determined to be eligible for inclusion or listed in the California Register of Historical Resources or included in a local register of historical resources. For these reasons, the proposed project is not expected to cause any substantial adverse change in the significance of a tribal cultural resource as defined in Public Resources Code §21074.

It is important to note that as part of releasing this CEQA document for public review and comment, the SCAQMD also provided a formal notice of the proposed project to all California Native American Tribes (Tribes) that requested to be on the Native American Heritage Commission's (NAHC) notification list per Public Resources Code §21080.3.1 (b)(1). The NAHC notification list provides a 30-day period during which a Tribe may respond to the formal notice, in writing, requesting consultation on the proposed project.

In the event that a Tribe submits a written request for consultation during this 30-day period, the SCAQMD will initiate a consultation with the Tribe within 30 days of receiving the request in accordance with Public Resources Code §21080.3.1 (b). Consultation ends when either: 1) both parties agree to measures to avoid or mitigate a significant effect on a Tribal Cultural Resource and agreed upon mitigation measures shall be recommended for inclusion in the environmental document [see Public Resources Code §21082.3 (a)]; or, 2) either party, acting in good faith and after reasonable effort, concludes that mutual agreement cannot be reached [see Public Resources Code §21080.3.2 (b)(1)-(2) and §21080.3.1 (b)(1)].

Based upon these considerations, significant cultural resources impacts are not expected from implementing the proposed project, and thus, this topic was not further analyzed in the ~~Draft~~ Final PEA. Since no significant cultural resources impacts were identified for any of the issues, no mitigation measures are necessary or required.

Geology and Soils

Since the proposed project would result in construction activities at existing RECLAIM facilities located in developed industrial settings to install or modify NOx control equipment, little site preparation is anticipated that could adversely affect geophysical conditions in the jurisdiction of the SCAQMD. Southern California is an area of known seismic activity. Accordingly, the installation of add-on controls at existing affected facilities to comply with the proposed project is expected to conform to the Uniform Building Code and all other applicable state and local building codes. As part of the issuance of building permits, local jurisdictions are responsible for assuring that the Uniform Building Code is adhered to and can conduct inspections to ensure compliance. The Uniform Building Code is considered to be a standard safeguard against major structural failures and loss of life. The basic formulas used for the Uniform Building Code seismic design require determination of the seismic zone and site coefficient, which represents the foundation condition at the site. The Uniform Building Code requirements also consider liquefaction potential and establish stringent requirements for building foundations in areas potentially subject to liquefaction. Thus, the proposed project would not alter the exposure of people or property to geological hazards such as earthquakes, landslides, mudslides, ground failure, or other natural hazards. As a result, substantial exposure of people or structures to the risk of loss, injury, or death involving the rupture of an earthquake fault, seismic ground shaking, ground failure or landslides is not anticipated.

Since add-on controls will likely be installed at existing developed facilities, during construction of the proposed project, a slight possibility exists for temporary erosion resulting from excavating and grading activities, if required. These activities are expected to be minor since the existing facilities are generally flat and have previously been graded and paved. Further, wind erosion is not expected to occur to any appreciable extent, because operators at dust generating sites would be required to comply with the best available control measure (BACM) requirements of SCAQMD Rule 403 – Fugitive Dust. In general, operators must control fugitive dust through a number of soil stabilizing measures such as watering the site, using chemical soil stabilizers, revegetating inactive sites, etc. The proposed project involves the installation or modification of add-on control equipment at existing facilities, so that grading could be required to provide stable foundations. Potential air quality impacts related to grading are addressed elsewhere in this Initial Study (as part of construction air quality impacts). No unstable earth conditions or changes in geologic substructures are expected to result from implementing the proposed project.

Since the proposed project will affect existing facilities, it is expected that the soil types present at the affected facilities will not be made further susceptible to expansion or liquefaction. Furthermore, subsidence is not anticipated to be a problem since only minor excavation, grading, or filling activities are expected occur at affected facilities. Additionally, the affected areas are not envisioned to be prone to new landslide impacts or have unique geologic features since the affected equipment units are located at existing facilities in industrial areas.

Since the proposed project will affect equipment units at existing facilities located in industrial zones, it is expected that people or property will not be exposed to new impacts related to expansive soils or soils incapable of supporting water disposal. Further, typically each affected facility has some degree of existing wastewater treatment systems that will continue to be used and are expected to be unaffected by the proposed project. Sewer systems are available to handle wastewater produced and treated by each affected facility. Each existing facility affected by the proposed project does not require installation of septic tanks or alternative wastewater disposal systems. As a result, the proposed project will not require facility operators to utilize septic systems or alternative wastewater disposal systems. Thus, implementation of the proposed project will not adversely affect soils associated with a septic system or alternative wastewater disposal system.

Based upon these considerations, significant geology and soils impacts are not expected from the implementation of the proposed project, and thus, this topic was not further analyzed in the ~~Draft~~ Final PEA. Since no significant geology and soils impacts were identified for any of the issues, no mitigation measures are necessary or required.

Land Use and Planning

The proposed project does not require the construction of new facilities, but any physical effects that will result from the proposed project, will occur at existing RECLAIM facilities located in heavy industrial areas and would not be expected to go beyond existing boundaries. Thus, implementing the proposed project will not result in physically dividing any established communities.

Further, there are no provisions in the proposed project that would affect land use plans, policies, or regulations. Land use and other planning considerations are determined by local governments and no land use or planning requirements will be altered by the proposed project. Further, the proposed project would be consistent with the typical industrial zoning of the affected facilities. Typically, all proposed construction activities are expected to occur within the confines of the existing facilities. The proposed project would not affect in any way habitat conservation or natural community conservation plans, agricultural resources or operations, and would not create divisions in any existing communities. Finally, no new development or alterations to existing land designations will occur as a result of the implementation of the proposed project. Therefore, present or planned land uses in the region will not be affected as a result of implementing the proposed project.

Based upon these considerations, significant land use planning impacts are not expected from the implementation of the proposed project, and thus, will not be further analyzed in the ~~Draft~~ Final PEA. Further, since no significant impacts were identified for any of these issues, no mitigation measures are necessary or required.

Mineral Resources

There are no provisions in the proposed project that would result in the loss of availability of a known mineral resource of value to the region and the residents of the state such as aggregate, coal, clay, shale, et cetera, or of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan.

Based upon these considerations, significant mineral resource impacts are not expected from the implementation of the proposed project, and thus, will not be further analyzed in the

~~Draft~~ Final PEA. Since no significant mineral resource impacts were identified for any of these issues, no mitigation measures are necessary or required.

Noise

Modifications or changes associated with the implementation of the proposed project will take place at existing RECLAIM facilities that are typically located in heavy industrial settings. The existing noise environment at each of the affected facilities is typically dominated by noise from existing equipment onsite, vehicular traffic around the facilities, and trucks entering and exiting facility premises. Construction activities associated with implementing the proposed project may generate some noise associated with the use of construction equipment and construction-related traffic. However, noise from the proposed project is not expected to produce noise in excess of current operations at each of the existing facilities. If NOx control devices are installed or existing devices are modified, the operations phase of the proposed project may add new sources of noise to each affected facility. However, control devices are not typically equipment that generate substantial amounts of noise. Nonetheless, for any noise that may be generated by the control devices, it is expected that each facility affected will comply with all existing noise control laws or ordinances. Further, Occupational Safety and Health Administration (OSHA) and California-OSHA (Cal/OSHA) have established noise standards to protect worker health. These potential noise increases are expected within the allowable noise levels established by the local noise ordinances for industrial areas, and thus are expected to be less than significant. Therefore, less than significant noise impacts are expected to result from the operation of the proposed project.

Though some of the facilities affected by the proposed project are located at sites within an airport land use plan, or within two miles of a public airport, the addition of new or modification of existing NOx control equipment would not expose people residing or working in the project area to the same degree of excessive noise levels associated with airplanes. All noise producing equipment must comply with local noise ordinances and applicable OSHA or Cal/OSHA workplace noise reduction requirements. Therefore, less than significant noise impacts are expected to occur at sites located within an airport land use plan, or within two miles of a public airport.

Based upon these considerations, significant noise impacts are not expected from the implementation of the proposed project and will not be further analyzed in the ~~Draft~~ Final PEA. Further, since no significant impacts were identified for any of these issues, no mitigation measures are necessary or required.

Population and Housing

The construction activities associated with the proposed project at each affected facility are not expected to involve the relocation of individuals, require new housing or commercial facilities, or change the distribution of the population. The reason for this conclusion is that operators of affected facilities who need to perform any construction activities to comply with the proposed project can draw from the large existing labor pool in the local southern California area. Further, it is not expected that the installation of new or the modification of existing NOx control equipment will require new employees during operation of the equipment. In the event that new employees are hired, it is expected that the number of new employees at any one facility would be small. Human population within the jurisdiction of the SCAQMD is anticipated to grow regardless of implementing the proposed project. As a result, the proposed project is not anticipated to generate any significant adverse effects, either direct or indirect, on population growth in the district or population distribution.

Because the proposed project includes modifications and/or changes at existing facilities located in heavy industrial settings, the proposed project is not expected to result in the creation of any industry that would affect population growth, directly or indirectly induce the construction of single- or multiple-family units, or require the displacement of people or housing elsewhere in the district.

Based upon these considerations, significant population and housing impacts are not expected from the implementation of the proposed project, and thus, will not be further evaluated in the ~~Draft~~ Final PEA. Since no significant population and housing impacts were identified for any of these issues, no mitigation measures are necessary or required.

Public Services

Implementation of the proposed project is expected to cause facility operators to install new or modify existing NOx control devices, all the while continuing current operations at existing affected facilities. The proposed project may result in a greater demand for catalyst, scrubbing agents and other chemicals, which will need to be transported to the affected facilities to support the function of NOx control equipment and stored onsite prior to use. As first responders to emergency situations, police and fire departments may assist local hazmat teams with containing hazardous materials, putting out fires, and controlling crowds to reduce public exposure to releases of hazardous materials. In addition, emergency or rescue vehicles operated by local, state, and federal law enforcement agencies, police and sheriff departments, fire departments, hospitals, medical or paramedic facilities, that are used for responding to situations where potential threats to life or property exist, including, but not limited to fire, ambulance calls, or life-saving calls, may be needed in the event of an accidental release or other emergency. While the specific nature or degree of such impacts is currently unknown, the affected facilities have existing emergency response plans so any changes to those plans would not be expected to dramatically alter how emergency personnel would respond to an accidental release or other emergency. In addition, due the low probability and unpredictable nature of accidental releases, the proposed project is not expected to increase the need or demand for additional public services (e.g., fire and police departments and related emergency services, et cetera) above current levels.

As noted in the previous "Population and Housing" discussion, the proposed project is not expected to induce population growth in any way because the local labor pool (e.g., workforce) is expected to be sufficient to accommodate any construction activities that may be necessary at affected facilities and operation of new or modified NOx control equipment is not expected to require additional employees. Therefore, there will be no increase in local population and thus no impacts are expected to local schools or parks.

The proposed project is expected to result in the use of new or modified add-on control equipment for NOx control. Besides permitting the equipment or altering permit conditions by the SCAQMD, there is no need for other types of government services. The proposed project would not result in the need for new or physically altered government facilities in order to maintain acceptable service ratios, response times, or other performance objectives. There will be no increase in population and, therefore, no need for physically altered government facilities.

Based upon these considerations, significant public services impacts are not expected from the implementation of the proposed project and will not be further evaluated in the ~~Draft~~ Final PEA. Since no significant public services impacts were identified for any of these issues, no mitigation measures are necessary or required.

Recreation

As discussed earlier under the topic of "Population and Housing," there are no provisions in the proposed project that would affect or increase the demand for or use of existing neighborhood and regional parks or other recreational facilities or require the construction of new or the expansion of existing recreational facilities that might have an adverse physical effects on the environment because the proposed project will not directly or indirectly increase or redistribute population. Based upon these considerations, including the conclusion of "no impact" for the topic of "Population and Housing," significant recreation impacts are not expected from implementing the proposed project, and thus, this topic was not further analyzed in the ~~Draft~~ Final PEA. Since no significant recreation impacts were identified, no mitigation measures are necessary or required.

4.8.2 Significant Environmental Effects Which Cannot Be Avoided

CEQA Guidelines §15126 (c) requires an environmental analysis to consider "any significant irreversible environmental changes which would be involved if the proposed action should be implemented." This PEA identified the topics of air quality and GHGs and water demand (under the topic of hydrology and water quality) as the environmental topic areas potentially adversely affected by the proposed project. The NOP/IS also identified the topics of aesthetics, energy, hazards and hazardous materials, solid and hazardous waste, and transportation and traffic as having potentially significant adverse impacts, but after further analysis, these topics were determined to have less than significant impacts. Significant adverse impacts from GHGs generated from both construction and operation activities may be considered irreversible. Facility operators that install new NOx controls or modify existing units are likely to operate these systems for the lifetime of the equipment.

4.8.3 Potential Growth-Inducing Impacts

CEQA Guidelines §15126 (d) requires an environmental analysis to consider the "growth-inducing impact of the proposed action." CEQA defines growth-inducing impacts as those impacts of a proposed project that "could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects, which would remove obstacles to population growth." [CEQA Guidelines §15126.2 (d)]

To address this issue, potential growth-inducing effects are examined through the following considerations:

- Facilitation of economic effects that could result in other activities that could significantly affect the environment;
- Expansion requirements for one or more public services to maintain desired levels of service as a result of the proposed project;
- Removal of obstacles to growth through the construction or extension of major infrastructure facilities that do not presently exist in the project area or through changes in existing regulations pertaining to land development;
- Adding development or encroachment into open space; and/or
- Setting a precedent that could encourage and facilitate other activities that could significantly affect the environment.

4.8.3.1 Economic and Population Growth, and Related Public Services

A project would be considered to directly induce growth if it would directly foster economic or population growth or the construction of new housing in the surrounding environment (e.g., if it would remove an obstacle to growth by expanding existing infrastructure such as new roads or wastewater treatment plants). The proposed project would not remove barriers to population growth, as it involves no changes to a General Plan, zoning ordinance, or a related land use policy.

Further, the proposed project does not include policies that would encourage the development of new housing or population-generating uses or infrastructure that would directly encourage such uses. The proposed project may indirectly increase the efficiency of the region's urban form through encouraging more air quality efficient development patterns in the form of NOx reductions. The proposed project does not change jurisdictional authority or responsibility concerning land use or property issues. Land use authority falls solely under the purview of the local governments. The SCAQMD is specifically excluded from infringing on existing city or county land use authority (California Health and Safety Code §40414). Therefore, the proposed project would not directly trigger new residential development in the area.

The proposed project may result in construction activities associated with installing new or modifying existing air pollution control equipment to achieve NOx reductions. However, the proposed project would not directly or indirectly stimulate substantial population growth, remove obstacles to population growth, or necessitate the construction of new community facilities that would lead to additional growth in the Basin. It is expected that construction workers will be largely drawn from the existing workforce pool in southern California. Considering the existing labor force of about 8.5 million in the region and current unemployment rate of about six percent, it is expected that a sufficient number of workers are available locally and that few or no workers would relocate for construction jobs potentially created by the proposed project as construction activities would be spread over a period from 2015 to 2022[1]. Further, the proposed project would not be expected to result in an increase in local population, housing, or associated public services (e.g., fire, police, schools, recreation, and library facilities) since no increase in population or the permanent number of workers is expected. Likewise, the proposed project would not create new demand for secondary services, including regional or specialty retail, restaurant or food delivery, recreation, or entertainment uses. As such, the proposed project would not foster economic or population growth in the surrounding area in a manner that would be growth-inducing.

Thus, implementing the proposed project will not, by itself, have any direct or indirect growth-inducing impacts on businesses in the SCAQMD's jurisdiction because it is not expected to foster economic or population growth or the construction of additional housing and primarily affects existing facilities.

4.8.3.2 Removal of Obstacles to Growth

The facilities that may be affected by the proposed project are located within an existing urbanized area. The proposed project would not employ activities or uses that would result in growth inducement, such as the development of new infrastructure (e.g., new roadway access or utilities) that would directly or indirectly cause the growth of new populations, communities, or currently undeveloped areas. The proposed project would require additional energy (electricity, diesel, gasoline, and natural gas) to implement but the increased energy requirements are expected to be within those projected for existing population growth of the region. While construction and operation activities that may occur as a result of the proposed project will require trips associated with construction workers, delivery of supplies and haul trips, the analysis in Subchapter 4.7 for Transportation and Traffic concluded that the trips will occur via existing roadways and transportation corridors. Thus, the proposed project is not expected to require the development of new roads or freeways. Likewise, the proposed project would not result in an expansion of existing public service facilities (e.g., police, fire, libraries, and schools) or the development of public service facilities that do not already exist.

4.8.3.3 Development or Encroachments into Open Space

Development can be considered growth-inducing when it is not contiguous to existing urban development and introduces development into open space areas. The proposed project is situated within the existing South Coast Air Basin, which is urbanized. The areas of the Basin where construction activities may occur would be at existing stationary sources and the associated trips would occur along existing transportation corridors. Stationary sources are generally located within commercial and industrial (urbanized) areas. Any related construction activities would be expected to be within the confines of the existing facilities and would not encroach into open space. Therefore, the proposed project would not result in development within or encroachment into an open space area.

4.8.3.4 Precedent Setting Action

Under the NOx RECLAIM program, a BARCT reassessment is required by the California Health and Safety Code ~~§~~§40440 ~~and 39616~~[2] and is needed to capture the advancement in control technology to assure that NOx RECLAIM facilities would achieve emission reductions as expeditiously as possible. In addition, the SCAQMD developed and adopted the 2012 AQMP which established a plan to meet and maintain the state and federal air quality standards. The 2012 AQMP identifies control measures needed to attain the federal 24-hour standard for PM2.5 by 2014 and provides updates on progress towards meeting the 8-hour ozone standard in 2024. In particular, Control Measure CMB-01 is one of the control measures addressed in the 2012 AQMP. This Control Measure reiterates the requirement for a BARCT reassessment for NOx RECLAIM facilities. Finally, since NOx is a precursor of ozone, reducing NOx as a result of implementing the proposed project will help the basin attain the National Ambient Air Quality Standards (NAAQS) for ozone in 2024 and 2032. Therefore, the proposed project is being prepared to comply with state and federal air quality planning regulations and requirements. This project would not result in precedent-setting actions that might cause other significant environmental impacts (other than those evaluated in other sections of this PEA).

4.8.3.5 Conclusion

The proposed project was developed to comply with local, state and federal air quality planning requirements and is not expected to foster economic or population growth or result in the construction of additional housing or other infrastructure, either directly or indirectly, that would further encourage growth. While the proposed project could result in construction projects at existing stationary sources, the proposed project would not be considered growth-inducing, because it would not result in an increase in production of resources or cause a progression of growth that could significantly affect the environment either individually or cumulatively.

4.8.4 Relationship Between Short-Term Uses and Long-Term Productivity

An important consideration when analyzing the effects of a proposed project is whether it will result in short-term environmental benefits to the detriment of achieving long-term goals or maximizing productivity of these resources. Implementing the proposed project is not expected to achieve short-term goals at the expense of long-term environmental productivity or goal achievement. The purpose of the proposed project is to achieve NOx reductions via a BARCT reassessment of NOx RECLAIM facilities in order to achieve emission reductions as expeditiously as possible and comply with local, state and federal air quality planning requirements. By achieving additional reductions in NOx, an ozone and PM2.5 precursor, the proposed project will help attain federal and state air quality standards which are expected to enhance short and long-term environmental productivity in the region.

[2] The reference to Health and Safety Code §39616 has been deleted because it does not require a BARCT analysis. The RECLAIM program proposed here satisfies the findings set forth in Health and Safety Code §39616, although it is not legally required to do so.

Implementing the proposed project does not narrow the range of beneficial uses of the environment. Of the potential environmental impacts discussed in Chapter 4, only those related to air quality and GHG impacts associated with construction and operation activities and water demand (under the topic of hydrology and water quality) are considered potentially significant. Implementation of the recommended mitigation measures will ensure such impacts are mitigated to the greatest degree feasible.

CHAPTER 5

ALTERNATIVES

Introduction

Methodology for Developing Project Alternatives

Description of Alternatives to the Proposed Project

Alternatives Analysis

Comparison of the Alternatives to the Proposed Project

Alternatives Rejected as Infeasible

Lowest Toxic and Environmentally Superior Alternative

Conclusion

5.0 INTRODUCTION

This ~~Draft~~ Final PEA provides a discussion of alternatives to the proposed project as required by CEQA. Pursuant to the CEQA Guidelines, alternatives should include realistic measures to attain the basic objectives of the proposed project but would avoid or substantially lessen any of the significant effects of the project, and provide a means for evaluating the comparative merits of each alternative (CEQA Guidelines §15126.6 (a)). A "No Project" alternative must also be evaluated. In addition, though the range of alternatives must be sufficient to permit a reasoned choice, they need not include every conceivable project alternative (CEQA Guidelines §15126.6 (a)). The key issue is whether the selection and discussion of alternatives fosters informed decision making and public participation. A CEQA document need not consider an alternative whose effect cannot be reasonably ascertained and whose implementation is remote and speculative. SCAQMD Rule 110 (the rule which implements the SCAQMD's certified regulatory program) does not impose any greater requirements for a discussion of project alternatives in a program environmental assessment than is required for an EIR under CEQA.

5.1 METHODOLOGY FOR DEVELOPING PROJECT ALTERNATIVES

The alternatives typically included in CEQA documents for proposed SCAQMD rules, regulations, or plans are developed by breaking down the project into distinct components (e.g., emission limits, compliance dates, applicability, exemptions, pollutant control strategies, etc.) and varying the specifics of one or more of the components. Different compliance approaches that generally achieve the objectives of the project may also be considered as project alternatives.

Alternatives to the proposed project were crafted by varying how the NOx RTC shave would be applied to the NOx RECLAIM facilities and RTC investors. The initial analysis of the proposed project in the NOP/IS determined that, of the amendments proposed, only the components that pertain to the lowered BARCT NOx emission factors could entail physical modifications to the affected equipment and that these physical modifications could create potential adverse significant impacts. As such, in addition to the no project alternative, three alternatives were developed by identifying and modifying major components of the proposed project. Specifically, the primary components of the proposed alternatives that have been modified are the source categories that may be affected, and the manner in which compliance with the proposed lowered BARCT NOx emission factors may be achieved. In addition, in response to comments made by industry, a fifth alternative, with parameters suggested by industry, is also included.

Typically, the existing setting is established at the time the NOP/IS is circulated for public review, which was December 2014. This baseline is used for all environmental topics analyzed in this ~~Draft~~ Final PEA. However, CEQA Guidelines §15125 (a) recognizes that a baseline may be established at times other than when the NOP/IS is circulated to the public by stating (emphasis added), "This environmental setting ***will normally*** constitute the baseline physical conditions by which a lead agency determines whether an impact is significant." As explained in Chapter 2, the baseline for the CPCC facility changed subsequent to when the NOP/IS was circulated for public review such that the installation of control technology and the secondary adverse environmental impacts that may be associated with such control technology is no longer a reasonably foreseeable consequence for CPCC under the present circumstances. Thus, this

PEA does not contain an environmental analysis of the control technologies that were originally contemplated in the NOP/IS as BARCT for the CPCC facility. In addition, none of the alternatives described in the chapter contain an environmental analysis of the control technologies specific to the Portland Cement Kilns or the CPCC facility[1].

In addition, since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs. Further, since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74. Thus, the analysis in this PEA for the refinery sector is conservative as it overestimates the potential adverse environmental impacts for the proposed project.

5.2 DESCRIPTION OF ALTERNATIVES

Five alternatives to the proposed project are summarized in Table 5-1: Alternative 1 (Across the Board), Alternative 2 (Most Stringent), Alternative 3 (Industry Approach), Alternative 4 (No Project), and Alternative 5 (Weighted by BARCT Reduction Contribution for all facilities and investors). The primary components of the proposed alternatives that have been modified are the source categories that may be affected, and the manner in which compliance with the proposed NOx BARCT emission limits may be achieved. Unless otherwise specifically noted, all other components of the project alternatives are identical to the components of the proposed project.

The following subsections provide a brief description of the alternatives.

5.2.1 Alternative 1 – Across the Board Shave of NOx RTCs

Alternative 1 consists of an across the board NOx RTC reduction (shave) of 14 tpd that would affect all NOx RECLAIM facilities and investors. Under Alternative 1, the NOx RTC holdings would be shaved by 53 percent overall. After BARCT is applied, 8.77 ~~8.79~~ tpd of actual NOx reductions from existing emission levels are projected to occur, with an additional 5.23 ~~5.21~~ tpd of NOx RTCs needed to fulfill the shave, post-BARCT. By applying a shave of 53 percent to all facilities, 219 ~~210~~ facilities, which represent the bottom 10 percent of RTC holders, would become potential future buyers of RTCs since the amount of RTC holdings for these facilities would become less than their current actual emissions.

Under Alternative 1, the amount of the proposed NOx RTC shave of 14 tpd is identical to the proposed project. However, the distribution of the shave under Alternative 1 would reduce the NOx RTC holdings differently than the proposed project. Specifically,

[1] Because of CPCC's current permitting status for their Portland cement kilns (e.g., the permits were surrendered), CPCC operators will not be able to retrofit the Portland cement kilns with air pollution control equipment in response to the proposed project without first dealing with the permitting issues for the cement kilns. Thus, the installation of control technology and the secondary adverse environmental impacts that may be associated with such control technology is not a reasonably foreseeable consequence for CPCC under the present circumstances. Further, there are no other facilities in SCAQMD's jurisdiction that operate Portland cement kilns. Thus, this PEA does not contain an environmental analysis of the control technologies that were originally contemplated in the NOP/IS for the CPCC facility.

Alternative 1 would reduce NOx RTC holdings from all 275 NOx RECLAIM facilities and investors by 53 percent overall. The proposed project, however, would reduce NOx RTC holdings by: 1) 66 ~~67~~ percent for 9 refineries and investors (treated as one facility); 2) 49 ~~47~~ percent for 21 EGFs~~30 power plants~~; 3) 49 ~~47~~ percent for 26 non-major facilities; and, 4) zero percent for the remaining 219 ~~210~~ facilities.

The amount of the shave is based on a recent BARCT analysis. For the refinery sector, a new level of BARCT is proposed for FCCUs, refinery boilers/heaters, refinery gas turbines, coke calciners, and SRU/TGUs. For the non-refinery sector, a new BARCT level is proposed for container glass melting furnaces, cement kilns, sodium silicate furnaces, metal heat treating furnaces, gas turbines and ICEs not located on the outer continental shelf (OCS). No new BARCT is proposed for 30 EGFs~~power plants~~. In order to achieve these new BARCT levels, the likely possibility is that operators of 20 facilities within the affected source categories will reduce actual NOx emissions via physical modifications to a wide variety of equipment by installing new air pollution control equipment or modifying existing air pollution control equipment. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 1. In particular, the number and type of control equipment that may be installed as a result of the proposed project and the corresponding adverse impacts that were analyzed for the proposed project, the same control equipment and corresponding adverse impacts will also occur under Alternative 1.

5.2.2 Alternative 2 – Most Stringent Shave of NOx RTCs

Alternative 2 consists of the most stringent approach by applying an across the board NOx RTC shave of 15.87 tpd. Alternative 2 would affect all RECLAIM facilities and investors, but without including the 10 percent compliance margin or the BARCT adjustment for refinery equipment. Under Alternative 2, the NOx RTC holdings would be shaved by 60 percent overall. After BARCT is applied, 8.77 ~~8.79~~ tpd of actual NOx reductions are projected to occur, with 7.10 ~~7.08~~ tpd of NOx RTCs needed to fulfill the shave, post-BARCT. By applying a shave of 60 percent to all facilities, 219 ~~210~~ facilities, which represent the bottom 10 percent of RTC holders, would become potential future buyers of RTCs since the amount of RTC holdings for these facilities would become less than their current actual emissions.

Under Alternative 2, the amount of the proposed NOx RTC shave of 15.87 tpd is greater than the 14 tpd NOx RTC shave that is contemplated by the proposed project. In addition, the distribution of the shave under Alternative 2 would reduce the NOx RTC holdings differently than the proposed project. Specifically, Alternative 2 would reduce NOx RTC holdings from all 275 NOx RECLAIM facilities and investors by 60 percent overall. The proposed project, however, would reduce NOx RTC holdings by: 1) 66 ~~67~~ percent for 9 refineries and investors (treated as one facility); 2) 49 ~~47~~ percent for 21 EGFs~~30 power plants~~; 3) 49 ~~47~~ percent for 26 non-major facilities; and, 4) zero percent for the remaining 219 ~~210~~ facilities.

For the refinery sector, a new level of BARCT is proposed for FCCUs, refinery boilers/heaters, refinery gas turbines, coke calciners, and SRU/TGUs. For the non-refinery sector, a new BARCT level is proposed for container glass melting furnaces, cement kilns, sodium silicate furnaces, metal heat treating furnaces, gas turbines and ICEs not located on the OCS. No new

BARCT is proposed for 30 EGFs~~power plants~~. In order to achieve these new BARCT levels, the likely possibility is that operators of 20 facilities with the affected source categories will reduce actual NOx emissions via physical modifications to a wide variety of equipment by installing new air pollution control equipment or modifying existing air pollution control equipment. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 2. In particular, the number and type of control equipment that may be installed as a result of the proposed project and the corresponding adverse impacts that were analyzed for the proposed project, the same control equipment and corresponding adverse impacts will also occur under Alternative 2.

It is possible that under Alternative 2, facilities could increase their level of control further than what is analyzed for the proposed project to obtain a compliance margin which would result in a greater air quality benefit from NOx reductions with possibly additional adverse environmental impacts. However, it would be speculative to predict how many and what type of additional controls would be proposed in order to obtain a compliance margin. For this reason, any potential increased environmental benefit and corresponding impacts that may occur from increasing the level of control to obtain a compliance margin beyond what has been analyzed for the proposed project is speculative and cannot be analyzed.

Thus, analysis of Alternative 2 contains the same number and type of control equipment that may be installed as a result of the proposed project and the same corresponding adverse impacts that were analyzed for the proposed project.

5.2.3 Alternative 3 – Industry Approach

Alternative 3, an approach that has been proposed by industry representatives, consists of an across the board NOx RTC shave of 8.77 ~~8.79~~ tpd from total RTC holdings that would affect all RECLAIM facilities and investors. The calculation under Alternative 3 subtracts the base year emissions at the proposed BARCT level from the base year emissions at the previous BARCT level (Year 2000 or 2005). Under Alternative 3, the NOx RTCs held by all RECLAIM facilities and investors would be shaved by 33 percent overall. Since there are currently more NOx RTCs than actual 2011 emissions, it is likely that much of the 8.77 ~~8.79~~ tons per day reduction in RTCs will occur by surrendering excess RTCs rather than installing additional controls. However, some amount of NOx reductions may need to be obtained by installing NOx controls. It is difficult for staff to predict how much NOx emission reductions would be needed from the installation of controls, but it is likely that substantially fewer controls will be installed (and thus, actual NOx reductions achieved) than under the proposed project. By applying a shave of 33 percent to all facilities, 219 ~~210~~ facilities, which represent the bottom 10 percent of RTC holders, would become potential future buyers of RTCs since the amount of RTC holdings for these facilities would become less than their current actual emissions.

Under Alternative 3, the amount of the proposed NOx RTC shave of 8.0 tpd is less than the 14.0 tpd NOx RTC shave that is contemplated by the proposed project. In addition, the distribution of the shave under Alternative 3 would reduce the NOx RTC holdings differently than the proposed project. Specifically, Alternative 3 would reduce NOx RTC holdings from all 275 NOx RECLAIM facilities and investors by 33 percent overall. The proposed project, however, would reduce NOx RTC holdings by: 1) 66 ~~67~~ percent for 9 refineries and investors (treated as one facility); 2) 49 ~~47~~ percent for 21 EGFs~~30 power plants~~; 3) 49 ~~47~~ percent for 26 non-major facilities; and, 4) zero percent for the remaining 219 ~~210~~ facilities.

For the refinery sector, a new level of BARCT is proposed for FCCUs, refinery boilers/heaters, refinery gas turbines, coke calciners, and SRU/TGUs. For the non-refinery sector, a new BARCT level is proposed for container glass melting furnaces, cement kilns, sodium silicate furnaces, metal heat treating furnaces, gas turbines and ICEs not located on the OCS. No new BARCT is proposed for 30 EGFs~~power plants~~. In order to achieve these new BARCT levels, the likely possibility is that operators of 20 facilities with the affected source categories will reduce actual NOx emissions via physical modifications to a wide variety of equipment by installing new air pollution control equipment or modifying existing air pollution control equipment. However, because the proposed NOx RTC shave under Alternative 3 is so much less than the proposed project (e.g., 8.0 tpd vs. 14.0 tpd), it is possible that the entire 8.0 tpd NOx RTC shave could be addressed with unused RTCs without having any facilities modifying their equipment to achieve actual NOx reductions from installing air pollution control equipment. Because not as many, if any, additional actual NOx emission reductions would be needed to achieve an overall NOx RTC shave of 8.0 tpd, fewer than the 20 facilities that may be affected by the proposed project will be affected by Alternative 3. Without knowing exactly how industry will react if Alternative 3 is implemented, to predict the number of facilities that would install NOx control equipment would be speculative and unquantifiable. However, to conduct a worst-case analysis without quantification, the number and type of control equipment that may be installed under Alternative 3 is assumed to be fewer than what was analyzed for the proposed project and the corresponding adverse impacts under Alternative 3 would also be fewer than what was analyzed for the proposed project. To be conservative, the same conclusions reached for the proposed project for each environmental topic area will be applied to Alternative 3, except that the impacts will be concluded to have fewer impacts than the proposed project.

5.2.4 Alternative 4 - No Project

Alternative 4 is the "No Project" approach such that no NOx RTC reductions would be applied to any RECLAIM facility or investor. CEQA requires the specific alternative of No Project to be evaluated. A No Project Alternative consists of what would occur if the proposed project was not approved; in this case, not adopting the proposed project. The net effect of not amending Regulation XX to reduce the available RTCs on the market would be a continuation of the 2005 amendments to the NOx RECLAIM program. This approach is consistent with CEQA Guidelines §15126.6 (e)(3)(B), which states: "If the project is other than a land use or regulatory plan, for example a development project on identifiable property, the "no project" alternative is the circumstance under which the project does not proceed." The discussion in this PEA would compare the environmental effects of the Regulation XX remaining in its existing state against any environmental effects which would occur if the project is approved. If disapproval of the project under consideration would result in predictable actions by others, such as the proposal of some other project, this "no project" consequence should be discussed. In certain instances, the no project alternative means "no build" wherein the existing environmental setting is maintained.

However, where failure to proceed with the project will not result in preservation of existing environmental conditions, the analysis should identify the practical result of the project's non-approval and not create and analyze a set of artificial assumptions that would be required to preserve the existing physical environment."

Thus, under Alternative 4, the No Project alternative would not achieve any NOx reductions, no NOx control equipment would be installed and consequently, no environmental impacts from constructing or operating NOx control equipment would occur. However, if Alternative 4 is implemented, the SCAQMD would be required to seek reductions from as yet unidentified other sources with potential but unknowable adverse impacts.

5.2.5 Alternative 5 – Weighted by BARCT Reduction Contribution

Alternative 5 consists of an across the board NOx RTC reduction (shave) of 14 tpd that would affect all NOx RECLAIM facilities and investors. However, the NOx RTC reductions under this alternative would be weighted by the BARCT reduction contribution for major refineries and all other facilities, with investors grouped with the major refineries. As such, NOx RTC holdings for major refineries and investors would be shaved by 66 ~~67~~ percent and the NOx RTC holdings for non-major refineries and all other facilities would be shaved by 37 ~~36~~ percent. After BARCT is applied, 8.77 ~~8.79~~ tpd of actual NOx reductions are projected to occur, with 5.23 ~~5.21~~ tpd of NOx RTCs needed to fulfill the shave, post-BARCT. By applying a shave of 37 ~~36~~ percent to facilities to non-major facilities, EGFs~~power plants~~, and the bottom 10 percent of RTC holders, 219 ~~210~~ facilities, which represent the bottom 10 percent of RTC holders, would become potential future buyers of RTCs since the amount of RTC holdings for these facilities would become less than their current actual emissions.

Under Alternative 5, the amount of the proposed NOx RTC shave of 14 tpd is identical to the proposed project. However, the distribution of the shave under Alternative 5 would reduce the NOx RTC holdings differently than the proposed project. Specifically, Alternative 5 would reduce NOx RTC holdings by: 1) 66 ~~67~~ percent for 9 refineries and investors (treated as one facility); 2) 37 ~~36~~ percent for 21 EGFs ~~30 power plants~~; 3) 37 ~~36~~ percent for 26 non-major facilities; and, 4) 37 ~~36~~ percent for the remaining 219 ~~210~~ facilities. The proposed project, however, would reduce NOx RTC holdings by: 1) 66 ~~67~~ percent for 9 refineries and investors (treated as one facility); 2) 49 ~~47~~ percent for 21 EGFs~~30 power plants~~; 3) 49 ~~47~~ percent for 26 non-major facilities; and, 4) zero percent for the remaining 219 ~~210~~ facilities.

For the refinery sector, a new level of BARCT is proposed for FCCUs, refinery boilers/heaters, refinery gas turbines, coke calciners, and SRU/TGUs. For the non-refinery sector, a new BARCT level is proposed for container glass melting furnaces, cement kilns, sodium silicate furnaces, metal heat treating furnaces, gas turbines and ICEs not located on the OCS. No new BARCT is proposed for 30 EGFs~~power plants~~. In order to achieve these new BARCT levels, the likely possibility is that operators of 20 facilities with the affected source categories will reduce actual NOx emissions via physical modifications to a wide variety of equipment by installing new air pollution control equipment or modifying existing air pollution control equipment. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 5. In particular to the number and type of control equipment that may be installed as a result of the proposed project and the corresponding adverse impacts that were analyzed for the proposed project, the same control equipment and corresponding adverse impacts will also occur under Alternative 5.

5.3 ALTERNATIVES ANALYSIS

The following subsections include the same environmental topic areas evaluated for the proposed project. Under each environmental topic area, impacts and significance conclusions are summarized for the proposed project. In addition, potential impacts generated by each alternative to that environmental topic are described, a significance determination is made for the alternative, and environmental impacts from each alternative are compared to the environmental impacts identified for the proposed project.

5.3.1 Aesthetics

The potential aesthetics impacts from implementing the proposed project and the project alternatives were evaluated. The following subsections provide brief discussions of aesthetics impacts from each alternative relative to the proposed project.

5.3.1.1 Proposed Project

Potential direct and indirect aesthetics impacts from the proposed project are summarized in the following subsection. For the complete analysis, refer to Subchapter 4.1 – Aesthetics.

Physical modifications may result as part of implementing the proposed project and will vary depending on the equipment source category/process. The aesthetics analysis in this CEQA document is based on the assumption that new air pollution control equipment is expected to be installed and existing air pollution control equipment is expected to be modified as part of implementing the proposed project. Aesthetic impacts associated with the installation of new or the modification of existing NOx control, were identified in the NOP/IS to be potentially significant and, as such, are evaluated in this PEA.

Implementation of the proposed project is expected to result in construction activities at some or all of the affected facilities, which are complex industrial facilities. Due to the large size profiles of the affected equipment, the construction activities associated with installing control equipment are expected to require the use of heavy-duty construction equipment, such as cranes, which may temporarily change the skyline of the affected facilities, depending on where they are located within each facility's property. However, because each affected facility is located in a heavy industrial area, the construction equipment is not expected to be substantially discernable from what would be needed for routine operations and maintenance activities. For these reasons, the construction activities are expected to blend in with the existing industrial environment and thus, are not expected to affect the visual continuity of the surrounding areas.

In addition, for any installation of a WGS, operational aesthetic impacts resulting from a substantial visible steam (water vapor) plume that would emanate from the WGS stack were evaluated in this PEA. The analysis will show that if any WGS is installed as part of the proposed project at any of the affected facilities, the steam plume, though visible, is not expected to significantly adversely affect the visual continuity of the surrounding area of each affected facility because no scenic highways or corridors exist within the areas of the refineries, the coke calciner, the sulfuric acid plants and the glass melting plant. Further, the visual continuity of the surrounding area is not expected to be adversely impacted because each WGS, if constructed, will be built within the confines of industrial areas and would be visually consistent with the profiles of the existing affected facilities. Thus, even if each WGS could be visible, depending on the location within each property boundary, the aesthetic significance criteria would not be exceeded. For these reasons, less than significant aesthetics impacts during operation are expected from the proposed project.

Overall, the aesthetics impacts were determined to be less than significant during both construction and operation for the proposed project.

5.3.1.2 Alternative 1 – Across the Board Shave of NOx RTCs

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 1, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 1 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 1. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical. Thus, since the aesthetics impacts were determined to be less than significant during both construction and operation for the proposed project, the aesthetics impacts were determined to be less than significant during both construction and operation under Alternative 1.

5.3.1.3 Alternative 2 – Most Stringent Shave of NOx RTCs

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 2, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 2 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 2. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical. However, it is possible that under this alternative, facilities could increase their level of control to obtain a compliance margin which would result in a greater air quality benefit from NOx reductions with greater adverse environmental impacts. Nonetheless, because the quantity and type of NOx control equipment that may be installed beyond what was analyzed for the proposed project is speculative, any potential increased environmental benefit and corresponding impacts that may occur from increasing the level of control to obtain a compliance margin beyond what has been analyzed for the proposed project cannot be analyzed.

Thus, analysis of Alternative 2 contains the same number and type of control equipment that may be installed as a result of the proposed project and the same corresponding adverse impacts that were analyzed for the proposed project

Thus, since the aesthetics impacts were determined to be less than significant during both construction and operation for the proposed project, the aesthetics impacts were determined to be less than significant during both construction and operation under Alternative 2.

5.3.1.4 Alternative 3 – Industry Approach

Because not as many, if any, additional actual NOx emission reductions would be needed to achieve an overall NOx RTC shave of 8.0 tpd, fewer than the 20 facilities that may be affected by the proposed project will be affected by Alternative 3. Without knowing exactly how industry will react if Alternative 3 is implemented, to predict the number of facilities that would install NOx control equipment would be speculative and unquantifiable. However, to conduct a worst-case analysis without quantification, the number and type of control equipment that may be installed under Alternative 3 is assumed to be fewer than what was analyzed for the proposed project and the corresponding adverse impacts under Alternative 3 would also be fewer than what was analyzed for the proposed project. To be conservative, the same conclusions reached for the proposed project for each environmental topic area will be applied to Alternative 3, except that the impacts will be concluded to have fewer impacts than the proposed project.

Thus, since the aesthetics impacts were determined to be less than significant during both construction and operation for the proposed project, the aesthetics impacts were determined to be less than significant during both construction and operation under Alternative 3.

5.3.1.5 Alternative 4 – No Project

Under the No Project alternative, no new NOx limits are proposed for any equipment/source category and no NOx RTC reductions are proposed. Thus, none of the 20 facilities that would be affected by the proposed project would be affected by Alternative 4 to the extent that no control equipment would be installed or modified, and no adverse impacts from construction and operating the new or modified control equipment would be expected to occur. Since no construction or operation activities associated with new or modified control equipment would occur under Alternative 4, no new impacts to the environment, including the topic of aesthetics would be expected. Thus, no significant impacts to aesthetics resources would be expected to occur under Alternative 4.

5.3.1.6 Alternative 5 – Weighted by BARCT Reduction Contribution

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 5, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 5 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 5. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical. Thus, since the aesthetics impacts were determined to be less than significant during both construction and operation for the proposed project, the aesthetics impacts were determined to be less than significant during both construction and operation under Alternative 5.

5.3.2 Air Quality and GHG Emissions

The potential direct and indirect air quality and GHG emissions impacts from implementing the proposed project and the project alternatives were evaluated. The following subsections provide brief discussions of direct and indirect air quality and GHG emissions impacts from each alternative relative to the proposed project.

5.3.2.1 Proposed Project

Potential direct and indirect air quality and GHG emissions impacts from the proposed project are summarized in the following subsection. For the complete analysis, refer to Subchapter 4.2 - Air Quality and Greenhouse Gases.

The proposed project is expected to result in a total of 14 tpd of NOx RTC reductions from the current RTC holdings of 26.5 tpd, to be implemented over a seven-year period from 2016 to 2022. For the 275 facilities that are in the NOx RECLAIM program, the 14 tpd of NOx RTC reductions will only affect 56 ~~65~~ facilities plus the investors that, together, hold 90 percent of the NOx RTC holdings. Investors are included in the refinery sector and treated as one facility. For the remaining 219 ~~210~~ facilities that hold 10 percent of the 26.5 tpd of the NOx RTCs, no NOx RTC shave is proposed because no new BARCT (not cost effective and/or infeasible) was identified for the types of equipment and source categories at these facilities. By following this approach, the shave of NOx RTC holdings is distributed as follows:

- 66 ~~67~~% shave for 9 refineries and investors (treated as one facility)
- 49 ~~47~~% shave for 21 EGFs~~30 power plants~~
- 49 ~~47~~% shave for 26 non-major facilities
- 0% shave for 219 ~~210~~ remaining facilities

SCAQMD staff has conducted a BARCT analysis for all 275 facilities and of these, 21 out of 30 EGFs ~~power producing facilities where~~ were shown to operate at current BARCT or BACT levels. For 224 non-power plant facilities plus 9 EGFs for a total of 233 facilities, either no new BARCT was identified or the installation of control equipment was determined to not be cost-effective. Further, only 35 ~~44~~ facilities are expected to comply with the proposed NOx RTC shave through the purchase of RTCs which will have no environmental impact. In addition, the sale and/or purchase of RTCs by investors (treated as one facility) will also have no environmental impact.

To reduce NOx from the remaining 21 facilities (e.g., 275 – 21 EGFs (with shave) ~~30 power producers~~ – 224 non-power plant facilities – 9 EGFs (without shave) = 21) which are either major or large sources of NOx for which new BARCT has been identified, the BARCT analysis found that it would be both feasible and cost-effective for facility operators to install new control equipment or modify existing control equipment at 20 facilities with 11 facilities belonging to the non-refinery sector and 9 facilities belonging to the refinery sector[2].

As a result, operators of these 20 facilities may choose to modify existing equipment by retrofitting with air pollution control technologies in order to comply with the shave of NOx RTCs. The physical changes involved that may occur as a result of implementing the proposed project focus on the installation of new or the modification of existing control equipment on the following types of equipment and processes: 1) fluid catalytic cracking units; 2) refinery boilers and heaters; 3) refinery gas turbines; 4) sulfur recovery units – tail gas treatment units; 5) non-refinery/non-power plant gas turbines; 6) non-refinery sodium silicate furnaces; 7) non-refinery/non-power plant internal combustion engines; 8) container glass melting furnaces; 9) coke calcining; and, 10) metal heat treating furnaces. Table 1-2 summarizes the potential NOx control technologies that may be considered as part of implementing the proposed project.

Table 5-2

Potential NOx Control Devices Per Sector and Equipment/Source Category

Sector	Equipment/Source Category	Potential NOx Control Devices
Refinery	Fluid Catalytic Cracking Units (FCCUs)	SCR LoTOx™ with WGS LoTOx™ without WGS
Refinery	Refinery Process Heaters and Boilers	SCR
Refinery	Refinery Gas Turbines	SCR
Refinery	Sulfur Recovery Unit / Tail Gas Units (SRU/TGUs)	LoTOx™ with WGSs SCR
Refinery	Petroleum Coke Calciner	LoTOx™ with WGS UltraCat with DGS
Non-Refinery	Container Glass Melting Furnaces	SCR UltraCat with DGS
Non-Refinery	Sodium Silicate Furnaces	SCR UltraCat with DGS
Non-Refinery	Metal Heat Treating Furnaces	SCR
Non-Refinery	Internal Combustion Engines (Non-Refinery/Non-Power Plant)	SCR
Non-Refinery	Turbines (Non-Refinery/Non-Power Plant)	SCRs

Construction activities associated with installing or modifying existing air pollution control equipment are expected and have the potential to generate significant adverse air quality impacts. In addition, operational activities due to periodic truck trips such as the delivery of supplies to support the operations of the various control technologies and the removal of waste from the control processes for disposal or recycling are also expected and have the potential to generate significant adverse air quality impacts for greenhouse gases (GHGs).

[2] Since one facility is no longer operating, the analysis is based on 20 facilities, instead of 21 facilities.

With regard to GHG emissions, the proposed project involves combustion processes which could generate GHG emissions such as CO2, CH4, and N2O. However, the proposed project does not affect equipment or operations that have the potential to emit other GHGs such as SF6, HFCs or PFCs. Implementing the proposed project is expected to increase GHG emissions that exceed the SCAQMD's GHG significance threshold for industrial sources. In addition, implementing the proposed project is expected to generate significant adverse cumulative GHG air quality impacts.

5.3.2.2 Alternative 1 – Across the Board Shave of NOx RTCs

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 1, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 1 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 1. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical.

The analysis of the proposed project concluded that construction activities associated with installing or modifying existing air pollution control equipment are expected and have the potential to generate significant adverse air quality impacts. In addition, the analysis of the proposed project concluded that operational activities due to periodic truck trips such as the delivery of supplies to support the operations of the various control technologies and the removal of waste from the control processes for disposal or recycling are also expected and have the potential to generate significant adverse air quality impacts for greenhouse gases (GHGs).

Thus, since the air quality impacts during construction were determined to be significant for the proposed project, the air quality impacts during construction were determined to be significant under Alternative 1. Similarly, since the GHG impacts were determined to be significant for the proposed project, the GHG impacts were also determined to be significant under Alternative 1.

5.3.2.3 Alternative 2 – Most Stringent Shave of NOx RTCs

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 2, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 2 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 2. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical. However, it is possible that under this alternative, facilities could increase their level of control to obtain a compliance margin which would result in a greater air quality benefit from NOx reductions with fewer adverse environmental impacts. Nonetheless, because the quantity and type of NOx control equipment that may be installed beyond what was analyzed for the proposed project is speculative, any potential increased environmental benefit and corresponding impacts that may occur from increasing the level of control to obtain a compliance margin beyond what has been analyzed for the proposed project cannot be analyzed.

The analysis of the proposed project concluded that construction activities associated with installing or modifying existing air pollution control equipment are expected and have the potential to generate significant adverse air quality impacts. In addition, the analysis of the proposed project concluded that operational activities due to periodic truck trips such as the delivery of supplies to support the operations of the various control technologies and the removal of waste from the control processes for disposal or recycling are also expected and have the potential to generate significant adverse air quality impacts for GHGs.

Thus, since the air quality impacts during construction were determined to be significant for the proposed project, the air quality impacts during construction were determined to be significant under Alternative 2. Similarly, since the GHG impacts were determined to be significant for the proposed project, the GHG impacts were also determined to be significant under Alternative 2.

5.3.2.4 Alternative 3 – Industry Approach

Because not as many, if any, additional actual NOx emission reductions would be needed to achieve an overall NOx RTC shave of 8.0 tpd, fewer than the 20 facilities that may be affected by the proposed project will be affected by Alternative 3. Without knowing exactly how industry will react if Alternative 3 is implemented, to predict the number of facilities that would install NOx control equipment would be speculative and unquantifiable. However, to conduct a worst-case analysis without quantification, the number and type of control equipment that may be installed under Alternative 3 is assumed to be fewer than what was analyzed for the proposed project and the corresponding adverse impacts under Alternative 3 would also be fewer than what was analyzed for the proposed project. To be conservative, the same conclusions reached for the proposed project for each environmental topic area will be applied to Alternative 3, except that the impacts will be concluded to have fewer impacts than the proposed project.

The analysis of the proposed project concluded that construction activities associated with installing or modifying existing air pollution control equipment are expected and have the potential to generate significant adverse air quality impacts. In addition, the analysis of the proposed project concluded that operational activities due to periodic truck trips such as the delivery of supplies to support the operations of the various control technologies and the removal of waste from the control processes for disposal or recycling are also expected and have the potential to generate significant adverse air quality impacts for GHGs.

Thus, since the air quality impacts during construction were determined to be significant for the proposed project, the air quality impacts during construction were determined to be significant under Alternative 3. Similarly, since the GHG impacts were determined to be significant for the proposed project, the GHG impacts were also determined to be significant under Alternative 3.

5.3.2.5 Alternative 4 – No Project

Under the No Project alternative, no new NOx limits are proposed for any equipment/source category and no NOx RTC reductions are proposed. Thus, none of the 20 facilities that would be affected by the proposed project would be affected by Alternative 4 to the extent that no control equipment would be installed or modified, and no adverse impacts from construction and operating the new or modified control equipment would be expected to occur. Since no construction or operation activities associated with new or modified control equipment would occur under Alternative 4, no new impacts to the environment, including the topic of air quality and GHGs would be expected. However, because Alternative 4 is the continued implementation of the 2005 amendments to the NOx RECLAIM program, no additional NOx emissions would occur even SCAQMD is required to conduct a BARCT assessment in accordance with Health and Safety Code ~~§~~§40440~~ and 39616~~[3] that demonstrates achievable NOx emission reductions. Thus, without any additional NOx reductions, no benefits to air quality and GHG emissions would occur. Although there are other existing rules that may have future compliance dates for NOx emission reductions, potential adverse impacts from these rules have already been evaluated in the Final Program EIR for the 2012 AQMP and their subsequent rule-specific CEQA documents. While air quality would continue to improve to a certain extent, it is unlikely that all state or federal ozone standards would be achieved as required by the federal and California CAAs. It is possible that the federal 24-hour PM2.5 standard may be achieved; however, it is unlikely that further progress would be made towards achieving the state PM2.5 standard as required by the California CAA.

5.3.2.6 Alternative 5 – Weighted by BARCT Reduction Contribution

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 5, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 5 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 5. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical.

The analysis of the proposed project concluded that construction activities associated with installing or modifying existing air pollution control equipment are expected and have the potential to generate significant adverse air quality impacts. In addition, the analysis of the proposed project concluded that operational activities due to periodic truck trips such as the delivery of supplies to support the operations of the various control technologies and the

[3] The reference to Health and Safety Code §39616 has been deleted because it does not require a BARCT analysis. The RECLAIM program proposed here satisfies the findings set forth in Health and Safety Code §39616, although it is not legally required to do so.

removal of waste from the control processes for disposal or recycling are also expected and have the potential to generate significant adverse air quality impacts for GHGs.

Thus, since the air quality impacts during construction were determined to be significant for the proposed project, the air quality impacts during construction were determined to be significant under Alternative 5. Similarly, since the GHG impacts were determined to be significant for the proposed project, the GHG impacts were also determined to be significant under Alternative 5.

5.3.3 Energy

The potential energy impacts from implementing the proposed project and the project alternatives were evaluated. The following subsections provide brief discussions of the energy impacts from each alternative relative to the proposed project.

5.3.3.1 Proposed Project

Potential direct and indirect energy impacts from the proposed project are summarized in the following subsection. For the complete analysis, refer to Subchapter 4.3 - Energy.

During installation or modification of add-on air pollution control devices, adverse energy impacts (e.g., increased demand in energy) may occur during construction due to the need for: 1) diesel fuel to operate onsite construction equipment that cannot utilize or access electricity; 2) diesel fuel to operate heavy-duty and medium-duty vehicles for delivering supplies and hauling waste during construction; and, 3) gasoline to operate offsite vehicles used for worker commuting. The analysis of the proposed project concluded that these projected increased usages of diesel fuel and gasoline would not create any significant effects on local or regional energy supplies and on requirements for additional energy. Further, these projected increased usages of diesel fuel and gasoline would not create any significant effects on peak and base period demands on the availability of diesel fuel and gasoline.

After the add-on air pollution control devices are installed and operating, adverse energy impacts (e.g., increased demand in energy) may occur during operation due to the need for: 1) electricity to operate the air pollution control devices; and, 2) diesel fuel to operate heavy-duty and medium-duty vehicles for delivering supplies and hauling waste during operation. The analysis of the proposed project concluded that the increased use of electricity and diesel fuel during operation would not exceed the significance threshold of one percent of supply. Since the proposed project would not exceed the SCAQMD's energy threshold of one percent of supply for electricity usage, implementation of the proposed project is expected to have less than significant energy impacts during operation.

5.3.3.2 Alternative 1 – Across the Board Shave of NOx RTCs

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 1, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 1 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential

NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 1. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical.

The analysis of the proposed project concluded that there would be increased usages of diesel fuel and gasoline and these projected increases would not create any significant effects on local or regional energy supplies and on requirements for additional energy. Further, these projected increased usages of diesel fuel and gasoline during construction would not create any significant effects on peak and base period demands on the availability of diesel fuel and gasoline. In addition, the analysis of the proposed project concluded that the increased use of electricity and diesel fuel during operation would also not exceed the significance threshold of one percent of supply. Since the proposed project would not exceed the SCAQMD's energy threshold of one percent of supply for electricity usage, implementation of the proposed project is expected to have less than significant energy impacts during operation.

Thus, since the energy impacts during construction and operation were determined to be less than significant for the proposed project, the air quality impacts during construction and operation were also determined to be less than significant under Alternative 1.

5.3.3.3 Alternative 2 – Most Stringent Shave of NOx RTCs

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 2, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 2 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 2. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical. However, it is possible that under this alternative, facilities could increase their level of control to obtain a compliance margin which would result in a greater air quality benefit from NOx reductions with fewer adverse environmental impacts. Nonetheless, because the quantity and type of NOx control equipment that may be installed beyond what was analyzed for the proposed project is speculative, any potential increased environmental benefit and corresponding impacts that may occur from increasing the level of control to obtain a compliance margin beyond what has been analyzed for the proposed project cannot be analyzed.

The analysis of the proposed project concluded that there would be increased usages of diesel fuel and gasoline and these projected increases would not create any significant effects on local or regional energy supplies and on requirements for additional energy. Further, these projected increased usages of diesel fuel and gasoline during construction would not create any significant effects on peak and base period demands on the availability of diesel fuel and gasoline. In addition, the analysis of the proposed project concluded that the increased use of electricity and diesel fuel during operation would also not exceed the significance threshold of one percent of supply. Since the proposed project would not exceed the SCAQMD's energy threshold of one percent of supply for electricity usage, implementation of the proposed project is expected to have less than significant energy impacts during operation.

Thus, since the energy impacts during construction and operation were determined to be less than significant for the proposed project, the air quality impacts during construction and operation were also determined to be less than significant under Alternative 2.

5.3.3.4 Alternative 3 – Industry Approach

Because not as many, if any, additional actual NOx emission reductions would be needed to achieve an overall NOx RTC shave of 8.0 tpd, fewer than the 20 facilities that may be affected by the proposed project will be affected by Alternative 3. Without knowing exactly how industry will react if Alternative 3 is implemented, to predict the number of facilities that would install NOx control equipment would be speculative and unquantifiable. However, to conduct a worst-case analysis without quantification, the number and type of control equipment that may be installed under Alternative 3 is assumed to be fewer than what was analyzed for the proposed project and the corresponding adverse impacts under Alternative 3 would also be fewer than what was analyzed for the proposed project. To be conservative, the same conclusions reached for the proposed project for each environmental topic area will be applied to Alternative 3, except that the impacts will be concluded to have fewer impacts than the proposed project.

The analysis of the proposed project concluded that there would be increased usages of diesel fuel and gasoline and these projected increases would not create any significant effects on local or regional energy supplies and on requirements for additional energy. Further, these projected increased usages of diesel fuel and gasoline during construction would not create any significant effects on peak and base period demands on the availability of diesel fuel and gasoline. In addition, the analysis of the proposed project concluded that the increased use of electricity and diesel fuel during operation would also not exceed the significance threshold of one percent of supply. Since the proposed project would not exceed the SCAQMD's energy threshold of one percent of supply for electricity usage, implementation of the proposed project is expected to have less than significant energy impacts during operation.

Thus, since the energy impacts during construction and operation were determined to be less than significant for the proposed project, the air quality impacts during construction and operation were also determined to be less than significant under Alternative 3.

5.3.3.5 Alternative 4 – No Project

Under the No Project alternative, no new NOx limits are proposed for any equipment/source category and no NOx RTC reductions are proposed. Thus, none of the 20 facilities that would be affected by the proposed project would be affected by Alternative 4 to the extent that no control equipment would be installed or modified, and no adverse impacts from construction and operating the new or modified control equipment would be expected to occur. Since no construction or operation activities associated with new or modified control equipment would occur under Alternative 4, no new impacts to the environment, including the topic of energy would be expected. Thus, no significant impacts to energy would be expected to occur under Alternative 4.

5.3.3.6 Alternative 5 – Weighted by BARCT Reduction Contribution

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 5, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 5 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 5. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical.

The analysis of the proposed project concluded that there would be increased usages of diesel fuel and gasoline and these projected increases would not create any significant effects on local or regional energy supplies and on requirements for additional energy. Further, these projected increased usages of diesel fuel and gasoline during construction would not create any significant effects on peak and base period demands on the availability of diesel fuel and gasoline. In addition, the analysis of the proposed project concluded that the increased use of electricity and diesel fuel during operation would also not exceed the significance threshold of one percent of supply. Since the proposed project would not exceed the SCAQMD's energy threshold of one percent of supply for electricity usage, implementation of the proposed project is expected to have less than significant energy impacts during operation.

Thus, since the energy impacts during construction and operation were determined to be less than significant for the proposed project, the air quality impacts during construction and operation were also determined to be less than significant under Alternative 5.

5.3.4 Hazards and Hazardous Materials

The potential hazards and hazardous materials impacts from implementing the proposed project and the project alternatives were evaluated. The following subsections provide brief discussions of hazards and hazardous materials impacts from each alternative relative to the proposed project.

5.3.4.1 Proposed Project

Potential hazards and hazardous materials impacts from the proposed project are summarized in the following subsection. For the complete analysis, refer to Subchapter 4.4 - Hazards and Hazardous Materials.

Several components with regard to reducing NOx emissions by installing new or modifying existing NOx controls as part of implementing the proposed project may affect the use, storage and transport of hazards and hazardous materials during operational-related activities. Thus, the routine transport of hazardous materials, use, and disposal of hazardous materials may increase as a result of implementing the proposed project. The key effects of implementing the proposed project and the determination of which aspects involve hazards and hazardous materials focus on: 1) the anticipated increase of substances used to operate the new or modified NOx controls; and, 2) the increased capture of hazardous substances as part of the overall NOx reduction effort. The analysis of hazards and hazardous materials impacts concluded that the proposed project is expected to generate less than significant adverse impacts related to any of the hazardous substances, such as ammonia and sodium hydroxide, which may be used to operate NOx control equipment.

5.3.4.2 Alternative 1 – Across the Board Shave of NOx RTCs

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 1, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 1 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 1. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical.

The analysis of hazards and hazardous materials impacts concluded that the proposed project is expected to generate less than significant adverse impacts related to any of the hazardous substances, such as ammonia and sodium hydroxide, which may be used to operate NOx control equipment.

Thus, since the hazards and hazardous materials impacts were determined to be less than significant for the proposed project, the hazards and hazardous materials impacts were also determined to be less than significant under Alternative 1.

5.3.4.3 Alternative 2 – Most Stringent Shave of NOx RTCs

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 2, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 2 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 2. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical. However, it is possible that under this alternative, facilities could increase their level of control to obtain a compliance margin which would result in a greater air quality benefit from NOx reductions with fewer adverse environmental impacts. Nonetheless, because the quantity and type of NOx control equipment that may be installed beyond what was analyzed for the proposed project is speculative, any potential increased environmental benefit and corresponding impacts that may occur from increasing the level of control to obtain a compliance margin beyond what has been analyzed for the proposed project cannot be analyzed.

The analysis of hazards and hazardous materials impacts concluded that the proposed project is expected to generate less than significant adverse impacts related to any of the hazardous substances, such as ammonia and sodium hydroxide, which may be used to operate NOx control equipment. Thus, since the hazards and hazardous materials impacts were determined to be less than significant for the proposed project, the hazards and hazardous materials impacts were also determined to be less than significant under Alternative 2.

5.3.4.4 Alternative 3 – Industry Approach

Because not as many, if any, additional actual NOx emission reductions would be needed to achieve an overall NOx RTC shave of 8.0 tpd, fewer than the 20 facilities that may be affected by the proposed project will be affected by Alternative 3. Without knowing exactly how industry will react if Alternative 3 is implemented, to predict the number of facilities that would install NOx control equipment would be speculative and unquantifiable. However, to conduct a worst-case analysis without quantification, the number and type of control equipment that may be installed under Alternative 3 is assumed to be fewer than what was analyzed for the proposed project and the corresponding adverse impacts under Alternative 3 would also be fewer than what was analyzed for the proposed project. To be conservative, the same conclusions reached for the proposed project for each environmental topic area will be applied to Alternative 3, except that the impacts will be concluded to have fewer impacts than the proposed project.

The analysis of hazards and hazardous materials impacts concluded that the proposed project is expected to generate less than significant adverse impacts related to any of the hazardous substances, such as ammonia and sodium hydroxide, which may be used to operate NOx control equipment.

Thus, since the hazards and hazardous materials impacts were determined to be less than significant for the proposed project, the hazards and hazardous materials impacts were also determined to be less than significant under Alternative 3.

5.3.4.5 Alternative 4 – No Project

Under the No Project alternative, no new NOx limits are proposed for any equipment/source category and no NOx RTC reductions are proposed. Thus, none of the 20 facilities that would be affected by the proposed project would be affected by Alternative 4 to the extent that no control equipment would be installed or modified, and no adverse impacts from construction and operating the new or modified control equipment would be expected to occur. Since no construction or operation activities associated with new or modified control equipment would occur under Alternative 4, no new impacts to the environment, including the topic of hazards and hazardous materials would be expected. Thus, no significant impacts to hazards and hazardous would be expected to occur under Alternative 4.

5.3.4.6 Alternative 5 – Weighted by BARCT Reduction Contribution

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 5, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 5 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 5. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical.

The analysis of hazards and hazardous materials impacts concluded that the proposed project is expected to generate less than significant adverse impacts related to any of the hazardous substances, such as ammonia and sodium hydroxide, which may be used to operate NOx control equipment.

Thus, since the hazards and hazardous materials impacts were determined to be less than significant for the proposed project, the hazards and hazardous materials impacts were also determined to be less than significant under Alternative 5.

5.3.5 Hydrology and Water Quality

The potential hydrology and water quality impacts from implementing the proposed project and the project alternatives were evaluated. The following subsections provide brief discussions of the hydrology and water quality impacts from each alternative relative to the proposed project.

5.3.5.1 Proposed Project

Potential hydrology and water quality materials impacts from the proposed project are summarized in the following subsection. For the complete analysis, refer to Subchapter 4.5 - Hydrology and Water Quality.

The proposed project is expected to result in the installation of the following new NOx air pollution control equipment: up to 117 SCRs, eight LoTOx^{TM} with WGSs, one LoTOx^{TM} without WGS, and three UltraCat DGSs. During installation these add-on air pollution control devices, adverse hydrology and water quality impacts may occur during construction due to the need for water for dust suppression. Depending on the proposed location within each facility's boundaries for the siting of any new control equipment that may be installed as a result of implementing the proposed project, construction activities such as digging, earthmoving, grading, slab pouring, or paving could occur if the proposed site for the new equipment is not suitable in its present form (e.g., graded with a foundation slab). However, for the few facility operators that may choose to modify or replace their existing NOx control equipment, site preparation activities are not expected because the existing foundation and the existing equipment are expected to be reused in their current location and current plot space. Therefore, no water for dust suppression purposes is expected to be needed for any construction upgrades to existing NOx control equipment.

The potential increase in water use for the facilities that may need to conduct watering for dust suppression activities is below the SCAQMD's significance thresholds of five million gallons per day of total water (e.g., potable, recycled, and groundwater) and 262,820 gallons per day of potable water. The amount of water that may be used on a daily basis for dust suppression activities during construction is less than significant.

Once constructed, but prior to operation of the new or modified air pollution control equipment, additional water is expected to be used to hydrostatically (pressure) test all storage tanks and pipelines, that are installed as part of support equipment to the air pollution control equipment, to ensure each structure's integrity and wastewater may be created during the testing. Pressure testing is typically a one-time event, unless a leak is found. The potential increase in water use for all 20 facilities conducting hydrotesting activities is estimated to be 353,724 gallons per day, which is less than the SCAQMD's significance thresholds of five million gallons per day of total water but greater than 262,820 gallons per day of potable water. Thus, the amount of water that may be used on a daily basis for hydrotesting activities post-construction but prior to operation is significant.

Any wastewater generated from hydrotesting or pressure testing is expected to flow to each affected facility's wastewater treatment or collection system and recycled or discharged after treatment with process wastewater. Thus, wastewater generation from pressure testing activities is not expected to affect groundwater quality. Further, the volume of wastewater that will be generated from pressure testing is expected to be minimal and within the capacity of each facility's wastewater treatment and collection systems. Also, because the proposed project is expected to disturb substantially less than one acre per facility, on-site collection of storm water in each facility's storm water collection system is expected to be about the same as the amount currently collected. Therefore, no significant impacts are expected from wastewater generation or storm water during construction.

Of the technologies proposed as BARCT for NOx control, only WGSs utilize water and generate wastewater as part of their day-to-day operations. For this reason, only WGS technology was identified as having the potential to generate adverse hydrology and water quality operational impacts. The analysis shows that WGS technology may be installed for two FCCUs, five SRU/TGUs, and one coke calciner at seven facilities in the refinery sector. Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the actual water demand and wastewater impacts may only occur at six of the seven facilities analyzed. However, for the non-refinery sector, WGS technology was not identified as BARCT for the affected equipment.

For water demand, there are three significance thresholds based on whether: 1) the total water demand of the proposed project is less than five million gallons per day; 2) the existing water supply has the capacity to meet the increased demands of the proposed project; and, 3) the potable water demand is less than 262,820 gallons per day. The analysis shows that the increased potential demand for total water during operation that may result from implementing the proposed project either during operation is not expected to exceed the significance threshold of five million gallons of total water demand per day.

Because the projected installation of WGS technology is expected to only occur at one of the two FCCUs, the corresponding increased water demand projections that were originally contemplated for one of the two FCCUs (e.g., Refineries 4 and 9) identified in Tables 4.5-9 and 4.5-10 are no longer expected to occur. Thus, the potential increase in operational water demand is expected to be less. To protect the identity of the refinery in this document, the revised potential increase in operational water demand has been presented as a range, from 553,499 gallons per day to 558,978 gallons per day, instead of 602,814 gallons per day as shown in Table 4.5-9.

Thus, ~~However,~~ the increased potential demand for potable water during operation of the WGS technology at six of the seven refineries originally analyzed ~~facilities~~ is estimated to be from 553,499 gallons per day to 558,978 ~~602,814~~ gallons per day, which exceeds the potable water threshold of 262,820 gallons per day. Of this amount, three ~~of the seven~~ refineries (e.g., Refineries 1, 5, and 6) have current access to recycled water. Should operators of these three refineries ~~facilities~~ commit to utilizing recycled water in lieu of potable water to satisfy the water demand for the NOx control equipment, then, their water suppliers would be able to supply the additional water (e.g., 398,767 gallons per day or approximately 71 ~~66~~ percent of the projected water demand) with recycled water.

Thus, while the amount of water demand that would be needed to operate NOx control equipment would be 398,767 gallons per day at Refineries 1, 5 and 6 and the amount of water demand at Refineries ~~Facilities~~ 2, 4, 8, and 9 would be in the range of 113,836 gallons per day to 160,211 ~~204,047~~ gallons per day, which collectively is greater ~~less~~ than the significance threshold of 262,820 gallons per day of potable water and less than the significance threshold of five million gallons per day of total water (e.g., potable, recycled, and groundwater), in consideration that Refineries 1, 5 and 6 have a high potential to use recycled water because of their current access and in light of the negotiations for recycled water at Refineries 4, 8, and 9, potable water only may be needed for a future project occurring at Refinery 2, or not at all if operators of Refinery 2 choose to install a DGS instead of a WGS. ~~it is not known at this time whether~~ In any case, the previous analysis shows that the water purveyors would be able to supply potable water to ~~for~~Refinery 2 and to Refineries 1, 4, 5, 6, 8 and 9, if needed. ~~these facilities and it is unknown whether all of the water used at the other three refineries would necessarily consist of recycled water. Because of the drought and the uncertainty of future water supplies, it is not clear at this time whether water suppliers would be able to accommodate the additional operational water demand if the proposed project goes forward, especially if potable water or groundwater would be relied upon to supply the water demand.~~ Thus, using an abundance of caution, because the peak daily water demand for the proposed project exceeds the potable water threshold of 262,820 gallons per day and because recycled water is not currently available at Refineries 4, 8 and 9, and no contractual commitments to increase recycled water demand above the existing recycled water baseline for the three refineries that already have access to recycled water (e.g., Refineries 1, 5 and 6) have been finalized, ~~For this reason,~~ the analysis conservatively concludes that ~~the amount of water that may be needed to operate WGS technology may create~~ significant adverse hydrology (water demand) impacts are expected from the proposed project during operation.

Relative to water quality, each affected facility provided their wastewater discharge limits and these limits were compared to each facility's estimated potential increase in wastewater that may result from implementing the proposed project. The peak percentage increase from baseline levels when compared to the proposed project was approximately nine ~~12~~ percent (Refinery 2~~9~~). An increase of 25 percent would trigger a permit revision and would be considered a significant adverse wastewater impact. Since all of the affected facilities have been shown to have a potential wastewater increase less than 25 percent, no modifications to any existing wastewater discharge permits are anticipated as a result of the proposed project. Thus, the operational impacts of the proposed project on each affected facility's wastewater discharge and the Industrial Wastewater Discharge Permit are expected to be less than significant. It is important to note that operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the installation of WGS technology along with the corresponding increased wastewater generation projections that were originally contemplated for one of the two FCCUs (e.g., Refineries 4 and 9) identified in Tables 4.5-9 and 4.5-10 are no longer expected to occur. Thus, the potential increase in operational wastewater generation is expected to be less. To protect the identity of the refinery in this document, the revised potential increase in operational wastewater generation will be reduced from 236,719 gallons per day to 214,801 gallons per day instead. Nonetheless, this reduction in operational wastewater generation will lessen the impacts further than what was analyzed at the time the Draft PEA was released for public review and comment. For this reason, the wastewater impacts from the proposed project are expected to be less than significant.

In conclusion, significant adverse water demand impacts are expected during hydrotesting (post-construction) and during operation. Further, less than significant impacts during construction are expected for water demand and wastewater and less than significant impacts during operation are expected for wastewater.

5.3.5.2 Alternative 1 – Across the Board Shave of NOx RTCs

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 1, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 1 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 1. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical.

In particular to the topic of hydrology and water quality, only 6~~7~~ of the 20 affected facilities would be expected to have water demand and water quality impacts as a result of the WGS technology that may be installed at these facilities in response to the proposed project. Further, the same 6~~7~~ facilities that may be affected by the proposed project and the same NOx control technology that may be installed as a result of the proposed project (e.g., WGSs) will also be occur under Alternative 1. Finally, the types and amounts of NOx control equipment that may be installed at the 6~~7~~ facilities and their corresponding environmental impacts and conclusions in response to the proposed project are also identical to Alternative 1.

The analysis of hydrology and water quality concluded that the proposed project is expected to generate: 1) significant adverse water demand impacts during hydrotesting (post-construction) and during operation; 2) less than significant water demand impacts during for dust suppression activities; and, 3) less than significant impacts during construction and operation for wastewater. Thus, since the analysis of hydrology and water quality impacts concluded that significant water demand impacts would occur during hydrotesting and during operation, and less than significant water demand impacts would occur during construction, the hydrology and water quality impacts analysis under Alternative 1 may also have significant water demand impacts during hydrotesting and operation, and less than significant water demand impacts during construction. Similarly, since the analysis of hydrology and water quality impacts concluded that less than significant water quality impacts would occur during construction and operation, less than significant water quality impacts during construction and operation would also be expected to occur under Alternative 1.

5.3.5.3 Alternative 2 – Most Stringent Shave of NOx RTCs

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 2, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 2 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 2. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical. However, it is possible that under this alternative, facilities could increase their level of control to obtain a compliance margin which would result in a greater air quality benefit from NOx reductions with fewer adverse environmental impacts. Nonetheless, because the quantity and type of NOx control equipment that may be installed beyond what was analyzed for the proposed project is speculative, any potential increased environmental benefit and corresponding impacts that may occur from increasing the level of control to obtain a compliance margin beyond what has been analyzed for the proposed project cannot be analyzed.

In particular to the topic of hydrology and water quality, only 6~~7~~ of the 20 affected facilities would be expected to have water demand and water quality impacts as a result of the WGS technology that may be installed at these facilities in response to the proposed project. Further, the same 6~~7~~ facilities that may be affected by the proposed project and the same NOx control technology that may be installed as a result of the proposed project (e.g., WGSs) will also be occur under Alternative 2. Finally, the types and amounts of NOx control equipment that may be installed at the 6~~7~~ facilities and their corresponding environmental impacts and conclusions in response to the proposed project are also identical to Alternative 2.

The analysis of hydrology and water quality concluded that the proposed project is expected to generate: 1) significant adverse water demand impacts during hydrotesting (post-construction) and during operation; 2) less than significant water demand impacts during for dust suppression activities; and, 3) less than significant impacts during construction and operation for wastewater. Thus, since the analysis of hydrology and water quality impacts concluded that significant water demand impacts would occur during hydrotesting and during operation, and less than significant water demand impacts would occur during construction, the hydrology and water quality impacts analysis under Alternative 2 may also have significant water demand impacts during hydrotesting and operation, and less than significant water demand impacts during construction. Similarly, since the analysis of hydrology and water quality impacts concluded that less than significant water quality impacts would occur during construction and operation, less than significant water quality impacts during construction and operation would also be expected to occur under Alternative 2.

5.3.5.4 Alternative 3 – Industry Approach

Because not as many, if any, additional actual NOx emission reductions would be needed to achieve an overall NOx RTC shave of 8.0 tpd, fewer than the 20 facilities that may be affected by the proposed project will be affected by Alternative 3. Without knowing exactly how industry will react if Alternative 3 is implemented, to predict the number of facilities that would install NOx control equipment would be speculative and unquantifiable. However, to conduct a worst-case analysis without quantification, the number and type of control equipment that may be installed under Alternative 3 is assumed to be fewer than what was analyzed for the proposed project and the corresponding adverse impacts under Alternative 3 would also be fewer than what was analyzed for the proposed project. To be conservative, the same conclusions reached for the proposed project for each environmental topic area will be applied to Alternative 3, except that the impacts will be concluded to have fewer impacts than the proposed project.

In particular to the topic of hydrology and water quality, only 6 ~~seven~~ of the 20 affected facilities would be expected to have water demand and water quality impacts as a result of the WGS technology that may be installed at these facilities in response to the proposed project. Further, the same 6 ~~seven~~ facilities that may be affected by the proposed project and the same NOx control technology that may be installed as a result of the proposed project (e.g., WGSs) may possibly occur under Alternative 3. Finally, the types and amounts of WGS equipment that may be installed at the 6 ~~seven~~ facilities and their corresponding environmental impacts and conclusions in response to Alternative 3 could be the same or less than the proposed project.

The analysis of hydrology and water quality concluded that the proposed project is expected to generate: 1) significant adverse water demand impacts during hydrotesting (post-construction) and during operation; 2) less than significant water demand impacts during for dust suppression activities; and, 3) less than significant impacts during construction and operation for wastewater. Thus, since the analysis of hydrology and water quality impacts concluded that significant water demand impacts would occur during hydrotesting and during operation, and less than significant water demand impacts would occur during construction, the hydrology and water quality impacts analysis under Alternative 3 may also have significant water demand impacts during hydrotesting and operation, and less than significant water demand impacts during construction. Similarly, since the analysis of hydrology and water quality impacts concluded that less than significant water quality impacts would occur during construction and operation, less than significant water quality impacts during construction and operation would also be expected to occur under Alternative 3.

5.3.5.5 Alternative 4 – No Project

Under the No Project alternative, no new NOx limits are proposed for any equipment/source category and no NOx RTC reductions are proposed. Thus, none of the 20 facilities that would be affected by the proposed project would be affected by Alternative 4 to the extent that no control equipment would be installed or modified, and no adverse impacts from construction and operating the new or modified control equipment would be expected to occur. Since no construction or operation activities associated with new or modified control equipment would occur under Alternative 4, no new impacts to the environment, including the topic of hydrology and water quality would be expected. Thus, no significant impacts to hydrology and water quality would be expected to occur under Alternative 4.

5.3.5.6 Alternative 5 – Weighted by BARCT Reduction Contribution

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 5, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 5 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 5. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical.

In particular to the topic of hydrology and water quality, only 6~~7~~ of the 20 affected facilities would be expected to have water demand and water quality impacts as a result of the WGS technology that may be installed at these facilities in response to the proposed project. Further, the same 6~~7~~ facilities that may be affected by the proposed project and the same NOx control technology that may be installed as a result of the proposed project (e.g., WGSs) will also be occur under Alternative 5. Finally, the types and amounts of NOx control equipment that may be installed at the 6~~7~~ facilities and their corresponding environmental impacts and conclusions in response to the proposed project are also identical to Alternative 5.

The analysis of hydrology and water quality concluded that the proposed project is expected to generate: 1) significant adverse water demand impacts during hydrotesting (post-construction) and during operation; 2) less than significant water demand impacts during for dust suppression activities; and, 3) less than significant impacts during construction and operation for wastewater. Thus, since the analysis of hydrology and water quality impacts concluded that significant water demand impacts would occur during hydrotesting and during operation, and less than significant water demand impacts would occur during construction, the hydrology and water quality impacts analysis under Alternative 5 may also have significant water demand impacts during hydrotesting and operation, and less than significant water demand impacts during construction. Similarly, since the analysis of hydrology and water quality impacts concluded that less than significant water quality impacts would occur during construction and operation, less than significant water quality impacts during construction and operation would also be expected to occur under Alternative 5.

5.3.6 Solid and Hazardous Waste

The potential solid and hazardous waste impacts from implementing the proposed project and the project alternatives were evaluated. The following subsections provide brief discussions of solid and hazardous waste impacts from each alternative relative to the proposed project.

5.3.6.1 Proposed Project

Potential solid and hazardous waste impacts from the proposed project are summarized in the following subsections. For the complete analysis, refer to Subchapter 4.6 – Solid and Hazardous Waste. The analysis in Subchapter 4.6 identified the following activities that have the potential to generate adverse solid hazardous waste impacts during construction and operation:

Construction activities associated with installing NOx control equipment such as demolition and site preparation/grading/excavating could generate solid waste as result of implementing the proposed project. However, the amount of debris generated during construction at 20 facilities would not be expected to exceed the designated capacity of local landfills. For this reason, the construction impacts of the proposed project on waste treatment/disposal facilities were concluded to be less than significant.

Solid waste may also be generated from the operation of the new NOx air pollution control equipment at both the refinery and non-refinery facilities. Further, it is possible that some, if not all, of the 20 affected facilities will address any increase in waste through their existing waste minimization plans. For example, some of the affected facilities in both the refinery and non-refinery sectors currently have existing catalyst-based operations and the spent catalysts are either regenerated, reclaimed or recycled, in lieu of disposal, and this practice would be expected to continue. The overall impacts of the proposed project on waste treatment/disposal facilities due to solid waste that may be generated from both refinery and non-refinery facilities during construction and operation were concluded to be less than significant.

Overall, it was concluded in Subchapter 4.6 that potential solid and hazardous waste impacts from implementing the proposed project would be less than significant. Therefore, project-specific solid and hazardous waste impacts associated with the proposed project are less than significant.

5.3.6.2 Alternative 1 – Across the Board Shave of NOx RTCs

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 1, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 1 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 1. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical.

Thus, since the solid and hazardous waste impacts were determined to be less than significant during both construction and operation for the proposed project, the solid and hazardous impacts were also determined to be less than significant during both construction and operation under Alternative 1.

5.3.6.3 Alternative 2 – Most Stringent Shave of NOx RTCs

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 2, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 2 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 2. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical. However, it is possible that under this alternative, facilities could increase their level of control to obtain a compliance margin which would result in a greater air quality benefit from NOx reductions with fewer adverse environmental impacts. Nonetheless, because the quantity and type of NOx control equipment that may be installed beyond what was analyzed for the proposed project is speculative, any potential increased environmental benefit and corresponding impacts that may occur from increasing the level of control to obtain a compliance margin beyond what has been analyzed for the proposed project cannot be analyzed.

Thus, since the solid and hazardous waste impacts were determined to be less than significant during both construction and operation for the proposed project, the solid and hazardous impacts were also determined to be less than significant during both construction and operation under Alternative 2.

5.3.6.4 Alternative 3 – Industry Approach

Because not as many, if any, additional actual NOx emission reductions would be needed to achieve an overall NOx RTC shave of 8.0 tpd, fewer than the 20 facilities that may be affected by the proposed project will be affected by Alternative 3. Without knowing exactly how industry will react if Alternative 3 is implemented, to predict the number of facilities that would install NOx control equipment would be speculative and unquantifiable. However, to conduct a worst-case analysis without quantification, the number and type of control equipment that may be installed under Alternative 3 is assumed to be fewer than what was analyzed for the proposed project and the corresponding adverse impacts under Alternative 3 would also be fewer than what was analyzed for the proposed project. To be conservative, the same conclusions reached for the proposed project for each environmental topic area will be applied to Alternative 3, except that the impacts will be concluded to have fewer impacts than the proposed project.

Thus, since the solid and hazardous waste impacts were determined to be less than significant during both construction and operation for the proposed project, the solid and hazardous impacts were also determined to be less than significant during both construction and operation under Alternative 3.

5.3.6.5 Alternative 4 – No Project

Alternative 4 would continue the implementation of the 2005 amendments to the NOx RECLAIM program. Under the No Project alternative, no new NOx limits are proposed for any equipment/source category and no NOx RTC reductions are proposed. Thus, none of the 20 facilities that would be affected by the proposed project would be affected by Alternative 4 to the extent that no control equipment would be installed or modified, and no adverse impacts from construction and operating the new or modified control equipment would be expected to occur. Since no construction or operation activities associated with new or modified control equipment would occur under Alternative 4, no new impacts to the environment, including the topic of solid and hazardous waste would be expected. Thus, no significant impacts to solid and hazardous waste would be expected to occur under Alternative 4.

5.3.6.6 Alternative 5 – Weighted by BARCT Reduction Contribution

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 5, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 5 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 5. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical.

Thus, since the solid and hazardous waste impacts were determined to be less than significant during both construction and operation for the proposed project, the solid and hazardous impacts were also determined to be less than significant during both construction and operation under Alternative 5.

5.3.7 Transportation and Traffic

The potential direct and indirect transportation and traffic impacts from implementing the proposed project and the project alternatives were evaluated. The following subsections provide brief discussions of direct and indirect hazards and hazardous materials impacts from each alternative relative to the proposed project.

5.3.7.1 Proposed Project

Potential direct and indirect transportation and traffic impacts from the proposed project are summarized in the following subsections. For the complete analysis, refer to Subchapter 4.7 – Transportation and Traffic.

Implementation of the proposed project may cause adverse transportation and traffic impacts associated with the existing facilities affected by the proposed project. Specifically, construction-based traffic associated with the installation of NOx control technology are expected from construction workers, delivery trucks and haul trucks. During operation of the proposed project, regular deliveries and waste disposal activities are also expected to increase at each of the affected facilities. Despite the increases, the analysis shows that the transportation and traffic impacts, though adverse, are less than significant for the proposed project during both construction and operation.

5.3.7.2 Alternative 1 – Across the Board Shave of NOx RTCs

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 1, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 1 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 1. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical.

Thus, since the transportation and traffic impacts were determined to be less than significant during both construction and operation for the proposed project, the transportation and traffic impacts were also determined to be less than significant during both construction and operation under Alternative 1.

5.3.7.3 Alternative 2 – Most Stringent Shave of NOx RTCs

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 2, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 2 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 2. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical. However, it is possible that under this alternative, facilities could increase their level of control to obtain a compliance margin which would result in a greater air quality benefit from NOx reductions with fewer adverse environmental impacts. Nonetheless, because the quantity and type of NOx control equipment that may be installed beyond what was analyzed for the proposed project is speculative, any potential increased environmental benefit and corresponding impacts that may occur from increasing the level of control to obtain a compliance margin beyond what has been analyzed for the proposed project cannot be analyzed.

Thus, since the transportation and traffic impacts were determined to be less than significant during both construction and operation for the proposed project, the transportation and traffic impacts were also determined to be less than significant during both construction and operation under Alternative 2.

5.3.7.4 Alternative 3 – Industry Approach

Because not as many, if any, additional actual NOx emission reductions would be needed to achieve an overall NOx RTC shave of 8.0 tpd, fewer than the 20 facilities that may be affected by the proposed project will be affected by Alternative 3. Without knowing exactly how industry will react if Alternative 3 is implemented, to predict the number of facilities that would install NOx control equipment would be speculative and unquantifiable. However, to conduct a worst-case analysis without quantification, the number and type of control equipment that may be installed under Alternative 3 is assumed to be fewer than what was analyzed for the proposed project and the corresponding adverse impacts under Alternative 3 would also be fewer than what was analyzed for the proposed project. To be conservative, the same conclusions reached for the proposed project for each environmental topic area will be applied to Alternative 3, except that the impacts will be concluded to have fewer impacts than the proposed project.

Thus, since the transportation and traffic impacts were determined to be less than significant during both construction and operation for the proposed project, the transportation and traffic impacts were also determined to be less than significant during both construction and operation under Alternative 3.

5.3.7.5 Alternative 4 – No Project

Alternative 4 would continue the implementation of the 2005 amendments to the NOx RECLAIM program. Under the No Project alternative, no new NOx limits are proposed for any equipment/source category and no NOx RTC reductions are proposed. Thus, none of the 20 facilities that would be affected by the proposed project would be affected by Alternative 4 to the extent that no control equipment would be installed or modified, and no adverse impacts from construction and operating the new or modified control equipment would be expected to occur. Since no construction or operation activities associated with new or modified control equipment would occur under Alternative 4, no new impacts to the environment, including the topic of transportation and traffic would be expected. Thus, no significant impacts to transportation and traffic would be expected to occur under Alternative 4.

5.3.7.6 Alternative 5 – Weighted by BARCT Reduction Contribution

Despite the differences in how facilities are affected by the NOx RTC shave and the amount of the NOx RTC shave under Alternative 5, the amount of potential NOx emission reductions that may be achieved by installing new or modifying existing air pollution control equipment under Alternative 5 is 8.77 ~~8.79~~ tpd, which is identical to the amount of potential NOx emissions reductions estimated for the proposed project. The same 20 facilities that may be affected by the proposed project will also be affected under Alternative 5. Further, the types and amounts of NOx control equipment that may be installed at the 20 affected facilities and their corresponding environmental impacts and conclusion are also identical.

Thus, since the transportation and traffic impacts were determined to be less than significant during both construction and operation for the proposed project, the transportation and traffic impacts were also determined to be less than significant during both construction and operation under Alternative 5.

5.4 COMPARISON OF THE PROPOSED PROJECT TO THE ALTERNATIVES

Pursuant to CEQA Guidelines §15126.6 (d), a CEQA document "shall include sufficient information about each alternative to allow meaningful evaluation, analysis, and comparison with the proposed project. A matrix displaying the major characteristics and significant environmental effects of each alternative may be used to summarize the comparison. If an alternative would cause one or more significant effects in addition to those that would be caused by the project as proposed, the significant effects of the alternative shall be discussed, but in less detail than the significant effects of the project as proposed." Accordingly, Table 5-3 provides a matrix displaying the major characteristics and significant environmental effects of the proposed project and each alternative.

Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the projected installation of WGS technology is expected to only occur at one of the two FCCUs. Further, since the release of the Draft PEA for public review and comment, the number of SCRs that may be installed for the refinery boiler and heater source category has been lowered to 73 units, instead of 74. Thus, the analysis in this PEA for the refinery sector is conservative as it overestimates the potential adverse environmental impacts summarized in Table 5-3.

Table 5-3

Comparison of Adverse Environmental Impacts of the Alternatives

Environmental Topic Area	Proposed Project: Shave Applied to 90 percent of RTC Holders – 56 ~~65~~ facilities	Alternative 1: Across the Board Shave *(All facilities reduce 53%)*	Alternative 2: Most Stringent Shave *(All facilities reduce 60%)*	Alternative 3: Industry Approach *(All facilities reduce 33%)*	Alternative 4: No Project	Alternative 5: Weighted by BARCT Reduction Contribution for all facilities & investors
Aesthetics	Visible steam plumes and new, tall stacks from installing/operating up to 8 WGSs at 7 facilities as follows: FCCU: 2 WGSs SRU/TGU: 5 WGSs Coke Calciner: 1 WGS	Same as proposed project	Same as proposed project, but if facility operators install additional WGSs beyond what is analyzed for the proposed project to obtain a compliance margin, then additional steam plumes and tall stacks could occur.	Less than proposed project	No installation of WGSs (e.g., no visible steam plumes and no new, tall stacks) expected	Same as proposed project
Aesthetics Impacts Significant?	Less than significant	Less than significant (same as proposed project)	Less than significant (same as proposed project, but potentially more adverse aesthetics impacts if facility operators install additional WGSs beyond what is analyzed for the proposed project)	Less than significant (less than proposed project)	No Impact - Not Significant	Less than significant (same as proposed project)
Air Quality & GHGs	• Reduces total operational NOx emissions by 8.77 ~~8.79~~ tpd • Reduces total NOx RTC holdings by 14.0 tpd • Unused NOx RTCs to be applied to shave is 5.23 ~~5.21~~ tpd • Increases total GHGs by: - 41,785 MT/yr without mitigation; & - 41,100 MT/yr with mitigation • Increases operational use of NaOH (a TAC) by 5.84 tpd	Same as proposed project	• Reduces total operational NOx emissions by 8.77 ~~8.79~~ tpd • Reduces total NOx RTC holdings by 15.87 tpd • Unused NOx RTCs to be applied to shave is 7.10 ~~7.08~~ tpd • Increases total GHGs by: • - 41,785 MT/yr without mitigation; & - 41,100 MT/yr with mitigation • Increases operational use of NaOH (a TAC) by 5.84 tpd	• Less operational NOx reductions than proposed project but not quantifiable • Reduces total NOx RTC holdings by 8.00 tpd • Less increases to GHGs than proposed project, but not quantifiable before or after mitigation • Less increases in operational use of NaOH (a TAC) but not quantifiable	• No decreases in total operational NOx emissions. • No increases in construction emissions for any pollutant.	Same as proposed project

Table 5-3 (continued)
Comparison of Adverse Environmental Impacts of the Alternatives

Environmental Topic Area	Proposed Project: Shave Applied to 90 percent of RTC Holders – 56 ~~65~~ facilities	Alternative 1: Across the Board Shave *(All facilities reduce 53%)*	Alternative 2: Most Stringent Shave *(All facilities reduce 60%)*	Alternative 3: Industry Approach *(All facilities reduce 33%)*	Alternative 4: No Project	Alternative 5: Weighted by BARCT Reduction Contribution for all facilities & investors
Air Quality & GHGs (concluded)	• Increases operational use of NH3 (a TAC) by 39.5 tpd • Increases peak daily operation emissions as follows: VOC: 17 lb/day CO: 75 lb/day NOx: 190 lb/day* PM10: 22 lb/day PM2.5: 19 lb/day • Increases peak daily emissions for construction in same year as follows: VOC: 429 lb/day CO: 2,745 lb/day NOx: 1,656 lb/day SOx: 3 lb/day PM10: 1,758 lb/day without mitigation; & 853 ~~1,009~~ lb/day with mitigation PM2.5: 883 lb/day without mitigation; & 430 ~~508~~ lb/day with mitigation	Same as proposed project	• Increases operational use of NH3 (a TAC) by 39.5 tpd Increases peak daily operation emissions as follows: VOC: 17 lb/day CO: 75 lb/day NOx: 190 lb/day* PM10: 22 lb/day PM2.5: 19 lb/day • Increases peak daily emissions for construction in same year as follows: VOC: 429 lb/day CO: 2,745 lb/day NOx: 1,656 lb/day SOx: 3 lb/day PM10: 1,758 lb/day without mitigation; & 853 ~~1,009~~ lb/day with mitigation PM2.5: 883 lb/day without mitigation; & 430 ~~508~~ lb/day with mitigation • If additional controls are installed beyond the proposed project for a compliance margin, more emission benefits as well as increased emissions impacts could occur.	• Less increases in operational use of NH3 (a TAC) but not quantifiable • Less increases in peak daily operation emissions but not quantifiable • Less increases in peak daily emissions for construction but not quantifiable with or without mitigation	• No decreases in total operational NOx emissions • No increases in construction emissions for any pollutant.	Same as proposed project

* The potential increases in NOx operational emissions are more than offset by the overall project reductions.

Table 5-3 (continued)

Comparison of Adverse Environmental Impacts of the Alternatives

Environmental Topic Area	**Proposed Project: Shave Applied to 90 percent of RTC Holders – 56 ~~65~~ facilities**	**Alternative 1: Across the Board Shave *(All facilities reduce 53%)***	**Alternative 2: Most Stringent Shave *(All facilities reduce 60%)***	**Alternative 3: Industry Approach *(All facilities reduce 33%)***	**Alternative 4: No Project**	**Alternative 5: Weighted by BARCT Reduction Contribution for all facilities & investors**
Air Quality & GHG Impacts Significant?	• Less than significant, achieves net NOx emission reductions during operation by 8.72 tpd. • Less than significant for VOC, CO, PM10 and PM2.5 during operation • Significant for GHGs • Less than significant for TACs use (NaOH and NH3) during operation • Significant for VOC, CO, NOx, PM10, and PM2.5 during construction	• Less than significant, achieves net NOx emission reductions during operation by 8.72 tpd (same as proposed project) • Less than significant for VOC, CO, PM10 and PM2.5 during operation (same as proposed project) • Significant for GHGs (same as proposed project) • Less than significant for TACs use (NaOH and NH3) during operation (same as proposed project) • Significant for VOC, CO, NOx, PM10, and PM2.5 during construction (same as proposed project)	• Less than significant, achieves net NOx emission reductions during operation by 8.72 tpd (same as proposed project) • Less than significant for VOC, CO, PM10 and PM2.5 during operation (same as proposed project) • Significant for GHGs (same as proposed project) • Less than significant for TACs use (NaOH and NH3) during operation (same as proposed project) • Significant for VOC, CO, NOx, PM10, and PM2.5 during construction (same as proposed project) • If additional controls are installed beyond the proposed project for a compliance margin, more emission benefits and increased emissions could occur.	• Less than significant; achieves net NOx emission reductions during operation (less reductions than the proposed project but not quantifiable) • Less than significant increases in VOC, CO, PM10 and PM2.5 during operation (less than the proposed project but not quantifiable) • Significant for GHGs, (less than proposed project but not quantifiable) • Less than significant for TACs use (NaOH and NH3) during operation (less than the proposed project but not quantifiable) • Significant for VOC, CO, NOx, PM10, and PM2.5 during construction (less than proposed project but not quantifiable)	• No Impact - Not Significant • Does not achieve required AQMP NOx emission reductions during operation • Does not comply with BARCT assessment requirements per Health and Safety Code	• Less than significant, achieves net NOx emission reductions during operation by 8.72 tpd (same as proposed project) • Less than significant for VOC, CO, PM10 and PM2.5 during operation (same as proposed project) • Significant for GHGs(same as proposed project) • Less than significant for TACs use (NaOH and NH3) during operation (same as proposed project) • Significant for VOC, CO, NOx, PM10, and PM2.5 during construction (same as proposed project)

Table 5-3 (continued)
Comparison of Adverse Environmental Impacts of the Alternatives

Environmental Topic Area	Proposed Project: Shave Applied to 90 percent of RTC Holders – 56 ~~65~~ facilities	Alternative 1: Across the Board Shave *(All facilities reduce 53%)*	Alternative 2: Most Stringent Shave *(All facilities reduce 60%)*	Alternative 3: Industry Approach *(All facilities reduce 33%)*	Alternative 4: No Project	Alternative 5: Weighted by BARCT Reduction Contribution for all facilities & investors
Energy	• During construction: -Increased use of diesel by 15,855 gal/day -Increase use of gasoline by 5,422 gal/day • During operation: -Increased use of electricity by 214 MWh/day -Increased use of diesel by 8,380 gal/day	Same as proposed project	Same as proposed project but if facility operators install additional NOx controls beyond what is analyzed for the proposed project to obtain a compliance margin, increased energy use during construction and operation could occur	Less than the proposed project	No increases in energy uses during construction or operation	Same as proposed project
Energy Significant?	Less than significant	Less than significant (same as proposed project)	Less than significant (same as proposed project but if additional controls are installed beyond the proposed project for a compliance margin, increased energy use than the proposed project could occur.)	Less than significant (less than the proposed project)	No Impact - Not Significant	Less than significant (same as proposed project)
Hazards & Hazardous Materials	Increased use of 5.84 tons/day of NaOH and 39.5 tons/day of NH3 (both TACs) used during operation.	Same as proposed project	Same as proposed project but if facility operators install additional NOx controls beyond what is analyzed for the proposed project to obtain a compliance margin, additional NaOH and NH3 may be needed.	Less than the proposed project	No change to existing hazards and hazardous materials used	Same as proposed project
Hazards & Hazardous Materials Impacts Significant?	Less than significant	Less than significant (same as proposed project)	Less than significant (same as proposed project but if additional controls are installed beyond the proposed project for a compliance margin, increased use of NaOH and NH3 could occur.)	Less than significant	No Impact - Not Significant	Less than significant (same as proposed project)

Table 5-3 (continued)
Comparison of Adverse Environmental Impacts of the Alternatives

Environmental Topic Area	Proposed Project: Shave Applied to 90 percent of RTC Holders – 56 ~~65~~ facilities	Alternative 1: Across the Board Shave *(All facilities reduce 53%)*	Alternative 2: Most Stringent Shave *(All facilities reduce 60%)*	Alternative 3: Industry Approach *(All facilities reduce 33%)*	Alternative 4: No Project	Alternative 5: Weighted by BARCT Reduction Contribution for all facilities & investors
Hydrology & Water Quality	• During construction: -Increased use of water for dust suppression by 12,501 gal/day -Increased use of water for hydrotesting by 353,724 gal/day • During operation -Increased use of potable water by 553,499 to 558,978 ~~602,814~~ gal/day (of which 512,603 up to 518,082 ~~204,047~~ gal/day could potentially be supplied by recycled water) -Increased generation of wastewater by 214,801 ~~236,719~~ gal/day.	Same as proposed project	Same as proposed project but if facility operators install additional NOx controls beyond what is analyzed for the proposed project to obtain a compliance margin, additional water demand and increased wastewater generation may occur.	Less than the proposed project	No change to existing water demand or wastewater discharge	Same as proposed project
Hydrology & Water Quality Impacts Significant?	• Significant for water demand during hydrotesting (assuming entire demand is based on potable water) • Significant for water demand during operation (assuming entire demand is based on potable water) • Less than significant for water demand during construction • Less than significant for wastewater discharge during construction and operation	-Significant for water demand (same as proposed project) -Less than significant for wastewater discharge (same as proposed project)	-Significant for water demand (same as proposed project but if additional controls are installed beyond the proposed project for a compliance margin, increased use of water during construction and operation may be needed) -Less than significant for wastewater discharge (same as proposed project but if additional controls are installed beyond the proposed project for a compliance margin, then additional wastewater may be discharged	-Significant for water demand (less than proposed project) -Less than significant for wastewater discharge (less than proposed project)	No Impact - Not Significant	-Significant for water demand (same as proposed project) -Less than significant for wastewater discharge (same as proposed project)

Table 5-3 (concluded)

Solid & Hazardous Waste	• During construction: -Increased generation of non-hazardous solid waste • During operation: -Increased generation of non-hazardous solid waste that can be recycled	Same as proposed project	Same as proposed project but if facility operators install additional NOx controls beyond what is analyzed for the proposed project to obtain a compliance margin, additional solid waste may be generated.	Less than the proposed project	No change to existing disposal of solid & hazardous waste	Same as proposed project
Solid & Hazardous Waste Impacts Significant?	Less than significant	Less than significant (same as proposed project)	Less than significant (same as proposed project but if additional controls are installed beyond the proposed project for a compliance margin, increased use of water during construction and operation may be needed)	Less than significant (less than the proposed project)	No Impact - Not Significant	Less than significant (same as proposed project)
Transportation & Traffic	Overall peak increase in transportation and traffic of 485 trips per day during construction and 65 trips per day during operation.	Same as proposed project	Same as proposed project but if facility operators install additional NOx controls beyond what is analyzed for the proposed project to obtain a compliance margin, additional daily trips during construction and operation may be needed.	Less than the proposed project	No change to existing transportation and traffic.	Same as proposed project
Transportation & Traffic Impacts Significant?	Less than significant	Less than significant (same as proposed project)	Less than significant (same as proposed project but if facility operators install additional NOx controls beyond what is analyzed for the proposed project to obtain a compliance margin, additional daily trips during construction and operation may be needed)	Less than significant (less than the proposed project)	No Impact - Not Significant	Less than significant (same as proposed project)

5.5 ALTERNATIVES REJECTED AS INFEASIBLE

In accordance with CEQA Guidelines §15126.6 (c), a CEQA document should identify any alternatives that were considered by the lead agency, but were rejected as infeasible during the scoping process and briefly explain the reasons underlying the lead agency's determination. Section 15126.6 (c) also states that among the factors that may be used to eliminate alternatives from detailed consideration in a CEQA document are: 1) failure to meet most of the basic project objectives; 2) infeasibility; or, 3) inability to avoid significant environmental impacts.

As noted in Section 5.1, the range of feasible alternatives to the proposed project is limited by the nature of the proposed project and associated legal requirements. Similarly, the range of alternatives considered, but rejected as infeasible is also relatively limited. The following subsection identifies Alternative 4 to the proposed project, as being rejected due to infeasibility for the reasons explained in the following subsection.

5.5.1 Alternative 4 - No Project

CEQA documents typically assume that the adoption of a No Project alternative would result in no further action on the part of the project proponent or lead agency. For example, in the case of a proposed land use project such as a housing development, adopting the No Project alternative terminates further consideration of that housing development or any housing development alternative identified in the associated CEQA document. In that case, the existing setting would typically remain unchanged.

The concept of taking no further action (and thereby leaving the existing setting intact) by adopting a No Project alternative does not readily apply to implementation of a control measure that has been adopted and legally mandated in the 2012 AQMP. ~~Adopting a No Project alternative for implementing a control measure in the 2012 AQMP does not automatically imply that no further action will be taken (e.g., halting implementation of the existing 2012 AQMP).~~ The federal and state Clean Air Acts require the SCAQMD to implement the AQMP in order to attain all state and national ambient air quality standards. More importantly, ~~Thus,~~ a No Project alternative in the case of the proposed project is not a legally viable alternative because it violates a state law requirement in Health and Safety Code §40440 that regulations mandate the use of BARCT for existing sources~~undermines the legal requirements in the 2012 AQMP. Consequently, the No Project alternative presented in this Draft PEA is the continued implementation of the 2005 amendments to the NOx RECLAIM program. Further, it is also unclear whether or not continued implementation of the 2005 amendments to the NOx RECLAIM program is a feasible alternative because the SCAQMD is required to conduct a BARCT reassessment in accordance with Health and Safety Code §§40440 and 39616 that demonstrates achievable NOx emission reductions.~~

"The 'no project' analysis shall discuss the existing conditions at the time the notice of preparation is published, or if no notice of preparation is published, at the time environmental analysis is commenced, *as well as what would be reasonably expected to occur in the foreseeable future if the project were not approved, based on current plans and consistent with available infrastructure and community services*…" It should be noted that, except for air quality and GHG emissions, there would be no further incremental impacts on the existing environment if no further action is taken. Although there are other existing rules that may have future compliance dates for NOx emission reductions, potential adverse impacts from these rules have already been evaluated in the Final Program EIR for the 2012 AQMP and their subsequent rule-specific CEQA documents. While air quality would continue to improve to a certain extent, it is unlikely that all state or federal ozone standards would be achieved as required by the federal and California CAAs. It is possible that the federal 24-hour PM2.5 standard may be achieved; however, it is unlikely that further progress would be made towards achieving the state PM2.5 standard as required by the California CAA.

5.6 LOWEST TOXIC AND ENVIRONMENTALLY SUPERIOR ALTERNATIVE

5.6.1 Lowest Toxic Alternative

In accordance with SCAQMD's policy document Environmental Justice Program Enhancements for FY 2002-03, Enhancement II-1 recommends for all SCAQMD CEQA documents which are required to include an alternatives analysis, the alternative analysis shall also include and identify a feasible project alternative with the lowest air toxics emissions. In other words, for any major equipment or process type under the scope of the proposed project that creates a significant environmental impact, at least one alternative, where feasible, shall be considered from a "least harmful" perspective with regard to hazardous or toxic air pollutants.

As explained in Subchapter 4.4 – Hazards and Hazardous Materials, implementation of the proposed project may alter the hazards and hazardous materials associated with the existing facilities affected by the proposed project. Air pollution control equipment and related devices are expected to be installed or modified at affected facilities such that their operations may increase the quantity of materials used in the control equipment, some of which are hazardous. . The main NOx reduction technologies considered for the proposed project are based on employing mostly SCR and WGS technologies. The analysis shows that of the possible NOx controls that may be employed, both SCR and WGS technologies may increase the use of toxic materials such as aqueous ammonia and sodium hydroxide (NaOH), respectively. In addition, one UltraCat DGS that may be considered for Refinery 2 would also utilize aqueous ammonia for its operation. Some WGSs, but not all, rely on the use of sodium hydroxide (NaOH) caustic solution as the scrubbing agent. NaOH is a toxic air contaminant (TAC) that is a non-cancerous but acutely hazardous substance and is used in WGSs for controlling NOx emissions from FCCUs, SRU/TGUs, coke calciners, and glass melting. Despite the potential increased use in ammonia and NaOH, the overall analysis concluded that the proposed project would generate less than significant adverse hazards and hazardous materials impacts.

To identify a lowest toxic alternative with respect to the proposed project, a lowest toxic alternative would be if NOx control technologies are employed that use the least amount of hazardous or toxic materials However, because each of the alternatives, except Alternative 3 – Industry Approach and Alternative 4 – the No Project alternative, assumes that the same type and amounts of NOx control equipment on at the same affected facilities will be installed, the amount of hazardous materials that may be needed to operate the various NOx control equipment under each alternative (except for Alternatives 3 and 4) would also be the same. While Alternative 3 results in fewer toxic emissions, it is not the environmentally superior alternative because it results in far fewer NOx benefits than the proposed project, which already has less than significant toxic impacts.

As explained in subsection 5.3.4.5, under Alternative 4, the No Project alternative, no new NOx limits are proposed for any equipment/source category and no NOx RTC reductions are proposed. Thus, none of the 20 facilities that would be affected by the proposed project would be affected by Alternative 4 to the extent that no control equipment would be installed or modified, and no adverse impacts from construction and operating the new or modified control equipment would be expected to occur. Since no construction or operation activities associated with new or modified control equipment would occur under Alternative 4, no new impacts to the environment, including the topic of hazards and hazardous materials would be expected. Thus, no increased use in the amount of hazardous or toxic materials would occur if Alternative 4 is implemented.

Thus, from a hazard and air toxics perspective, when compared to the proposed project and the other alternatives under consideration, if implemented, Alternative 4 is considered to be the lowest toxic alternative, but it is not the environmentally superior alternative because it does not achieve that NOx reductions that would result from the proposed project.

5.6.2 Environmentally Superior Alternative

Pursuant to CEQA Guidelines §15126.6 (e)(2), if the environmentally superior alternative is the "no project" alternative, the CEQA document shall also identify an alternate environmentally superior alternative from among the other alternatives. Alternative 4, the No Project alternative, would result in the continued implementation of the 2005 amendments to the NOx RECLAIM program and is considered to be the least toxic alternative because it is not expected to generate any significant adverse impacts to any environmental topic areas without providing any environmental benefits.

Alternative 4, the No Project alternative, is not the environmentally superior alternative because it does not achieve the NOx reductions as the proposed project or Alternatives 1, 2 and 5. However, if the amount of shave that would be applied by each of these alternatives is taken into consideration as an indicator to how facility operators may respond to the reduced amount of available NOx RTCs in the market, then the alternative with highest amount of proposed shave of NOx RTC holdings, Alternative 2, would have the greatest chance of ensuring that all control equipment that is contemplated would be installed in order to ensure that the maximum amount of NOx emissions reductions projected would actually occur. Thus, of Alternatives 1, 2, 3 and 5, Alternative 2 would be considered the environmentally superior alternative.

5.7 CONCLUSION

Of the five alternatives analyzed, Alternative 4 would generate the least severe and fewest number of environmental impacts compared to the proposed project. However, of the project alternatives, Alternative 4 would achieve the fewest of the project objectives and would have the fewest NOx reduction benefits.

Alternatives 1, 2, and 5 would all be expected to generate equivalent impacts to proposed project in all environmental topic areas analyzed. Alternative 3 would provide the least amount of actual NOx emission reductions (except for the Alternative 4 – the No Project alternative), while Alternative 2 would provide the greatest amount of actual NOx emission reductions. Alternatives 1, 2, 3, and 5 all propose to shave the NOx RTC holdings of 219 ~~210~~ facilities which represent the bottom 10 percent of NOx RTC holders. By applying a shave in this manner, the 219 ~~210~~ facilities would become potential future buyers of RTCs since the amount of RTC holdings for these facilities would become less than their current actual emissions for Alternatives 1, 2, 3 and 5. For this reason, none of Alternatives 1, 2, 3 and 5 would satisfy Objective No. 2 "to modify the RTC "shaving" methodology to implement the emission reductions per the BARCT assessment" (the project objectives are described on page 2-4 in Chapter 2). Thus, the proposed project is considered to provide the best balance between emission reductions and the adverse environmental impacts due to construction and operation activities while meeting the objectives of the project. Therefore, the proposed project is preferred over the project alternatives.

6.1 ORGANIZATIONS AND PERSONS CONSULTED

The CEQA statutes and Guidelines require that organizations and persons consulted be provided in the PEA. A number of organizations, state and local agencies, and private industry have been consulted. The following organizations and persons have provided input into this document.

Steven Mac
California Energy Commission

Uzi Daniel and Joe Walters
West Basin Municipal Water District

Edward Hutter
Dupont

Rob Wood
Native American Heritage Commission

Matthew P. Lyons
Long Beach Water Department

Sean Gamette
Port of Long Beach

CHAPTER 7

ACRONYMS

7.0 ACRONYMS

ABBREVIATION = DESCRIPTION

μg/m3 = micrograms per cubic meter
ACGIH = American Conference of Governmental Industrial Hygiene
APS = Alternative Planning Strategy
AQMP = Air Quality Management Plan
ASME = American Society of Mechanical Engineers
ATCM = Airborne Toxic Control Measure
ATCP = Air Toxics Control Plan
AVTA = Advanced Vehicle Testing Activity
B100 = biodiesel
BACM = Best Available Control Measure
BACT = Best Available Control Technology
BARCT = Best Available Retrofit Control Technology
BART = Best Available Control Technology
Basin = South Coast Air Basin
BAU = business-as-usual
BLEVE = boiling liquid expanding vapor explosion
BLM = Bureau of Land Management
BMP = best management practice
BPTCP = Bay Protection and Toxic Cleanup Plan
C3H8 = propane
CAA = Clean Air Act
CAFE = Corporate Average Fuel Economy
CalARP = California Accidental Release Prevention Program
CalEMA = California Emergency Management Agency
CalEPA = California Environmental Protection Agency
CalOSHA = California Occupational Safety and Health Administration
Caltrans = California Department of Transportation
CaOH = calcium hydroxide
CAPCOA = California Air Pollution Control Officers Association
CARB = California Air Resources Board
CCAR = California Climate Action Registry
CCP = Clean Communities Plan
CCR = California Code of Regulations
CEC = California Energy Commission
CEMS = continuous emissions monitor system
CEQA = California Environmental Quality Act
CERCLA = Comprehensive Environmental Response, Compensation, and Liability Act
CERs = Certified Emission Reductions

CFR = Code of Federal Regulations
CH4 = methane
CHMIRS = California Hazardous Materials Incident Reporting System
CHP = California Highway Patrol
CI = compressed engines
CIP = Capital Improvement Program
CIWMP = Countrywide Integrated Waste Management Plan
CM = control measure
CMA = Congestion Management Agency
CNG = compressed natural gas
CO = carbon monoxide
CO2 = carbon dioxide
CO2eq = carbon dioxide equivalent
COD = chemical oxygen demand
COHb = carboxyhemoglobin
CPCC = California Portland Cement Company
CPSC = Consumer Products Safety Commision
CPUC = California Public Utilities Commission
CRA = Colorado River Aqueduct
CS2 = carbon disulfide
CUPA = Certified Unified Program Agency
CWA = Clean Water Act
CWAP = Clean Water Action Plan
DC = direct current
DEA = diethanolamine
DFW = Department of Fish and Wildlife
DGS = dry gas scrubber
DHS = Department of Health Services
DPH = Department of Public Heath
DTSC = Department of Toxic Substance Control
DWR = California Department of Water Resources
EA = Environmental Assessment
EAP = Emergency Action Plan
EDV = Electro Dynamic Venturi
EGF = electric generating facility
EIR = Environmental Impact Report
EISA = Energy Independence and Security Act
EJ = Environmental Justice
EJAG = Environmental Justice Advisory Group
EMWD = Eastern Municipal Water District
ERPG = Emergency Response Planning Guidelines
ESP = electrostatic precipitator

EV = electric vehicle
FCCU = fluid catalytic cracking unit
Fe203 = iron oxide
FedOSHA = Federal Occupational Safety and Health Administration
FEMA = Federal Emergency Management Agency
FFV = flexible fuel vehicle
FGT = fuel gas treatment
FHWA = Federal Highway Administration
FR = Federal Register
FUA = Fuel Use Act
gal = gallons
GHG = greenhouse gases
GHGRP = Greehouse Gas Reporting Program
gWh = gigawatt-hour
GWP = global warming potential
H2S = hydrogen sulfide
H2SO4 = sulfuric acid
HAP = hazardous air pollutant
HCFC = hydrochlorofluorocarbon
HCl = hydrochloric acid
HDRD = hydrogeneration-derived renewable diesel
HF = hydrofluoric acid
HMTA = Hazardous Material Transportation Act
HOV = high occupancy vehicle
HRSG = heat recovery steam generation
HSC = Health and Safety Code
HWCL = Hazardous Waste Control Law
HWMP = San Bernardino County's Hazardous Waste Management Plan
ICE = internal combustion engines
IDLH = Immediately Dangerous to Life and Health
inH20 = inches water column
IRP = Integrated Water Resources Plan
IS = Initial Study
kW = kilowatt
kWh = kilowatt-hour
LAA = Los Angeles Aqueduct
LACSD = Los Angeles County Sanitation District
LADWP = Los Angeles Department of Water and Power
LAER = Lowest Achievable Emission Rate
LBGOD = Long Beach Gas and Oil Dept.
LCFS = Low Carbon Fuel Standard
LCP = Local Coastal Program

LEA = Local Enforcement Agencies
LEED = Leadership in Energy and Environmental Design
LEL = lower explosive limit
LEPC = Local Emergency Planning Committee
LOS = level of service
LPG = liquefied petroleum gas
LRP = Local Resources Program
LTCP = Long-Term Conservation Plan
LUP = land use plan
M&I = municipal and industrial
MATES = Multiple Air Toxics Exposure Studies
MCL = Maximum Contaminant Levels
MDAB = Mojave Desert Air Basin
mmBTU or MMBTU = million British Thermal Units
MoO3 = molybdic anhydride
MPO = Metropolitan Planning Organization
MPO = Metropolitan Planning Organizations
MS4s = municipal separate storm sewer systems
MSBACT = Minor Source Best Available Control Technology
MSDS = Material Safety Data Sheet
MTBE = methyl tertiary butyl ether
MW = megawatt
MWD = Metropolitan Water District
N2O = nitrous oxide
Na2CO3 = sodium carbonate
Na2S2O5 = sodium pyrosulfate
Na2SO3 = sodium sulfite
NAAQS = National Ambient Air Quality Standards
NaHSO3 = sodium bisulfite
NaOH = sodium hydroxide
NCP = National Contingency Plan
NECPA = National Energy Conservation Policy Act
NESHAP = National Emission Standard for Hazardous Air Pollutants
NFC = National Fire Code
NFPA = National Fire Protection
NH03 = nitric oxide
NH3 = ammonia
NHTSA = National Highway Traffic and Safety Administration
NIOSH = National Institute for Occupational Safety and Health
NO = nitric oxide
NOP/IS = Notice of Preparation/Initial Study
NOx = oxides of nitrogen

NPDES = National Pollutant Discharge Elimination System
NSCR = non-selective catalytic reduction
NSR = New Source Review
O2 = oxygen
O3 = ozone
OCHCA = Orange County Health Care Agency
OCS = outer continental shelf
OCTA = Orange County Transportation Authority
ODS = ozone depleting substance
OEHA = Office of Environmental Health Hazard Assessment
OES = Office of Emergency Services
OHMS = Office of Hazardous Materials Safety
OPR = Office of Planning and Research
OSHA = Occupational Safety and Health Administration
PAR = Proposed Amended Rule
PAReg = Proposed Amended Regulation
PCU = publicly owned utilities
PEA = Program Environmental Assessment
PEL = permissible exposure limit
PEV = plug-in electric vehicle
PFC = perfluorocarbon
PM = particulate matter
PM10 = particulate matter with an aerodynamic diameter of 10 microns or less
PM2.5 = particulate matter with an aerodynamic diameter of 2.5 microns or less
POTW = publicly-owned treatment works
ppm = parts per million
ppmv = parts per million by volume'
PSD = Prevention of Significant Deterioration
PSM = Process Safety Management
PG&E = Pacific Gas and Electric
PURPA = Public Utilities Regulatory Policies Act
PV = photovoltaic
PVC = polyvinyl chloride
Qfs = qualifying facilities
QSA = Quantification Settlement Agreement
QV = qualified vehicle testers
RCRA = Resource Conservation and Recovery Act
RCTC = Riverside County Transportation Commission
RECLAIM = Regional Clean Air Incentives Market
REL = Reference Exposure Level
RFS = renewable fuel standard
RIN = renewable identification number

RMP = Risk Management Programs
RPS = renewables portfolio standard
RTAC = Regional Target Advisory Committee
RTC = RECLAIM Trading Credit
RTIP = Regional Transportation Improvement Program
RTP = Regional Transportation Plan
RWQCB = Regional Water Quality Control Board
SANBAG = San Bernardino Associated Governments
SCAB = South Coast Air Basin
SCAG = Southern California Association of Governments
SCAQMD = South Coast Air Quality Management District
SCE = Southern California Edison
SCHWMA = Southern California Hazardous Waste Management Authority
SCR = selective catalytic reduction
SCS = sustainable communities strategy
SDG&E = San Diego Gas and Electric
SEA = Supplemental Environmental Assessment
SF6 = sulfur hexafluoride
SGVEWP = San Gabriel Valley Energy Wise Program
SI = spark ignited
SIP = State Implementation Plan
SNCR = selective non-catalytic reduction
SO2 = sulfur dioxide
SO3 = sulfur trioxide
SoCal Gas = San Gabriel Valley Energy Wise Pgram
SOx = oxides of sulfur
SRRE = Source Reduction and Recycling Element
SRU/TGU = sulfur recovery unit/tail gas unit
SSAB = Salton Sea Air Basin
STE = Solar thermal energy
STEL = short-term exposure limits
SWMP = Storm Water Management Plan
SWP = State Water Project
SWPPP = Storm Water Pollution Prevention Plan
SWRCB = State Water Resources Control Board
TDM = Transportation Demand Management
TEA-21 = Transportation Equity Act for the 21st Century
Ti02 = titanium dioxide
TIMP = Transportation Improvement and Mitigation Program
TLVs = Threshold Limit Values
TMCs = Transportation Management Centers
tons/day = tons per day

tpd = tons per day
TRI = Toxic Release Inventory
TSCA = Toxic Substances Control Act
TSS = total suspended solids
TWA = time-weighted average
UEL = upper explosive limt
USC = United States Code
USDOE = United States Department of Energy
USDOT = United States Department of Transportation
USEPA = United States Environmental Protection Agency
USFS = United States Forest Service
V2O5 = vanadium pentoxide
VC = volume-to-capacity
VHT = vehicle hours of travel
VMT = vehicle miles of travel
VOC = Volatile Organic Compounds
WCI = Western Climate Incentive
WDR = waste discharge requirements
WGS = wet gas scrubber

APPENDIX A1

PROPOSED AMENDED RULE 2001 – APPLICABILITY

Since the release of the Draft PEA, new amendments to Rule 2001 are proposed that would include a provision that would allow the owner or operator of an electricity generating facility (EGF) to opt out of the NOx RECLAIM program. In order to save space and avoid repetition, please refer to the latest version of Proposed Amended Rule 2001 located elsewhere in the Governing Board Package.

Original hard copies of the Draft PEA, which do not include the draft version of the proposed amended rule listed above, can be obtained through the SCAQMD Public Information Center at the Diamond Bar headquarters or by calling (909) 396-2039.

APPENDIX A2

PROPOSED AMENDED RULE 2002 – ALLOCATIONS FOR OXIDES OF NITROGEN (NOX) AND OXIDES OF SULFUR (SOX)

In order to save space and avoid repetition, please refer to the latest version of proposed amended Rule 2002 located elsewhere in the Governing Board Package. The version of Proposed Amended Rule 2002 that was circulated with the Draft PEA and released on August 14, 2015 for a 45-day public review and comment period ending September 29, 2015 was "PAR2002 08072015" dated August 7, 2015.

Original hard copies of the Draft PEA, which include the draft version of the proposed amended rule listed above, can be obtained through the SCAQMD Public Information Center at the Diamond Bar headquarters or by calling (909) 396-2039.

APPENDIX B

PROPOSED AMENDED RULE 2005 – NEW SOURCE REVIEW FOR RECLAIM

In order to save space and avoid repetition, please refer to the latest version of proposed amended Rule 2005 located elsewhere in the Governing Board Package. The version of Proposed Amended Rule 2005 that was circulated with the Draft PEA and released on August 14, 2015 for a 45-day public review and comment period ending September 29, 2015 was dated July 2015.

Original hard copies of the Draft PEA, which include the draft version of the proposed amended rule listed above, can be obtained through the SCAQMD Public Information Center at the Diamond Bar headquarters or by calling (909) 396-2039.

APPENDIX C

PROPOSED AMENDED RULE 2011 APPENDIX A – PROTOCOL FOR MONITORING, REPORTING, AND RECORDKEEPING OXIDES OF OXIDES OF SULFUR (SOX) EMISSIONS (ATTACHMENT C – QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES)

In order to save space and avoid repetition, please refer to the latest version of proposed amended Protocol for Rule 2011 located elsewhere in the Governing Board Package. The version of Proposed Amended Rule 2011 Protocol that was circulated with the Draft PEA and released on August 14, 2015 for a 45-day public review and comment period ending September 29, 2015 was (PAR 2011 07222015) dated July 22, 2015.

Original hard copies of the Draft PEA, which include the draft version of the proposed amended protocol listed above, can be obtained through the SCAQMD Public Information Center at the Diamond Bar headquarters or by calling (909) 396-2039.

APPENDIX D

PROPOSED AMENDED RULE 2012 APPENDIX A – PROTOCOL FOR MONITORING, REPORTING, AND RECORDKEEPING OXIDES OF OXIDES OF NITROGEN (NOX) EMISSIONS (ATTACHMENT C – QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES)

In order to save space and avoid repetition, please refer to the latest version of proposed amended Protocol for Rule 2012 located elsewhere in the Governing Board Package. The version of Proposed Amended Rule 2012 Protocol that was circulated with the Draft PEA and released on August 14, 2015 for a 45-day public review and comment period ending September 29, 2015 was (PAR 2012 07222015) dated July 22, 2015.

Original hard copies of the Draft PEA, which include the draft version of the proposed amended protocol listed above, can be obtained through the SCAQMD Public Information Center at the Diamond Bar headquarters or by calling (909) 396-2039.

APPENDIX E

CONSTRUCTION AND OPERATION CALCULATIONS)

PROPOSED PROJECT: GRAND TOTALS - OPERATION

SRU/TGUs
4 refineries (Facilities 1, 5,6 & 8) - 5 LoTox with WGSs & 1 SCR

Usage Rates

31,093	kWh/day	Electricity
468,767	gal/day	Water
175,890	gal/day	Wastewater
1,028	Mmbtu/day	Cooling Water
1,233	scf/day	Compressed Air
3.64	tons/day	Solid Waste Disposal
1.39	tons/day	Soda Ash
1397.00	lbs/day	NH3 (aqueous 19%)
25,696	sf	plot space needed
2,100	round trip miles/day	truck miles driven
11	trucks/day	no. of trucks
24,747	round trip miles/year	truck miles driven
96	trucks/year	no. of trucks

FCCU
5 refineries (Facilities 4, 5, 6, 7, & 9) - 3 LoTox w/WGSs & 2 SCRs

Usage Rates

40,543	kWh/day	Electricity
93,151	gal/day	Water
43,836	gal/day	Wastewater
1	Mmbtu/day	Cooling Water
1,479	scf/day	Compressed Air
2.33	tons/day	Solid Waste Disposal
2.47	tons/day	NaOH (50%)
2,794	lbs/day	NH3 (aqueous 19%)
7,950	lbs/day	oxygen
10,959	sf	plot space needed
1,550	round trip miles/day	truck miles driven
11	trucks/day	no. of trucks
20621	round trip miles/year	truck miles driven
135	trucks/year	no. of trucks

Coke Calciner
1 refinery (Facility 2) - 1 Ultracat DGS or 1 LoTox w/WGS

Usage Rates

11,621	kWh/day	Electricity
40896.00	gal/day	Water
16992.00	gal/day	Wastewater
36,576	scf/day	Compressed Air
0.44	tons/day	Solid Waste Disposal
3,068	lbs/day	NH3 (aqueous 19%)
1.81	tons/day	Hydrated Lime Ca(OH)2
3.37	tons/day	NaOH (50%)
1,200	sf	plot space needed
616	round trip miles/day	truck miles driven
4	trucks/day	no. of trucks
6,345	round trip miles/year	truck miles driven
86	trucks/year	no. of trucks

Boilers/Heaters
8 refineries (Facilities 1, 3, 4, 5, 6, 7, 8, & 9) - SCRs

Usage Rates

78,389	kWh/day	Electricity
58,307	lbs/day	NH3 (aqueous 19%)
23,672	sf	plot space needed
2,400	round trip miles/day	truck miles driven
24	trucks/day	no. of trucks
47,900	round trip miles/year	truck miles driven
479	trucks/year	no. of trucks

Gas Turbines
5 refineries (Facilities 1, 4, 5, 6, & 7) - SCRs

Usage Rates		
6,524	kWh/day	Electricity
3,576	lbs/day	NH3 (aqueous 19%)
0	sf	plot space needed
1,500	round trip miles/day	truck miles driven
15	trucks/day	no. of trucks
4,000	round trip miles/year	truck miles driven
40	trucks/year	no. of trucks

GRAND TOTALS (For Operation)

Usage Rates					Notes	Net Effect of Project		Percentage Change	Significant?	
168,170	kWh/day	168.17	MWh/day	Electricity	Significance Threshold: 1% of supply (8362 MW - instantaneous electricity)	7.01	MW (instantaneous)	0.08%	NO	Note 1: Instantaneous Electricity Equation: 168,170 kW-hr/day x 1 work day/24 hr x 1 MW/1000 kW = 7.0 MW. Note 2: This calculation takes into account the electricity needed to make 5.84 tons per day of NaOH to satisfy demand (13,235 kWh/day).
602,814	gal/day	0.60	MMgal/day	Water	Significance Threshold: 5,000,000 gal/day water	602,814	gal/day	12.06%	NO	*See Hydrology/Water Quality Analysis
236,718	gal/day	0.24	MMgal/day	Wastewater	Significance Threshold: 25% increase above permitted wastewater limits	236,718	gal/day	<25%*	NO	*See Hydrology/Water Quality Analysis
		1,029	MMbtu/day	Cooling Water	This data already included in energy calculations.					
		39,288	scf/day	Compressed Air	This data already included in energy calculations.					
		6.41	tons/day	Solid Waste Disposal	Solid Waste Disposal, Air Quality off-site transportation emissions, & Energy (fuel usage)					
		1.39	tons/day	Soda Ash (Na2CO3)	Air Quality: off-site transportation emissions & Energy (fuel usage)					
		5.84	tons/day	NaOH (50% by weight)	Air Quality: off-site transportation emissions & Energy (fuel usage)					
		69,142	lbs/day	NH3 (aqueous 19%)	Air Quality: off-site transportation emissions & Energy (fuel usage)					
		7,950	lbs/day	Oxygen	Air Quality: off-site transportation emissions & Energy (fuel usage)					
		1.81	tons/day	Hydrated Lime Ca(OH)2	Air Quality: off-site transportation emissions & Energy (fuel usage)					
		95,127	sf	Plot Space Needed	Air Quality: grading/site-preparation construction emissions					
		8,166	round trip miles/day	Daily truck miles driven	Air Quality: off-site transportation emissions & Energy (fuel usage)					
		65	trucks/day	Daily no. of trucks	Air Quality: off-site transportation emissions & Energy (fuel usage)					
		103,613	round trip miles/year	Annual truck miles driven	Air Quality: off-site transportation emissions & Energy (fuel usage)					
		836	trucks/year	Annual no. of trucks	Air Quality: off-site transportation emissions & Energy (fuel usage)					

Key:
Cooling water already accounted for in both water demand and energy demand.

NaOH is 50% by weight, usually delivered by tanker truck in an aqueous solution due to high concentration

1 MW = 1000 KW

1 tcf (trillion cubic feet) = 1000 bcf (billion cubic feet) = 1,000,000 MMcf (million cubic feet)
1 metric ton = 2205 lbs

Operations - On-Road Vehicles and Fuel Use

Operation	Peak Daily Round-trip Distance (miles/day)	Annual Round-trip Distance (miles/year)	Mileage Rate (miles/ gallon)	2016 Mobile Source Emission Factors							
On-Road Equipment Type				VOC (lb/mile)	CO (lb/mile)	NOx (lb/mile)	SOx (lb/mile)	PM10 (lb/mile)	PM2.5 (lb/mile)	CO2 (lb/mile)	CH4 (lb/mile)
Offsite (Heavy-Heavy Duty Truck)	8,166	103,613	4.89	0.00145203	0.00650533	0.01690387	0.00004033	0.00084894	0.00069721	4.20820129	0.00006722

Incremental Increase in Offsite Combustion Emissions from Operation Vehicles	VOC (lb/day)	CO (lb/day)	NOx (lb/day)	SOx (lb/day)	PM10 (lb/day)	PM2.5 (lb/day)
Heavy-Heavy Duty Trucks	11.86	53.12	138.04	0.33	6.93	5.69
TOTAL	**12**	**53**	**138**	**0**	**7**	**6**
Significance Threshold	55	550	55	150	150	150
Exceed Significance?	**NO**	**NO**	**YES**	**NO**	**NO**	**NO**

*1 metric ton (MT) = 2,205 pounds

Incremental Increase in Offsite Combustion Emissions from Operation Vehicles	CO2 (lb/yr)	CH4 (lb/yr)	CO2e (lb/yr)	CO2e (MT*/year)
Heavy-Heavy Duty Trucks	436,025	6.97	436,171	198
TOTAL	**436,025**	**7**	**436,171**	**198**
Significance Threshold	n/a	n/a	n/a	10,000
Exceed Significance?	**n/a**	**n/a**	**n/a**	**n/a**

*1 metric ton (MT) = 2,205 pounds
Equation: No. of Vehicles x Emission Factor (lb/mile) x No. of Round-Trips/Day or year x Round-Trip length (mile/day or year) = Offsite Operation Emissions (lb/day or year)

Incremental Increase in Fuel Usage From Operation (Truck Trips)	Equipment Type	Total Miles Driven in a Peak Day (miles/day)	Total Annual Miles Driven (miles/year)	Mileage Rate (miles/gal)	Total Peak Daily Diesel Fuel Usage (gal/day)*	Total Annual Diesel Fuel Usage (gal/year)
Workers' Vehicles - Offsite Delivery/Haul	Heavy Duty Truck	8,166	103,613	4.89	1,670	21,189
				TOTAL	**1,670**	**21,189**

Operations - Criteria Pollutants From Electricity Generation

Operation	Peak Daily Electricity Demand (MWh/day)	Simple Cycle Turbine Emission Factors					
Electricity Generation		VOC (lb/MWh)	CO (lb/MWh)	NOx (lb/MWh)	SOx (lb/MWh)	PM10 (lb/MWh)	PM2.5 (lb/MWh)
Electricity Needed by 9 Refineries	168	0.02	0.08	0.09	0.00	0.06	0.06

Incremental Increase in Criteria Pollutant Emissions from Electricty Generation	VOC (lb/day)	CO (lb/day)	NOx (lb/day)	SOx (lb/day)	PM10 (lb/day)	PM2.5 (lb/day)
Emissions from Electricity Needed by 9 Refineries	3.36	13.45	15.14	0.00	10.09	9.89
TOTAL	**3**	**13**	**15**	**0**	**10**	**10**

Example Calculation: NOx: 0.09 lbs/MWh x 45.3 MWh = 4.08 lbs

						TOTAL CO2e	**32,832**
						Significance Threshold	**10,000**
						Exceed Significance?	**YES**

GHG Emission Factors:
1 metric ton (MT) = 2,205 pounds
120,000 lb CO_2/MMscf fuel burned
0.64 lb N20/MMscf fuel burned
2.3 lb CH_4/MMscf fuel burned
1,110 lb CO_2e/MWh for electricity when source of power is not identified
(CEC, September 6, 2007 - Reporting and Verification of Greenhouse Gas Emissions in the Electricity Sector)
12,700 kWh/MMgallons for electricity use for water conveyance - potable water[1]
1,200 kWh/MMgallons for electricity use for water conveyance - recycled water as mitigation[2]
640 lb CO_2/MWh for electricity use due to water conveyance
0.0067 lb CH_4/MWh for electricity use due to water conveyance
0.0037 lb N_2O/MWh for electricity use due to water conveyance

	Exceed Significance?	**NO**	**NO**	**YES**	**NO**	**YES**	**NO**	**YES**	**YES**				

*For Facility 1, a total of 15 SCRs (14 for Boilers/Heaters and 1 for 1 Gas Turbine) could be installed, but peak construction is based on a 1/3rd overlap of 15 SCRs and corresponding containment berms at one time.
1 new NH3 storage tank is assumed to be constructed for each SCR, which requires construction of containment one berm per storage tank.
Construction equipment emissions are already included, except fugitive dust/mitgation.

Facility 2	Emissions from Construction Activities									Incremental Increase in Fuel Usage From Construction Equipment and Workers' Vehicles			
Equipment/Source Category	Construction Emissions Summary	VOC (lb/day)	CO (lb/day)	NOx (lb/day)	SOx (lb/day)	PM10 Unmitigated (lb/day)	PM10 Mitigated (lb/day)	PM2.5 Unmitigated (lb/day)	PM2.5 Mitigated (lb/day)	Total Diesel Fuel Usage (gal/day)	Total Gasoline Fuel Usage (gal/day)	Total Diesel Fuel Usage (gal/project)	Total Gasoline Fuel Usage (gal/project)

	Exceed Significance?	**NO**	**NO**	**NO**	**NO**	**NO**	**NO**	**NO**	**NO**				

*For Boilers/Heaters, Facility 3 could install 2 new SCRs so peak construction is based on construction of both units overlapping at one time.
1 new NH3 storage tank is assumed to be constructed for each SCR, which requires construction of containment one berm per storage tank.
Construction equipment emissions are already included, except fugitive dust/mitgation.

Facility 4	Emissions from Construction Activities									Incremental Increase in Fuel Usage From Construction Equipment and Workers' Vehicles			
Equipment/Source Category	**Construction Emissions Summary**	**VOC (lb/day)**	**CO (lb/day)**	**NOx (lb/day)**	**SOx (lb/day)**	**PM10 Unmitigated (lb/day)**	**PM10 Mitigated (lb/day)**	**PM2.5 Unmitigated (lb/day)**	**PM2.5 Mitigated (lb/day)**	**Total Diesel Fuel Usage (gal/day)**	**Total Gasoline Fuel Usage (gal/day)**	**Total Diesel Fuel Usage (gal/project)**	**Total Gasoline Fuel Usage (gal/project)**

[1]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 10 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
250 tons/yr solid waste x 1 truck/25 tons = 10 trucks/year to haul extra solid waste away for recycling
This facility either sends its solid waste to a Class III landfill for disposal which is 80.64 miles (one-way) away or to a cement plant cement plant outside of the SCAQMD for recycling.
A maximum of 200 miles, one-way to the California/Arizona border is assumed.

[2]Assumes delivery of soda ash arrives in a 25 ton capacity truck. It will take an extra 4 trucks to deliver one year's worth of soda ash.
95 tons/yr soda ash x 1 truck/25 tons = 3.8 trucks/year to deliver soda ash

[3, 4]Assumes delivery of aqueous ammonia to fill one 2,000 gallon tank. It will take an extra 4 trucks to deliver one year's worth of aqueous ammonia for 1 scr.
6,654 gal/yr NH3 x 1 tank/2,000 gal = 3.3 refills via truck/year to deliver aqueous ammonia

However, to fill 14 aqueous ammonia tanks, one delivery truck can hold up to 7,000 gallons. Thus, the annual number of deliveries to supply all 14 tanks would be 29 trucks.
201,206 gal/yr NH3 x 1 truck/7,000 gal = 28.7 trucks/year to deliver aqueous ammonia

Facility 1 already accesses recycled water and will have increased future access to recycled water.

Total No. of Trucks	49	trucks	3	trucks		

[1]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 2 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
48.4 tons/yr solid waste x 1 truck/25 tons = 1.9 trucks/year to haul extra solid waste away for recycling
This facility sends its solid waste to a cement plant outside of the SCAQMD for recycling. A maximum of 200 miles, one-way to the California/Arizona border is assumed.

Facility 2 - Coke Calciner
Belco wet gas scrubber

Utility/Infrastructure	Annual Usage		Daily Usage		Daily Usage			
Electricity	3,679,200	kWh	17,711	kWh	17.71	MWh	Note: This calculation takes into account the electricity needed to make 3.37 tons per day of NaOH to satisfy demand (7,631 kWh/day).	
Water	14.93	MMgal	40,896	gal	0.04	Mmgal		
Wastewater	6.2	MMgal	16,992	gal	0.02	Mmgal		
Solid Waste Disposal	160	tons	0.44	tons				
NaOH (50%)	1,228	tons	3.37	tons	22	gal/hr	280	lb/hr
Plot Space Needed	1,200	sf			density = 12.747 lb/gal for NaOH at 50%			
1 Truck Hauling Away Solid Waste[2]	2,800	round trip miles	400	round trip miles				
1 Truck Delivering NaOH[3]	1,600	round trip miles	50	round trip miles				
No. of Trucks Hauling Away Solid Waste	7	trucks	1	truck				
No. of Trucks Delivering NaOH	32	trucks	1	truck				
Total Truck Miles	4,400	round trip miles	450	round trip miles				
Total No. of Trucks	39	trucks	2	trucks				

[2]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 7 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
160 tons/yr solid waste x 1 truck/25 tons = 6.4 trucks/year to haul extra solid waste away for recycling
This facility sends its solid waste to a cement plant outside of the SCAQMD for recycling. A maximum of 200 miles, one-way to the California/Arizona border is assumed.

[3]Assumes that one 10,000 gallon capacity storage tank will be installed for NaOH storage. It will take 32 trucks to deliver one year's worth of NaOH 50% solution, but the peak would be one truck per day.
1,228 tons/yr NaOH x 2,000 lbs/ ton = 854,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 192,326 gal/year x 1 truck/6,000 gallons = 32 trucks/year

FACILITY 2

[1,2] Assumes delivery of aqueous ammonia to fill one tank. It will take an extra 9 trucks to deliver one year's worth of aqueous ammonia.
One delivery truck can hold up to 7,000 gallons.
61,118 gal/yr NH3 x 1 truck/7,000 gal = 8.7 trucks/year to deliver aqueous ammonia

[1,2] Assumes delivery of aqueous ammonia to fill one tank. It will take an extra 5 trucks to deliver one year's worth of aqueous ammonia for one tank

To fill 6 aqueous ammonia tanks, one delivery truck can hold up to 7,000 gallons. Thus, the annual number of deliveries to supply all 6 tanks would be 26 trucks.

183,355 gal/yr NH3 x 1 truck/7,000 gal = 26.2 trucks/year to deliver aqueous ammonia

[3]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 7 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
160 tons/yr solid waste x 1 truck/25 tons = 6.4 trucks/year to haul extra solid waste away for recycling
This facility either sends its solid waste to a cement plant cement plant outside of the SCAQMD for recycling.
A maximum of 200 miles, one-way to the California/Arizona border is assumed.

[4]Assumes that one 10,000 gallon capacity storage tank will be installed for NaOH storage. It will take 5 trucks to deliver one year's worth of NaOH 50% solution, but the peak would be one truck per day.
164 tons/yr NaOH x 2,000 lbs/ ton = 328,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 25,685 gal/year x 1 truck/6,000 gallons = 4.28 trucks/year

[1,2] Assumes delivery of aqueous ammonia to fill one tank. It will take an extra 19 trucks to deliver one year's worth of aqueous ammonia.

One delivery truck can hold up to 7,000 gallons.
132,788 gal/yr NH3 x 1 truck/7,000 gal = 19 trucks/year to deliver aqueous ammonia

[3]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 26 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
640 tons/yr solid waste x 1 truck/25 tons = 25.6 trucks/year to haul extra solid waste away for recycling
This facility sends its solid waste to a cement plant outside of the SCAQMD for recycling. A maximum of 200 miles, one-way to the California/Arizona border is assumed.

[4]Assumes delivery of soda ash arrives in a 25 ton capacity truck. It will take an extra 10 trucks to deliver one year's worth of soda ash.
246 tons/yr soda ash x 1 truck/25 tons = 9.84 trucks/year to deliver soda ash

Facility 5 already accesses recycled water.

Facility 5 has two distinct wastewater systems. System One is the un-segregated system, which handles water from cooling towers, boiler blowdowns, and stormwater.
This wastewater receives primary treatment, the maximum capacity for this system is 5000 gpm; the facility is currently running at about 3000 gpm.

System Two is the segregated system, which handles process water. This wastewater receives primary and secondary (biological) treatment.

FACILITY 5

The maximum capacity for this system is 2000 gpm; the facility is currently running at about 1800 gpm.
Facility 5 has some wastewater storage capacity to handle surges due to storms and upsets.

[1]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 30 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
120 tons/yr solid waste x 1 truck/25 tons = 4.8 trucks/year to haul extra solid waste away for recycling

[2]Assumes delivery of soda ash arrives in a 25 ton capacity truck. It will take an extra 2 trucks to deliver one year's worth of soda ash.
45 tons/yr soda ash x 1 truck/25 tons = 1.8 trucks/year to deliver soda ash

[3,4] Assumes delivery of aqueous ammonia to fill one tank. It will take an extra 8 trucks to deliver one year's worth of aqueous ammonia.
One delivery truck can hold up to 7,000 gallons.
55,273 gal/yr NH3 x 1 truck/7,000 gal = 7.9 trucks/year to deliver aqueous ammonia

It is not known at this time if Facility 8 will have future access to recycled water. Facility 8 currently uses non-potable well water to supply the facility.

[1]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 28 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
690 tons/yr solid waste x 1 truck/25 tons = 27.6 trucks/year to haul extra solid waste away for recycling
This facility sends its solid waste to a cement plant outside of the SCAQMD for recycling. A maximum of 200 miles, one-way to the California/Arizona border is assumed.

[2]Assumes that one 10,000 gallon capacity storage tank will be installed for NaOH storage. It will take 19 trucks to deliver one year's worth of NaOH 50% solution, but the peak would be one truck per day.

738 tons/yr NaOH x 2,000 lbs/ ton = 1,476,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 115,583 gal/year x 1 truck/6,000 gallons = 19.2 trucks/year

[3,4] Assumes delivery of aqueous ammonia to fill one tank. It will take an extra 29 trucks to deliver one year's worth of aqueous ammonia.
One delivery truck can hold up to 7,000 gallons.
199,942 gal/yr NH3 x 1 truck/7,000 gal = 28.6 trucks/year to deliver aqueous ammonia

Facility 9 may have future access to recycled water.

GRAND TOTALS (during Operation)

Note: This calculation takes into account the electricity needed to make 2.02 tons per day of NaOH to satisfy demand (4,585 kWh/day).

operational truck trips	32.17	MT/year	Operation GHGs in CO2e				32
						TOTAL CO2e	3,979

GHG Emission Factors:
1 metric ton (MT) = 2,205 pounds
120,000 lb CO2/MMscf fuel burned
0.64 lb N20/MMscf fuel burned
2.3 lb CH4/MMscf fuel burned
1,110 lb CO2e/MWh for electricity when source of power is not identified
(CEC, September 6, 2007 - Reporting and Verification of Greenhouse Gas Emissions in the Electricity Sector)
12,700 kWh/MMgallons for electricity use for water conveyance - potable water[1]
1,200 kWh/MMgallons for electricity use for water conveyance - recycled water as mitigation[2]
640 lb CO2/MWh for electricity use due to water conveyance
0.0067 lb CH4/MWh for electricity use due to water conveyance
0.0037 lb N2O/MWh for electricity use due to water conveyance

PROPOSED PROJECT: NaOH LOSSES

Facility ID	NaOH Demand (tons/day)	Q = Fill Rate = NaOH Demand (MMgal/day)	S = Saturation Factor	P = Vapor Pressure of material Loaded (psia)	M = NaOH vapor molecular weight (lb/lbmole)	T= temperature of liquid loaded (°R)	Daily PM10 Filling Loss (lb/day)	$E_{loading}$ = Hourly PM10 Filling Loss (lb/hr)	$E_{working}$ = Hourly PM10 Working Loss (lb/hr)	Total Hourly PM10 Loss (lb/hr)	Acute Screening Level - 25 meters (lb/hr)	Does Hourly Filling Loss Exceed Acute Screening Level? (Yes/No)	Significant?	Electricity Needed to Produce NaOH* (kWh/day)
2	3.37	0.53	1.45	0.0420	24.8	544.67	1.82E-02	7.60E-04	2.28E-03	3.04E-03	4.00E-03	NO	NO	7631
4	0.45	0.07	1.45	0.0420	24.8	544.67	2.44E-03	1.01E-04	3.04E-04	4.06E-04	4.00E-03	NO	NO	1019
9	2.02	0.32	1.45	0.0420	24.8	544.67	1.10E-02	4.57E-04	1.37E-03	1.83E-03	4.00E-03	NO	NO	4585
TOTAL	**5.84**	**0.92**					**0.03**							**13,235**

NaOH @ 50% solution density = 12.747 lb/gal
Mv for NaOH solution = 24.8 lb/lbmol
Vapor Pressure for NaOH = 2.18 mmHg at 29.4oC or 85oF = 0.042 psia
Loading Temperature = 85oF to 100oF (544.67oR to 559.67oR)
Breathing Loss = 3 * Filling Loss

Filling Loss:

$$E_{Loading}, {}^{lb}\!/_{day} = (12.46)\frac{(S)(P)(M)(Q)}{T}$$

where:

S = saturation factor (dimensionless; obtained from Table 5.2-1 in AP-42)
= 1.45 (Splash loading: dedicated normal service)
P = vapor pressure of the material loaded at temperature T (psia)
M = vapor molecular weight (lb/lb-mole)
Q = volume of material loaded (1,000 gal/day)
T = temperature of liquid loaded (°R).

*It takes approximately 2,500 kWh to produce one metric ton of NaOH.
Thus, approximately 22,444 kWh per day of additional electricity may be needed to produce additional NaOH to meet the needs of the proposed project, calculated as follows:

$$\frac{9.9 \text{ tons NaOH}}{\text{Day}} \times \frac{2{,}000 \text{ lbs}}{\text{ton}} \times \frac{1 \text{ metric ton}}{2{,}205 \text{ lbs}} \times \frac{2{,}500 \text{ kWh}}{1 \text{ metric ton of NaOH produced}} = 22{,}444 \text{ kWh/day}$$

[1] Water three times per day per SCAQMD Rule 403 (61% control efficiency)

Diesel Idling Health Risk Assessment

Peak Operational Truck Trips per year at one facility (Refinery 6) = 147

EF, g/hr	Annual No of Trips	Idling, h/y	Emisions, lb/yr	Emisions, ton/yr
1.67	147	36.75	0.14	6.78E-05

Heavy-duty idling rates from emfac2011_idling_emission_rates.xlsx (http://www.arb.ca.gov/msei/emfac2011_idling_emission_rates.xlsx).

Emisions, ton/yr	Cancer Potency Factor, (mg/kg-d)-1	X/Q at 25 m, (ug/m3)/(ton/yr)	CEF	MP	MWHF	Carcinogenic Health Risk	Screening Level	Significant?
6.78E-05	1.1	29.64	676.63	1	1	1.50E-06	1.00E-05	NO

Carcinogenic health risk = emissions, ton/yr x cancer potency, (mg/kg-day)-1 x X/Q, (ug/m3)/(ton/yr) x CEF x MP x MWHF

Offsite Consequence Analysis for Aqueous Ammonia Spill at a Refinery

Offsite Consequence Input Data for NH3 spill of one 11,000 gallon storage tank at a refinery facility

Ammonia Storage, gal	Berm Capacity, gal	Ammonia Berm, ft3	Height of Berm, ft	Area, ft2
11,000	12,100	1,618	3.0	539

Berms must be able to contain 110% the volume of the tank
Typical berm heights are three feet tall.

Ammonia Slip Calculation

Ammonia Slip Conc at the Exit of the Stack, ppm	Dispersion Factor	Molecular Weight, g/mol	Peak Conc at a Receptor 25 m from the Stack, ug/m3	Acute REL, ug/m3	Chronic REL, ug/m3	Acute Hazard Index	Chronic Hazard Index
5	0.01	17.03	35	3,200	200	0.01	0.17

Ammonia slip is limited to five ppm by permitting.
Conc., ug/m3 = (conc., ppm x 1,000 x molecular weight, g/mol)/24.5 m3/kmol

Based on the Staff Report for Toxic Air Contaminants 1401.1 – Requirements for New and Relocated Facilities Near Schools, and 1402 – Control of Toxic Air Contaminants from Existing Source, June 2015 the concentration at a receptor 25 m from a stack would be much less than one percent of the concentration at the release from the exist of the stack.

Hazard index = conc. at receptor 25 m from stack, ug/m3/REL, ug/m3

Estimated Distance Calculation

Estimated distance to toxic endpoint: 0.1 miles (0.2 kilometers)

This is the downwind distance to the toxic endpoint specified for this regulated substance under the RMP Rule. Report all distances shorter than 0.1 mile as 0.1 mile, and all distances longer than 25 miles as 25 miles.

Scenario Summary

Chemical:	Ammonia (water solution)
Initial concentration:	20 %
CAS number:	7664-41-7
Threat type:	Toxic Liquid
Scenario type:	Worst-case
Liquid temperature:	25 C
Quantity released:	12100 gallons
Mitigation measures:	
Diked area:	539 square feet
Dike height:	3 feet
Release rate to outside air:	11.7 pounds per minute
Surrounding terrain type:	Urban surroundings (many obstacles in the immediate area)
Toxic endpoint:	0.14 mg/L; basis: ERPG-2

Assumptions about this scenario

Wind speed:	1.5 meters/second (3.4 miles/hour)
Stability class:	F
Air temperature:	77 degrees F (25 degrees C)

Construction of 1 Scrubber (Wet or Dry)

Phase II: Fugitive PM10 Emissions (e.g., Fugitive Dust) Associated with foundation work for WGS or DGS Installation

1. GRADING ACTIVITIES (Backhoe)		
G = Fugitive PM10 Emission Rate (lbs/day) = 0.75 x T x 1.0 x $(S)^{1.5}$ x $(M)^{-1.4}$		*Source: AP-42, 10/98, Table 11.9-1 (PM10 Equation for Overburden Bulldozing)*
S = Silt Content	7.5 %	*Source: AP-42, 10/98, Table 11.9-3 (Correction Factors for Overburden Bulldozing)*
M = Moisture Content	2 %	*Source: AP-42, 10/98, Table 11.9-3 (Correction Factors for Overburden Bulldozing)*
T = max hours of operation/day	8 hr/day	
G = Fugitive PM10 =	**46.70 lbs/day**	

2. TRENCHING/STOCKPILE LOADING (Backhoe)		
LPM10 = Emission Factor per particle size (lbs/ton) = kPM10 x (0.0032) x $(U/5)^{1.3}$ x $(M/2)^{-1.4}$		*Source: AP-42, 01/95, p. 13.2.4-3 (Equation 1 for English Units)*
U = Mean Wind Speed	12 mile/hr	*Source: AP-42, 10/98, Table 11.9-5 (See Mine I)*
M = Material Moisture Content	2 %	*Source: AP-42, 10/98, Table 11.9-3 (Overburden Bulldozing)*
kPM10 = Particle Size Multiplier for PM10	0.35 dimensionless	*Source: AP-42, 01/95, p. 13.2.4-3*
G = Maximum Daily Weight of Material Moved	1 tons/day	Note: One backhoe can trench approximately 0.1 acre per day or 4,356 square feet per day, with a cut of 3 feet in depth, 13,068 cubic feet = 484 cubic yards and 1 cubic yard = 1 ton soil.
Tday, t = Truck Operating time, maximum	5 hr/day	
LPM10 = Emission Factor per particle size =	0.0035 lbs PM10/ton soil moved	
PPM10 = Emission Rate based on particle size = (LPMx G) =	**0.0035 lbs PM10/day**	

3. STOCKPILE WIND EROSION		
Q = Wind Erosion Emission Rate based on particle size (lbs/day) = kPM10* 0.72 x U x Tc * (A x B /43,560 sq. ft/acre)		*Source: AP-42, 10/98, Table 11.9-1 (Emission Factor Equation for Active Storage Pile)*
A = Length of Stockpile	21 ft	
B = Width of Stockpile	21 ft	
U = Mean Wind Speed	12 mile/hr	*Source: AP-42, 10/98, Table 11.9-5 (General Characteristics of Surface Coal Mines - Mine I)*
kPM10 = Particle Size Multiplier for PM10	0.5 dimensionless	*Source: AP-42, 01/95, p. 13.2.5-3 (PM10 Aerodynamic Particle Size Multiplier (k) for Equation 2)*
Tc = Time Piles Remain Uncovered	24 hr/day	Note: This calculation assumes that the piles remain uncovered for 24 hours/day.
QPM10 =	**1.05 lbs PM10/day**	

4. TRUCK FILLING/DUMPING	
TF = Fugitive PM10 Emissions From Truck Filling = G (ton/day) x TF, PM10 (lb/ton)	
TD = Fugitive PM10 Emissions From Truck Dumping = G (ton/day) x TD, PM10 (lb/ton)	
TFPM10 = Emission Factor for Truck Filling =	0.0221 lb/ton of material moved
TDPM10 = Emission Factor for Truck Dumping =	0.0091 lb/ton of material moved
G = Maximum Daily Weight of Material Trucked Away	1 ton/day
TF =	**0.02 lbs PM10/day**
TD =	**0.01 lbs PM10/day**

Facility 8 has two options, SCR or DGS.
Faciliy 11 has an existing NH3 tank and the annual usage is existing, not an increase.
The type of ammonia to be used is aqueous, 19% by weight.
Assumed that haul and delivery trucks can hold 20 yd3 of material.

SUMMARY OF CONSTRUCTION EMISSIONS OUTPUT FROM CALEEMOD

Peak Daily Criteria Construction Emissions per Control Equipment at Non-Refinery Facility

Description	ROG, lb/day	NOx, lb/day	CO, lb/day	SO2, lb/day	PM10 Total, lb/day	PM2.5 Total, lb/day
Daily Unmitigated	3.7	31.7	21.7	0.03	7.1	4.1
Daily Mitigated	3.7	31.7	21.7	0.03	3.5	2.3

Emissions estimated with CalEEMod for 2016.

Project Peak Daily Criteria Construction Emissions for Non-Refinery Facilities

Description	ROG, lb/day	NOx, lb/day	CO, lb/day	SO2, lb/day	PM10 Total, lb/day	PM2.5 Total, lb/day
Daily Unmitigated	40	349	239	0.38	78	45
Daily Mitigated	40	349	239	0.38	39	25

Emissions estimated with CalEEMod for 2016.
Assumed construction at all 11 non-refinery facilities could occur at the same time.
Assumed that facilties with multiple control equipment installation would occur in series, so the same daily number of construction equipment would be used, but over a longer period of time.

Greenhouse Gas Construction Emissions for Non-Refinery Facilities

CO2e per Piece of Control Equipment, metric ton/yr	Amoritized CO2e per Project, metric ton/yr
286	325

Emissions estimated with CalEEMod for 2016.
For project CO2e, the CO2e per facilty was multipled by the number of control equipment installed (i.e., 34 control equipment installed)

Heavy-duty Truck Trips

Description	NH3/Urea Number of Delivery Trips	Adsorbent Number of Delivery Trips	Solid Waste Number of Haul Trips	Filter Waste Number of Haul Trips	Catalyst Number of Delivery Trips	Total Heavy Duty Truck Trips
Annual	437	5	11	1	11	465
Peak Day	11	1	1	1	11	25

Adsorbent, solid waste and filter waste based on vendor calcs for SOx portion of Ultracat system
One catalyst delivery trips per facilty was assumed.
Peak day assumed one ammonia/urea delivery occurs at each non-refinery facility and adsorbent, solid waste and haul trip occurs on same day.

Peak Day

Vehicle Type	No of Trips	Distance, mile/trip	ROG, lb/day	CO, lb/day	NOx, lb/day	SOx, lb/day	PM10, lb/day	PM2.5, lb/day	Total Miles Per Day	Total Gallons Per Day
Heavy Duty Truck	25	100	0.88	3.73	24.5	0.06	1.43	0.92	2,500	511
Medium Duty Truck	11	80	0.29	1.40	8.58	0.02	0.37	0.23	880	99
			1.17	**5.13**	**33.1**	**0.07**	**1.80**	**1.14**	**3,380**	**610**

Assumed one tech trip for control system mantainance occurs at each of the ten non-refinery facilities
Default truck trips were assumed to 80 miles round trip. Ammonia deliveries were assumed to be 100 miles round trip.

OPERATION EMISSIONS SUMMARY

Annual

Vehicle Type	No of Trips	Distance, mile/trip	CO_2, metric ton/yr	Total Miles Per Year	Total Gallons Per Year
Heavy Duty Truck	465	100	51	46,536	9,517
Medium Duty Truck	286	80	25	22,880	2,574
			77	**69,416**	**12,090**

Assumed one tech trip every other week for control system mantainance occurs at each of the 11 non-refinery facilities
Default truck trips were assumed to 80 miles round trip. Ammonia deliveries were assumed to be 100 miles round trip.

Operations - Criteria Pollutants From Electricity Generation

Operation	Peak Daily Electricity Demand	Simple Cycle Turbine Emission Factors					
Electricity Generation		VOC (lb/MWh)	CO (lb/MWh)	NOx (lb/MWh)	SOx (lb/MWh)	PM10 (lb/MWh)	PM2.5 (lb/MWh)
Electricity Needed by 11 Non-Refineries	45	0.02	0.08	0.09	0.00	0.06	0.06

Incremental Increase in Criteria Pollutant Emissions from Electricty Generation	VOC (lb/day)	CO (lb/day)	NOx (lb/day)	SOx (lb/day)	PM10 (lb/day)	PM2.5 (lb/day)
Emissions from Electricity Needed by 11 Non-Refineries	0.91	3.63	4.08	0.00	2.72	2.67
TOTAL	1	4	4	0	3	3

Example Calculation: NOx: 0.09 lbs/MWh x 45.3 MWh = 4.08 lbs

OFFSITE CONSEQUENCE ANALYSIS

Offsite Consequence Input Data for NH3 spill of one 5,000 gallon storage tank at a non-refinery facility

Non-Refinery

Ammonia Storage, gal	Berm Capacity, gal	Ammonia Berm, ft3	Height of Berm, ft	Area, ft2
5,000	5,500	735	3.0	245

Berms must be able to contain 110% the volume of the tank
Typical berm heights are three feet tall.

AMMONIA SLIP CALCULATION

Ammonia Slip Estimate For Non-Refinery Facilities

Ammonia Slip Conc at the Exit of the Stack, ppm	Dispersion Factor	Molecular Weight, g/mol	Peak Conc at a Receptor 25 m from the Stack, ug/m3	Acute REL, ug/m3	Chronic REL, ug/m3	Acute Hazard Index	Chronic Hazard Index
5	0.01	17.03	35	3,200	200	0.01	0.17

Ammonia slip is subject to a permit limit of 5 ppm.
Conc., ug/m3 = (conc., ppm x 1,000 x molecular weight, g/mol)/24.5 m3/kmol

Based on the Staff Report for Toxic Air Contaminants 1401.1 – Requirements for New and Relocated Facilities Near Schools, and 1402 – Control of Toxic Air Contaminants from Existing Source, June 2015 the concentration at a receptor 25 m from a stack would be much less than one percent of the concentration at the release from the exist of the stack.

Hazard index = conc. at receptor 25 m from stack, ug/m3/REL, ug/m3

DIESEL IDLING HEALTH RISK ASSESSMENT

Non-Refinery - Diesel Idling Emissions

Facility 8 has the peak annual trips per year = 123 +26 tech trips (bi-weekly)=149 total trips

EF, g/hr	Annual No of Trips	Idling, h/y	Emisions, lb/yr	Emisions, ton/yr
1.67	149	37.267448	0.14	6.88E-05

Heavy-duty idling rates from emfac2011 idling emission rates.xlsx (http://www.arb.ca.gov/msei/emfac2011 idling emission rates.xlsx).

Emisions, ton/yr	Cancer Potency Factor, (mg/kg-d)-1	X/Q at 25 m, (ug/m3)/(ton/yr)	CEF	MP	MWHF	Carcinogenic Health Risk	Screening Level	Significant?
6.88E-05	1.1	29.64	676.63	1	1	1.52E-06	1.00E-05	NO

Carcinogenic health risk = emissions, ton/yr x cancer potency, (mg/kg-day)-1 x X/Q, (ug/m3)/(ton/yr) x CEF x MP x MWHF

RMP*Comp

RMP*Comp

Back

Estimated Distance Calculation

Estimated distance to toxic endpoint: <0.1 miles (<0.16 kilometers); report as 0.1 mile

This is the downwind distance to the toxic endpoint specified for this regulated substance under the RMP Rule. Report all distances shorter than 0.1 mile as 0.1 mile, and all distances longer than 25 miles as 25 miles.

Scenario Summary

Chemical:	Ammonia (water solution)
Initial concentration:	20 %
CAS number:	7664-41-7
Threat type:	Toxic Liquid
Scenario type:	Worst-case
Liquid temperature:	25 C
Quantity released:	5500 gallons
Mitigation measures:	
Diked area:	245 square feet
Dike height:	3 feet
Release rate to outside air:	5.3 pounds per minute
Surrounding terrain type:	Urban surroundings (many obstacles in the immediate area)
Toxic endpoint:	0.14 mg/L; basis: ERPG-2

Assumptions about this scenario

Wind speed:	1.5 meters/second (3.4 miles/hour)
Stability class:	F
Air temperature:	77 degrees F (25 degrees C)

NOTICE OF PREPARATION/INITIAL STUDY (NOP/IS) (ENVIRONMENTAL CHECKLIST)

South Coast
Air Quality Management District
21865 Copley Drive, Diamond Bar, CA 91765-4178
(909) 396-2000 • www.aqmd.gov

SUBJECT: **NOTICE OF PREPARATION OF A DRAFT PROGRAM ENVIRONMENTAL ASSESSMENT**

PROJECT TITLE: **PROPOSED AMENDED REGULATION XX - REGIONAL CLEAN AIR INCENTIVES MARKET (RECLAIM)**

In accordance with the California Environmental Quality Act (CEQA), the South Coast Air Quality Management District (SCAQMD), as the Lead Agency, has prepared this Notice of Preparation (NOP) and Initial Study (IS). This NOP serves two purposes: 1) to solicit information on the scope of the environmental analysis for the proposed project; and, 2) to notify the public that the SCAQMD will prepare a Draft Program Environmental Assessment (PEA) to further assess potential environmental impacts that may result from implementing the proposed project.

This letter, NOP and the attached IS are not SCAQMD applications or forms requiring a response from you. Their purpose is simply to provide information to you on the above project. If the proposed project has no bearing on you or your organization, no action on your part is necessary.

Comments focusing on your area of expertise, your agency's area of jurisdiction, if applicable, or issues relative to the environmental analysis should be addressed to Ms. Barbara Radlein (c/o CEQA) at the address shown above, or sent by fax to (909) 396-3324 or by email to bradlein@aqmd.gov . Comments must be received no later than 5:00 p.m. on Friday, January 16, 2015. Please include the name and phone number of the contact person. Questions relative to the proposed amended regulation for the refinery sector should be directed to Ms. Minh Pham at (909) 396-2613 or by email to mpham@aqmd.gov. Questions relative to the proposed amended regulation for the non-refinery sector should be directed to Mr. Kevin Orellana at (909) 396-3492 or by email to korellana@aqmd.gov.

The Public Hearing for the proposed amended regulation is scheduled for March 6, 2015. (Note: Public meeting dates are subject to change).

Date: December 4, 2014 **Signature:** Michael Krause

Draft Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM)

Project Location:
South Coast Air Quality Management District (SCAQMD) area of jurisdiction consisting of the four-county South Coast Air Basin (Orange County and the non-desert portions of Los Angeles, Riverside and San Bernardino counties), and the Riverside County portions of the Salton Sea Air Basin and the Mojave Desert Air Basin

Description of Nature, Purpose, and Beneficiaries of Project:
SCAQMD staff is proposing amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM), Rule 2002 – Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx), to reduce the allowable NOx emission limits based on current Best Available Retrofit Control Technology (BARCT) to achieve additional NOx emission reductions for the following industrial equipment and processes: 1) fluid catalytic cracking units (FCCUs); 2) refinery boilers and heaters; 3) refinery gas turbines; 4) sulfur recovery units – tail gas treatment units (SRU/TGUs); 5) non-refinery/non-power plant gas turbines; 6) non-refinery sodium silicate furnaces; 7) non-refinery/non-power plant internal combustion engines (ICEs); 8) container glass melting furnaces; 9) coke calcining; 10) Portland cement kilns; and, 11) metal heat treating furnaces. Additional amendments are proposed to establish procedures and criteria for reducing NOx RECLAIM Trading Credits (RTCs) and NOx RTC adjustment factors for year 2016 and later. For clarity and consistency throughout the regulation, other minor changes are proposed to: 1) Rule 2011 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping Oxides of Sulfur (SOx) Emissions; and, 2) Rule 2012 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping Oxides of Nitrogen (NOx) Emissions. The Initial Study identifies the following environmental topics as areas that may be adversely affected by the proposed project: aesthetics; air quality and greenhouse gas emissions; energy; hydrology and water quality; hazards and hazardous materials; solid and hazardous waste; and, transportation and traffic. Impacts to these environmental areas will be further analyzed in the Draft Program Environmental Assessment (PEA).

INTRODUCTION

The California Legislature created the South Coast Air Quality Management District (SCAQMD) in 1977[1] as the agency responsible for developing and enforcing air pollution control rules and regulations in the South Coast Air Basin (Basin) and portions of the Salton Sea Air Basin and Mojave Desert Air Basin referred to herein as the District. By statute, the SCAQMD is required to adopt an air quality management plan (AQMP) demonstrating compliance with all federal and state ambient air quality standards for the District[2]. Furthermore, the SCAQMD must adopt rules and regulations that carry out the AQMP[3]. The Final 2012 AQMP concluded that reductions in emissions of particulate matter (PM), oxides of sulfur (SOx), oxides of nitrogen (NOx), and volatile organic compounds (VOC) are necessary to attain the state and national ambient air quality standards for ozone, and particulate matter with an aerodynamic diameter of 2.5 microns or less (PM2.5). Ozone, a criteria pollutant which has been shown to adversely affect human health, is formed when VOCs react with NOx in the atmosphere. VOCs, NOx, SOx (especially sulfur dioxide) and ammonia also contribute to the formation of PM10 and PM2.5.

The Basin is designated by the United States Environmental Protection Agency (EPA) as a non-attainment area for PM2.5 emissions because the federal PM2.5 standards have been exceeded. For this reason, the SCAQMD is required to evaluate all feasible control measures in order to reduce direct PM2.5 emissions, as well as PM2.5 precursors, such as NOx and SOx. The Final 2012 AQMP sets forth a comprehensive program for the Basin to comply with the federal 24-hour PM2.5 air quality standard, satisfy the planning requirements of the federal Clean Air Act, and provide an update to the Basin's commitments towards meeting the federal 8-hour ozone standard. In particular, the Final 2012 AQMP contains a multi-pollutant control strategy to achieve attainment with the federal 24-hour PM2.5 air quality standard with direct PM2.5 and NOx reductions identified as the two most effective tools in reaching attainment with the PM2.5 standard. The 2012 AQMP also serves to satisfy the recent requirements promulgated by the EPA for a new attainment demonstration of the revoked 1-hour ozone standard, as well as to provide additional measures to partially fulfill long-term reduction obligations under the 2007 8-hour Ozone State Implementation Plan (SIP).

As part of this ongoing PM2.5 reduction effort, SCAQMD staff is proposing amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM) to achieve additional NOx emission reductions to address best available retrofit control technology (BARCT) requirements. The primary focus of the proposed project is to bring the NOx RECLAIM program up-to-date with the latest BARCT requirements while achieving the proposed NOx emission reductions in the 2012 AQMP Control Measure #CMB-01: Further NOx Reductions from RECLAIM (e.g., at least three to five tons per day by 2023). The proposed project may achieve additional NOx emission reductions depending on the actual BARCT NOx emission control efficiencies. In addition, the proposed project is designed to implement both the Phase I and Phase II reduction commitments described in #CMB-01.

The proposed project may require installation of new or modification of existing NOx emission control equipment for the following industrial equipment and processes at NOx RECLAIM facilities: 1) fluid catalytic cracking units (FCCUs); 2) refinery boilers and heaters; 3) refinery

[2] Health and Safety Code, §40460 (a).
[3] Health and Safety Code, §40440 (a).

gas turbines; 4) sulfur recovery units – tail gas treatment units (SRU/TGUs); 5) non-refinery/non-power plant gas turbines; 6) non-refinery sodium silicate furnaces; 7) non-refinery/non-power plant internal combustion engines (ICEs); 8) container glass melting furnaces; 9) coke calcining; 10) Portland cement kilns, and, 11) metal heat treating furnaces. Additional amendments are proposed to establish procedures and criteria for reducing NOx RECLAIM RTCs and NOx RTC adjustment factors for year 2016 and later. Other minor changes are proposed for clarity and consistency throughout the proposed amended regulation.

The proposed project is estimated to reduce at least three tons per day of NOx emissions or more starting in 2016. Despite this projected direct environmental benefit to air quality, this Initial Study, prepared pursuant to the California Environmental Quality Act (CEQA), identifies the following environmental topics as areas that may be adversely affected by the proposed project: aesthetics; air quality and greenhouse gas emissions; energy; hydrology and water quality; hazards and hazardous materials; solid and hazardous waste; and, transportation and traffic. A Draft Program Environmental Assessment (PEA) will be prepared to analyze further whether the potential impacts to these environmental topics are significant. Any other potentially significant environmental impacts identified through this Notice of Preparation/Initial Study (NOP/IS) process will also be analyzed in the Draft PEA.

CALIFORNIA ENVIRONMENTAL QUALITY ACT

The California Environmental Quality Act (CEQA), California Public Resources Code §21000 *et seq.*, requires environmental impacts of proposed projects to be evaluated and feasible methods to reduce, avoid or eliminate significant adverse impacts of these projects to be identified and implemented. The lead agency is the "public agency that has the principal responsibility for carrying out or approving a project that may have a significant effect upon the environment" (Public Resources Code §21067). Since the SCAQMD has the primary responsibility for supervising or approving the entire project as a whole, it is the most appropriate public agency to act as lead agency (CEQA Guidelines[4] §15051 (b)).

CEQA requires that all potential adverse environmental impacts of proposed projects be evaluated and that methods to reduce or avoid identified significant adverse environmental impacts of these projects be implemented if feasible. The purpose of the CEQA process is to inform the SCAQMD Governing Board, public agencies, and interested parties of potential adverse environmental impacts that could result from implementing the proposed project and to identify feasible mitigation measures or alternatives, when an impact is significant.

Public Resources Code §21080.5 allows public agencies with regulatory programs to prepare a plan or other written documents in lieu of an environmental impact report once the Secretary of the Resources Agency has certified the regulatory program. The SCAQMD's regulatory program was certified by the Secretary of Resources Agency on March 1, 1989, and has been adopted as SCAQMD Rule 110 – Rule Adoption Procedures to Assure Protection and Enhancement of the Environment.

CEQA includes provisions for the preparation of program CEQA documents in connection with issuance of rules, regulations, plans, or other general criteria to govern the conduct of a continuing program, including adoptions of broad policy programs as distinguished from those prepared for specific types of projects such as land use projects (CEQA Guidelines §15168). A

[4] The CEQA Guidelines are codified at Title 14 California Code of Regulations, §15000 et seq.

program CEQA document also allows consideration of broad policy alternatives and program-wide mitigation measures at a time when an agency has greater flexibility to deal with basic problems of cumulative impacts. Lastly, a program CEQA document also plays an important role in establishing a structure within which CEQA review of future related actions can effectively be conducted. This concept of covering broad policies in a program CEQA document and incorporating the information contained therein by reference into subsequent CEQA documents for specific projects is known as "tiering" (CEQA Guidelines §15152).

A program CEQA document will provide the basis for future environmental analyses and will allow future project-specific CEQA documents, if necessary, to focus solely on the new effects or detailed environmental issues not previously considered. If an agency finds that no new effects could occur, or no new mitigation measures would be required, the agency can approve the activity as being within the scope of the project covered by the program CEQA document and no new environmental document would be required (CEQA Guidelines §15168 (c)(2)).

The proposed amendments to Regulation XX (PAReg XX) are considered a "project" as defined by CEQA. Specifically, PARegXX includes amendments to Rule 2002 – Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx), Rule 2011 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping Oxides of Sulfur (SOx) Emissions (Attachment C – Quality Assurance and Quality Control Procedures), and Rule 2012 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping Oxides of Nitrogen (NOx) Emissions (Attachment C – Quality Assurance and Quality Control Procedures), to be discussed in further detail under "Project Description." PAReg XX will assure that the BARCT commitments for NOx emission reductions in the Final 2012 AQMP are achieved and maintained as well as provide an overall environmental benefit to air quality. However, SCAQMD's review of the proposed project also shows that implementation of PAReg XX may also have a significant adverse effect on the environment. Since PAReg XX may have statewide, regional or areawide significance, a CEQA scoping meeting is also required to be held for the proposed project pursuant to Public Resources Code §21083.9 (a)(2). Information regarding the CEQA scoping meeting can be found on the NOP.

In addition, since the proposed project: 1) is connected to the issuance of rules, regulations, plans, or other general criteria to govern the conduct of a continuing program (CEQA Guidelines §15168 (a)(3)); and, 2) contains a series of actions that can be characterized as one large project and the series of actions are related as individual activities that would be carried out under the same authorizing regulatory authority and having similar environmental effects which can be mitigated in similar ways (CEQA Guidelines §15168 (a)(4)), the appropriate type of CEQA document to be prepared for the proposed project will be a Program Environmental Assessment (PEA). The PEA is a substitute CEQA document, prepared in lieu of a program environmental impact report (EIR) (CEQA Guidelines §15252), pursuant to the SCAQMD's Certified Regulatory Program (CEQA Guidelines §15251 (l); codified in SCAQMD Rule 110). The PEA is also a public disclosure document intended to: 1) provide the lead agency, responsible agencies, decision makers and the general public with information on the environmental impacts of the proposed project; and, 2) be used as a tool by decision makers to facilitate decision making on the proposed project.

The first step of preparing a Draft PEA is to prepare a Notice of Preparation (NOP) with an Initial Study (IS) that includes an Environmental Checklist and project description. The Environmental Checklist provides a standard evaluation tool to identify a project's adverse environmental impacts. The NOP/IS is also intended to provide information about the proposed project to other public agencies and interested parties prior to the release of the Draft PEA.

Thus, the SCAQMD as Lead Agency has prepared this NOP/IS for the proposed project. The initial evaluation in the NOP/IS identified the following topics as potentially being adversely affected by the proposed project: aesthetics; air quality and greenhouse gas emissions; energy; hydrology and water quality; hazards and hazardous materials; solid and hazardous waste; and, transportation and traffic. Written comments received on the scope of the environmental analysis will be considered when preparing the Draft PEA.

PROJECT LOCATION

The proposed amendments to Regulation XX would apply to equipment and processes operated at NOx RECLAIM facilities located throughout the entire SCAQMD jurisdiction. The SCAQMD has jurisdiction over an area of approximately 10,743 square miles, consisting of the four-county South Coast Air Basin (Basin) (Orange County and the non-desert portions of Los Angeles, Riverside and San Bernardino counties), and the Riverside County portions of the Salton Sea Air Basin (SSAB) and Mojave Desert Air Basin (MDAB). The Basin, which is a subarea of the SCAQMD's jurisdiction, is bounded by the Pacific Ocean to the west and the San Gabriel, San Bernardino, and San Jacinto mountains to the north and east. It includes all of Orange County and the nondesert portions of Los Angeles, Riverside, and San Bernardino counties. The Riverside County portion of the SSAB is bounded by the San Jacinto Mountains in the west and spans eastward up to the Palo Verde Valley. The federal nonattainment area (known as the Coachella Valley Planning Area) is a subregion of Riverside County and the SSAB that is bounded by the San Jacinto Mountains to the west and the eastern boundary of the Coachella Valley to the east (Figure 1-1).

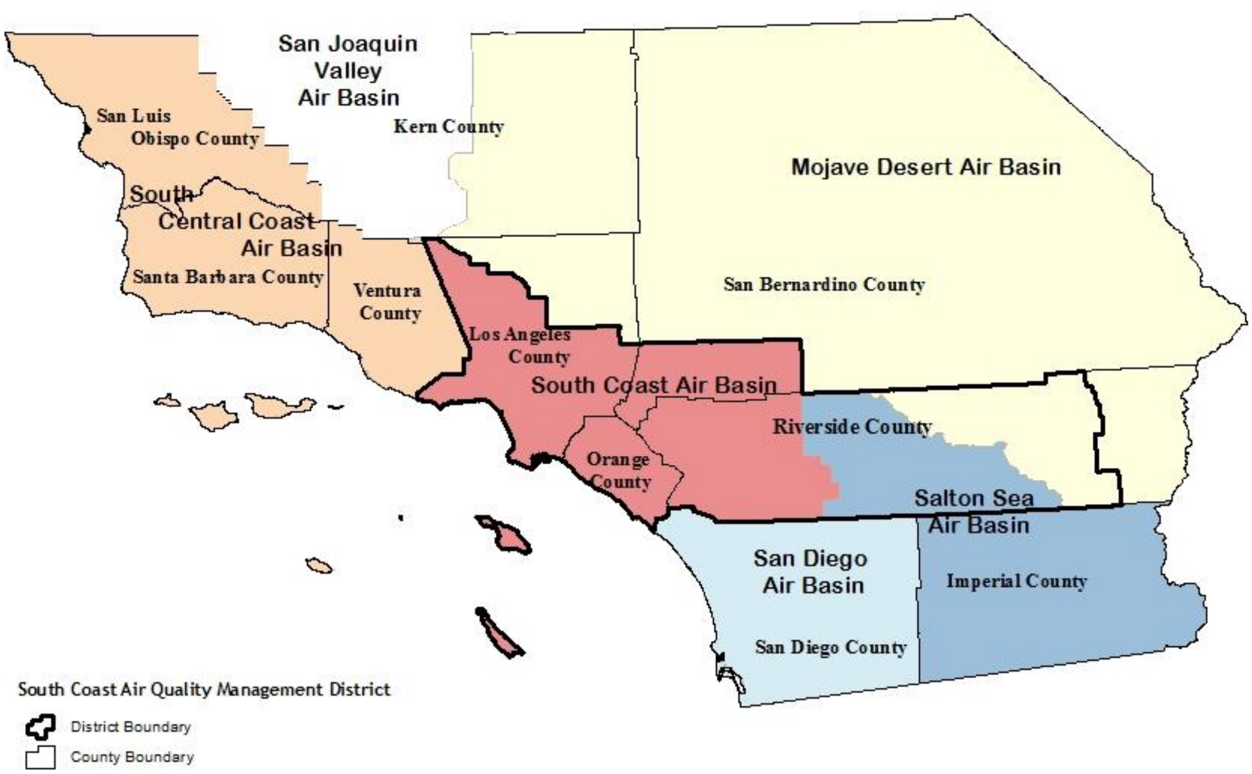

Figure 1-1: Southern California Air Basins

PROJECT BACKGROUND

On October 15, 1993, the SCAQMD Governing Board adopted Regulation XX, referred to herein as the RECLAIM program. Regulation XX is comprised of 15 rules which contain a declining market-based cap and trade mechanism to reduce NOx and SOx emissions from the largest stationary sources in the Basin and subsequently help meet air quality standards while providing facilities with the flexibility to seek the most cost-effective solution for achieving the required reductions. Instead of setting specific limits on each piece of equipment and each process that contributes to air pollution as is stipulated by traditional 'command-and-control' regulations, under the RECLAIM program each facility has a NOx and/or SOx annual emissions limit (allocation) and facility operators can decide what equipment, processes and materials they will use to reduce emissions to meet or go further below their annual emission limits. In lieu of reducing emissions, facility owners or operators may elect to use the trading market to purchase RTCs from other facilities that have reduced emissions below their annual target.

The portion of Regulation XX that focuses on reducing NOx emissions is referred to as "NOx RECLAIM" while the portion that focuses on reducing SOx emissions is referred to as "SOx RECLAIM." Regulation XX contains applicability requirements, NOx and SOx facility allocations, general requirements, as well as monitoring, reporting, and recordkeeping requirements for NOx and SOx sources located at RECLAIM facilities. The RECLAIM program started with 41 SOx facilities and 392 NOx facilities, but by the end of the 2005 compliance year, the program was populated with 33 SOx facilities and 304 NOx facilities. The population at the end of compliance year 2011 consists of 33 SOx facilities and 276 NOx facilities. The reduction in the number of facilities participating in the RECLAIM program since inception has been primarily due to facility shutdowns and/or consolidations.

Under the NOx RECLAIM program, the RECLAIM facilities were issued annual allocations of NOx emissions (also known as facility caps), which declined annually from 1993 until 2003 and remained constant after 2003, until SCAQMD staff conducted a BARCT reassessment for NOx in 2005. In 1993, annual allocations were issued to the RECLAIM facilities and the facility cap reflected BARCT in effect at that time. A BARCT reassessment is now necessary for NOx RECLAIM to assure that the participating facilities will continue to achieve emission reductions as expeditiously as possible to carry out the commitments in the 2012 AQMP. Under the RECLAIM program, the facilities have the flexibility to install air pollution control equipment, change method of operations, or purchase RTCs to meet BARCT levels.

To assure a more liquid market, as well as protect RECLAIM participants from price fluctuations that may be caused if all the RTCs expire at the same time, two trading cycles were established. Further, to balance emissions among the participating facilities in the RECLAIM program, the affected facilities were randomly divided into two cycles which vary by compliance year. That is, the Cycle 1 compliance year spans from January 1 to December 31 while the Cycle 2 compliance year spans from July 1 to June 30. A backstop level of $15,000 per ton was established to trigger program reevaluation.

Between compliance year 1994 and compliance year 1999, NOx emissions at RECLAIM facilities, in aggregate, were below the annual allocations, and the price of NOx RTCs remained relatively stable, ranging from $1,500 to $3,000 per ton. However, beginning June 2000, RECLAIM program participants experienced a sharp and sudden increase in NOx RTC prices for both 1999 and 2000 compliance years. This was mainly due to an increased demand for power generation due to the California energy situation and the delay of installing NOx control equipment by many power plant operators, which resulted in the power-generating industry purchasing a large quantity of RTCs and depleting the supply of available RTCs. The average price of NOx RTCs for compliance year 2000, traded in the year 2000 increased sharply to over $45,000 per ton compared to the average price of $4,284 per ton traded in 1999. Since the RTC price for NOx exceeded the backstop price of $15,000 per ton, an evaluation of the RECLAIM program was triggered.

The Governing Board, at its October 2000 meeting, directed staff to examine the issues affecting the high price of NOx RTCs and recommend actions to stabilize NOx RTC prices. Additionally, the Governing Board directed the Executive Officer to form an Advisory Committee to provide input to staff regarding possible approaches to stabilize NOx RTC prices. Fourteen power producing facilities, each with a generating capacity of 50 megawatts (MW) or greater, purchased 67 percent of the NOx RTCs that were traded during compliance year 2000, suggesting that the increased demand and high prices of NOx RTCs were primarily due to the power producers. However, the annual allocations for all the power producers only accounted for approximately 14 percent of total RECLAIM annual allocations for compliance year 2000. At the same time, the RECLAIM program reached the 'cross-over point' where emissions equal allocations because many RECLAIM facilities, relying on previously low RTC prices, did not determine that it was more cost-effective to begin installing controls until after the RTC prices had peaked.

In recognition of the inherent lag time between the ability of facility operators to actually install and operate new control equipment, the Governing Board concluded that immediate changes to the RECLAIM program were necessary and, at the January 19, 2001 Board Meeting, directed staff to form a working group to develop and propose amendments to the RECLAIM program. The goal of the proposed amendments was to implement realistic, effective solutions to reduce and stabilize the prices of NOx RTCs. In May 2001, Regulation XX was amended to place trading restrictions on power producing facilities with the caveat that they could fully rejoin the trading market in the 2004 compliance year, provided that the Governing Board determined prior to July 2003 that their re-entry would not result in any negative effect on the remainder of the RECLAIM facilities or on California's energy security needs. In addition, the amendments also required the power plants to install BARCT and introduced credit generating rules. Lastly, a Mitigation Fee Program was established for the power plants to make up excess emissions through an option to pay a fee used to mitigate emissions through alternative means or programs.

Pursuant to these requirements, SCAQMD staff examined the energy security needs of California and the potential impacts on the RECLAIM market. The Governing Board determined that reentry of the power plants would not be expected to have a negative effect on California's energy security needs or on other RECLAIM facilities. Overall, power plants equipped with BARCT have reduced their NOx emission rates by approximately 80 percent or more from previously uncontrolled levels.

Based on these emission levels, the 14 power producing facilities are anticipated to emit a total of 1,395 tons per year of NOx and their total annual allocations are 1,705 tons per year for each year from 2003 to 2010. Further, the RTC holdings for the compliance years 2003 through 2010 range from 1,550 to 2,330 tons per year of NOx. This represented a surplus in the NOx RTC holdings at the time ranging from 155 to 935 tons per year. When considering the data relative to the typical annual operational capacity of a power producing unit at below 30 percent, except for 2001 when in-Basin units operated at 35 percent capacity, on average it would take all units operating at a capacity of 55 percent to cause a shortage in NOx RTCs. Therefore, based on the projected excess RTCs and typical operating capacities, power producers were then considered likely to be sellers of NOx RTCs in the RECLAIM program. For these reasons, the Governing Board at the June 6, 2003 public hearing, made the finding that lifting the trading restrictions for power producers in the RECLAIM trading market would not have a negative effect on the remainder of the RECLAIM facilities or on California's energy security needs. Subsequently, the Governing Board adopted proposed changes to RECLAIM Rules 2007, 2011, and 2012 at the December 5, 2003 public hearing which removed most of the trading restrictions on power producers. As a result, effective September 2004, the power producers were given unrestricted use of RTCs.

On January 7, 2005, amendments were made to the NOx RECLAIM program that resulted in a reduction of RTCs across the board by 7.7 tons per day, based on a BARCT evaluation. The RTCs were reduced from compliance years 2007 to 2011. The total RTCs in the NOx RECLAIM universe allocated in compliance year 2011 amounted to 26.5 tons per day. The audited emissions in compliance year 2011 were 20.01 tons per day, equating to 6.49 tons per day of excess holdings. The proposed RTC shave reduction will be based on compliance year 2011 activity levels for the affected facilities.

PROJECT DESCRIPTION

The proposed project will affect the following types of equipment and processes at the top NOx emitting facilities in the NOx RECLAIM program: 1) FCCUs; 2) refinery boilers and heaters; 3) refinery gas turbines; 4) SRU/TGUs; 5) non-refinery/non-power plant gas turbines; 6) non-refinery sodium silicate furnaces; 7) non-refinery/non-power plant ICEs; 8) container glass melting furnaces; 9) coke calcining; 10) Portland cement kilns; and, 11) metal heat treating furnaces. The proposed amendments to the RECLAIM regulation contain the following key elements:

- Amend Rule 2002 - Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx), to establish procedures and criteria for reducing NOx RTCs and NOx RTC adjustment factors for year 2016 and later.
- Amend Rule 2002 to add new BARCT emission factors ending in 2021 for an assortment of equipment/process categories.
- Amend Rule 2011 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping Oxides of Sulfur (SOx) Emissions (Attachment C – Quality Assurance and Quality Control Procedures)
- Amend Rule 2012 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping Oxides of Nitrogen (NOx) Emissions (Attachment C – Quality Assurance and Quality Control Procedures)
- Make administrative and other minor changes such as correcting typographical errors as well as clarifying and updating the rule and rule protocol language for consistency.

The following is a summary of the key proposed amendments. A copy of the proposed amended Rule (PAR) 2002 can be found in Appendix A of this NOP/IS. A copy of the proposed amended protocols for Rules 2011 and 2012 can be found in Appendices B and C, respectively.

PAR 2002

Annual Allocations for NOx and SOX and Adjustments to RTC Holdings – subdivision (f)

- Change compliance year "2011 and after" to "2011 to 2015" for the existing NOx RTC adjustment factors in subparagraph (f)(1)(A).
- Add new RTC adjustment factors to subparagraph (f)(1)(B) in order to achieve projected NOx emission reductions from NOx RTC holders beginning in compliance year 2016 and later. It should be noted that the proposed rule language describes an evenly distributed percent of NOx RTC reductions applicable to all RECLAIM facilities. However, an alternate approach of distributing the NOx RTC reductions among the top NOx RECLAIM facilities would not be precluded.
- Clarify procedures for entering the RECLAIM program after January 7, 2005 in subparagraph (f)(1)(I) to reflect the new RTC adjustment factors added to subparagraph (f)(1)(B).

RTC Reduction Exemption – subdivision (i)

- Clarify paragraph (i)(1) that the RTC reduction exemption does not include RTC holdings for compliance year 2016 and thereafter.
- Clarify subparagraph (i)(1)(B) that the application for an RTC reduction exemption needs to demonstrate that the reported emissions for Compliance Year 2013 are not from equipment listed in existing Table 3 or new Table 6 and that the achieved emission rates are less than the emission factors listed in existing Table 3 or new Table 6, whichever is lower.
- Clarify subparagraph (i)(1)(C) that the application for an RTC reduction exemption needs to demonstrate that the RTCs for Compliance Year 2016 have never been transferred or sold by the facility.
- Clarify clause (i)(1)(D)(i) to allow the exclusion of control costs for any equipment listed in existing Table 3 or new Table 6.
- Clarify paragraph (i)(3) that an application for an RTC reduction exemption shall be submitted no later than six months after the adoption of the proposed project.
- Clarify paragraph (i)(8) to require a facility qualifying for an exemption to include emissions from equipment listed in existing Table 3 or new Table 6 in its Annual Permit Emission Program (APEP) report.

RECLAIM NOx 2021 Ending Emission Factors – new Table 6

- Add new BARCT emission factors ending in 2021 for certain boilers and heaters, cement kilns, FCCUs, gas turbines, container glass melting furnaces, permitted ICEs, metal heat treating furnaces, petroleum coke calciners, sodium silicate furnaces, and SRU/TGUs.

Rule 2011 Appendix A (SOx Protocol for Rule 2011)

Attachment C - Quality Assurance and Quality Control Procedures

- Add new procedures and criteria for postponing the due date of semi-annual or annual assessments of a major source.
- Add new procedures and criteria for postponing the due date of semi-annual or annual assessments of an electrical generating facility (EGF).

Rule 2012 Appendix A (NOx Protocol for Rule 2012)

Attachment C - Quality Assurance and Quality Control Procedures

- Add new procedures and criteria for postponing the due date of semi-annual or annual assessments of a major source.
- Add new procedures and criteria for postponing the due date of semi-annual or annual assessments of an electrical generating facility (EGF).

TECHNOLOGY OVERVIEW

NOx Emission Sources

The NOx RECLAIM program currently consists of 276 facilities as of the 2011 compliance year. Of these, 139 facilities operate NOx emitting equipment for which there is no new BARCT identified. For this reason, the proposed project will focus on reducing NOx emissions from the major and large sources of the top emitters of NOx for which new BARCT has been identified (e.g., facilities that emit 85 percent of the total NOx emissions from all RECLAIM facilities). However, a BARCT assessment for approximately ICEs that are operating at the 139 remaining NOx RECLAIM facilities would not be precluded from the proposed project. The following are the top emitters of NOx in the RECLAIM program:

- Six refineries owned by five companies operate FCCUs, refinery boilers and heaters, refinery gas turbines, and SRU/TGUs: Tesoro (two locations: Wilmington and Carson); Phillips 66 (two locations: Wilmington and Carson); Chevron; ExxonMobil; and, Ultramar (also referred to as Valero)
- One coke calciner plant: Tesoro (Wilmington location)
- One cement manufacturing plant: California Portland Cement (CPCC)
- One container glass manufacturing plant: Owens-Brockway Glass Container Inc.
- One sodium silicate manufacturing plant: PQ Corporation
- One steel plant operating two metal heat treating furnaces rated > 150 million British Thermal Units per hr (mmBTU/hr): California Steel
- Seven facilities operating gas turbines: Southern California Gas Company, SDGE, THUMS Long Beach, Wheelabrator Norwalk Energy, LA City Dept. of Airports, Tin Inc., and Berry Petroleum
- Three facilities operating IC Engines: SDGE and Southern California Gas Company (two facilities)

Of the above-listed facilities, six refineries operate one FCCU each, one SRU/TGU each, and a multitude of refinery process heaters and boilers and refinery gas turbines. The quantity of major and large source NOx emissions from the six refineries alone comprises approximately 54 percent of the total NOx emitted from the universe of RECLAIM facilities. The major and large sources belonging to non-refineries among the top NOx emitting facilities emit 25 percent of the RECLAIM universe's total. The remaining 11 percent of emissions that contribute to the 85 percent total come from process units and equipment that is exempt from SCAQMD Rule 219 - Equipment Not Requiring A Written Permit Pursuant To Regulation II.

Combustion Equipment

To appreciate the mechanics of NOx control equipment and techniques, it is necessary to first understand how NOx emissions are generated from the affected equipment and processes. Combustion is a high temperature chemical reaction resulting from burning a gas, liquid, or solid fuel (e.g., natural gas, diesel, fuel oil, gasoline, propane, and coal) in the presence of air (oxygen and nitrogen) to produce: 1) heat energy; and, 2) water vapor or steam. An ideal combustion reaction is when the entire amount of fuel needed is completely combusted in the presence of air so that only carbon dioxide (CO2) and water are produced as by-products. However, since fuel contains other components such as nitrogen and sulfur plus the amount of air mixed with the fuel can vary, in practice, the combustion of fuel is not a "perfect" reaction. As such, uncombusted fuel plus smog-forming by-products such as NOx, SOx, carbon monoxide (CO), and soot (solid carbon) can be discharged into the atmosphere.

Of the total NOx emissions that can be generated, there are two types of NOx formed during combustion: 1) thermal NOx; and, 2) fuel NOx. Thermal NOx is produced from the reaction between the nitrogen and oxygen in the combustion air at high temperatures while fuel NOx is formed from a reaction between the nitrogen already present in the fuel and the available oxygen in the combustion air. As the source of nitrogen in fuel is more prevalent in oil and coal, and is negligible in natural gas, the amount of fuel NOx generated is dependent on fuel type. For example, with oil that contains significant amounts of fuel-bound nitrogen, fuel NOx can account for up to 50 percent of the total NOx emissions generated. Though boilers, process heaters, petroleum coke calciners, FCCUs, gas turbines, and other miscellaneous equipment have varying purposes in commercial, industrial, and utility applications, at a minimum, they all generate thermal NOx as a combustion by-product. The following provides a brief description of the various types of existing combustion equipment that may be affected by the proposed amendments to Regulation XX and subsequently retrofitted with NOx control equipment.

REFINERY CATEGORY

Refinery Process Heaters and Boilers

Refinery process heaters and boilers are used extensively throughout various processes in refinery operations such as distillation, hydrotreating, fluid catalytic cracking, alkylation, reforming, and delayed coking.

A process heater is a type of combustion equipment that burns liquid, gaseous, or solid fossil fuel for the purpose of transferring heat from combustion gases to heat water or process streams. Process heaters are not kilns or ovens used for drying, curing, baking, cooking, calcining, or vitrifying; or any unfired waste heat recovery heater that is used to recover sensible heat from the exhaust of any combustion equipment.

A typical boiler, also referred to as a steam generator, is a steel or cast-iron pressure vessel equipped with burners that combust liquid, gas, or solid fossil fuel to produce steam or hot water. Boilers are classified according to the amount of energy output in millions of British Thermal Units per hour (mmBTU/hr), the type of fuel burned (natural gas, diesel, fuel oil, etc.), operating steam pressure in pounds per square inch (psi), and heat transfer media. In addition, boilers are further defined by the type of burners used and air pollution control techniques. The burner is where the fuel and combustion air are introduced, mixed, and then combusted.

There are about 23 boilers and 189 heaters in the refineries classified as major or large NOx sources. There are a total of 212 boilers and heaters classified as major and large NOx sources at the refineries. Collectively, the 212 boilers and heaters emitted approximately 7.39 tons per day in 2011.

Refinery process heaters and boilers are primarily fueled by refinery gas, one of several products generated at the refinery. In addition, most of the refinery process heaters and boilers are designed to also operate on natural gas, but liquid or solid fuels are rarely used. The combustion of fuel generates NOx, primarily "thermal" NOx with small contribution from "fuel" NOx and "prompt" NOx.

Commercially available technologies for controlling NOx from refinery boilers and process heaters are selective catalytic reduction (SCR), Great Southern Flameless Heaters, and LoTOx^{TM} applications with scrubbers. Other potential technologies on the horizon are ClearSign, Cheng Low NOx and KnowNOx^{TM}. All of these control technologies can be designed to reach two parts per million by volume (ppmv) NOx at three percent oxygen. For a full description of these control technologies, see the NOx Control Technologies section. The Draft PEA will evaluate the possibility that each refinery may rely on any of these control technologies in order to comply with the refinery process heaters and boilers portion of the proposed project.

<u>Refinery Gas Turbines</u>

Gas turbines are used in refineries to produce both electricity and steam. Refinery gas turbines are typically combined cycle units that use two work cycles from the same shaft operation. Refinery gas turbines also have an additional element of heat recovery from its exhaust gases to produce more power by way of a steam generator. Gas turbines can operate on both gaseous and liquid fuels. Gaseous fuels include natural gas, process gas, and refinery gas. Liquid fuels typically include diesel. The units in this category are power plant turbines (turbines that produce solely electric utility power) and some of these units are cogenerating units that, in addition to producing in-house power, also recover the useful energy from heat recovery for producing process steam. There are a total of 21 gas turbines/duct burners classified as major NOx sources at the refineries in the SCAQMD. Collectively, the 21 gas turbines/duct burners emitted about 1.33 tons per day of NOx in 2011.

Frame gas turbines are exclusively used for power generation and continuous base load operation ranging up to 250 MW with simple-cycle efficiencies of approximately 40 percent and combined-cycle efficiencies of 60 percent. The existing gas turbines operating at the refineries are rated from seven MW to 83 MW. Most of the refinery gas turbines are operated with duct burners, heat recovery steam generator (HRSG), SCR, and CO catalysts. In addition, some refinery gas units utilize water or steam injection, Ammonia Slip Catalysts (ASC), Cheng Low NOx, and Dry Low Emissions (DLN or DLE) combustors. Figure 1-2 shows a typical layout of a combined cycle utility gas turbine with a duct burner, HRSG, and control system.

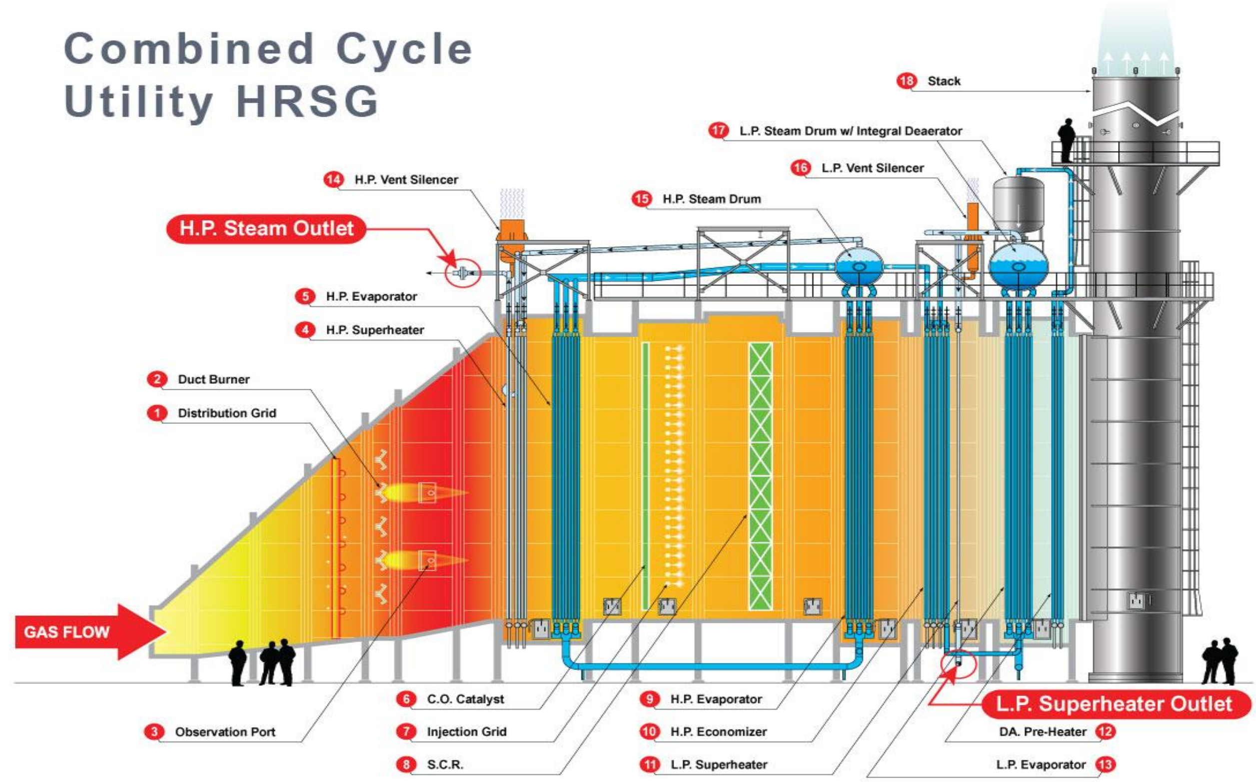

Figure 1-2: Gas Turbine with Duct Burner

The type of NOx control option to be utilized for refinery gas turbines will depend on each refinery's individual operations and the current control technologies and techniques in place. For a full description of these control technologies, see the NOx Control Technologies section. The Draft PEA will evaluate the possibility that each refinery may rely on any of these control technologies in order to comply with the refinery gas turbines portion of the proposed project.

Sulfur Recovery Units and Tail Gas Units (SRU/TGUs)

Refinery SRU/TGTUs, including their incinerators, are classified as major sources of both NOx and SOx emissions. Because sulfur is a naturally occurring and undesirable component of crude oil, refineries employ a sulfur recovery system to maximize sulfur removal. A typical sulfur removal or recovery system will include a sulfur recovery unit (e.g., Claus unit) followed by a tail gas treatment unit (e.g., amine treating) for maximum removal of hydrogen sulfide (H_2S). A Claus unit consists of a reactor, catalytic converters and condensers. Two chemical reactions occur in a Claus unit. The first reaction occurs in the reactor, where a portion of H_2S reacts with air to form sulfur dioxide (SO_2) followed by a second reaction in the catalytic converters where SO_2 reacts with H_2S to form liquid elemental sulfur. Side reactions producing carbonyl sulfide (COS) and carbon disulfide (CS_2) can also occur. These side reactions are problematic for Claus plant operators because COS and CS_2 cannot be easily converted to elemental sulfur and carbon dioxide. Liquid sulfur is recovered after the final condenser. The combination of two converters with two condensers in series will generally remove as much as 95 percent of the sulfur from the incoming acid gas. To increase removal efficiency, some newer sulfur recovery units may be designed with three to four sets of converters and condensers.

To recover the remaining sulfur compounds after the final pass through the last condenser, the gas is sent to a tail gas treatment process such as a SCOT or Wellman-Lord treatment process. For example, the SCOT tail gas treatment is a process where the tail gas is sent to a catalytic reactor and the sulfur compounds in the tail gas are converted to H_2S. The H_2S is absorbed by a solution of amine or diethanol amine (DEA) in the H_2S absorber, steam-stripped from the absorbent solution in the H_2S stripper, concentrated, and recycled to the front end of the sulfur recovery unit. This approach typically increases the overall sulfur recovery efficiency of the Claus unit to 99.8 percent or higher. However, the fresh acid gas feed rate to the sulfur recovery unit is reduced by the amount of recycled stream, which reduces the capacity of the sulfur recovery unit. The residual H_2S in the treated gas from the absorber is typically vented to a thermal oxidizer where it is oxidized to sulfur dioxide (SO_2) before venting to the atmosphere.

The Wellman-Lord tail gas treatment process is when the sulfur compounds in the tail gas are first incinerated to oxidize to SO_2. After the incinerator, the tail gas enters a SO_2 absorber, where the SO_2 is absorbed in a sodium sulfite (Na_2SO_3) solution to form sodium bisulfite ($NaHSO_3$) and sodium pyrosulfate ($Na_2S_2O_5$). The absorbent rich in SO_2 is then stripped, and the SO_2 is recycled back to the beginning of the Claus unit. The residual sulfur compounds in the treated tail gas from the SO_2 absorber is then vented to a thermal (or catalytic) oxidizer (incinerator) where the residual H_2S in the tail gas is oxidized to SO_2 before venting to the atmosphere. NOx is a by-product of operating the incinerator.

There are three main strategies that can be employed to further reduce NOx emissions from each SRU/TGU operating at the six refineries: 1) increase the efficiency of the sulfur recovery unit; 2) improve the efficiency of the tail gas treatment process; and, 3) install a wet gas scrubber (WGS) as an alternative to the thermal oxidizer[5]. The type of NOx control option to be utilized in response to this portion of the proposed project will depend on each refinery's individual operations and the current control technologies and techniques in place. Commercially available control technologies for NOx emissions are SCR, LoTOx™ with scrubber, and KnowNOx™. While SCR is considered as a high temperature NOx reduction technology, LoTOx™ and KnowNOx™ technologies are known for low temperature multi-pollutant control systems since they can be integrally connected with a WGS to reduce NOx, SOx, PM, VOC, hazardous air pollutants (HAPs), and other toxic compounds. For a full description of these control technologies, see the NOx Control Technologies section.

The Draft PEA will evaluate the possibility that each refinery may rely on any of these control technologies in order to comply with the SRU/TGU portion of the proposed project.

<u>Petroleum Coke Calciner</u>

Petroleum coke, the heaviest portion of crude oil, cannot be recovered in the normal oil refining process. Instead, it is processed in a delayed coker unit to generate a carbonaceous solid referred to as "green coke," a commodity. To improve the quality of the product, if the green coke has a low metals content, it will be sent to a calciner to make calcined petroleum coke. Calcined petroleum coke can be used to make anodes for the aluminum, steel, and titanium smelting industry. If the green coke has a high metals content, it is used as fuel grade coke by the fuel, cement, steel, calciner and specialty chemicals industries.

[5] All six refineries have thermal oxidizers at the end of their tail gas treatment units.

As shown in Figure 1-3, the process of making calcined petroleum coke begins when the green coke feed produced by the delayed coker unit is screened and transported to the calciner unit where it is stored in a covered coke storage barn. The screened and dried green coke is introduced into the top end of a rotary kiln and is tumbled by rotation under high temperatures that range between 2000 and 2500 degrees Fahrenheit (^oF). The rotary kiln relies on gravity to move coke through the kiln countercurrent to a hot stream of combustion air produced by the combustion of natural gas or fuel oil. As the green coke flows to the bottom of the kiln, it rests in the kiln for approximately one additional hour to eliminate any remaining moisture, impurities, and hydrocarbons. Once discharged from the kiln, the calcined coke is dropped into a cooling chamber, where it is quenched with water, treated with de-dusting agents to minimize dust, carried by conveyors to storage tanks. Eventually, the calcined coke is transported by truck to the Port of Long Beach for export, or is loaded onto railcars for shipping to domestic customers. As the green coke is processed under high heat conditions in the rotary kiln, NOx emissions are generated. NOx is also generated from combusting fuel oil to generate high heating values in the rotary kiln.

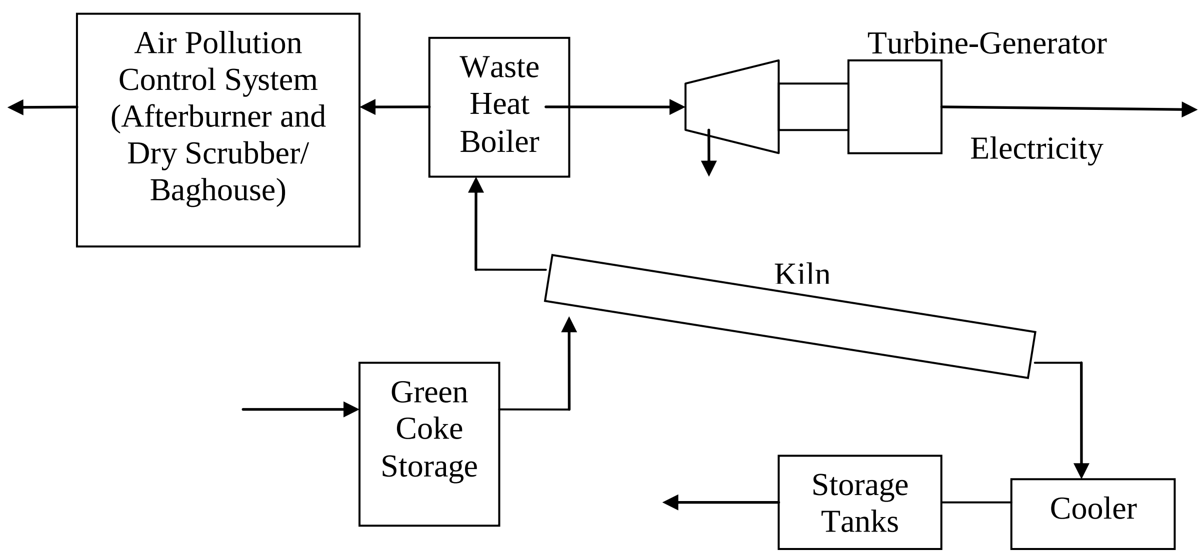

Figure 1-3: Coke Calciner Process

The Tesoro Wilmington coke calciner is only petroleum coke calciner in the Basin and produces approximately 400,000 short tons per year of calcined products. This petroleum coke calciner is a global supplier of calcined coke to the aluminum industry, and fuel grade coke to the fuel, cement, steel, calciner, and specialty chemicals businesses. The existing control system also includes a spray dryer, a reverse-air baghouse, a slurry storage system, a slurry circulating system, and a pneumatic conveying system. Calcium hydroxide (CaOH) slurry is the absorbing medium for SO_2 control.

There are two commercially available multi-pollutant control technologies for the low temperature removal of NOx emissions from the coke calciner: 1) LoTOx^{TM} with scrubber; and, 2) UltraCat. For a full description of these control technologies, see the NOx Control Technologies section. The type of NOx control option to be utilized for the coke calciner in response to the proposed project will depend on this facility's individual operations and the current control technologies and techniques in place. Thus, the Draft PEA will evaluate the possibility that operators of the petroleum coke calcining facility may rely on either of the above-mentioned control technologies to further control NOx emissions in order to comply with the BARCT requirements for the petroleum coke calcining portion of the proposed project.

<u>FCCUs</u>

The purpose of an FCCU at a refinery is to convert or "crack" heavy oils (hydrocarbons), with the assistance of a catalyst, into gasoline and lighter petroleum products. Each FCCU consists of three main components: a reaction chamber, a catalyst regenerator and a fractionator. All six refineries each operate one FCCU.

As shown in Figure 1-4, the cracking process begins in the reaction chamber where fresh catalyst is mixed with pre-heated heavy oils (crude) known as the fresh feed. The catalyst typically used for cracking is a fine powder made up of tiny particles with surfaces covered by several microscopic pores. A high heat-generating chemical reaction occurs that converts the heavy oil liquid into a cracked hydrocarbon vapor mixed with catalyst. As the cracking reaction progresses, the cracked hydrocarbon vapor is routed to a distillation column or fractionator for further separation into lighter hydrocarbon components than crude such as light gases, gasoline, light gas oil, and cycle oil.

Towards the end of the reaction, the catalyst surface becomes inactive or spent because the pores are gradually coated with a combination of heavy oil liquid residue and solid carbon (coke), thereby reducing its efficiency or ability to react with fresh heavy liquid oil in the feed. To prepare the spent catalyst for re-use, the remaining oil residue is removed by steam stripping. The spent catalyst is later cycled to the second component of the FCCU, the regenerator, where hot air burns the coke layer off of the surface of each catalyst particle to produce reactivated or regenerated catalyst. Subsequently, the regenerated catalyst is cycled back to the reaction chamber and mixed with more fresh heavy liquid oil feed. Thus, as the heavy oils enter the cracking process through the reaction chamber and exit the fractionator as lighter components, the catalyst continuously circulates between the reaction chamber and the regenerator.

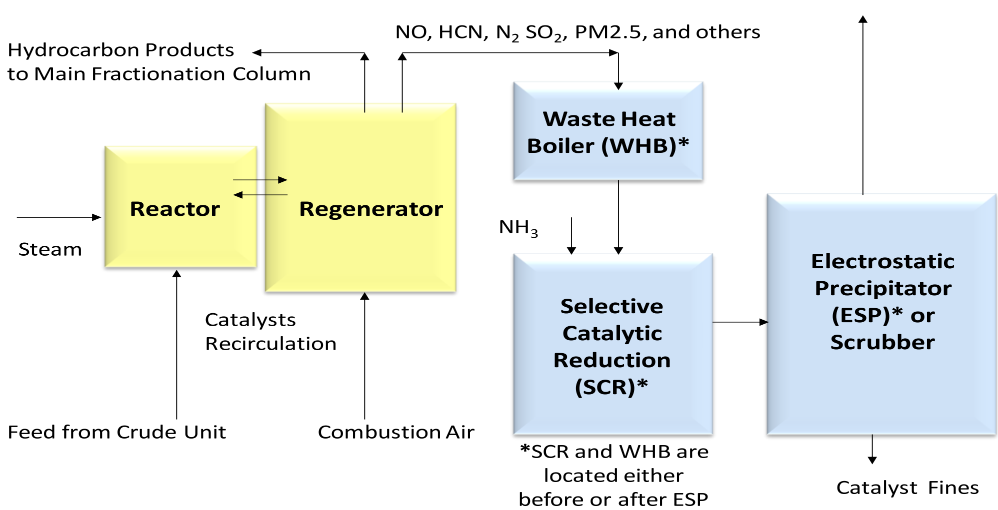

Figure 1-4: Simplified Schematic of FCCU Process

During the regeneration cycle, large quantities of catalyst are lost in the form of catalyst fines or particulates thus making FCCUs a major source of primary particulate emissions (PM10 and

PM2.5) at refineries. In addition, particulate (PM) precursor emissions such as SOx (because crude oil naturally contains sulfur) and NOx, additional secondary particulates (i.e., formed as a result of various chemical reactions), plus carbon monoxide (CO) and carbon dioxide (CO_2) are produced due to coke burn-off during the regenerator process.

Approximately 90 percent of the NOx generated from the FCCUs are from the nitrogen in the feed that is accumulated in the coke which is then burned-off in the regenerator. This portion of the NOx is called "fuel" NOx. "Fuel" NOx is a combination of nitric oxide (NO), nitrogen dioxide (NO_2), and nitrous oxide (N_2O). The remaining 10 percent of the NOx generated from the FCCUs are "thermal" NOx which is generated in the high temperature zones in the regenerator, and "prompt" NOx generated from the reaction between nitrogen and oxygen in the combustion air. The potential available control technologies to reduce NOx emissions from a FCCU are: 1) SCR; 2) LoTOx™ with scrubber; and/or, 3) NOx reducing additives.

The type of NOx control option to be utilized for FCCUs in response to the proposed project will depend on each refinery's individual operations and the current control technologies and techniques in place. Thus, the Draft PEA will evaluate the possibility that refinery operators of the FCCUs may rely on the above-mentioned control technologies to further control NOx emissions in order to comply with the BARCT requirements for FCCUs.

NON-REFINERY / NON-POWER PLANT CATEGORY

Portland Cement Kilns

In the NOx RECLAIM program, there is one facility (CPCC) with two cement kilns capable of producing gray cement from limestone, sand, shale, and clay raw materials. The CPCC facility, under normal operation, has typically been among the highest NOx emitters in the RECLAIM program. However, on November 20, 2009, CPCC operators announced the shutdown of both cement kilns. CPCC operators indicated that the shutdown is not permanent to the extent that when the economy improves, they plan to bring the cement kilns back on-line.

The manufacturing of gray Portland cement follows a four-step process of: 1) acquiring raw materials; 2) preparing the raw materials to be blended into a raw mix; 3) pyroprocessing of the raw mix to make clinker (e.g., lumps of limestone and clay); and, 4) grinding and milling clinker into cement. The raw materials used for manufacturing cement include calcium, silica, alumina and iron, with calcium having the highest concentration. These raw materials are obtained from a limestone quarry for calcium, sand for silica; and shale and clay for alumina and silica.

The raw materials are crushed, milled, blended into a raw mix and stored. Primary, secondary and tertiary crushers are used to crush the raw materials until they are about ¾-inch or smaller in size. Raw materials are then conveyed to rock storage silos. Belt conveyors are typically used for this transport. Roller mills or ball mills are used to blend and pulverize raw materials into fine powder. Pneumatic conveyors are typically used to transport the fine raw mix to be stored in silos until it is ready to be pyroprocessed.

The pyroprocess in a kiln consists of three phases during which clinker is produced from raw materials undergoing physical changes and chemical reactions. The first phase in a kiln, the drying and pre-heating zone, operates at a temperature between 70 ^{o}F and 1650 ^{o}F and evaporates any remaining water in the raw mix of materials entering the kiln. Essentially this is the warm-up phase which stabilizes the temperature of the refractory fire brick inside the mouth opening of the kiln. The second phase, the calcining zone, operates at a temperature between 1100 ^oF and 1650 ^oF and converts the calcium carbonate from the limestone in the kiln feed into calcium oxide and releases carbon dioxide. During the third phase, the burning zone operates on average at 2200 ^oF to 2700 ^oF (though the flame temperature can exceed 3400 ^oF) during which several reactions and side reactions occur. The first reaction is calcium oxide (produced during the calcining zone) with silicate to form dicalcium silicate and the second reaction is the melting of calcium oxide with alumina and iron oxide to form the liquid phase of the materials. Despite the high temperatures, the constituents of the kiln feed do not combust during pyroprocessing. As the materials move towards the discharge end of the kiln, the temperature drops and eventually clinker nodules form and volatile constituents, such as sodium, potassium, chlorides, and sulfates, evaporate. Any excess calcium oxide reacts with dicalcium silicate to form tricalcium silicate. The red hot clinker exits the kiln, is cooled in the clinker cooler, passes through a crusher and is conveyed to storage for protection from moisture. Since clinker is water reactive, if it gets wet, it will set into concrete.

Heat needed to operate CPCC's kilns is supplied through the combustion of different fuels such as coal, coke, oil, natural gas, and discarded automobile tires. The combustion gases are vented to a baghouse for dust control, and the collected dust is returned to the process or recycled if they meet certain criteria, or is discarded to landfills. CPCC does not currently have any post-combustion control for NOx emissions.

NOx emissions from the cement kilns are generated from the following: 1) from combusting fuel to generate high heating values in the kilns; and, 2) oxidation of sulfides (e.g., pyrites) in the raw materials entering the cement kiln. As is the case with CPCC, long, dry cement kilns have achieved NOx reductions to the 2000 (Tier 1) level by utilizing low NOx burners and mid-kiln firing with tire-derived fuel (TDF). With TDF, whole tires are introduced at an inlet location about midway along the kiln's calcining zone. TDF lowers NOx emissions by lowering the flame temperatures and reducing thermal NOx with the introduction of a slower burning fuel.

In the event that CPCC operators decide to fire up its kilns, the type of NOx control technology to be utilized to comply with the proposed project will depend on CPCC's individual operations and how the kilns will function with the current control technologies and techniques in place at CPCC (e.g., the baghouse). The potential available control technologies to reduce NOx emissions from cement kilns are: 1) SCR with or without a WGS; 2) UltraCat; or, 3) SNCR. For a full description of these control technologies, see the NOx Control Technologies section. Thus, the Draft PEA will evaluate the possibility that CPCC operators may rely on the above-mentioned control technologies to further control NOx emissions from cement kilns to comply with the proposed project.

Container Glass Melting Furnaces

In the NOx RECLAIM program there is one facility among the top NOx emitting facilities that operates glass melting furnaces. This facility produces container glass from dry, solid raw materials that are melted in the furnaces and then formed into glass container bottles.

A container glass melting furnace is the main equipment used for manufacturing glass products, such as bottles, glass wares, pressed and blown glass, tempered glass, and safety glass. The manufacturing process consists of four phases: 1) preparing the raw materials; 2) melting the mixture of raw materials in the furnace; 3) forming the desired shape; and, 4) finishing the final product. Raw materials, such as sand, limestone, and soda ash, are crushed and mixed with cullets (recycled glass pieces) to ensure homogeneous melting. The raw materials mixture is then conveyed to a continuous regenerative side-port melting furnace. As the mixture enters the furnace through a feeder, it melts and blends with the molten glass already in the furnace, and eventually flows to a refiner section, to a forming machine, and then, to annealing ovens. The final products undergo inspection, testing, packaging and storage. Any damaged or undesirable glass is transferred back to be recycled as cullet suitable for remelting.

NOx is generated from a container glass melting furnace in two ways: 1) during the decomposition of the silica in the raw materials; and, 2) from combusting fuel to generate high heating values in the furnace. The container glass melting furnace contributes over 99 percent of the total NOx emissions from a glass manufacturing plant. To effectively achieve the largest reduction of NOx emissions, SCR and UltraCat technologies are commercially available options for treating the flue gas of glass melting furnaces. For a full description of these control technologies, see the NOx Control Technologies section. The Draft PEA will evaluate the possibility that these control technologies may be relied up in order to comply with the glass melting furnace portion of the proposed project.

Sodium Silicate Furnace

In the NOx RECLAIM program, there is only one facility that produces sodium silicate in a melting furnace. Sodium silicate, a type of glass with a wide variety of industrial uses, should not to be confused with container or flat glass. Sodium silicate exists in a solid or liquid form, depending on the temperature. The combination of heating a batch-fed mixture of soda ash and sand causes the materials to produce sodium silicate and CO_2. NOx emissions are also created from combusting fuel needed to heat the furnace. In order to generate high heating values, the furnace is fired by several natural gas-fired burners. The flue gas then exits the furnace via a stack into the atmosphere.

Approximately 15 to 20 percent of NOx emission reductions can be achieved by utilizing blower air staging to lower the flue gas temperature in the furnace. To effectively achieve the largest reduction of NOx emissions, however, SCR technology is best suited for treating the flue gas of sodium silicate furnaces.

In addition, UltraCat, an alternate to SCR technology, is also available for multi-pollutant control. For a full description of these control technologies, see the NOx Control Technologies section. The Draft PEA will evaluate the possibility that these control technologies may be relied up in order to comply with the sodium silicate furnace portion of the proposed project.

Metal Heat Treating Furnaces

A metal melting furnace burns liquid or gaseous fuel to generate enough pre-heated air at a temperature high enough to melt solid metal and into a liquid molten consistency and to maintain the metal in a liquid state until it is ready for later use. The types of furnaces that are used for metal melting are reverberatory, cupola, induction, direct arc furnaces, sweat furnaces, and refining kettles. The burner flame and combustion products come in direct contact with the metal.

Heat treating operations are directly related to the metal producing and secondary metal processing industries. Materials handled by the heat treating industry are a variety of products provided by manufacturers that are used by other manufacturers, to make consumable or usable products. Typical materials used for heat treating are iron, steel, ferro-alloys, glass, and other nonferrous metals. Heat treatment furnaces are used for activities that include forging, hardening, tempering, annealing, normalizing, sintering, and case hardening of steels and solution and heat treatment of corrosion resistant and aluminum metals. Kilns are not considered heat treating furnaces. Among the top NOx emitting facilities in the NOx RECLAIM program, there is only one facility that processes steel in two metal heat furnaces with individual heat ratings above 150 mm BTU/hr.

As with all combustion sources, the type of burner used can affect the emissions. Some burners are lower NOx emitting than others. But for these types of furnaces, there are often dozens of burners that cumulatively require a high heat input. To achieve higher efficiency and to consume less fuel, recuperative and regenerative burners are used. These burners employ the principle of using preheated inlet air which is heated by the exhaust gases for more efficient combustion. However, to effectively achieve a substantial NOx reduction from these metal heat treating furnaces, SCR is the technology that is best suited for the flue gas treatment of NOx. For a full description of these control technologies, see the NOx Control Technologies section.

The Draft PEA will evaluate the possibility that the operator of the metal heat treating furnaces may rely on a combination of recuperative and regenerative burners along with SCR technology to further control NOx emissions in order to comply with the BARCT requirements for the metal heat treating furnace portion of the proposed project.

<u>Gas Turbines (Non-Refinery/Non-Power Plant)</u>
Stationary gas turbines are used primarily to drive compressors or to generate power. Gas turbines operate either in simple cycle or combined cycle. Simple cycle units use the mechanical energy of shaft work that is transferred to and used by a gas compressor, for example, or to run an electrical generator to produce electricity. A combined cycle unit adds an additional element of heat recovery from its exhaust gases to produce more power by way of a steam generator. Combined cycle units are more efficient due to their use of two work cycles from the same shaft operation. Gas turbines can operate on both gaseous and liquid fuels. Gaseous fuels include natural gas, process gas, and refinery gas. Liquid fuels typically include diesel. The units in this category are not power plant turbines (turbines that produce solely electric utility power). Some of these units are cogenerating units that, in addition to producing in-house power, also recover the useful energy from heat recovery for producing process steam.

Among the top non-power plant NOx emitting facilities in the RECLAIM universe, there are twenty gas turbines that are either major or large source units. Four of these units are currently utilizing some level of NOx control along with SCR. Six of these units are operated on an offshore oil drilling platform (outer continental shelf, or OCS). The OCS turbines, which are fired on diesel or process gas, have the highest NOx emission concentrations in this source category. Four of the OCS units with lower NOx parts per million (ppm) concentrations currently are equipped with SCR systems.

There are several methods of NOx control for gas turbines, with differing levels of reduction, such as steam or water injection, dry low emissions (DLE or DLN), and SCR. For a full description of these control technologies, see the NOx Control Technologies section. The type of NOx control option to be utilized for gas turbines will depend on the facility's individual operations and the current control technologies and techniques in place. The Draft PEA will evaluate the possibility that these control technologies may be relied up in order to comply with the stationary gas turbine portion of the proposed project.

Internal Combustion Engines (Non-Refinery/Non-Power Plant)
Stationary Internal Combustion Engines (ICEs) are used primarily to drive pumps, compressors, or to generate power. There are generally two types of engines, spark-ignited (SI) or compression ignited (CI) engines. SI engines ignite the air/fuel mixture with a spark while CI engines use the heat of compression to ignite the fuel that is injected into the combustion chamber. Engines can run at either stoichiometrically rich burn or lean burn conditions, depending on the air to fuel ratio. Rich burn combustion corresponds to an air-to-fuel ratio that is fuel-rich while lean burn combustion corresponds to a fuel-lean air-to-fuel ratio. Small SI engines typically run as rich burn, but many larger units as well as CI engines operate under lean burn conditions. For lean burn engines, more air is inducted than is required for complete combustion and the resultant exhaust oxygen level is high (over five percent). Rich burn engines typically operate very close to stoichiometric conditions by drawing only the necessary air to combust the fuel. SI engines are typically fired on gaseous fuels such as natural gas, while CI engines are fired on liquid fuels such as diesel.

Among the top NOx emitting facilities in the RECLAIM universe, there are 31 engines that are either major or large source units. Currently, there are nine rich burn engines equipped non-selective catalytic reduction (NSCR). Of the remaining 22 engines, there are 16 SI lean burn engines units and six CI lean burn units. The CI lean burn units are all operated on an offshore oil drilling platform (outer continental shelf, or OCS). The engine sizes range from a little over 700 brake horsepower (bhp) to 5,500 bhp. Diesel-fueled CI engines have the highest NOx emission concentrations in this source category while two-stroke SI engines have higher NOx emissions than four-stroke SI engines since the higher efficiencies in two-stroke engines translate to a hotter combustion temperature that can create more NOx.

Because the flue gas from rich burn engines has typically very low excess oxygen, NOx reductions can be achieved with NSCR technology. For lean burn exhaust with higher oxygen content, SCR is more effective at reducing NOx emissions. For a full description of these control technologies, see the NOx Control Technologies section. The type of NOx control option to be utilized for stationary ICEs will depend on the facility's individual operations and the current control technologies and techniques in place. For the ICEs operating at the 139 remaining NOx RECLAIM faculties, the ICEs would also need to meet the BARCT levels on a programmatic basis. The Draft PEA will evaluate the possibility that these control technologies may be relied up in order to comply with the stationary ICEs portion of the proposed project.

NOx Control Technologies

As reducing NOx emissions is the main objective of the currently proposed amendments to the RECLAIM program, there are two primary approaches for reducing NOx emissions: 1) by combustion control techniques that minimize the amount of NOx formed by the combustion equipment; or, 2) by installing a device that controls the NOx after it has been generated or post-combustion. On an equipment/process basis, Table 1-1 summarizes the potential control technologies that will be considered as part of the BARCT analysis for the proposed project. The following discussions will elaborate on the various technologies listed in Table 1-1.

Table 1-1
BARCT Control Technology Options for Top NOx Emitting Equipment/Processes

Equipment/Process	BARCT Control Technology Options
FCCUs	1. SCR 2. LoTOx^{TM} with scrubber 3. NOx reducing additives
Refinery Process Heaters and Boilers	1. SCR 2. LoTOx^{TM} with scrubber 3. KnowNOx^{TM} with scrubber 4. Great Southern Flameless Heaters 5. ClearSign 6. Cheng Low NOx
Refinery Gas Turbines	1. SCR 2. Ammonia Slip Catalyst (ASC) 3. CO Catalyst 4. Dry Low Emissions (DLE or DLN) 5. Cheng Low NOx
SRU/TGUs	1. SCR 2. LoTOx^{TM} with scrubber 3. KnowNOx^{TM} with scrubber
Petroleum Coke Calciner	1. LoTOx^{TM} with scrubber 2. UltraCat
Portland Cement Kilns	1. SCR with or without scrubber 2. UltraCat 3. SNCR
Container Glass Melting Furnaces	1. SCR 2. UltraCat
Sodium Silicate Furnaces	3. SCR 4. UltraCat
Metal Heat Treating Furnaces	SCR
ICEs (Non-Refinery/Non-Power Plant)	1. SCR 2. NSCR
Non-Refinery/Non-Power Plant Gas Turbines	6. SCR 7. Flue Gas Recirculation 8. Staged Combustion/Low NOx Burners 9. Water/Steam Injection 10. Dry Low Emissions (DLE or DLN)

<u>Flue Gas Recirculation</u>

Flue Gas Recirculation (FGR) is a very common NOx reduction method used in boilers and process heaters that recycles a portion of low oxygen combustion by-products from the stack. These recirculated gases reduce the overall combustion temperature, which in turn, helps to reduce the formation of NOx. FGR can reduce thermal NOx emissions by as much as 70 percent or greater, depending on the method of introduction of the recirculated flue gases, the amount of FGR flow, and the type of fuel combusted. For example, when firing natural gas, typical NOx reductions are 45 percent with a 10 percent recirculation rate, and 75 percent with a 20 percent recirculation rate.

Staged Combustion & Low-NOx Burners

Staged combustion is another technique utilized in boilers, process heaters, metal melting furnaces, heat treating furnaces and other miscellaneous equipment to help achieve lower NOx emissions by dividing the combustion process into a number of stages in which the air-to-fuel ratio is varied to manipulate the conditions that would make NOx formation less ideal. Staged combustion is divided into two categories: staged air combustion and staged fuel combustion. Staged air combustion controls the formation of NOx by staging or staggering the total amount of air required for combustion to occur and can be achieved by installing low-NOx burners. Only a portion of the total air needed for combustion is used to form a fuel-rich primary combustion zone, in which all of the fuel is partially burned. Then, combustion is fully completed when the remainder of the combustion air is injected in a secondary zone which is located downstream of the fuel-rich primary zone. Because some heat is transferred prior to the completion of combustion, peak combustion temperatures are lower (which reduces formation of thermal NOx) with stage air combustion than with conventional combustion.

Without limiting the combustion air, staged fuel combustion controls the formation of NOx by staging the amount of fuel needed for combustion. With a high level of excess air in the primary combustion zone, the peak combustion temperature drops and subsequently reduces NOx formation. Additional fuel is later injected in the secondary combustion zone at a higher pressure and velocity than in the primary combustion zone, to stimulate FGR, further reduce combustion temperature, and decrease the availability of oxygen needed to form NOx.

Water/Steam Injection

The process of injecting water or steam into the flame in the combustion equipment reduces the flame temperature which lowers the formation of thermal NOx. Water/steam injection is typically used in conjunction with other NOx control methods such as FGR or burner modifications (e.g., low-NOx burners). Estimated reductions in NOx emissions from utilizing water/steam injection vary with the type of fuel combusted. For example, the use of water/steam injection and natural gas can achieve as much as 80 percent reduction in NOx.

Selective Catalytic Reduction

Selective Catalytic Reduction (SCR) is post-combustion control equipment that is considered to be BARCT, if cost-effective, for NOx control of existing combustion sources such as boilers, process heaters, and FCCUs as it is capable of reducing NOx emissions by as much as 95 percent or higher. A typical SCR system design consists of an ammonia storage tank, ammonia vaporization and injection equipment, a booster fan for the flue gas exhaust, an SCR reactor with catalyst, an exhaust stack plus ancillary electronic instrumentation and operations control equipment. The way an SCR system reduces NOx is by a matrix of nozzles injecting a mixture of ammonia and air directly into the flue gas exhaust stream from the combustion equipment. As this mixture flows into the SCR reactor that is replete with catalyst, the catalyst, ammonia, and oxygen (from the air) in the flue gas exhaust reacts primarily (i.e., selectively) with NO and NO_2 to form nitrogen and water in the presence of a catalyst. The amount of ammonia introduced into the SCR system is approximately a one-to-one molar ratio of ammonia to NOx for optimum control efficiency, though the ratio may vary based on equipment-specific NOx reduction requirements. There are two main types of catalysts: one in which the catalyst is coated onto a metal structure and a ceramic-based catalyst onto which the catalyst components are calcified. Commercial catalysts used in SCRs are available in two types of solid, block configurations or modules, plate or honeycomb type, and are comprised of a base material of titanium dioxide (TiO_2) that is coated with either tungsten trioxide (WO_3), molybdic anhydride (MoO_3), vanadium pentoxide (V_2O_5), iron oxide (Fe_2O_3), or zeolite catalysts. These catalysts are used for SCRs because of their high activity, insensitivity to sulfur in the exhaust, and useful life span of approximately five years or more. Ultimately, the material composition of the catalyst is dependent upon the application and flue gas conditions such as gas composition, temperature, et cetera.

For conventional SCRs, the minimum temperature for NOx reduction is 500 ^oF and the maximum operating temperature for the catalyst is 800 ^oF. Depending on the application, the type of fuel combusted, and the presence of sulfur compounds in the exhaust gas, the optimum flue gas temperature of an SCR system is case-by-case and will range between 550 ^oF and 750 ^oF to limit the occurrence of several undesirable side reactions at certain conditions. One of the major concerns with the SCR process is the poisoning of the catalyst due to the presence of sulfur and the oxidation of sulfur dioxide (SO_2) in the exhaust gas to sulfur trioxide (SO_3) and the subsequent reaction between SO_3 and ammonia to form ammonium bisulfate or ammonium sulfate. The formation of either ammonium bisulfate or ammonium sulfate depends on the amount of SO_3 and ammonia present in the flue gas and can cause equipment plugging downstream of the catalyst. The presence of particulates, heavy metals and silica in the flue gas exhaust can also limit catalyst performance. However, minimizing the quantity of injected ammonia and maintaining the ammonia temperature within a predetermined range will help avoid these undesirable reactions while minimizing the production of unreacted ammonia which is commonly referred to as 'ammonia slip.' Depending on the type of combustion equipment utilizing SCR technology, the typical amount of ammonia slip can vary between less than five ppmv when the catalyst is fresh and 20 ppmv at the end of the catalyst life.

In addition to the conventional SCR catalysts, there are high temperature SCR catalysts that can withstand temperatures up to 1200 ^oF and low temperature SCR catalysts that can operate below 500 ^oF.

<u>Non-Selective Catalytic Reduction</u>
Non-selective catalytic reduction (NSCR) is an add-on NOx control technology for high temperature exhaust streams with low O_2 content. NSCR uses a catalyst reaction to simultaneously convert NOx, CO, and VOC into water, CO_2, and nitrogen (N_2).

One type of NSCR system injects a reducing agent into the exhaust gas stream prior to the catalyst reactor to reduce the NOx. Another type of NSCR system has an afterburner and two catalytic reactors (one reduction catalyst and one oxidation catalyst). In this latter system, natural gas is injected into the afterburner to combust unburned hydrocarbons at a minimum temperature of 1,700 °F and the gas stream is cooled prior to entering the first catalytic reactor where CO and NOx are reduced. A second heat exchanger cools the gas stream to reduce the potential reformation of NOx before the second catalytic reactor where the remaining CO is converted to CO_2.

NSCR can achieve a NOx control efficiency ranging from 80 to 90 percent. The NOx reduction efficiency is dependent upon similar factors as for SCR, including the catalyst material and condition, the space velocity, and the catalyst bed operating temperature, air-to-fuel ratio, the exhaust gas temperature, and the presence of masking or poisoning agents. The operating temperatures for NSCR system range from approximately 700 °F to 1500 °F, depending on the catalyst. In order to achieve NOx reductions of 90 percent, the temperature must be between 800 °F and 1200 °F and the O_2 concentration must be less than four percent. To control NOx, CO, and VOC simultaneously, NSCR catalyst must operate in a narrow air-to-fuel ratio band (15.9-to-16.1 for natural gas-fired engines) that is close to stoichiometric. An electronic controller, which includes an oxygen sensor and feedback mechanism, is often necessary to maintain the air-to-fuel ratio in this narrow band. At this air-to-fuel ratio, the oxygen concentration in the exhaust is low, while concentrations of VOC and CO are not excessive.

<u>Selective Non-Catalytic Reduction</u>
Selective non-catalytic reduction (SNCR) is another post-combustion control technique typically used to reduce the quantity of NOx produced in the hot flue gas, by injecting ammonia. The main differences between SNCR and SCR is that the SNCR reaction between ammonia and NOx in the hot flue gas occurs without the need for a catalyst and at much higher temperatures (i.e., between 1200 ^{o}F to 2000 ^{o}F). The SNCR reaction is also affected by the short residence time of ammonia and the molecular ratio between ammonia and the initial quantities of NOx such that small quantities of unreacted ammonia remains (i.e., as ammonia slip) and is subsequently released in the flue gas. With a control efficiency ranging between 80 and 85 percent, SNCR does not achieve as great of NOx emission reductions as SCR. The need for the exhaust temperature to be high limits the applicability of SNCR to boilers, cement kilns, and in some cases, FCCUs. Therefore, the use of SNCR alone would not be considered equivalent to BARCT.

<u>Wet Gas Scrubbers (WGSs)</u>
WGS technology is a multi-pollutant control system that primarily controls SOx and PM emissions but can be installed to function with NOx control equipment. WGSs can be used to control emissions from FCCUs, refinery process heaters and boilers, SRU/TGUs, petroleum coke calciners, and cement kilns. There are two types of wet gas scrubbers: 1) caustic-based non-regenerative WGS; and, 2) regenerative WGS.

In non-regenerative wet gas scrubbing, caustic soda (sodium hydroxide - NaOH) or other alkaline reagents, such as soda ash, are used as an alkaline absorbing reagent (absorbent) to capture SO_2 emissions. The absorbent captures SO_2 and sulfuric acid mist (H_2SO4) and converts it to various types of sulfites and sulfates (e.g., $NaHSO_3$, Na_2SO_3, and Na_2SO_4). The absorbed sulfites and sulfates are later separated by a purge treatment system and the treated water, free of suspended solids, is either discharged or recycled.

One example of the caustic-based non-regenerative scrubbing system is the proprietary Electro Dynamic Venturi (EDV) scrubbing system offered by BELCO Technologies Corporation (see Figure 1-6). An EDV scrubbing system consists of three main modules: 1) a spray tower module; 2) a filtering module; and, 3) a droplet separator module. The flue gas enters the spray tower module, which is an open tower with multiple layers of spray nozzles. The nozzles supply a high density stream of caustic/water solution that is directed in a countercurrent flow to the gas flow and encircles, encompasses, wets, and saturates the flue gas. Multiple stages of liquid/gas absorption occur in the spray tower module and SO_2 and acid mist are captured and converted to sulfites and sulfates. Large particles in the flue gas are also removed by impaction with the water droplets.

The flue gas saturated with heavy water droplets continues to move up the wet scrubber to the filtering module where the flue gas reaches super-saturation. At this point, water continues to condense and the fine particles in the gas stream begin to cluster together, to form larger and heavier groups of particles. Next, the flue gas, super-saturated with heavy water droplets, enters the droplet separator module causing the water droplets to impinge on the walls of parallel spin vanes and drain to the bottom of the scrubber.

The spent caustic/water solution purged from the WGS is later processed in a purge treatment unit. The purge treatment unit contains a clarifier that removes suspended solids for disposal. The effluent from the clarifier is oxidized with agitated air to help convert sulfites to sulfates and also reduce the chemical oxygen demand (COD) so that the effluent can be safely discharged to a wastewater system.

A regenerative WGS removes SO_2 from the flue gas by using a buffer solution that can be regenerated. The buffer is then sent to a regenerative plant where the SO_2 is extracted as concentrated SO_2. The concentrated SO_2 is then sent to a sulfur recovery unit (SRU) to recover the liquid SO_2, sulfuric acid and elemental sulfur as a by-product. When the inlet SO_2 concentrations are high, a substantial amount of sulfur-based by-products can be recovered and later sold as a commodity for use in the fertilizer, chemical, pulp and paper industries. For this reason, the use of a regenerative WGS is favored over a non-regenerative WGS.

One example of a regenerative scrubber is the proprietary LABSORB offered by BELCO Technologies Corporation [6, 7]. The LABSORB scrubbing process uses a patented non-organic aqueous solution of sodium phosphate salts as a buffer. This buffer is made from two common available products, caustic and phosphoric acid. The LABSORB system consists of: 1) a quench pre-scrubber; 2) an absorber; and, 3) a regeneration section which typically includes a stripper and a heat exchanger.

In the scrubbing side of the regenerative scrubbing system, the quench pre-scrubber is used to wash out any large particles that are carried over, plus any acid components in the flue gas such as hydrofluoric acid (HF), hydrochloric acid (HCl), and SO_3. The absorption of SO_2 is carried out in the absorber. The absorber typically consists of one single, high-efficiency packed bed scrubber filled with high-efficiency structural packing material. However, if the inlet SO_2 concentration is low, a multiple-staged packed bed scrubber, or a spray-and-plate tower scrubber, may be used instead to achieve an ultra-low outlet SO_2 concentration.

[6] *Evaluating Wet Scrubbers*, Edwin H. Weaver of BELCO Technologies Corporation, Petroleum Technology Quarterly, Quarter 3, 2006.

[7] *A Logical and Cost Effective Approach for Reducing Refinery FCCU Emissions.* S.T. Eagleson, G. Billemeyer, N. Confuorto, and E. H. Weaver of BELCO, and S. Singhania and N. Singhania of Singhania Technical Services Pvt., India, Presented at PETROTECH 6th International Petroleum Conference in India, January 2005.

The third step in the regenerative wet gas scrubbing system is the regenerative section in which the SO_2-rich buffer stream is steam heated to evaporate the water from the buffer. The buffer stream is then sent to a stripper/condenser unit to separate the SO_2 from the buffer. The buffer free of SO_2 is returned to the buffer mixing tank while the condensed-SO_2 gas stream is sent back to the SRU for further treatment.

LoTOx™ Application with Scrubber

The LoTOx™ is a registered trademark of Linde LLC (previously BOC Gases) and was later licensed to BELCO of Dupont for refinery applications. LoTOx™ stands for "Low Temperature Oxidation" process in which ozone (O_3) is used to oxidize insoluble NOx compounds into soluble NOx compounds which can then be removed by absorption in a caustic, lime or limestone solution. The LoTOx™ process is a low temperature application, optimally operating at about 325 ^{o}F.

A typical combustion process produces about 95 percent NO and five percent NO_2. Because both NO and NO_2 are relatively insoluble in an aqueous solution, a WGS alone is not efficient in removing these insoluble compounds from the flue gas stream. However, with a LoTOx™ system and the introduction of O_3, NO and NO_2 can be easily oxidized into a highly soluble compound N_2O_5 (see Reactions 5 and 6) and subsequently converted to nitric acid (HNO_3) (see Reaction 7). Then, in a wet gas scrubber for example, the HNO_3 is rapidly absorbed in caustic (NaOH) (see Reaction 8), limestone or lime solution (see Reactions 9 and 10). In addition, because the rates of oxidizing reactions for NOx (see Reactions 5 and 6) are fast compared to the very slow SO_2 oxidation reaction (see Reaction 11), no ammonium bisulfate ($(NH_4)HSO_4$) or sulfur trioxide (SO_3) is formed.

$NO + O_3 \rightarrow NO_2 + O_2$	(Reaction 5 - Fast)
$2\ NO_2 + O_3 \rightarrow N_2O_5 + O_2$	(Reaction 6 – Fast)
$N_2O_5 + H_2O \rightarrow 2\ HNO_3$	(Reaction 7)
$HNO_3 + NaOH \rightarrow NaNO_3 + H_2O$	(Reaction 8)
$2HNO3 + CaCO3 \rightarrow Ca(NO_3)_2 + H_2O + CO_2$	(Reaction 9)
$2HNO3 + Ca(OH) \rightarrow Ca(NO_3)_2 + 2H_2O$	(Reaction 10)
$SO_2 + O_3 \rightarrow SO_3 + O_2$	(Reaction 11 - Very slow)

The LoTOx™ process requires a source of oxygen and generates O_3 on site. Typically oxygen (O_2) is stored as a liquid in vacuum-jacketed vessels or is delivered by pipeline. O_3 is an unstable gas and it is typically generated on demand from the O_2 supply using an O_3 generator. An O_3 generator is shaped similar to a shell and tube heat exchanger and uses a corona discharge to dissociate the O_2 molecules into individual atoms so that the individual oxygen atoms combine with each other to form O_3. The LoTOx™ process contains an ozone injection manifold designed to achieve uniform distribution and complete mixing. A ratio of 1.75 parts NOx to 2.5 parts O_3 is needed in order to achieve a NOx conversion and reduction of 90 percent to 95 percent. Since sulfur dioxiode (SO_2) is an ozone scavenger because it readily bonds with O_3 to form sulfur trioxide (SO_3), the LoTOx™ process typically has a very low O_3 slip (excess O_3) that ranges from zero ppmv to three ppmv. Figure 1-5 shows a schematic of the O_3 generation process.

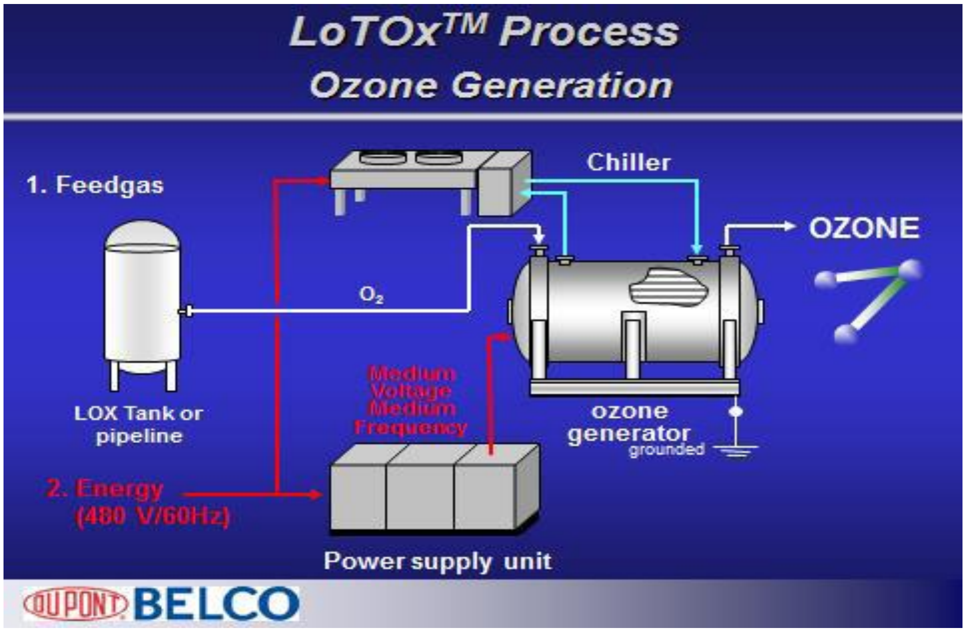

Figure 1-5: Ozone Generation Process

The LoTOx™ process can be integrated with any type of wet scrubbers (e.g., venturi, packed beds), semi-dry scrubbers, or wet electrostatic precipitators (ESPs). For example, Linde has engineered more than 24 LoTOx™ applications for EDV™ scrubbers engineered by BELCO since 2007 for refinery FCCU applications. A LoTOx™ system with an EDV™ scrubber is shown in Figure 1-6.

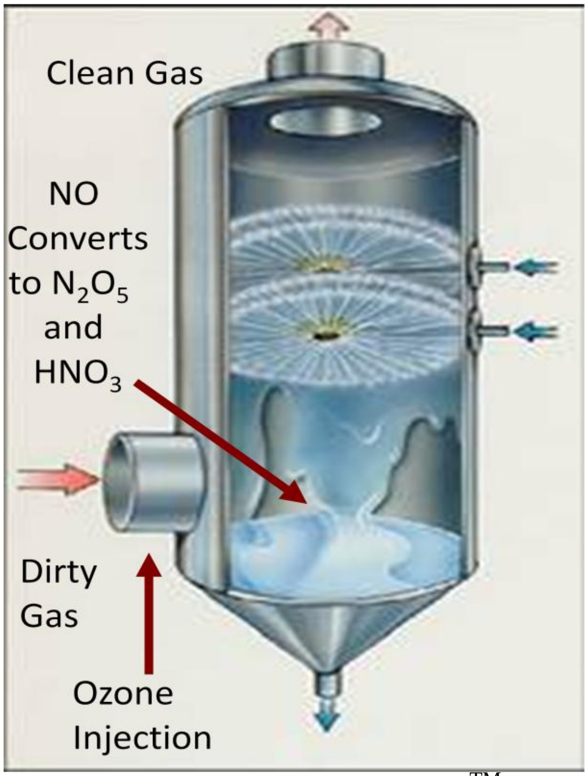

Figure 1-6: EDV Scrubber with LoTOx™ Application

In addition, MECS, BELCO's sister company, has engineered more than two dozen DynaWave scrubbers with LoTOx™ systems specifically designed for refinery SRU/TGUs. Figure 1-7 shows a schematic for a DynaWave scrubber with a LoTOx™ application.

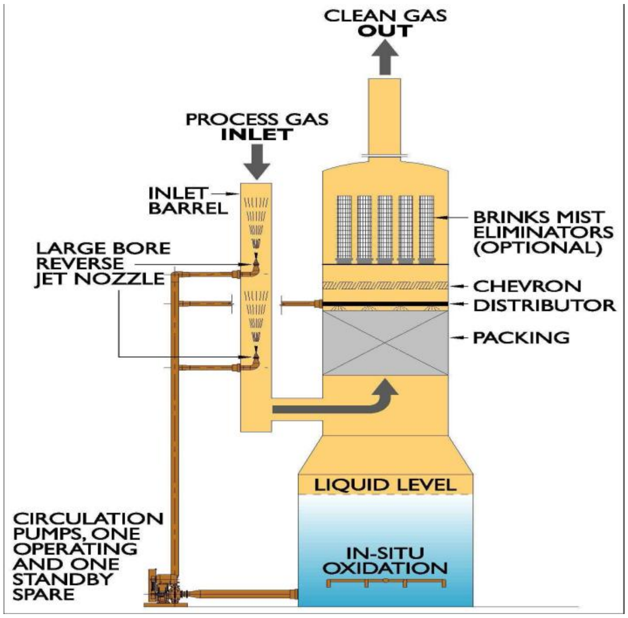

Figure 1-7: DynaWave Scrubber with LoTOx™ Application

When compared to SCR technology, the LoTOx™ application has several advantages, as follows:

- Unlike SCR which operates at high temperatures, LoTOx™ is a low temperature operating system that does not require additional heat input to maintain operational efficiency and enable maximum heat recovery of high temperature combustion gases.
- Unlike SCR which is primarily designed to reduce only NOx, LoTOx™ can be integrally connected to a scrubber (e.g., wet or semi-dry scrubber, or wet electrostatic ESP) and become a multi-component air pollution control system capable of reducing NOx, SOx and PM in one system.
- There is no formation of ammonia slip, SO_3, or $(NH_4)HSO_4$ with the LoTOx™ process.

<u>KnowNOx™ Application with Scrubber</u>
In lieu of using O_3 to convert NO and NO_2 to N_2O_5 and HNO_3, the KnowNOx™ technology uses chlorine dioxide ClO_2. The manufacturer of KnowNOx™ claims that the conversion reactions (see Reactions 12 and 13) are in the gas phase, which can occur much faster than the liquid phase reactions with O_3 (see Reactions 5 through 8 in the previous LoTOx™ Application discussion).

$5\ NO + 2\ ClO_2 + H_2O \rightarrow 5\ NO_2 + 2\ HCl$ (Reaction 12 - Gas Phase)

$5\ NO_2 + ClO_2 + 3\ H_2O \rightarrow 5\ HNO_3 + 2\ HCl$ (Reaction 13 – Gas Phase)

$5\ SO_2 + 2\ ClO_2 + 6\ H_2O \rightarrow 5\ H_2SO_4 + 2\ HCl$ (Reaction 10)

With the KnowNOx^{TM} technology, it takes less than 0.5 seconds to achieve 99.8 percent or more conversion. The reactions require a smaller vessel relative to the size needed for the LoTOx^{TM} reaction chamber. In addition, the KnowNOx^{TM} process can simultaneously reduce NOx, SO_2, PM and other contaminants.

The KnowNOx^{TM} process includes a three-staged scrubbing system: 1) SO_2 is removed via a DynaWave scrubber; 2) then ClO_2 is injected into the scrubber exhaust stream where the NO and NO_2 are converted into HNO_3 and other soluble salts; and, 3) any H_2S that is generated during the second stage is converted to soluble salts. To date, the KnowNOx^{TM} technology has been installed at two locations in the U.S. but has not yet been tested in any refinery applications. Figure 1-8 shows a schematic of a scrubber with KnowNOx^{TM}.

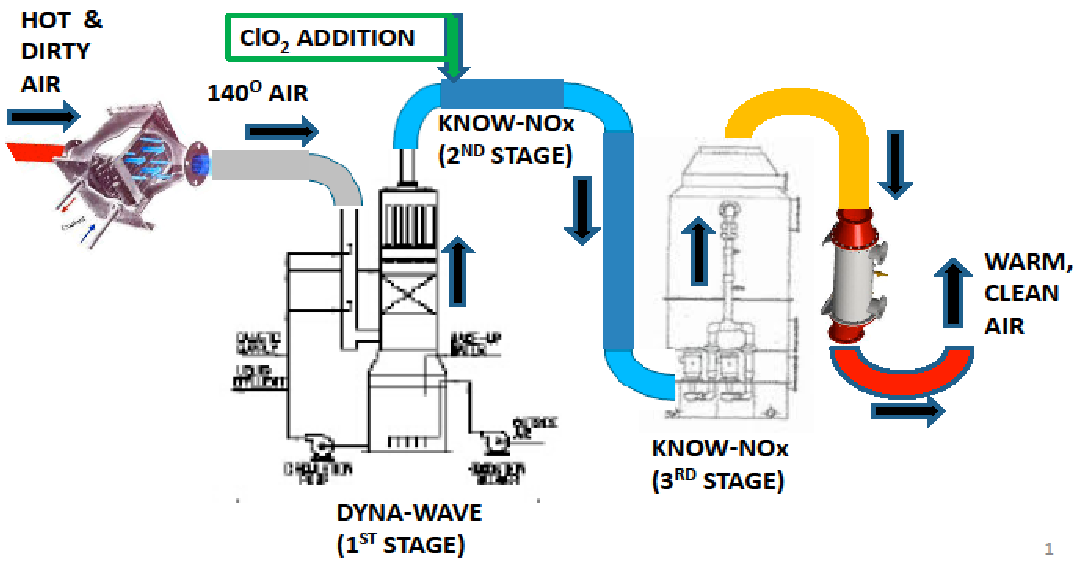

Figure 1-8: Scrubber with KnowNOx^{TM} Application

<u>NOx Reducing Additives</u>

Combustion in a FCCU regenerator generates various pollutants (e.g., NO, N_2O, NO_2, HCN, NH_3, SO_2, etc.) and their dynamic interaction with each other is complex. "Fuel" nitrogen in the coke is first converted to HCN. HCN is thermodynamically unstable and it is converted to NH_3, N_2, NO, N2O, and NO_2. The rates of these reactions depend heavily on the FCCU regenerator temperatures and configuration. NOx reducing additives can be used to promote the conversion of NOx, HCN, and NH_3 to elemental nitrogen (N_2) and reduce NOx emissions. The removal efficiency for NOx reducing additives can range between 50 percent and 80 percent. A simplified version of the chemical reactions in the FCCU regenerator is shown in Figure 1-9.

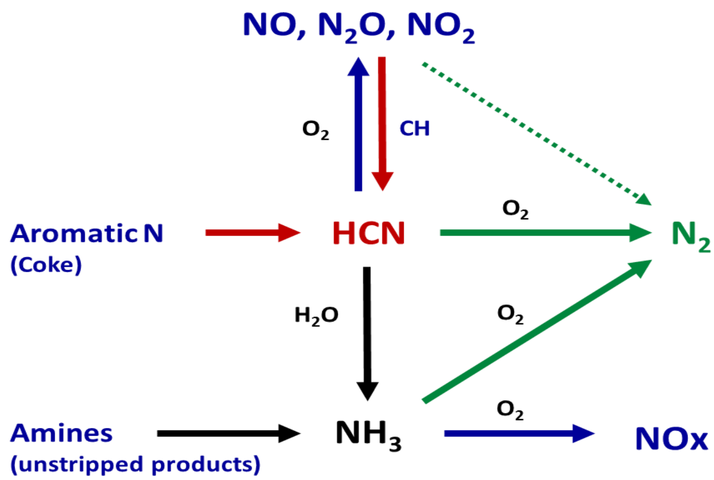

Figure 1-9: Nitrogen Chemistry in the FCCU Regenerator

When using NOx reducing additives, manufacturers recommend the following best practices to minimize the formation of NOx and simultaneously promote the conversion of CO to CO_2: 1) minimize excess oxygen since higher amounts of excess oxygen favors the undesirable formation of NOx rather than N_2; 2) reduce nitrogen in the feed stream; and, 3) utilize non-platinum CO promoters.

Ammonia Slip Catalyst (ASC) and CO Catalyst

SCR manufacturers have developed Ammonia Slip Catalyst (ASC) which is a layer of catalyst that is installed downstream of the SCR catalyst to enhance the selective reduction of NO to N2 and supporting the oxidation of CO to CO2 while suppressing the oxidation of NH3 to NOx. Early generation of ASCs were based on precious metal which is highly active for NH_3 oxidation. The use of ASCs allow for operations at higher NH_3/NOx ratios to ensure complete NOx conversion while maintaining low ammonia slip.

Similar to ASC, CO catalyst is used in conjunction with the SCR catalyst to concurrently reduce NOx to N2 and oxidize CO and hydrocarbon to CO2 and water. CO catalyst is typically made of platinum, palladium or rhodium, and is capable of removing approximately 90 percent of CO and 85 percent to 90 percent of hydrocarbon or hazardous air pollutants from an exhaust stream.

Great Southern Flameless Heaters

In 2012, Coffeyville Resources purchased the world's first flameless crude heater designed by Great Southern Flameless for their Coffeyville refinery in Kansas to comply with a Consent Decree issued by the U.S. EPA. The flameless heater has been in operation for over one year and has proven an achieved-in-practice performance of five ppmv NOx at three percent O_2 with pilot lights in operation, and three ppmv NOx without pilot lights for flameless technology.

Great Southern can supply flameless heaters or oxy-fuel flameless heaters with maximum rating from 10 mmBTU/hr to 320 mmBTU/hr (e.g., equivalent to 240 mmBTU/hr process duty.) Their production capacity is 30 heaters per year. The modules are designed and fabricated in Oklahoma and then they are shipped in pieces to the field where they are assembled at the site. The heaters can use the same foundation of the conventional heaters. From cold start, the heater is brought up in natural draft mode in the same manner as any typical conventional heater. The firing rate of the heater is gradually increased to the required level while the combustion air is gradually increased to 850 ^oF. Once the combustion air temperature exceeds 850 ^oF, it will sustain the automatic ignition of fuel, and the heater is transitioned into the staged fuel firing mode with pilots off-line. The heater is operated in the staged firing mode until steady state operation is achieved. At this point, the heater is transitioned into flameless firing mode. Visible flame from the conventional nozzles disappears and the NOx emissions decrease substantially in the flameless mode operation. The heater can also be designed for combustion with oxygen.

According to Great Southern Flameless, flameless heaters can be designed to achieve: 1) five ppmv NOx at three percent O_2; or, 2) two ppmv NOx at three percent O_2 with the pilot lights off during flameless firing and with a fuel mix of 25 percent natural gas and 75 percent refinery gas. In addition, oxy-fuel flameless heaters can be designed to achieve: 1) two ppmv NOx at three percent O_2; or, 2) one ppmv with the pilot lights off during flameless firing.

<u>UltraCat</u>

UltraCat is a commercially available multi-pollutant control technology designed to remove NOx and other pollutants such as SO_2, PM, HCl, Dioxins, and HAPs such as mercury in low temperature applications. UltraCat technology is comprised of filter tubes which are made of fibrous ceramic materials embedded with proprietary catalysts. The optimal operating temperature range of an UltraCat system is approximately 350 ^oF to 750 ^oF. In order to achieve a NOx removal efficiency of approximately 95 percent, aqueous ammonia is injected upstream of the UltraCat filters. In addition, to remove SO_2, HCl, and other acid gases with a removal efficiency ranging from 90 percent to 98 percent, dry sorbent such as hydrated lime, sodium bicarbonate or trona is also injected upstream of the UltraCat filters. UltraCat is also capable of controlling particulates to a level of 0.001 grains per standard cubic foot of dry gas (dscf).

The UltraCat filters are arranged in a baghouse configuration with a low pressure drop such as five inches water column (inH20) across the system. The UltraCat system is equipped with a reverse pulse-jet cleaning action that back flushes the filters with air and inert gas to dislodge the PM deposited on the outside of the filter tubes. Depending on the loading, catalytic filter tubes need to be replaced every five to 10 years. The UltraCat system is shown in Figure 1-10.

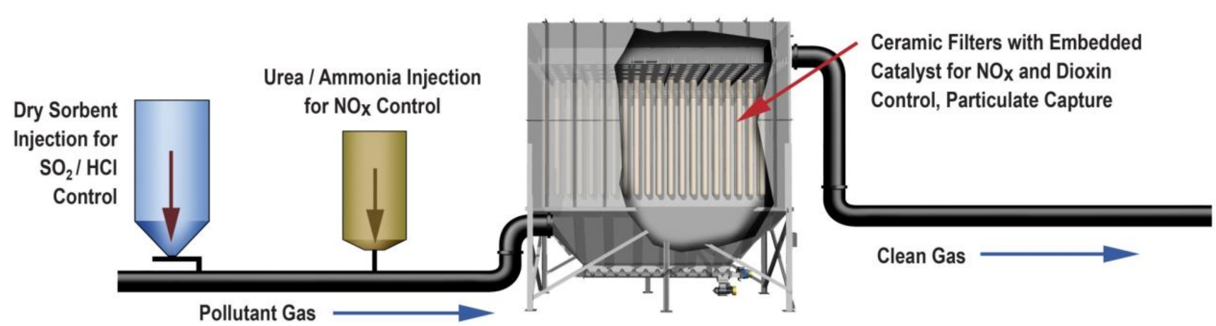

Figure 1-10: UltraCat System

<u>ClearSign Technology</u>

The ClearSign Combustion Corporation in Seattle has developed two technologies applicable for boilers and heaters: 1) DUPLEX™ technology; and, 2) Electrodynamic Combustion Control (ECC™). These technologies are expected to generate very low NOx and CO emissions without the need for FGR, SCR, or large quantities of excess air.

DUPLEX™ technology can be installed in new boilers or heaters. Also, existing boilers and heaters can be retrofit with DUPLEX™ technology. The DUPLEX™ technology comprises a proprietary DUPLEX™ tile installed downstream of the conventional burners. The hot combustion flame from the conventional burners impinges onto the DUPLEX™ tile, and the tile helps evenly radiate the heat with a high emissivity to the combustion products. The DUPLEX™ operation also creates more mixing and shorter flames. Since the flame length is one parameter that limits the total heat release in a furnace, decreased flame length can allow for significantly higher process throughputs. The DUPLEX™ tile is expected to have a three- to five-year lifespan.

The ECC™ technology uses an electric field to effectively shape the flame, accelerate flame speed, and improve flame stability. The total electrical field power required to generate such effects is less than 0.1 percent of the firing rate. Emission performance from a bench test has been demonstrated for both DUPLEX™ and ECC™ and the NOx and CO emissions were both demonstrated to be less than five ppmv as long as the furnace temperatures were steadily maintained between 1200 ^{o}F and 1800 ^{o}F. Beside the benefits of reducing air pollution, ClearSign believes that their burners will provide substantial economic benefits from more uniform heat distribution, improved process throughput, and potentially reduced maintenance costs.

Cheng Low NOx

Cheng Low NOx burner technology applies steam injection to the inlet fuel for combustion in the gas turbine. This is different than traditional steam injection which involves the injection of the steam to the compressed combustion air before entering the combustion chamber. The burner retrofits involve the installation of a new set of nozzles that can deliver a uniform, homogenous mix of steam and fuel to the combustion chamber, and in turn, will reduce NOx formation. Steam injection also provides an added boost to the gas turbine's output power due to the increased mass flow rate. The heat recovery steam generator (HRSG) typically will produce the process steam for the system. The NOx emission level that can be achieved by utilizing Cheng Low NOx burner technology is typically under five ppm and can go as low as two ppm with a 3:1 or 4:1 steam-to-fuel ratio.

Dry Low NOx (DLN) or Dry Low Emissions (DLE)

Staged combustion is identified through a variety of names, including Dry Low NOx (DLN) and Dry Low Emissions (DLE), and is a type of dry control which involves a major modification to a turbine's combustion system. The majority of gas turbines manufactured today are lean-premix dual-staged combustion turbines. Two stage rich/lean combustors are essentially air-staged, premixed combustors in which the primary zone is operated fuel rich and the secondary zone is operated fuel lean. The rich mixture produces lower flame temperatures and higher concentrations of CO and H_2, because of incomplete combustion, while decreasing the amount of oxygen available for the formation of NOx. Before entering the secondary zone, the exhaust of the primary zone is quenched (to extinguish the flame) by large amounts of air and a lean mixture is created. Thus, by staging DLE combustors so that the air and fuel is pre-mixed and combusting the mixture to produce a lower flame temperature, lower NOx emissions (e.g., in the range between three ppm and 25 ppm for gaseous fuel and 10 ppm for liquid fuel) are created as a by-product.

ALTERNATIVES

The Draft PEA will discuss and compare a range of reasonable alternatives to the proposed project as required by CEQA Guidelines §15126.6 and by SCAQMD Rule 110 where there are potential significant adverse environmental impacts. Alternatives must include realistic measures for attaining the basic objectives of the proposed project and provide a means for evaluating the comparative merits of each alternative. In addition, the range of alternatives must be sufficient to permit a reasoned choice and it need not include every conceivable project alternative. The key issue is whether the selection and discussion of alternatives fosters informed decision making and public participation. A CEQA document need not consider an alternative whose effect cannot be reasonably ascertained and whose implementation is remote and speculative.

SCAQMD Rule 110 does not impose any greater requirements for a discussion of project alternatives in an environmental assessment than is required for an Environmental Impact Report under CEQA. Alternatives will be developed based in part on the major components of the proposed project. The rationale for selecting alternatives rests on CEQA's requirement to present "realistic" alternatives; that is alternatives that can actually be implemented. CEQA also requires an evaluation of a "No Project Alternative."

SCAQMD’s policy document Environmental Justice Program Enhancements for fiscal year (FY) 2002-03, Enhancement II-1 recommends that all SCAQMD CEQA environmental assessments include a feasible project alternative with the lowest air toxics emissions. In other words, for any major equipment or process type under the scope of the proposed project that creates a significant environmental impact, at least one alternative, where feasible, shall be considered from a “least harmful” perspective with regard to hazardous air emissions.

The Governing Board may choose to adopt any portion or all of any alternative presented in the PEA with appropriate findings as required by CEQA. The Governing Board is able to adopt any portion or all of any of the alternatives presented because the impacts of each alternative will be fully disclosed to the public and the public will have the opportunity to comment on the alternatives and impacts generated by each alternative. Written suggestions on potential project alternatives received during the comment period for the Initial Study will be considered when preparing the Draft PEA.

ENVIRONMENTAL CHECKLIST

Introduction

General Information

Potentially Significant Impact Areas

Determination

Environmental Checklist and Discussion

INTRODUCTION

The environmental checklist provides a standard evaluation tool to identify a project's adverse environmental impacts. This checklist identifies and evaluates potential adverse environmental impacts that may be created by adopting the proposed amendments to Regulation XX.

GENERAL INFORMATION

Project Title:	Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM)
Lead Agency Name:	South Coast Air Quality Management District
Lead Agency Address:	21865 Copley Drive, Diamond Bar, CA 91765
CEQA Contact Person:	Barbara Radlein, (909) 396-2716
Regulation XX Contact Person:	Minh Pham, (909) 396-2613
Project Sponsor's Name:	South Coast Air Quality Management District
Project Sponsor's Address:	21865 Copley Drive, Diamond Bar, CA 91765
General Plan Designation:	Not applicable
Zoning:	Not applicable
Description of Project:	SCAQMD staff is proposing amendments to Regulation XX – RECLAIM, Rule 2002 – Allocations for NOx and SOx, to reduce the allowable NOx emission limits based on current BARCT to achieve additional NOx emission reductions for the following industrial equipment and processes: 1) FCCUs; 2) refinery boilers and heaters; 3) refinery gas turbines; 4) SRU/TGUs; 5) non-refinery/non-power plant gas turbines; 6) non-refinery sodium silicate furnaces; 7) non-refinery/non-power plant ICEs; 8) container glass melting furnaces; 9) coke calcining; 10) Portland cement kilns; and, 11) metal heat treating furnaces. Additional amendments are proposed to establish procedures and criteria for reducing NOx RTCs and NOx RTC adjustment factors for year 2016 and later. For clarity and consistency throughout the regulation, other minor changes are proposed to: 1) Rule 2011 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping SOx Emissions (Attachment C – Quality Assurance and Quality Control Procedures); and, 2) Rule 2012 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping NOx Emissions (Attachment C – Quality Assurance and Quality Control Procedures). The Initial Study identifies the following environmental topics as areas that may be adversely affected by the proposed project: aesthetics; air quality and greenhouse gas emissions; energy; hydrology and water quality; hazards and hazardous materials; solid and hazardous waste; and, transportation and traffic. Impacts to these environmental areas will be further analyzed in the Draft PEA.
Surrounding Land Uses and Setting:	Industrial, commercial, and residential
Other Public Agencies Whose Approval is Required:	Not applicable

POTENTIALLY SIGNIFICANT IMPACT AREAS

The following environmental impact areas have been assessed to determine their potential to be affected by the proposed project. Any checked items represent areas that may be adversely affected by the proposed project. An explanation relative to the determination of impacts can be found following the checklist for each area.

☑	Aesthetics	☐	Geology and Soils	☐	Population and Housing
☐	Agriculture and Forest Resources	☑	Hazards and Hazardous Materials	☐	Public Services
☑	Air Quality and Greenhouse Gas Emissions	☑	Hydrology and Water Quality	☐	Recreation
☐	Biological Resources	☐	Land Use and Planning	☑	Solid and Hazardous Waste
☐	Cultural Resources	☐	Mineral Resources	☑	Transportation and Traffic
☑	Energy	☐	Noise	☑	Mandatory Findings of Significance

DETERMINATION
On the basis of this initial evaluation:

☐ I find the proposed project, in accordance with those findings made pursuant to CEQA Guideline §15252, COULD NOT have a significant effect on the environment, and that an ENVIRONMENTAL ASSESSMENT with no significant impacts has been prepared.

☐ I find that although the proposed project could have a significant effect on the environment, there will NOT be significant effects in this case because revisions in the project have been made by or agreed to by the project proponent. An ENVIRONMENTAL ASSESSMENT with no significant impacts will be prepared.

☑ I find that the proposed project MAY have a significant effect(s) on the environment, and an ENVIRONMENTAL ASSESSMENT will be prepared.

☐ I find that the proposed project MAY have a "potentially significant impact" on the environment, but at least one effect 1) has been adequately analyzed in an earlier document pursuant to applicable legal standards, and 2) has been addressed by mitigation measures based on the earlier analysis as described on attached sheets. An ENVIRONMENTAL ASSESSMENT is required, but it must analyze only the effects that remain to be addressed.

☐ I find that although the proposed project could have a significant effect on the environment, because all potentially significant effects (a) have been analyzed adequately in an earlier ENVIRONMENTAL ASSESSMENT pursuant to applicable standards, and (b) have been avoided or mitigated pursuant to that earlier ENVIRONMENTAL ASSESSMENT, including revisions or mitigation measures that are imposed upon the proposed project, nothing further is required.

Date: December 4, 2014 **Signature:** Michael Krause

Planning, Rules, and Area Sources

ENVIRONMENTAL CHECKLIST AND DISCUSSION

Since NOx is a precursor pollutant to fine particulate matter (PM10 and PM2.5) and ozone, SCAQMD staff is proposing amendments to Regulation XX – RECLAIM, to achieve additional NOx emission reductions as outlined in the Final 2012 AQMP. Specifically, amendments are proposed to Rule 2002 – Allocations for NOx and SOx to address BARCT requirements, which may require installation or modification of NOx emission control equipment or techniques. For clarity and consistency throughout the regulation, other minor changes that are administrative in nature and include minor clarifications are proposed to: 1) Rule 2011 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping SOx Emissions (Attachment C – Quality Assurance and Quality Control Procedures); and, 2) Rule 2012 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping NOx Emissions (Attachment C – Quality Assurance and Quality Control Procedures).

The amendments proposed in Rule 2002 for the overall reductions in NOx RTC allocations, which include the anticipated feasible NOx emissions reductions due to compliance with proposed BARCT requirements, are expected to involve physical changes at affected facilities which may cause potentially significant impacts to the following environmental topics: aesthetics; air quality and GHG emissions; energy; hydrology and water quality; hazards and hazardous materials; solid and hazardous waste; and, transportation and traffic. Therefore, the type of emission reduction projects that may be undertaken to comply with the proposed project, primarily the reduced total amounts of NOx credits available in the RECLAIM program, are the main focus of the analysis in this Initial Study.

Preliminary review of the SCAQMD's RECLAIM database indicates that certain equipment at the top emitting NOx RECLAIM facilities are currently not operating at proposed BARCT levels. This analysis assumes that operators at RECLAIM facilities will elect to reduce emissions at their facilities through further control of emissions from equipment not operating at BARCT rather than purchasing NOx RTCs, as is currently allowed under the RECLAIM program. The rationale for this assumption is that controlling emissions from equipment not operating at BARCT will produce the most conservative analysis of secondary adverse environmental impacts. The physical changes involved with the type of emission control strategies that are expected to occur focus on the installation of new or the modification of existing NOx emission control equipment for the following industrial equipment and processes: 1) FCCUs; 2) refinery boilers and heaters; 3) refinery gas turbines; 4) SRU/TGUs; 5) non-refinery/non-power plant gas turbines; 6) non-refinery sodium silicate furnaces; 7) non-refinery/non-power plant ICEs; 8) container glass melting furnaces; 9) coke calcining; 10) Portland cement kilns; and, 11) metal heat treating furnaces. To control NOx emissions from these sources, an assortment of technologies may be applied individually or in combination to meet proposed BARCT, depending on the source category, as follows (in alphabetical order): Cheng Low NOx; ClearSign; Dry Low Emissions (DLE or DLN); Flue Gas Recirculation; Great Southern Flameless Heaters; KnowNOx™ with scrubber; LoTOx™ with scrubber; NOx reducing additives; NSCR; SCR with or without scrubber; SNCR; Staged Combustion/Low NOx Burners; UltraCat; and Water/Steam Injection. For the purpose of the CEQA analysis, the selection of certain control technology is based on the potential to cause secondary adverse environmental impacts in order to render the analysis conservative regardless of costs. It is important to note that the rule development process, including the proposed BARCT determination and RTC shave methodology, are ongoing and as such may be revised based on input from stakeholders and the public. As additional information becomes available, the project will be updated and any additional environmental impacts will be evaluated in the Draft PEA.

It must be also noted that the projects assumed to occur as a means of reducing NOx emissions in response to the proposed amendments could occur voluntarily under the existing RECLAIM program. In addition, as with the current regulation or with the proposed project, affected facilities may purchase NOx RTCs instead of implementing physical changes to achieve a reduction in NOx emissions. However, the proposed amendments to the RECLAIM program would further induce such control strategies to occur as facility allocations are being reduced.

		Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
I.	**AESTHETICS.** Would the project:				
a)	Have a substantial adverse effect on a scenic vista?	☐	☐	☐	☑
b)	Substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway?	☐	☐	☐	☑
c)	Substantially degrade the existing visual character or quality of the site and its surroundings?	☑	☐	☐	☐
d)	Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area?	☐	☐	☑	☐

Significance Criteria

The proposed project impacts on aesthetics will be considered significant if:

- The project will block views from a scenic highway or corridor.
- The project will adversely affect the visual continuity of the surrounding area.
- The impacts on light and glare will be considered significant if the project adds lighting which would add glare to residential areas or sensitive receptors.

Discussion

I. a) & b) No Impact. Depending on how the affected facilities choose to comply with the proposed NOx reductions, implementation of the proposed project could involve construction activities related to the modification of existing equipment at the top NOx emitting RECLAIM facilities.

The physical changes involved with the type of NOx emission control strategies that are expected focus on the installation of new or the modification of existing control equipment at the following stationary sources of NOx: 1) FCCUs; 2) refinery boilers and heaters; 3) refinery gas turbines; 4) SRU/TGUs; 5) non-refinery/non-power plant gas turbines; 6) non-refinery sodium silicate furnaces; 7) non-refinery/non-power plant ICEs; 8) container glass melting furnaces; 9) coke calcining; 10) Portland cement kilns; and, 11) metal heat treating furnaces. To control NOx emissions from these sources, an assortment of technologies may be applied individually or in combination to meet proposed BARCT, depending on the source category, as follows (in alphabetical order): Cheng Low NOx; ClearSign; Dry Low Emissions (DLE or DLN); Flue Gas Recirculation; Great Southern Flameless Heaters; KnowNOx™; LoTOx™ with scrubber; NOx reducing additives; NSCR; SCR with or without scrubber; SNCR; Staged Combustion/Low NOx Burners; UltraCat; and Water/Steam Injection.

Construction activities are expected as part of the proposed project. However, the construction activities would be temporary and would not be expected to adversely impact views and aesthetics resources since most of the heavy equipment and activities would be expected to occur within the confines of each existing facility and would be expected to introduce only minor visual changes to areas outside each facility, if at all, depending on the location of the construction activities within the facility. Except for the potential use of cranes, the majority of the construction equipment is expected to be low in height and not substantially visible to the surrounding area due to existing fencing along the property lines and existing structures currently within the facilities that would buffer the views of the construction activities. Further, the construction activities are expected to be temporary in nature and will cease following completion of the equipment installation or modifications.

Depending on the type of NOx emissions control employed, the proposed project could potentially introduce minor visual changes at some facilities. The affected units, depending upon their locations within each facility, could potentially be visible to areas outside of each facility. However, the affected units are expected to be about the same size profile relative to the existing equipment or structures present at each affected facility. The general appearance of the affected units is not expected to differ significantly from other equipment units such that no significant impacts to aesthetics are expected. Further, no scenic highways or corridors are located in the vicinities of the affected facilities such that the proposed project would not obstruct scenic resources or degrade the existing visual character of a site, including but not limited to, trees, rock outcroppings, or historic buildings. Accordingly, these impact issues will not be further analyzed in the Draft PEA. Further, since no significant aesthetics impacts were identified for these issues, no mitigation measures are necessary or required.

I. c) Potentially Significant Impact. All construction and operational activities associated with the proposed project are expected to take place within the boundaries of the existing RECLAIM facilities. As explained in 1. a) and b), during construction, cranes may be needed during construction and they may be visible to the surrounding areas. However, except for the use of cranes, the majority of construction equipment that will be used to comply with the proposed project will be low in height and will not be visible to the surrounding areas due to the presence of existing fences and other structures that buffer views. Since the construction activities are temporary in nature, all construction equipment will be removed following completion of the proposed project.

Of the new equipment that may be installed, or the existing equipment that may be modified as part of the proposed project, all of the control technologies except for WGSs will be similar in size, appearance, and profile to the existing equipment and surrounding structures. Thus, no operational aesthetics impacts from the installation or application of the following technologies would be expected to substantially degrade the existing visual character or quality of the site and its surroundings: Cheng Low NOx; ClearSign; Dry Low Emissions (DLE or DLN); Flue Gas Recirculation; Great Southern Flameless Heaters; KnowNOx™; NOx reducing additives; NSCR; SCR without scrubber; SNCR; Staged Combustion/Low NOx Burners; UltraCat; and Water/Steam Injection.

However, wet gas scrubber (WGS) technology in combination with LoTOx™ or an SCR is potentially BARCT for five FCCUs, six SRU/TGUs, multiple refinery process heaters and boilers, a petroleum coke calciner, and Portland cement kilns. If a WGS scrubber is installed for any of these source categories, upon completion of construction, the operation of the WGS will emit flue gas that is saturated with water that, depending on weather conditions, could form a visible steam plume. Depending on the size of the WGS installed, the flue gas stack could be as tall as 200 feet above grade. For this reason, each WGS, its stack, and subsequent steam plume may have the potential to generate significant aesthetic impacts. Therefore, these potential impacts to aesthetics will be addressed in the Draft PEA for the proposed project.

I. d) Less Than Significant Impact. There are no components in the proposed project that would require construction activities to occur at night. Therefore, no additional lighting at the affected facilities would be required as a result of complying with the proposed project. However, if facility operators determine that the construction schedule requires nighttime activities, temporary lighting may be required. Nonetheless, since construction of the proposed project would be completely located within the boundaries of each affected facility, additional temporary lighting is not expected to be discernable from the existing permanent night lighting.

Some facilities, such as refineries for example, operate 24 hours per day, so lighting is already part of the existing setting. However, additional permanent light sources may be installed on any installation of new equipment, to provide illumination for operations personnel at night, in accordance with applicable safety standards. Similarly, any existing equipment that would be modified as part of the proposed project are located in existing structures or areas that already have lighting systems in place for the same reasons. These additional light sources are not expected to create an impact because each component of the proposed project will be located within an existing industrial facility that operates up to 24 hours per day and the equipment is not restricted to operate during a specific time of day. The proposed project contains no provisions that would require affected equipment to operate differently during existing daytime or nighttime operations. Further, any new lighting that will be installed on the proposed equipment will be consistent in intensity and type with the existing lighting on equipment and other structures within each affected facility. While residential areas are located near some of the affected facilities, any additional lighting will be placed by and focused on the new equipment. For the aforementioned reasons, the proposed project is not expected to create a new source of substantial light or glare that would adversely affect day or nighttime views in the area. Therefore, less than significant impacts to light and glare are expected from the proposed project. Accordingly, this impact issue will not be further analyzed in the Draft PEA. Further, since no significant aesthetics impacts were identified for this issue, no mitigation measures are necessary or required.

Based upon these considerations, significant adverse impacts to aesthetics may occur from implementing the proposed project and thus, impact issue I. c) will be further analyzed in the Draft PEA.

		Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
II.	**AGRICULTURE AND FOREST RESOURCES.** Would the project:				
a)	Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland), as shown on the maps prepared pursuant to the Farmland mapping and Monitoring Program of the California Resources Agency, to non- agricultural use?	☐	☐	☐	☑
b)	Conflict with existing zoning for agricultural use, or a Williamson Act contract?	☐	☐	☐	☑
c)	Conflict with existing zoning for, or cause rezoning of, forest land (as defined in Public Resources Code §12220(g)), timberland (as defined by Public Resources Code §4526), or timberland zoned Timberland Production (as defined by Government Code §51104 (g))?	☐	☐	☐	☑
d)	Result in the loss of forest land or conversion of forest land to non-forest use?	☐	☐	☐	☑

Significance Criteria

Project-related impacts on agriculture and forest resources will be considered significant if any of the following conditions are met:

- The proposed project conflicts with existing zoning or agricultural use or Williamson Act contracts.
- The proposed project will convert prime farmland, unique farmland or farmland of statewide importance as shown on the maps prepared pursuant to the farmland mapping and monitoring program of the California Resources Agency, to non-agricultural use.

- The proposed project conflicts with existing zoning for, or causes rezoning of, forest land (as defined in Public Resources Code §12220 (g)), timberland (as defined in Public Resources Code §4526), or timberland zoned Timberland Production (as defined by Government Code § 51104 (g)).
- The proposed project would involve changes in the existing environment, which due to their location or nature, could result in conversion of farmland to non-agricultural use or conversion of forest land to non-forest use.

Discussion

II. a), b), c), & d) No Impact. Land use, including agriculture- and forest-related uses, and other planning considerations are determined by local governments. While implementation of the proposed project may cause air pollution control equipment to be installed and operated on existing equipment to control NOx emissions, these activities will occur at established NOx RECLAIM facilities which are located on previously developed land in primarily industrial areas and are not located in the vicinity of agricultural or forest areas.

Further, no new construction of buildings or other structures is expected that would require conversion of farmland to non-agricultural use or conflict with zoning for agricultural uses or a Williamson Act contract. Further, because the proposed project does not require construction or operation activities within an area designated as forest land, implementation of the proposed project is not expected to conflict with any forest land zoning codes or convert forest land to non-forest uses. Similarly, there is nothing in the proposed project that would affect or conflict with existing land use plans, policies, or regulations or require conversion of farmland to non-agricultural uses or forest land to non-forest uses. Thus, no agricultural land use or planning requirements will be altered by the proposed project.

Finally, in the event the proposed project is implemented, the installation of NOx control equipment will ensure that projected NOx emission reductions will occur and that air quality in the region will improve. Thus, assuring that these air quality improvements occur could provide benefits to agricultural and forest land resources by reducing the adverse oxidation impacts of ozone on plants and animals located in the Basin. Accordingly, these impact issues will not be further analyzed in the Draft PEA.

Based upon these considerations, significant agricultural and forest resources impacts are not expected from implementing the proposed project, and thus, this topic will not be further analyzed in the Draft PEA. Since no significant agriculture and forest resources impacts were identified for any of the issues, no mitigation measures are necessary or required.

	Potentially Significant Impact	**Less Than Significant With Mitigation**	**Less Than Significant Impact**	**No Impact**
III. AIR QUALITY AND GREENHOUSE GAS EMISSIONS. Would the project:				
a) Conflict with or obstruct implementation of the applicable air quality plan?	☐	☐	☐	☑
b) Violate any air quality standard or contribute to an existing or projected air quality violation?	☑	☐	☐	☐
c) Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is non-attainment under an applicable federal or state ambient air quality standard (including releasing emissions that exceed quantitative thresholds for ozone precursors)?	☑	☐	☐	☐
d) Expose sensitive receptors to substantial pollutant concentrations?	☑	☐	☐	☐
e) Create objectionable odors affecting a substantial number of people?	☑	☐	☐	☐
f) Diminish an existing air quality rule or future compliance requirement resulting in a significant increase in air pollutant(s)?	☐	☐	☐	☑
g) Generate greenhouse gas emissions, either directly or indirectly, that may have a significant impact on the environment?	☑	☐	☐	☐
h) Conflict with an applicable plan, policy or regulation adopted for the purpose of reducing the emissions of greenhouse gases?	☐	☐	☑	☐

Significance Criteria

To determine whether or not air quality and GHG impacts from adopting and implementing the proposed project are significant, impacts will be evaluated and compared to the criteria in Table 2-1. The project will be considered to have significant adverse air quality impacts if any one of the thresholds in Table 2-1 are equaled or exceeded.

Discussion

Upon initial examination of the proposed project, the main focus of this analysis pertains to establishing BARCT for the multiple stationary source categories in the NOx RECLAIM program. To control NOx emissions from these sources, an assortment of technologies may be applied individually or in combination to meet proposed BARCT, depending on the source category, as follows (in alphabetical order): Cheng Low NOx; ClearSign; Dry Low Emissions (DLE or DLN); Flue Gas Recirculation; Great Southern Flameless Heaters; KnowNOx^{TM}; LoTOx^{TM} with scrubber; NOx reducing additives; NSCR; SCR with or without scrubber; SNCR; Staged Combustion/Low NOx Burners; UltraCat; and Water/Steam Injection.

The physical changes involved with the type of NOx emission control strategies that are expected to be utilized focus on the installation of new or the modification of existing control equipment. The possibility of these types of NOx control technologies being used to comply with the proposed project and potential secondary adverse air quality and GHG impacts they may generate will be further evaluated in the Draft PEA. The remaining portions of the proposed project are procedural in nature and will not result in any physical changes that could cause an adverse air quality impact.

III. a) No Impact. The SCAQMD is required by law to prepare a comprehensive district-wide AQMP which includes strategies (e.g., control measures) to reduce emission levels to achieve and maintain state and federal ambient air quality standards, and to ensure that new sources of emissions are planned and operated to be consistent with the SCAQMD's air quality goals. The AQMP's air pollution reduction strategies include control measures which target stationary, mobile and indirect sources. These control measures are based on feasible methods of attaining ambient air quality standards. Pursuant to the provisions of both the state and federal Clean Air Acts, the SCAQMD is required to attain the state and federal ambient air quality standards for all criteria pollutants, including PM10 and PM2.5. Although the District is currently classified as in attainment for both state and federal NO_2 ambient air quality standards, NOx is a precursor pollutant to PM10, PM2.5, and ozone. The proposed project implements 2012 AQMP Control Measure #CMB-01 which will bring the NOx RECLAIM program up-to-date with the latest BARCT requirements to achieve, at a minimum, the proposed NOx emission reductions in #CMB-01 (e.g., at least three to five tons per day by 2023). Therefore, the proposed project will not obstruct or conflict with the implementation of the 2012 AQMP.

Although the proposed project has the potential to temporarily increase criteria pollutants and TAC emissions (as diesel PM) that could exceed the air quality significance thresholds for construction activities, the proposed project is not expected to interfere with achieving at least three to five tons per day of NOx emission reductions by the year 2023, which is consistent with the goals of the 2012 AQMP to achieve additional NOx emission reductions (and reduce NOx precursors as PM 2.5 and PM10) from stationary sources, which will assist in attaining state and federal PM2.5 and PM10 ambient air quality standards. Further, the temporary increase in criteria pollutant and TAC emissions (as diesel PM) due to construction is not expected to impede the emission reduction goals of the 2012 AQMP because the inventory prepared for the 2012 AQMP already takes into account the future emission estimates from all construction activities associated with implementing the proposed control measures[8]. Further, implementation of all other SCAQMD NOx rules along with AQMP control measures, when considered together, is expected to reduce NOx emissions throughout the region overall by 2023. Therefore, implementing the proposed project will not conflict or obstruct implementation of the AQMP. Accordingly, this impact issue will not be further analyzed in the Draft PEA. Further, since no significant impacts were identified for this issue, no mitigation measures are necessary or required.

III. b) Potentially Significant Impact. The objective of the proposed project is to reduce NOx emissions from the top NOx emitting stationary sources in the NOx RECLAIM program. The proposed project is estimated to reduce emissions, at a minimum, of up to three to five tons per day of NOx by 2023 from these affected sources. Compliance with the proposed project is expected to be achieved by applying a wide assortment of NOx technologies, either individually or in combination on the affected sources.

Implementation of the proposed project is expected to involve construction activities related to the installation or modification of the aforementioned NOx control technologies at the top NOx emitting facilities. The proposed project may also involve the construction of new buildings or other structures as part of installation or modification of the NOx controls. Construction-related activities are also expected to generate emissions from worker vehicles, trucks, and construction equipment. Due to the large scale of construction that would be expected from implementing the proposed project, project-specific construction emissions are potentially significant.

While the operational-related activities are expected to reduce emissions of NOx, a simultaneous increase in emissions of other criteria pollutants are expected from operations of stationary support equipment associated with the installed or modified NOx control equipment, as well as operational emissions associated with periodic truck deliveries of supplies and waste haul trips associated with operation and maintenance of the NOx control equipment. Thus, the air quality impacts associated with the construction and operational phases of the proposed project are potentially significant and will be evaluated in the Draft PEA.

III. c) & g) Potentially Significant Impact. The anticipated NOx emission reductions that would result from implementing the proposed project are expected to improve the overall air quality in the Basin by enhancing the probability of attaining and maintaining state and federal ambient air quality standards for PM10 and PM2.5. The primary effect of implementing the proposed project would be the installation of various types of air pollution control equipment to reduce NOx emissions. Because construction equipment may be utilized to install air pollution control equipment, air pollutants, including GHG emissions, would be generated during their use. Some types of air pollution control equipment contemplated by the proposed project could have the potential to create secondary adverse air quality impacts, including GHG emissions. For this reason, operational activities associated with the proposed project also have the potential to increase emissions of air pollutants and GHGs. Thus, while the purpose of the proposed project is to reduce NOx emissions from the top NOx emitting facilities in the NOx RECLAIM program, a simultaneous increase in GHG emissions could occur from the operation of some

[8] SCAQMD Final Program Environmental Impact Report for the 2012 Air Quality Management Plan, SCH# 2012061093, November 2012. http://www.aqmd.gov/home/library/documents-support-material/lead-agency-scaqmd-projects/aqmd-projects---year-2012/aqmp-2012

types of air pollution control equipment, if installed. Thus, the secondary construction and operation impacts associated with reducing NOx have the potential for creating significant adverse cumulative air quality impacts that will be evaluated in the Draft PEA. These potential increases will also be evaluated in the Draft PEA as part of the cumulative impacts discussion.

III. d) Potentially Significant Impact. Emission sources associated with the construction-related activities as a result of implementing the proposed project may temporarily emit TACs. Further, emissions sources associated with the operational-related activities as a result of implementing the proposed project may also emit TACs. The impact of these emissions on sensitive populations, including individuals at hospitals, nursing facilities, daycare centers, schools, and elderly intensive care facilities, as well as residential and off-site occupational areas, will be evaluated in the Draft PEA.

III. e) Potentially Significant Impact. The installation of NOx control equipment could result in combustion-source criteria pollutant emissions from construction activity through the use of heavy-duty construction equipment and from vehicle trips generated by construction workers/haul trucks traveling to and from the project site, as well as fugitive dust emissions related to site work and general grading. Mobile source emissions, primarily NO_x and diesel PM, typically result from the use of diesel-fueled construction equipment such as graders, scrapers, bulldozers, wheeled loaders, cranes, etc. During structure erection/finishing phases, paving operations and the application of architectural coatings (e.g., paints) and other building materials, VOCs would be released. Operation-period impacts, which could include criteria pollutant and TAC emissions from permitted stationary sources, may also occur. Depending on the type of control equipment installed, the proposed project could potentially result in an increase in vehicle trips (both passenger vehicles and trucks) on local roadways, which could in turn result in an increase in operational-period criteria pollutant emissions. As such, the impacts of implementing the proposed project could create objectionable odors affecting a substantial number of people. Thus, the potential impacts of objectionable odors affecting a substantial number of people will be analyzed in the Draft PEA.

III. f) No Impact. The proposed project will be required to comply with all applicable SCAQMD, CARB, and EPA rules and regulations. Thus, the proposed project is not expected to diminish an existing air quality rule or future compliance requirements. Further, adopting and implementing the proposed project enhances existing air pollution control rules that are expected to assist the SCAQMD in its efforts to attain and maintain with a margin of safety the state and federal ambient air quality standards for PM10 and PM2.5. Accordingly, this impact issue will not be further analyzed in the Draft PEA. Further, since no significant impacts were identified for this issue, no mitigation measures are necessary or required.

III. h) Less Than Significant Impact. As mentioned in the discussion in Section III. b), c) and g), construction equipment may be utilized as part of implementing the proposed project and as such, GHG emissions would be generated during their use. Although the primary effect of installing air pollution control equipment is to reduce NOx emissions, some types of control equipment contemplated by the proposed project could also have the potential to create secondary adverse air quality impacts, including GHG emissions. While the purpose of the proposed project is to reduce NOx emissions from the top NOx emitting facilities in the NOx RECLAIM program, a simultaneous increase in GHG emissions could occur from the operation of some types of air pollution control equipment, if installed.

In December 2010, CARB adopted regulations establishing a cap and trade program for the largest sources of GHG emissions in the state that altogether are responsible for about 85 percent of California's GHGs. While the proposed project would not be subject to a GHG reduction plan, all of the affected facilities are currently subject to individual GHG emission reductions pursuant to AB32, the state-wide GHG reduction plan. Among these facilities are fossil-fuel fired power plants, including both plants that generate power within California's borders, and those located outside of California that generate power imported to the state. GHG emissions from this universe of sources were capped for 2013 at a level approximately two percent below the emissions level forecast for 2012, and the cap will steadily decrease at a rate of two to three percent annually from now to 2020. Sources regulated by the cap must reduce their GHG emissions or buy credits from others who have done so. This means that the any additional power needed to operate air pollution control equipment as a result of the proposed project cannot result in an increase in GHG emissions from the increased use of third-party power, compared to GHG emissions at the time of issuance of this NOP/IS. Further, even in the event that some of the affected facilities may experience increases in GHG emissions as a result of implementing the proposed project, the affected facilities would still be required to comply with their overall GHG reduction requirements pursuant to AB32. For these reasons, the proposed project would not conflict with AB32 as well as any applicable GHG reduction plan, policy, and regulations that have been adopted to implement AB32. Accordingly, this impact issue will not be further analyzed in the Draft PEA. Further, since less than significant impacts were identified for this issue, no mitigation measures are necessary or required.

Based upon these considerations, significant adverse impacts to air quality and GHGs may occur from implementing the proposed project and thus, impact issues III. b), c), d), e), and g) will be further analyzed in the Draft PEA.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
IV. BIOLOGICAL RESOURCES. Would the project:				
a) Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Game or U.S. Fish and Wildlife Service?	☐	☐	☐	☑

		Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
b)	Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, or regulations, or by the California Department of Fish and Game or U.S. Fish and Wildlife Service?	☐	☐	☐	☑
c)	Have a substantial adverse effect on federally protected wetlands as defined by §404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means?	☐	☐	☐	☑
d)	Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites?	☐	☐	☐	☑
e)	Conflicting with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance?	☐	☐	☐	☑
f)	Conflict with the provisions of an adopted Habitat Conservation plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan?	☐	☐	☐	☑

Significance Criteria

Impacts on biological resources will be considered significant if any of the following criteria apply:

- The project results in a loss of plant communities or animal habitat considered to be rare, threatened or endangered by federal, state or local agencies.
- The project interferes substantially with the movement of any resident or migratory wildlife species.

- The project adversely affects aquatic communities through construction or operation of the project.

Discussion

IV. a), b), c), & d) No Impact. The proposed project would only affect units operating at the top NOx emitting facilities in the NOx RECLAIM program facilities with locations scattered throughout the District. All of the affected units operating at existing facilities are located primarily in developed industrial areas, which have already been greatly disturbed and paved. These areas currently do not support riparian habitat, federally protected wetlands, or migratory corridors. Additionally, special status plants, animals, or natural communities are not expected to be found within close proximity to the affected facilities. Therefore, the proposed project would have no direct or indirect impacts that could adversely affect plant or animal species or the habitats on which they rely in the SCAQMD's jurisdiction. The current and expected future land use development to accommodate population growth is primarily due to economic considerations or local government planning decisions. A conclusion in the Final Program EIR for the 2012 AQMP was that population growth in the region would have greater adverse effects on plant species and wildlife dispersal or migration corridors in the basin than SCAQMD regulatory activities, (e.g., air quality control measures or regulations). In addition, by reducing air pollutants, biological resources will benefit. Moreover, the current and expected future land use development to accommodate population growth is primarily due to economic considerations or local government planning decisions. Accordingly, these impact issues will not be further analyzed in the Draft PEA.

IV. e) & f) No Impact. The proposed project is not envisioned to conflict with local policies or ordinances protecting biological resources or local, regional, or state conservation plans. Land use and other planning considerations are determined by local governments and no land use or planning requirements will be altered by the proposed project. Additionally, the proposed project will not conflict with any adopted Habitat Conservation Plan, Natural Community Conservation Plan, or any other relevant habitat conservation plan, and would not create divisions in any existing communities because all activities associated with complying with the proposed project will occur at existing industrial facilities. Accordingly, these impact issues will not be further analyzed in the Draft PEA.

Based upon these considerations, significant biological resources impacts are not expected from implementing the proposed project, and thus, this topic will not be further analyzed in the Draft PEA. Since no significant biological resources impacts were identified for any of the issues, no mitigation measures are necessary or required.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
V. CULTURAL RESOURCES. Would the project:				
a) Cause a substantial adverse change in the significance of a historical resource as defined in §15064.5?	☐	☐	☐	☑
b) Cause a substantial adverse change in the significance of an archaeological resource as defined in §15064.5?	☐	☐	☐	☑
c) Directly or indirectly destroy a unique paleontological resource, site, or feature?	☐	☐	☐	☑
d) Disturb any human remains, including those interred outside formal cemeteries?	☐	☐	☐	☑

Significance Criteria

Impacts to cultural resources will be considered significant if:

- The project results in the disturbance of a significant prehistoric or historic archaeological site or a property of historic or cultural significance to a community or ethnic or social group.
- Unique paleontological resources are present that could be disturbed by construction of the proposed project.
- The project would disturb human remains.

Discussion

V. a) No Impact. There are existing laws in place that are designed to protect and mitigate potential impacts to cultural resources. Since construction-related activities associated with the implementation of the proposed project are expected to be confined within the existing footprint of the affected facilities that have been fully developed and paved, no impacts to historical resources are expected to occur as a result of implementing the proposed project. Accordingly, this impact issue will not be further analyzed in the Draft PEA.

V. b), c), & d) No Impact. Installing or modifying add-on controls and other associated equipment to comply with the proposed project may require disturbance of previously disturbed areas at the affected existing industrial facilities. However, since construction-related activities are expected to be confined within the existing footprint of the affected facilities that have been fully developed and paved, the proposed project is not expected to require physical changes to the environment, which may disturb paleontological or archaeological resources. Furthermore, it is envisioned that these areas are already either devoid of significant cultural resources or whose cultural resources have been previously disturbed. Therefore, the proposed project has no potential to cause a substantial adverse change to a historical or archaeological resource, directly or indirectly destroy a unique paleontological resource or site or unique geologic feature, or disturb any human remains, including those interred outside a formal cemeteries. The proposed project is, therefore, not anticipated to result in any activities or promote any programs that could have a significant adverse impact on cultural resources in the District. Accordingly, these impact issues will not be further analyzed in the Draft PEA.

Based upon these considerations, significant cultural resources impacts are not expected from implementing the proposed project, and thus, this topic will not be further analyzed in the Draft PEA. Since no significant cultural resources impacts were identified for any of the issues, no mitigation measures are necessary or required.

		Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
VI.	**ENERGY.** Would the project:				
a)	Conflict with adopted energy conservation plans?	☐	☐	☐	☑
b)	Result in the need for new or substantially altered power or natural gas utility systems?	☑	☐	☐	☐
c)	Create any significant effects on local or regional energy supplies and on requirements for additional energy?	☑	☐	☐	☐
d)	Create any significant effects on peak and base period demands for electricity and other forms of energy?	☑	☐	☐	☐
e)	Comply with existing energy standards?	☐	☐	☐	☑

Significance Criteria

Impacts to energy and mineral resources will be considered significant if any of the following criteria are met:

- The project conflicts with adopted energy conservation plans or standards.
- The project results in substantial depletion of existing energy resource supplies.
- An increase in demand for utilities impacts the current capacities of the electric and natural gas utilities.
- The project uses non-renewable resources in a wasteful and/or inefficient manner.

Discussion

The proposed project would reduce emissions of NOx from various stationary sources at facilities that are the top NOx emitters in the NOx RECLAIM program. The expected options for compliance are either installing or modifying air pollution control equipment appropriate to the type of process unit. Further, it is expected that the installation and operation of any equipment used to comply with the proposed project will also comply with all applicable existing energy standards.

VI. a) & e) No Impact. The proposed project is not subject to any existing energy conservation plans. If a facility that is subject to Regulation XX and the proposed project is also subject to energy conservation plans, it is not expected that the proposed project will affect in any way or interfere with that facility's ability to comply with its energy conservation plan or energy standards. Further, project construction and operation activities will not utilize non-renewable energy resources in a wasteful or inefficient manner. Accordingly, these impact issues will not be further analyzed in the Draft PEA. Further, since no significant impacts were identified for these issues, no mitigation measures are necessary or required.

VI. b), c) & d. **Potentially Significant Impact.** Installation or modification of air pollution control equipment to comply with the proposed project is expected to increase demand for gasoline and diesel fuel to operate construction equipment and to fuel worker vehicles and haul/delivery trucks. In addition, installation or modification of air pollution control equipment to comply with the proposed project is also expected to increase demand for energy used (e.g., electricity) for operating the primary equipment as well as support equipment such as pumps, fans, controllers, et cetera. Any additional electricity required is typically either supplied by each affected facility's cogeneration units, for those that have them, or by the local electrical utility, as appropriate. It is possible that some facilities may need new or substantially altered power utility systems to be built to accommodate any additional electricity demands created by the proposed project. In some cases, an increase in natural gas use may also be needed for operations subject to the proposed project. Finally, operation and maintenance activities associated with operating the installed or modified air pollution control equipment may also increase demand for gasoline and diesel fuel for worker vehicles and haul/delivery trucks.

Based upon these considerations, significant adverse impacts to energy may occur from the implementation of the proposed project and thus, impact issues VI. b), c), and d) will be further analyzed in the Draft PEA.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
VII. GEOLOGY AND SOILS. Would the project:				
a) Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:	☐	☐	☐	☑
• Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault?	☐	☐	☐	☑
• Strong seismic ground shaking?	☐	☐	☐	☑
• Seismic–related ground failure, including liquefaction?	☐	☐	☐	☑
b) Result in substantial soil erosion or the loss of topsoil?	☐	☐	☐	☑
c) Be located on a geologic unit or soil that is unstable or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse?	☐	☐	☐	☑
d) Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property?	☐	☐	☐	☑
e) Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for the disposal of wastewater?	☐	☐	☐	☑

Significance Criteria

Impacts on the geological environment will be considered significant if any of the following criteria apply:

- Topographic alterations would result in significant changes, disruptions, displacement, excavation, compaction or over covering of large amounts of soil.

- Unique geological resources (paleontological resources or unique outcrops) are present that could be disturbed by the construction of the proposed project.
- Exposure of people or structures to major geologic hazards such as earthquake surface rupture, ground shaking, liquefaction or landslides.
- Secondary seismic effects could occur which could damage facility structures, e.g., liquefaction.
- Other geological hazards exist which could adversely affect the facility, e.g., landslides, mudslides.

Discussion

VII. a) No Impact. Since the proposed project would result in construction activities at existing RECLAIM facilities located in developed industrial settings to install or modify NOx control equipment, little site preparation is anticipated that could adversely affect geophysical conditions in the jurisdiction of the SCAQMD. Southern California is an area of known seismic activity. Accordingly, the installation of add-on controls at existing affected facilities to comply with the proposed project is expected to conform to the Uniform Building Code and all other applicable state and local building codes. As part of the issuance of building permits, local jurisdictions are responsible for assuring that the Uniform Building Code is adhered to and can conduct inspections to ensure compliance. The Uniform Building Code is considered to be a standard safeguard against major structural failures and loss of life. The basic formulas used for the Uniform Building Code seismic design require determination of the seismic zone and site coefficient, which represents the foundation condition at the site. The Uniform Building Code requirements also consider liquefaction potential and establish stringent requirements for building foundations in areas potentially subject to liquefaction. Thus, the proposed project would not alter the exposure of people or property to geological hazards such as earthquakes, landslides, mudslides, ground failure, or other natural hazards. As a result, substantial exposure of people or structures to the risk of loss, injury, or death involving the rupture of an earthquake fault, seismic ground shaking, ground failure or landslides is not anticipated. Accordingly, this impact issue will not be further analyzed in the Draft PEA.

VII. b) No Impact. Since add-on controls will likely be installed at existing developed facilities, during construction of the proposed project, a slight possibility exists for temporary erosion resulting from excavating and grading activities, if required. These activities are expected to be minor since the existing facilities are generally flat and have previously been graded and paved. Further, wind erosion is not expected to occur to any appreciable extent, because operators at dust generating sites would be required to comply with the best available control measure (BACM) requirements of SCAQMD Rule 403 – Fugitive Dust. In general, operators must control fugitive dust through a number of soil stabilizing measures such as watering the site, using chemical soil stabilizers, revegetating inactive sites, etc. The proposed project involves the installation or modification of add-on control equipment at existing facilities, so that grading could be required to provide stable foundations. Potential air quality impacts related to grading are addressed elsewhere in this Initial Study (as part of construction air quality impacts). No unstable earth conditions or changes in geologic substructures are expected to result from implementing the proposed project. Accordingly, this impact issue will not be further analyzed in the Draft PEA.

VII. c) No Impact. Since the proposed project will affect existing facilities, it is expected that the soil types present at the affected facilities will not be made further susceptible to expansion or liquefaction. Furthermore, subsidence is not anticipated to be a problem since only minor excavation, grading, or filling activities are expected occur at affected facilities. Additionally, the affected areas are not envisioned to be prone to new landslide impacts or have unique geologic features since the affected equipment units are located at existing facilities in industrial areas. Accordingly, this impact issue will not be further analyzed in the Draft PEA.

VII. d) & e) No Impact. Since the proposed project will affect equipment units at existing facilities located in industrial zones, it is expected that people or property will not be exposed to new impacts related to expansive soils or soils incapable of supporting water disposal. Further, typically each affected facility has some degree of existing wastewater treatment systems that will continue to be used and are expected to be unaffected by the proposed project. Sewer systems are available to handle wastewater produced and treated by each affected facility. Each existing facility affected by the proposed project does not require installation of septic tanks or alternative wastewater disposal systems. As a result, the proposed project will not require facility operators to utilize septic systems or alternative wastewater disposal systems. Thus, implementation of the proposed project will not adversely affect soils associated with a septic system or alternative wastewater disposal system. Accordingly, these impact issues will not be further analyzed in the Draft PEA.

Based upon these considerations, significant geology and soils impacts are not expected from the implementation of the proposed project, and thus, this topic will not be further analyzed in the Draft PEA. Since no significant geology and soils impacts were identified for any of the issues, no mitigation measures are necessary or required.

	Potentially Significant Impact	**Less Than Significant With Mitigation**	**Less Than Significant Impact**	**No Impact**
VIII. HAZARDS AND HAZARDOUS MATERIALS. Would the project:				
a) Create a significant hazard to the public or the environment through the routine transport, use, and disposal of hazardous materials?	☑	☐	☐	☐
b) Create a significant hazard to the public or the environment through reasonably foreseeable upset conditions involving the release of hazardous materials into the environment?	☑	☐	☐	☐

		Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
c)	Emit hazardous emissions, or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school?	☑	☐	☐	☐
d)	Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code §65962.5 and, as a result, would create a significant hazard to the public or the environment?	☐	☐	☑	☐
e)	For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public use airport or a private airstrip, would the project result in a safety hazard for people residing or working in the project area?	☐	☐	☐	☑
f)	Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan?	☐	☐	☐	☑
g)	Expose people or structures to a significant risk of loss, injury or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands?	☐	☐	☐	☑
h)	Significantly increased fire hazard in areas with flammable materials?	☑	☐	☐	☐

Significance Criteria

Impacts associated with hazards will be considered significant if any of the following occur:

- Non-compliance with any applicable design code or regulation.
- Non-conformance to National Fire Protection Association standards.
- Non-conformance to regulations or generally accepted industry practices related to operating policy and procedures concerning the design, construction, security, leak detection, spill containment or fire protection.

- Exposure to hazardous chemicals in concentrations equal to or greater than the Emergency Response Planning Guideline (ERPG) 2 levels.

Discussion

VIII. a) & b) Potentially Significant Impact. In general, the major types of public safety risks associated with hazards and hazardous materials consist of impacts resulting from toxic substance releases, fires, and explosions. At the affected RECLAIM facilities, a number of hazardous materials are currently in use. However, the proposed project may alter the hazards associated with these facilities because new or modified air pollution control equipment and related components could be installed at any or all of the affected facilities such that their operations may increase the quantity of hazardous materials (e.g., catalysts, scrubbing agents) used by the control equipment. In addition, any increases in the shipping, handling, storing, and disposing of hazardous materials inherently poses a certain risk of a release to the environment. Thus, the routine transport of hazardous materials, use, and disposal of hazardous materials may increase as a result of implementing the proposed project.

For example, if the control option chosen by each affected facility operator involves the installation of a wet gas scrubber, the proposed project may alter the transportation modes for catalyst and scrubbing agent feedstock and any other associated chemicals to/from the existing facilities. In addition, since SCR and SNCR technologies utilize ammonia, a toxic air contaminant (TAC) and acutely hazardous material, adverse hazard and hazardous materials impacts could occur as a result of the use, transport and storage of ammonia as well as the potential for an accidental release of ammonia into the environment. Moreover, the utilization of ammonia in these technologies can release unreacted ammonia referred to ammonia slip.

For these reasons, implementation of the proposed project may alter the hazards associated with the existing affected facilities. Therefore, potential hazards impacts as a result of implementing the proposed project are potentially significant and will be addressed in the Draft PEA.

VIII. c) Potentially Significant Impact. Some affected facilities may be located within one-quarter mile of a sensitive receptor (e.g., a day care center). Therefore, a potential for significant impacts from hazardous emissions or the handling of acutely hazardous materials, substances and wastes near sensitive-receptors may occur and will be addressed in the Draft PEA.

VIII. d) Less Than Significant Impact. Government Code §65962.5 refers to the "Hazardous Waste and Substances Site List," which is a list of facilities that may be subject to the Resource Conservation and Recovery Act (RCRA) corrective action program. While none of the affected facilities are included on the list prepared by the Department of Toxic Substances Control (DTSC) pursuant to Government Code §65962.5, some of the facilities are included on a list of RCRA-permitted sites that require corrective action as identified by DTSC. Furthermore, some of the affected facilities may be subject to corrective action under the Spill Cleanup Program (SCP) formerly "Spills, Leaks, Investigation & Cleanup (SLIC) Program" administered by the Regional Water Quality Control Board (RWQCB) pursuant to California Water Code §13304.

In the event that the installation of new or modification of existing air pollution control equipment would involve soil disturbing activities such as grading and excavation during construction of the proposed project, there is the potential for uncovering some contaminated soil. Contaminated soil is defined in SCAQMD Rule 1166 - Volatile Organic Compound Emissions From Decontamination of Soil, as soil with the potential to meet or exceed a VOC concentration of 50 ppmv. Rule 1166 includes requirements for SCAQMD notification at least 24 hours prior to the start of excavation activities, monitoring (at least once every 15 minutes, within three inches of the excavated soil surface), as well as implementation of a mitigation plan when VOC-contaminated soil is detected. To ensure compliance with SCAQMD Rule 1166, the affected facility or a construction contractor will need to obtain a pre-approved SCAQMD Rule 1166 VOC-Contaminated Soil Mitigation Plan (Plan) in order to assure that fugitive emissions will be controlled prior to the start of excavation activities. In general, a SCAQMD Rule 1166 Plan will require the contaminated soil pile to be covered with heavy plastic sheeting and will include watering requirements to assure the soil remains moist and will require removal of the VOC-contaminated soils from the disturbed site within 30 days from the time of excavation.

Soil remediation activities are also under the jurisdiction of the RWQCB and are implemented via a Soil Management Plan for the management of small quantities of contaminated soil. Following SCAQMD approval of a Rule 1166 Plan, a Soil Management Plan will need to be submitted to the RWQCB for approval. The RWQCB, when considering the Soil Management Plan, relies on the analysis in this CEQA document and the SCAQMD Rule 1166 Plan.

In the event that any excavated soils contain concentrations of certain substances, such as heavy metals and hydrocarbons, the handling, processing, transportation and disposal of the contaminated soil would also be subject to applicable hazardous waste regulations (i.e., Title 22 of the California Code of Regulations and other local and federal rules). Title 22, Division 4.5 - Environmental Health Standards for the Management of Hazardous Waste has multiple requirements for hazardous waste characterization, handling, transport, and disposal, such as requirements to use approved disposal and treatment facilities, to use certified hazardous waste transporters, and to have manifests for tracking the hazardous materials. If discovered, contaminated excavated soil would be properly characterized to determine an appropriate offsite processing method(s). These methods may include recycling of the soil if it is considered a non-hazardous waste, off-site treatment to reduce the contaminant concentrations to non-hazardous levels so that the treated soil could be used as landfill cover, or disposal as a hazardous waste at a permitted hazardous waste facility.

In addition, there are other regulatory requirements that address the discovery and remediation of contaminated sites, including the discovery of such sites during construction activities. Further, health and safety plans, worker training, and various other activities which serve to protect workers from exposure to contamination are also required. The following federal and state regulatory requirements are specific to worker protection and contaminated soil discovery:

- Hazardous Waste Operations and Emergency Response Standard (HAZWOPER, Fed-OSHA, 29 CFR 1910.120 and Cal-OSHA HAZWOPER, 8 CCR 5192) including the requirements for health and safety plans, worker training, evaluation of the potential for chemical exposure, and physical hazards at the site.

- Resource Conservation and Recovery Act and Associated Hazardous and Solid Waste Amendments (40 CFR 260) are the federal laws and regulations that govern the generation, transportation, treatment, and disposal of hazardous waste.

- Hazardous Waste Control Law (California Health and Safety Code, Chapter 6.5) governs the generation, transportation, treatment, and disposal of hazardous waste.

- Cal-OSHA Construction Worker Safety Orders in Title 8 CCR including Permissible Exposure Levels (8 CCR 5155), injury and illness prevention plans, and workplace safety.

Hazardous wastes from the existing affected facilities are required to be managed in accordance with applicable federal, state, and local rules and regulations. Thus, while the types of additional waste that may be generated from implementing the proposed project could potentially change from the existing setting, the affected facilities would still be required to comply with all of the aforementioned regulations. For example, if the use of a new or increased use of an existing catalyst is needed to operate the installed or modified air pollution control equipment, for those affected facilities which already use catalyst for other operational activities on-site, the additional collected spent catalyst will continue to be handled in the same manner as currently handled such that it will be disposed and/or recycled at approved facilities. Further, if any of other affected facilities are new to handling catalyst waste, the same disposal/recycling procedures are expected to be followed.

For any affected RECLAIM facility that is designated pursuant to Government Code §65962.5 as a large quantity generator of hazardous waste, complying with the proposed project will not alter in any way how each facility would manage their hazardous wastes and each affected facility would be expected to continue to be managed in accordance with all applicable federal, state, and local rules and regulations. Similarly, for any affected RECLAIM facility that is not designated pursuant to Government Code §65962.5 as a large quantity generator, implementing the proposed project would not change a facility's status regarding hazardous waste generation. Thus, implementing the proposed project would not be expected to interfere with site cleanup activities or create additional site contamination. Thus, for the aforementioned reasons, less than significant hazards impacts from the soil disturbing activities as well as the disposal and/or recycling of hazardous materials are expected from implementing the proposed project. Accordingly, this impact issue will not be further analyzed in the Draft PEA. Further, since no significant impacts were identified for this issue, no mitigation measures are necessary or required.

VIII. e) No Impact. Federal Aviation Administration, 14 CFR Part 77 – Safe, Efficient Use and Preservation of the Navigable Airspace[9], provides information regarding the types of projects that may affect navigable airspace. Projects may adversely affect navigable airspace if they involve construction or alteration of structures greater than 200 feet above ground level within a specified distance from the nearest runway or objects within 20,000 feet of an airport or seaplane base with at least one runway more than 3,200 feet in length and the object would exceed a slope of 100:1 horizontally (100 feet horizontally for each one foot vertically from the nearest point of the runway).

[9] Department of Transportation. Federal Aviation Administration, 14 CFR Part 77 [Docket No. FAA–2006–25002; Amendment No. 77–13] RIN 2120–AH31. *Safe, Efficient Use and Preservation of the Navigable Airspace*. 42296 Federal Register / Vol. 75, No. 139 / Wednesday, July 21, 2010 / Rules and Regulations. http://www.gpo.gov/fdsys/pkg/FR-2010-07-21/pdf/2010-17767.pdf.

Construction activities from implementing the proposed project are expected to occur within the existing confines of the affected facilities. However, some of these facilities may be located within two miles of an airport (either public or private) and are located within an airport land use plan. Nonetheless, the installation of the NOx control devices is expected to be constructed according to the all appropriate building, land use and fire codes and operated at a low enough height relative to existing flight patterns so that the structure would not interfere with plane flight paths consistent with Federal Aviation Regulation, Part 77. Such codes are designed to protect the public from hazards associated with normal operation. Therefore, the proposed project is not expected to result in a safety hazard for people residing or working in the area of the affected facilities even if construction would occur within the vicinity of an airport. Accordingly, this impact issue will not be further analyzed in the Draft PEA. Further, since no significant impacts were identified for this issue, no mitigation measures are necessary or required.

VIII. f) No Impact. Health and Safety Code §25506 specifically requires all businesses handling hazardous materials to submit a business emergency response plan to assist local administering agencies in the emergency release or threatened release of a hazardous material. Business emergency response plans generally require the following:

- Identification of individuals who are responsible for various actions, including reporting, assisting emergency response personnel and establishing an emergency response team;
- Procedures to notify the administering agency, the appropriate local emergency rescue personnel, and the California Office of Emergency Services;
- Procedures to mitigate a release or threatened release to minimize any potential harm or damage to persons, property or the environment;
- Procedures to notify the necessary persons who can respond to an emergency within the facility;
- Details of evacuation plans and procedures;
- Descriptions of the emergency equipment available in the facility;
- Identification of local emergency medical assistance; and
- Training (initial and refresher) programs for employees in:
  1. The safe handling of hazardous materials used by the business;
  2. Methods of working with the local public emergency response agencies;
  3. The use of emergency response resources under control of the handler;
  4. Other procedures and resources that will increase public safety and prevent or mitigate a release of hazardous materials.

In general, every county or city and all facilities using a minimum amount of hazardous materials are required to formulate detailed contingency plans to eliminate, or at least minimize, the possibility and effect of fires, explosion, or spills. In conjunction with the California Office of Emergency Services, local jurisdictions have enacted ordinances that set standards for area and business emergency response plans. These requirements include immediate notification, mitigation of an actual or threatened release of a hazardous material, and evacuation of the emergency area. Emergency response plans are typically prepared in coordination with the local city or county emergency plans to ensure the safety of not only the public (surrounding local communities), but the facility employees as well.

The existing industrial facilities affected by the proposed project already have their own emergency response plans in place. The proposed project would not impair implementation of, or physically interfere with any adopted emergency response plan or emergency evacuation plan. However, depending on the physical changes that may be taken in order to reduce NOx emissions such as installing NOx control equipment, an affected facility's emergency response plan may need to be updated to accommodate any changes that may occur. For example, if additional storage of hazardous materials (e.g., ammonia) is needed in order to operate a new SCR unit at an affected facility, then such modifications may require a revision to an affected facility's emergency response plan. However, these modifications would not be expected to interfere with the existing emergency response procedures in place.

Thus, the proposed project is not expected to impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan, but may require changes or updates. Accordingly, this impact issue will not be further analyzed in the Draft PEA. Further, since no significant impacts were identified for this issue, no mitigation measures are necessary or required.

VIII. g) No Impact. Flammable materials such as natural gas, diesel and gasoline are currently used at several of the affected facilities and additional fuels may be used during either construction or operation of the proposed project. While the hazards associated with these fuels could result in a torch fire in the event that a release occurred and caught fire, a torch fire would be expected to remain on-site because the affected RECLAIM facilities are located at existing, established industrial sites in urban areas where wildlands are not prevalent. In addition, no substantial or native vegetation typically exists on or near the affected facilities (specifically because they could be a fire hazard), so the proposed project is not expected to expose people or structures to wild fires. For these reasons, the proposed project is not expected to increase the existing risk of fire hazards in areas with flammable brush, grass, or trees, so there would be no public exposure to fire hazards and as such no risk of loss or injury associated with wildland fires would be expected. Accordingly, this impact issue will not be further evaluated in the Draft PEA. Further, since no significant impacts were identified for this issue, no mitigation measures are necessary or required.

VIII. h) Potentially Significant Impact. The Uniform Fire Code and Uniform Building Code set standards intended to minimize risks from flammable or otherwise hazardous materials. Local jurisdictions are required to adopt the uniform codes or comparable regulations. Local fire agencies require permits for the use or storage of hazardous materials and permit modifications for proposed increases in their use. Permit conditions depend on the type and quantity of the hazardous materials used. Permit conditions may include, but are not limited to, specifications for sprinkler systems, electrical systems, ventilation, and containment. The fire departments make annual business inspections to ensure compliance with permit conditions and other appropriate regulations. Further, businesses are required to report increases in the storage or use of flammable and otherwise hazardous materials to local fire departments. Local fire departments ensure that adequate permit conditions are in place to protect against the potential risk of upset.

For any affected facility that installs NOx control equipment as a result of implementing the proposed project, the increased transport, handling, or use of flammable or hazardous materials could occur. For example, for control equipment that utilizes ammonia (e.g., SCR or SNCR), explosion risks resulting from the industrial handling of aqueous ammonia solutions could increase. As such, the potential for increased probability of explosion, fire, or other hazards will be addressed in the Draft PEA. Impacts related to public exposure to toxic air contaminants will be addressed in the "Air Quality and Greenhouse Gas" section of the Draft PEA.

Based upon these considerations, significant adverse impacts to hazards and hazardous materials may occur from implementing the proposed project and thus, impact issues VIII. a), b), c), and h) will be further analyzed in the Draft PEA.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
IX. HYDROLOGY AND WATER QUALITY. Would the project:				
a) Violate any water quality standards, waste discharge requirements, exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board, or otherwise substantially degrade water quality?	☑	☐	☐	☐
b) Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g. the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted)?	☑	☐	☐	☐
c) Substantially alter the existing drainage pattern of the site or area, including through alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in substantial erosion or siltation on- or off-site or flooding on- or off-site?	☐	☐	☑	☐

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
d) Create or contribute runoff water which would exceed the capacity of existing or planned storm water drainage systems or provide substantial additional sources of polluted runoff?	☐	☐	☑	☐
e) Place housing or other structures within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map, which would impede or redirect flood flows?	☐	☐	☐	☑
f) Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of the failure of a levee or dam, or inundation by seiche, tsunami, or mudflow?	☐	☐	☐	☑
g) Require or result in the construction of new water or wastewater treatment facilities or new storm water drainage facilities, or expansion of existing facilities, the construction of which could cause significant environmental effects?	☑	☐	☐	☐
h) Have sufficient water supplies available to serve the project from existing entitlements and resources, or are new or expanded entitlements needed?	☑	☐	☐	☐
i) Result in a determination by the wastewater treatment provider which serves or may serve the project that it has adequate capacity to serve the project’s projected demand in addition to the provider’s existing commitments?	☑	☐	☐	☐

Significance Criteria

Potential impacts on water resources will be considered significant if any of the following criteria apply:

Water Demand:

- The existing water supply does not have the capacity to meet the increased demands of the project, or the project would use more than 262,820 gallons per day of potable water.
- The project increases demand for total water by more than five million gallons per day.

Water Quality:

- The project will cause degradation or depletion of ground water resources substantially affecting current or future uses.
- The project will cause the degradation of surface water substantially affecting current or future uses.
- The project will result in a violation of National Pollutant Discharge Elimination System (NPDES) permit requirements.
- The capacities of existing or proposed wastewater treatment facilities and the sanitary sewer system are not sufficient to meet the needs of the project.
- The project results in substantial increases in the area of impervious surfaces, such that interference with groundwater recharge efforts occurs.
- The project results in alterations to the course or flow of floodwaters.

Discussion

IX. a), g) & i) Potentially Significant Impact. In the event that the proposed project is implemented, operators of the affected RECLAIM facilities may install new or modify existing air pollution control equipment to reduce NOx emissions. Operational activities associated with some types of NOx control equipment utilize water such that if there is an increase in the demand for water, a subsequent increase in the amount wastewater discharged at an affected facility may occur. For example, water/steam injection and WGS technology both utilize water in their processes. In addition, operators of the affected RECLAIM facilities could choose to install control equipment that utilize SCR or SNCR, which both utilize ammonia, a TAC and acutely hazardous material, that if spilled, an accidental ammonia release into the environment could cause adverse water quality impacts.

Depending on the type of NOx controls employed, the impacts of the proposed project on each affected facility's wastewater discharge and the Industrial Wastewater Discharge Permit could be potentially significant. Thus, implementing the proposed project may result in the potential for generating increased volumes of wastewater that could adversely affect water quality standards or waste discharge requirements resulting in the need for new or increased wastewater treatment capacity. Accordingly, these topic areas will be evaluated further in the Draft PEA.

IX. b) & h) Potentially Significant Impact. In the event that the proposed project is implemented, operators of the affected RECLAIM facilities may install new or modify existing air pollution control equipment to reduce NOx emissions. Construction activities associated with the proposed project may require site preparation/earthmoving activities such as grading and the limited use of water may be utilized as a dust suppressant. In addition, operational activities associated with some types of NOx control equipment utilize water such that there may be an increase in the demand for water. For example, water/steam injection and WGS technology both utilize water in their processes.

In addition, each affected facility may not have sufficient water supplies available for implementing the proposed project since WGSs could be installed along with NOx control equipment at the affected facilities and WGSs heavily rely on water for their operation. Thus, the need for new or expanded water supply entitlements may be necessary. While it is not possible to predict water availability in the future, existing entitlements and resources in the district are currently at historically low drought levels. Thus, the water demand that would result from implementing the proposed project may result in significant adverse water impacts.

Thus, implementing the proposed project would require additional water, some of which could come from ground water supplies, require new water supply facilities, or require an expansion of existing water supply facilities. Accordingly, these topic areas are potentially significant and as such, will be evaluated further in the Draft PEA.

IX. c) & d) Less Than Significant Impact. Changes to each affected RECLAIM facility's storm water collection systems are expected to be less than significant since most of the changes that may be associated with the proposed project will occur within existing units (e.g., by installing NOx control equipment). Further, typically most of the areas likely to be affected by the proposed project are currently paved and are expected to remain paved. Any new units constructed will be curbed and the existing units will remain curbed to contain any runoff. Any runoff occurring will continue to be handled by each affected facility's wastewater system and sent to an on-site wastewater treatment system prior to discharge. The surface water runoff is expected to be handled with each affected facility's current wastewater treatment system. Storm water runoff will be collected and discharged in accordance with each facility's discharge permit terms and conditions. Storm Water Pollution Prevention Plans may need to be updated, as necessary, to reflect any operational modifications and included additional Best Management Practices, if required. Thus, the proposed project would not be expected to substantially increase the rate or amount of surface runoff in a manner that would result in substantial erosion or siltation on- or off-site or flooding on- or off-site. Further, any construction that may occur as a result of implementing the proposed project will occur at the existing affected facilities, and as such, would not involve modifications that would alter the course of a stream or river.

Therefore, less than significant storm water quality impacts may result from the operation of the proposed project. Accordingly, these impact issues will not be further evaluated in the Draft PEA. Further, since no significant impacts were identified for these issues, no mitigation measures are necessary or required.

IX. e) No Impact. Once implemented, the proposed project is not expected to require additional workers, except during construction activities. Further, the proposed project is expected to involve construction activities located at the affected RECLAIM facilities and would not require the construction of any new housing so it would not place new housing in 100-year flood areas as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood delineation map. Since the proposed project would not require locating new facilities within a flood zone, it is not expected that implementation of the proposed project would expose people or property to any known water-related flood hazards.

As a result, the proposed project would not be expected to create or substantially increase risks from flooding or expose people or structures to significant risk of loss, injury or death involving flooding. Consequently, this topic will not be evaluated further in the Draft PEA. Further, since no significant impacts were identified for this issue, no mitigation measures are necessary or required.

IX. f) No Impact. The proposed project does not require construction in areas that could be affected by tsunamis. Of the RECLAIM facilities affected by the proposed project, some are located near the Ports of Long Beach, Los Angeles, and San Pedro. The port areas are protected from tsunamis by the construction of breakwaters. Construction of breakwaters combined with the distance of each facility from the water is expected to minimize the potential impacts of a tsunami or seiche so that no significant impacts are expected. The proposed project does not require construction of facilities in areas that are susceptible to mudflows (e.g., hillside or slope areas). Existing affected facilities that are currently located on hillsides or slope areas may be susceptible to mudflow, but this would be considered part of the existing setting. As a result, the proposed project is not expected to generate significant adverse mudflow impacts. Finally, the proposed project will not affect in any way any potential flood hazards inundation by seiche, tsunami, or mud flow that may already exist at the affected RECLAIM facilities. Accordingly, this impact issue will not be further evaluated in the Draft PEA. Further, since no significant impacts were identified for this issue, no mitigation measures are necessary or required.

Based upon these considerations, significant adverse impacts to hydrology and water quality may occur from implementing the proposed project and thus, impact issues IX. a), b), g), h), and i) will be further analyzed in the Draft PEA.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
X. LAND USE AND PLANNING. Would the project:				
a) Physically divide an established community?	☐	☐	☐	☑
b) Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to the general plan, specific plan, local coastal program or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect?	☐	☐	☐	☑

Significance Criteria

Land use and planning impacts will be considered significant if the project conflicts with the land use and zoning designations established by local jurisdictions.

Discussion

X. a) No Impact. The proposed project does not require the construction of new facilities, but any physical effects that will result from the proposed project, will occur at existing RECLAIM facilities located in heavy industrial areas and would not be expected to go beyond existing boundaries. Thus, implementing the proposed project will not result in physically dividing any established communities.

X. b) No Impact. There are no provisions in the proposed project that would affect land use plans, policies, or regulations. Land use and other planning considerations are determined by local governments and no land use or planning requirements will be altered by the proposed project. Further, the proposed project would be consistent with the typical industrial zoning of the affected facilities. Typically, all proposed construction activities are expected to occur within the confines of the existing facilities. The proposed project would not affect in any way habitat conservation or natural community conservation plans, agricultural resources or operations, and would not create divisions in any existing communities. Further, no new development or alterations to existing land designations will occur as a result of the implementation of the proposed project. Therefore, present or planned land uses in the region will not be affected as a result of implementing the proposed project.

Based upon these considerations, significant land use planning impacts are not expected from the implementation of the proposed project, and thus, will not be further analyzed in the Draft PEA. Further, since no significant impacts were identified for any of these issues, no mitigation measures are necessary or required.

		Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
XI.	**MINERAL RESOURCES.** Would the project:				
a)	Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state?	☐	☐	☐	☑
b)	Result in the loss of availability of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan?	☐	☐	☐	☑

Significance Criteria

Project-related impacts on mineral resources will be considered significant if any of the following conditions are met:

- The project would result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state.
- The proposed project results in the loss of availability of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan.

Discussion

XI. a) & b) No Impact. There are no provisions in the proposed project that would result in the loss of availability of a known mineral resource of value to the region and the residents of the state such as aggregate, coal, clay, shale, et cetera, or of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan.

Based upon these considerations, significant mineral resource impacts are not expected from the implementation of the proposed project, and thus, will not be further analyzed in the Draft PEA. Since no significant mineral resource impacts were identified for any of these issues, no mitigation measures are necessary or required.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
XII. NOISE. Would the project result in:				
a) Exposure of persons to or generation of permanent noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies?	☐	☐	☑	☐
b) Exposure of persons to or generation of excessive groundborne vibration or groundborne noise levels?	☐	☐	☑	☐
c) A substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project?	☐	☐	☑	☐

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
d) For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public use airport or private airstrip, would the project expose people residing or working in the project area to excessive noise levels?	☐	☐	☑	☐

Significance Criteria

Noise impact will be considered significant if:

- Construction noise levels exceed the local noise ordinances or, if the noise threshold is currently exceeded, project noise sources increase ambient noise levels by more than three decibels (dBA) at the site boundary. Construction noise levels will be considered significant if they exceed federal Occupational Safety and Health Administration (OSHA) noise standards for workers.
- The proposed project operational noise levels exceed any of the local noise ordinances at the site boundary or, if the noise threshold is currently exceeded, project noise sources increase ambient noise levels by more than three dBA at the site boundary.

Discussion

XII. a), b), & c) Less Than Significant Impact. Modifications or changes associated with the implementation of the proposed project will take place at existing RECLAIM facilities that are located in heavy industrial settings. The existing noise environment at each of the affected facilities is typically dominated by noise from existing equipment onsite, vehicular traffic around the facilities, and trucks entering and exiting facility premises. Construction activities associated with implementing the proposed project may generate some noise associated with the use of construction equipment and construction-related traffic. However, noise from the proposed project is not expected to produce noise in excess of current operations at each of the existing facilities. If NOx control devices are installed or existing devices are modified, the operations phase of the proposed project may add new sources of noise to each affected facility. However, control devices are not typically equipment that generate substantial amounts of noise. Nonetheless, for any noise that may be generated by the control devices, it is expected that each facility affected will comply with all existing noise control laws or ordinances. Further, Occupational Safety and Health Administration (OSHA) and California-OSHA (Cal/OSHA) have established noise standards to protect worker health. These potential noise increases are expected within the allowable noise levels established by the local noise ordinances for industrial areas, and thus are expected to be less than significant. Therefore, less than significant noise impacts are expected to result from the operation of the proposed project will not be further evaluated in the Draft PEA. Accordingly, these impact issues will not be further evaluated in the Draft PEA.

XII. d) Less Than Significant Impact. Though some of the facilities affected by the proposed project are located at sites within an airport land use plan, or within two miles of a public airport, the addition of new or modification of existing NOx control equipment would not expose people residing or working in the project area to the same degree of excessive noise levels associated with airplanes. All noise producing equipment must comply with local noise ordinances and applicable OSHA or Cal/OSHA workplace noise reduction requirements. Therefore, less than significant noise impacts are expected to occur at sites located within an airport land use plan, or within two miles of a public airport. Accordingly, this impact issue will not be further evaluated in the Draft PEA.

Based upon these considerations, significant noise impacts are not expected from the implementation of the proposed project and will not be further analyzed in the Draft PEA. Further, since no significant impacts were identified for any of these issues, no mitigation measures are necessary or required.

		Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
XIII.	**POPULATION AND HOUSING.** Would the project:				
a)	Induce substantial growth in an area either directly (for example, by proposing new homes and businesses) or indirectly (e.g. through extension of roads or other infrastructure)?	☐	☐	☐	☑
b)	Displace substantial numbers of people or existing housing, necessitating the construction of replacement housing elsewhere?	☐	☐	☐	☑

Significance Criteria

Impacts of the proposed project on population and housing will be considered significant if the following criteria are exceeded:

- The demand for temporary or permanent housing exceeds the existing supply.
- The proposed project produces additional population, housing or employment inconsistent with adopted plans either in terms of overall amount or location.

Discussion

XIII. a) No Impact. The construction activities associated with the proposed project at each affected facility are not expected to involve the relocation of individuals, require new housing or commercial facilities, or change the distribution of the population. The reason for this conclusion is that operators of affected facilities who need to perform any construction activities to comply with the proposed project can draw from the large existing labor pool in the local southern California area. Further, it is not expected that the installation of new or the modification of existing NOx control equipment will require new employees during operation of the equipment. In the event that new employees are hired, it is expected that the number of new employees at any one facility would be small. Human population within the jurisdiction of the SCAQMD is anticipated to grow regardless of implementing the proposed project. As a result, the proposed project is not anticipated to generate any significant adverse effects, either direct or indirect, on population growth in the district or population distribution.

XIII. b) & c) No Impact. Because the proposed project includes modifications and/or changes at existing facilities located in heavy industrial settings, the proposed project is not expected to result in the creation of any industry that would affect population growth, directly or indirectly induce the construction of single- or multiple-family units, or require the displacement of people or housing elsewhere in the district.

Based upon these considerations, significant population and housing impacts are not expected from the implementation of the proposed project, and thus, will not be further evaluated in the Draft PEA. Since no significant population and housing impacts were identified for any of these issues, no mitigation measures are necessary or required.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
XIV. PUBLIC SERVICES. Would the proposal result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, need for new or physically altered government facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives for any of the following public services:				
a) Fire protection?	☐	☐	☑	☐
b) Police protection?	☐	☐	☑	☐
c) Schools?	☐	☐	☐	☑
d) Other public facilities?	☐	☐	☐	☑

Significance Criteria

Impacts on public services will be considered significant if the project results in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, or the need for new or physically altered government facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response time or other performance objectives.

Discussion

XIV. a) & b) Less Than Significant Impact. Implementation of the proposed project is expected to cause facility operators to install new or modify existing NOx control devices, all the while continuing current operations at existing affected facilities. The proposed project may result in a greater demand for catalyst, scrubbing agents and other chemicals, which will need to be transported to the affected facilities to support the function of NOx control equipment and stored onsite prior to use. As first responders to emergency situations, police and fire departments may assist local hazmat teams with containing hazardous materials, putting out fires, and controlling crowds to reduce public exposure to releases of hazardous materials. In addition, emergency or rescue vehicles operated by local, state, and federal law enforcement agencies, police and sheriff departments, fire departments, hospitals, medical or paramedic facilities, that are used for responding to situations where potential threats to life or property exist, including, but not limited to fire, ambulance calls, or life-saving calls, may be needed in the event of an accidental release or other emergency. While the specific nature or degree of such impacts is currently unknown, the affected facilities have existing emergency response plans so any changes to those plans would not be expected to dramatically alter how emergency personnel would respond to an accidental release or other emergency. In addition, due the low probability and unpredictable nature of accidental releases, the proposed project is not expected to increase the need or demand for additional public services (e.g., fire and police departments and related emergency services, et cetera) above current levels. Accordingly, these impact issues will not be further evaluated in the Draft PEA.

XIV. c) No Impact. As noted in the previous "Population and Housing" discussion, the proposed project is not expected to induce population growth in any way because the local labor pool (e.g., workforce) is expected to be sufficient to accommodate any construction activities that may be necessary at affected facilities and operation of new or modified NOx control equipment is not expected to require additional employees. Therefore, there will be no increase in local population and thus no impacts are expected to local schools or parks. Accordingly, this impact issue will not be further evaluated in the Draft PEA.

XIV. d) No Impact. The proposed project is expected to result in the use of new or modified add-on control equipment for NOx control. Besides permitting the equipment or altering permit conditions by the SCAQMD, there is no need for other types of government services. The proposed project would not result in the need for new or physically altered government facilities in order to maintain acceptable service ratios, response times, or other performance objectives. There will be no increase in population and, therefore, no need for physically altered government facilities. Accordingly, this impact issue will not be further evaluated in the Draft PEA.

Based upon these considerations, significant public services impacts are not expected from the implementation of the proposed project and will not be further evaluated in the Draft PEA. Since no significant public services impacts were identified for any of these issues, no mitigation measures are necessary or required.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
XV. RECREATION.				
a) Would the project increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated?	☐	☐	☐	☑
b) Does the project include recreational facilities or require the construction or expansion of recreational facilities that might have an adverse physical effect on the environment or recreational services?	☐	☐	☐	☑

Significance Criteria

Impacts to recreation will be considered significant if:

- The project results in an increased demand for neighborhood or regional parks or other recreational facilities.
- The project adversely affects existing recreational opportunities.

Discussion

XV. a) & b) No Impact. As discussed earlier under the topic of "Population and Housing," there are no provisions in the proposed project that would affect or increase the demand for or use of existing neighborhood and regional parks or other recreational facilities or require the construction of new or the expansion of existing recreational facilities that might have an adverse physical effects on the environment because the proposed project will not directly or indirectly increase or redistribute population. Based upon these considerations, including the conclusion of "no impact" for the topic of "Population and Housing," significant recreation impacts are not expected from implementing the proposed project, and thus, this topic will not be further analyzed in the Draft PEA. Since no significant recreation impacts were identified, no mitigation measures are necessary or required.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
XVI. SOLID AND HAZARDOUS WASTE. Would the project:				
a) Be served by a landfill with sufficient permitted capacity to accommodate the project's solid waste disposal needs?	☑	☐	☐	☐
b) Comply with federal, state, and local statutes and regulations related to solid and hazardous waste?	☐	☐	☐	☑

Significance Criteria

The proposed project impacts on solid and hazardous waste will be considered significant if the following occurs:

- The generation and disposal of hazardous and non-hazardous waste exceeds the capacity of designated landfills.

Discussion

XVI. a) Potentially Significant Impact. Construction activities associated with installing new or modifying existing NOx control equipment such as demolition and site preparation/grading/excavating could generate solid waste as result of implementing the proposed project. Demolition activities could generate demolition waste while site preparation, grading, and excavating could uncover contaminated soils since the facilities affected by the proposed project are located in existing heavy industrial areas. Excavated soil, which may be contaminated, will need to be characterized, treated, and disposed of offsite in accordance with applicable regulations. Where appropriate, the soil will be recycled if it is considered or classified as non-hazardous waste or it can be disposed of at a landfill that accepts non-hazardous waste. Otherwise, the material will need to be disposed of at a hazardous waste facility. (Potential soil contamination is addressed in the Hazards and Hazardous Materials discussion in Section VIII. d.)

Solid or hazardous wastes generated from construction-related activities would consist primarily of materials from the demolition and/or alteration of any existing structure to make room for the new equipment to be installed. Construction-related waste would be disposed of at a Class II (industrial) or Class III (municipal) landfill. In addition, the generation of solid or hazardous waste could occur if air pollution control equipment is installed that relies on activated carbon, filters, and catalysts to function.

Solid waste impacts would be significant if the additional potential waste volume exceeded the existing capacity of landfills in the District. The potential solid and hazardous waste impacts from implementing the proposed project will be analyzed in the Draft PEA.

XVI. b) No Impact. Implementation of the proposed project is not expected to interfere with the affected RECLAIM facilities' abilities to comply with federal, state, or local statutes and regulations related to solid and hazardous waste handling or disposal. Further, nothing in the proposed project would interfere with the compliance requirements for waste handling or disposal. Thus, this specific topic will not be further evaluated in the Draft PEA. Since no significant solid and hazardous waste impacts were identified for this topic, no mitigation measures are necessary or required.

Based upon these considerations, significant adverse impacts to solid and hazardous waste may occur from implementing the proposed project and thus, impact issue XVI. a) will be further analyzed in the Draft PEA.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
XVII. TRANSPORTATION AND TRAFFIC. Would the project:				
a) Conflict with an applicable plan, ordinance or policy establishing measures of effectiveness for the performance of the circulation system, taking into account all modes of transportation including mass transit and non-motorized travel and relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass transit?	☑	☐	☐	☐
b) Conflict with an applicable congestion management program, including but not limited to level of service standards and travel demand measures, or other standards established by the county congestion management agency for designated roads or highways?	☑	☐	☐	☐
c) Result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks?	☐	☐	☐	☑

		Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
d)	Substantially increase hazards due to a design feature (e.g. sharp curves or dangerous intersections) or incompatible uses (e.g. farm equipment)?	☐	☐	☐	☑
e)	Result in inadequate emergency access?	☐	☐	☐	☑
f)	Conflict with adopted policies, plans, or programs regarding public transit, bicycle, or pedestrian facilities, or otherwise decrease the performance or safety of such facilities?	☐	☐	☐	☑

Significance Criteria

Impacts on transportation and traffic will be considered significant if any of the following criteria apply:

- Peak period levels on major arterials are disrupted to a point where level of service (LOS) is reduced to D, E or F for more than one month.
- An intersection's volume to capacity ratio increase by 0.02 (two percent) or more when the LOS is already D, E or F.
- A major roadway is closed to all through traffic, and no alternate route is available.
- The project conflicts with applicable policies, plans or programs establishing measures of effectiveness, thereby decreasing the performance or safety of any mode of transportation.
- There is an increase in traffic that is substantial in relation to the existing traffic load and capacity of the street system.
- The demand for parking facilities is substantially increased.
- Water borne, rail car or air traffic is substantially altered.
- Traffic hazards to motor vehicles, bicyclists or pedestrians are substantially increased.
- The need for more than 350 employees
- An increase in heavy-duty transport truck traffic to and/or from the facility by more than 350 truck round trips per day
- Increase customer traffic by more than 700 visits per day.

Discussion

XVII. a) & b) Potentially Significant Impact. Construction activities resulting from implementing the proposed project may generate a temporary increase in traffic in the areas of each affected facility associated with construction workers, construction equipment, and the delivery of construction materials. Also, the proposed project may exceed, either individually or cumulatively, the current level of service of the areas surrounding the affected facilities. The impacts of the traffic load and capacity of the street system during construction will be analyzed in the Draft PEA.

The work force at each affected facility is not expected to significantly increase during operations of the proposed project operations because few, if any, new employees are expected to be needed to operate any new or modified NOx control equipment. As a result, operation-related traffic is expected to be limited more towards supply deliveries and waste haul trips, but less than significant. Thus, the operational traffic impacts will not be evaluated further in the Draft PEA.

XVII. c) No Impact. Though some of the facilities that will be affected by the proposed project are located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, actions that would be taken to comply with the proposed project, such as installing new or modifying existing NOx control equipment, are not expected to significantly influence or affect air traffic patterns. Further, the size and type of air pollution control devices that would be installed would not be expected to affect navigable air space. Thus, the proposed project would not result in a change in air traffic patterns including an increase in air traffic levels or a change in location that results in substantial safety risks. As such, this specific topic will not be further evaluated in the Draft PEA. Since no significant transportation and traffic impacts were identified for this topic, no mitigation measures are necessary or required.

XVII. d) & e) No Impact. The siting of each affected facility is consistent with surrounding land uses and traffic/circulation in the surrounding areas of the affected facilities. Thus, the proposed project is not expected to substantially increase traffic hazards or create incompatible uses at or adjacent to the affected facilities. Aside from the temporary effects due to a slight increase in truck traffic for those facilities that will undergo construction activities during installation of air pollution control equipment, the proposed project is not expected to alter the existing long-term circulation patterns. Further, the proposed project is not expected to require a modification to circulation, thus, no long-term impacts on the traffic circulation system are expected to occur. The proposed project is not expected to involve the construction of any roadways, so there would be no increase in roadway design feature that could increase traffic hazards. Emergency access at each affected facility is not expected to be impacted by the proposed project because each affected facility is expected to continue to maintain their existing emergency access gates. Thus, these specific topics will not be further evaluated in the Draft PEA. Since no significant transportation and traffic impacts were identified for this topic, no mitigation measures are necessary or required.

XVII. f) No Impact. Construction and operation activities resulting from implementing the proposed project are not expected to conflict with policies supporting alternative transportation since the proposed project does not involve or affect alternative transportation modes (e.g.

bicycles or buses) because the construction and operation activities related to the proposed project will occur solely in existing industrial areas. Thus, this specific topic will not be further evaluated in the Draft PEA. Since no significant transportation and traffic impacts were identified for this topic, no mitigation measures are necessary or required.

Based upon these considerations, significant adverse impacts to transportation and traffic may occur from implementing the proposed project and thus, impact issues XVII. a) and b) will be further analyzed in the Draft PEA.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
XVIII. MANDATORY FINDINGS OF SIGNIFICANCE.				
a) Does the project have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, reduce the number or restrict the range of a rare or endangered plant or animal or eliminate important examples of the major periods of California history or prehistory?	☐	☐	☐	☑
b) Does the project have impacts that are individually limited, but cumulatively considerable? ("Cumulatively considerable" means that the incremental effects of a project are considerable when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects)	☑	☐	☐	☐
c) Does the project have environmental effects that will cause substantial adverse effects on human beings, either directly or indirectly?	☑	☐	☐	☐

Discussion

XVIII. a) No Impact. The proposed project is not expected to reduce or eliminate any plant or animal species or destroy prehistoric records of the past. As indicated in the Biological Resources discussion in Section IV., each site affected by the proposed project is part of an existing facility, which has been previously graded, such that the proposed project is not expected to extend into environmentally sensitive areas. In addition, overall air quality improvements that are expected to occur as a result of implementing the proposed project will also be expected to benefit plant and animal life.

XVIII. b) Potentially Significant Impact. The Environmental Checklist indicates that the proposed project has potentially significant adverse impacts on the following topic areas: aesthetics; air quality and GHG emissions; energy; hydrology and water quality; hazards and hazardous materials; solid and hazardous waste; and, transportation and traffic. The potential for cumulative impacts on these resources will be evaluated in the Draft PEA.

XVIII. c) Potentially Significant Impact. Even though the objective of the proposed project is to reduce NOx emissions from the top emitters in the RECLAIM program, the proposed project may result in secondary effects, emissions of regulated air pollutants, toxic air contaminants, GHGs and may also increase the hazards at some of the affected facilities. The potential for these impacts to have adverse impacts on human beings, either directly or indirectly, will be evaluated in the Draft PEA.

APPENDIX A

PROPOSED AMENDED RULE 2002 – ALLOCATIONS FOR OXIDES OF NITROGEN (NOX) AND OXIDES OF SULFUR (SOX)

The BARCT evaluation and the RTC shaving methodology are ongoing, so a RECLAIM industry's required RTC shave may change due to the public review process. The programmatic RTC shave could range from five to 14 tons per day. To provide a worst case scenario of adverse environmental impacts, the adjustment factors and the Non-tradable/Non-usable NOx RTC adjustment factors in Proposed Amended Rule 2002 subparagraph (f)(1)(B) reflect an RTC shave at the higher end of the range to capture a conservative estimate of potential control technologies needed that could generate secondary environmental impacts. As the staff proposal is being refined, if a lesser RTC shave is proposed, the adverse environmental impacts would be less and the Draft PEA and its alternatives will also be further defined.

(Adopted October 15, 1993)(Amended March 10, 1995)(Amended December 7, 1995)
(Amended July 12, 1996)(Amended February 14, 1997)(Amended May 11, 2001)
(Amended January 7, 2005)(Amended November 5, 2010)
(PAR2002 120214)

PROPOSED AMENDED RULE 2002. ALLOCATIONS FOR OXIDES OF NITROGEN (NO_X) AND OXIDES OF SULFUR (SOx)

(a) Purpose

The purpose of this rule is to establish the methodology for calculating facility Allocations and adjustments to RTC holdings for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx).

(b) RECLAIM Allocations

(1) RECLAIM Allocations will begin in 1994.

(2) An annual Allocation will be assigned to each facility for each compliance year starting from 1994.

(3) Allocations and RTC holdings for each year after 2011 are equal to the 2011 Allocation and RTC holdings, as determined pursuant to subdivision (f) unless, as part of the AQMP process, and pursuant to Rule 2015 (b)(1), (b)(3), (b)(4), or (c), the District Governing Board determines that additional reductions are necessary to meet air quality standards, taking into consideration the current and projected state of technology available and cost-effectiveness to achieve further emission reductions.

(4) The Facility Permit or relevant sections thereof shall be re-issued at the beginning of each compliance year to include allocations determined pursuant to subdivisions (c), (d), (e), and (f) and any RECLAIM Trading Credits (RTC) obtained pursuant to Rule 2007 - Trading Requirements for the next fifteen years thereafter and any other modifications approved or required by the Executive Officer.

(c) Establishment of Starting Allocations

(1) The starting Allocation for RECLAIM NO_X and SO_X facilities initially permitted by the District prior to October 15, 1993, shall be determined by the Executive Officer utilizing the following methodology:

Starting Allocation=Σ [A X B_1]+ERCs+External Offsets

where

A = the throughput for each NO_X and SO_X source or process unit in the facility for the maximum throughput year from 1989 to 1992 inclusive; and

B_1 = the applicable starting emission factor for the subject source or process unit as specified in Table 1 or Table 2

(2) (A) Use of 1992 data is subject to verification and revision by the Executive Officer or designee to assure validity and accuracy.

(B) The maximum throughput year will be determined by the Executive Officer or designee from throughput data reported through annual emissions reports submitted pursuant to Rule 301 - Permit Fees, or may be designated by the permit holder prior to issuance of the Facility Permit.

(C) To determine the applicable starting emission factor in Table 1 or Table 2, the Executive Officer or designee will categorize the equipment at each facility based on information relative to hours of operation, equipment size, heating capacity, and permit information submitted pursuant to Rule 201 - Permit to Construct, and other relevant parameters as determined by the Executive Officer or designee. No information used for purposes of this subparagraph may be inconsistent with any information or statement previously submitted on behalf of the facility to the District, including but not limited to information and statements previously submitted pursuant to Rule 301 - Permit Fees, unless the facility can demonstrate, by clear and convincing documentation, that such information or statement was inaccurate.

(D) Throughput associated with each piece of equipment or NOx or SOx source will be multiplied by the starting emission factors specified in Table 1 or Table 2. If a lower emission factor was utilized for a given piece of equipment or NOx or SOx source pursuant to Rule 301 - Permit Fees, than the factor in Table 1 or Table 2, the lower factor will be used for determining that portion of the Allocation.

(E) Fuel heating values may be used to convert throughput records into the appropriate units for determining Allocations based on the emission factors in Table 1 or Table 2. If a different unit basis than set forth in Tables 1 and 2 is needed for emissions calculations, the Executive Officer shall use a default heating value to determine source emissions, unless the Facility Permit holder can demonstrate with substantial evidence to the Executive Officer that a different value should be used to determine emissions from that source.

(3) All NO_X and SO_X ERCs generated at the facility and held by a RECLAIM Facility Permit holder shall be reissued as RTCs. RECLAIM facilities will have these RTCs added to their starting Allocations. RTCs generated from the conversion of ERCs shall have a zero rate of reduction for the year 1994 through the year 2000. Such RTCs shall have a cumulative rate of reduction for the years 2001, 2002, and 2003, equal to the percentage inventory adjustment factor applied to 2003 Allocations pursuant to paragraph (e)(1) of this rule and shall have a rate of reduction for compliance year 2004 and subsequent years determined pursuant to paragraph (f)(1) of this rule.

(4) Non-RECLAIM facilities may elect to have their ERCs converted to RTCs and listed on the RTC Listing maintained by the Executive Officer or designee pursuant to Rule 2007 - Trading Requirements, so long as the written request is filed before July 1, 1994. Such RTCs will be assigned to the trading zone in which the generating facility is located. RTCs generated from the conversion of ERCs shall have a zero rate of reduction for the year 1994 through the year 2000. Such RTCs shall have a cumulative rate of reduction for the years, 2001, 2002, and 2003, equal to the percentage inventory adjustment factor applied to 2003 Allocations pursuant to paragraph (e)(1) of this rule.

(5) External offsets provided pursuant to Regulation XIII - New Source Review, not including any offsets in excess of a 1 to 1 ratio, will be added to the starting Allocation pursuant to paragraph (c)(1) provided:

(A) The offsets were not received from either the Community Bank or the Priority Reserve.

(B) External offsets will only be added to the starting Allocation to the extent that the Facility Permit holder demonstrates that they have not already been included in the starting Allocation or as an ERC. RTCs issued for external offsets shall not include any offsets in excess of a 1 to 1 ratio required under Regulation XIII - New Source Review.

(C) RTCs generated from the conversion of external offsets shall have a zero rate of reduction for the year 1994 through the year 2000. These RTCs shall have a cumulative rate of reduction for the years 2001, 2002, and 2003, equal to the percentage inventory adjustment factor applied to 2003 Allocations pursuant to paragraph (e)(1) of this rule, and for compliance year 2004 and subsequent years allocations shall be determined pursuant to paragraph (f)(1) of this rule. The rate of reduction for the year 2001 through year 2003 shall not be applied to new facilities initially totally permitted on or after January 7, 2005.

(D) Existing facilities with units that have Permits to Construct issued pursuant to Regulation II - Permits, dated on or after January 1, 1992, or existing facilities which have, between January 1, 1992 and October 15, 1993, installed air pollution control equipment that was exempt from offset requirements pursuant to Rule 1304 (a)(5), shall have their starting Allocations increased by the total external offsets provided, or the amount that would have been offset if the exemption had not applied.

(E) Existing facilities with units whose reported emissions are below capacity due to phased construction, and/or where the Permit to Operate issued pursuant to Regulation II - Permits, was issued after January 1, 1992, shall have their starting Allocations increased by the total external offsets provided.

(6) If a Facility Permit holder can demonstrate that its 1994 Allocation is less than the 1992 emissions reported pursuant to Rule 301 - Permit Fees, and that the facility was, in 1992, operating in compliance with all applicable District rules in effect as of December 31, 1993, the facility's starting Allocation will be equal to the 1992 reported emissions.

(7) For new facilities initially totally permitted on or after January 1, 1993 but prior to October 15, 1993, the starting Allocation shall be equal to the external offsets provided by the facility to offset emission increases at the facility pursuant to Regulation XIII - New Source Review, not including any offsets in excess of a 1 to 1 ratio.

(8) The Allocation for new facilities initially totally permitted on and after October 15, 1993, shall be equal to the total RTCs provided by the facility to offset emission increases at the facility pursuant to Rule 2005- New Source Review for RECLAIM.

(9) The starting Allocation for existing facilities which enter the RECLAIM

program pursuant to Rule 2001 - Applicability, shall be determined by the methodology in paragraph (c)(1) of this rule. The most recent two years reported emission fee data filed pursuant to Rule 301 - Permit Fees, may be used if 1989 through 1992 emission fee data is not available. For facilities lacking reported emission fee data, the Allocation shall be equal to the external offsets provided pursuant to Regulation XIII - New Source Review, not including any offsets in excess of a 1 to 1 ratio. The Allocation shall not include any emission offsets received from either the Community Bank or the Priority Reserve.

(10) A facility may not receive more than one set of Allocations.

(11) A facility that is no longer holding a valid District permit on January 1, 1994 will not receive an Allocation, but may, if authorized by Regulation XIII, apply for ERCs.

(12) Clean Fuel Adjustment to Starting Allocation

Any refiner who is required to make modifications to comply with CARB Phase II reformulated gasoline production (California Code of Regulations, Title 13, Sections 2250, 2251.5, 2252, 2260, 2261, 2262, 2262.2, 2262.3, 2262.4, 2262.5, 2262.6, 2262.7, 2263, 2264, 2266, 2267, 2268, 2269, 2270, and 2271) or federal requirements (Federal Clean Air Act, Title II, Part A, Section 211; 42 U.S.C. Section 7545) may receive (an) increase(s) in his Allocations except to the extent that there is an increase in maximum rating of the new or modified equipment. Each facility requesting an increase to Allocations shall submit an application for permit amendment specifying the necessary modifications and tentative schedule for completion. The Facility Permit holder shall establish the amount of emission increases resulting from the reformulated gasoline modifications for each year in which the increase in Allocations is requested. The increase to its Allocations will be issued contemporaneously with the modification according to a schedule approved by the Executive Officer or designee (i.e., 1994 through 1997 depending on the refinery). Each increase to the Allocations shall be equal to the increased emissions resulting from the modifications solely to comply with the state or federal reformulated gasoline requirements at the refinery or facility producing hydrogen for reformulated gasoline production, and shall be established according to present and future compliance limits in current District rules or permits. Allocation increases for each refiner pursuant to this paragraph, shall not exceed 5 percent of the refiner's total starting Allocation, unless any refiner emits less than 0.0135 tons of NO_X per thousand barrels of crude processed, in which case the Allocation increases for such refiner shall not exceed 20 percent of that refiner's starting Allocation. The emissions per amount of crude processed will be determined on the basis of information reported to the District pursuant to Rule 301 - Permit Fees, for the same calendar year as the facility's peak activity year for their NO_X starting Allocation.

(d) Establishment of Year 2000 Allocations

(1) (A) The year 2000 Allocations for RECLAIM NO_X and SO_X facilities will be determined by the Executive Officer or designee utilizing the following methodology:

$$\text{Year 2000 Allocation} = \Sigma\,[A \times B_2] + \text{RTCs created from ERCs} + \text{External Offsets},$$

where

A = the throughput for each NO_X or SO_X source or process unit in the facility for the maximum throughput year from 1987 to 1992, inclusive, as reported pursuant to Rule 301 - Permit Fees; and

B_2 = the applicable Tier I year Allocation emission factor for the subject source or process unit, as specified in Table 1 or Table 2.

(B) The maximum throughput year will be determined by the Executive Officer or designee from throughput data reported through annual emissions reports pursuant to Rule 301 - Permit Fees, or may be designated by the permit holder prior to issuance of the Facility Permit.

(C) To determine the applicable emission factor in Table 1 or Table 2, the Executive Officer or designee will categorize the equipment at each facility based on information on hours of operation, equipment size, heating capacity, and permit information submitted pursuant to Rule 201 - Permit to Construct, and other parameters as determined by the Executive Officer or designee. No information used for purposes of this subparagraph may be inconsistent with any information or statement previously submitted on behalf of the facility to the District including but not limited to information and statements previously submitted pursuant to Rule 301 - Permit Fees, unless the facility can demonstrate, by clear and convincing documentation, that such information or statement was inaccurate.

(D) Throughput associated with each piece of equipment or NO_X or SO_X source will be multiplied by the Tier I emission factor specified in Table 1 or Table 2. If a factor lower than the factor in Table 1 or Table 2 was utilized for a given piece of equipment or NO_X or SO_X source pursuant to Rule 301, the lower factor will be used for determining that portion of the Allocation.

(E) The fuel heating value may be considered in determining Allocations and will be set to 1.0 unless the Facility Permit holder demonstrates that it should receive a different value.

(F) The year 2000 Allocation is the sum of the resulting products for each piece of equipment or NO_X or SO_X source multiplied by any inventory adjustment pursuant to paragraph (d)(4) of this rule.

(2) For facilities existing prior to October 15, 1993 which enter RECLAIM after October 15, 1993, the year 2000 Allocation will be determined according to paragraph (d)(1). The most recent two years reported emission fee data filed pursuant to Rule 301 - Permit Fees, may be used if 1989 through 1992 emission fee data is not available. For facilities lacking reported emission fee data, the Allocation shall be equal to their external offsets provided pursuant to Regulation XIII - New Source Review, not including any offsets in excess of a 1 to 1 ratio.

(3) No facility shall have a year 2000 Allocation [calculated pursuant to subdivision (d)] greater than the starting Allocation [calculated pursuant to subdivision (c)].

(4) If the sum of all RECLAIM facilities' year 2000 Allocations differs from the year 2000 projected inventory for these sources under the 1991 AQMP, the Executive Officer or designee will establish a percentage inventory adjustment factor that will be applied to adjust each facility's year 2000 Allocation. The inventory adjustment will not apply to RTCs generated from ERCs or external offsets.

(e) Allocations for the Year 2003

(1) The 2003 Allocations will be determined by the Executive Officer or designee applying a percentage inventory adjustment to reduce each facility's unadjusted year 2000 Allocation so that the sum of all RECLAIM facilities' 2003 Allocations will equal the 1991 AQMP projected inventory for RECLAIM sources for the year 2003, corrected

based on actual facility data reviewed for purposes of issuing Facility Permits and to reflect the highest year of actual Basin-wide economic activity for RECLAIM sources considered as a whole during the years 1987 through 1992.

(2) No facility shall have a 2003 Allocation (calculated pursuant this subdivision) greater than the year 2000 Allocation [calculated pursuant to subdivision (d)].

(f) Annual Allocations for NO_X and SOx and Adjustments to RTC Holdings

(1) Allocations for the years between 1994 and 2000, for RECLAIM NO_X and SO_X facilities shall be determined by a straight line rate of reduction between the starting Allocation and the year 2000 Allocation. For the years 2001 and 2002, the Allocations shall be determined by a straight line rate of reduction between the year 2000 and year 2003 Allocations. NOx Allocations for 2004, 2005, and 2006 and SOx Allocations for 2004 through 2012 are equal to the facility's 2003 Allocation, as determined pursuant to subdivision (e). NOx RTC Allocations and holdings subsequent to the year 2006 and SOx Allocations and holdings subsequent to the year 2012 shall be adjusted to the nearest pound as follows:

(A) The Executive Officer will adjust NOx RTC holdings, as of January 7, 2005 for compliance years 2007 and thereafter by multiplying the amount of RTC holdings by the following adjustment factors for the relevant compliance year, to obtain tradable/usable and non-tradable/non-usable holdings:

Compliance Year	Tradable/Usable NOx RTC Adjustment Factor	Non-tradable/ Non-usable NOx RTC Adjustment Factor
2007	0.883	0
2008	0.856	0.027
2009	0.829	0.054
2010	0.802	0.081
2011 ~~and after~~ through 2015	0.775	0.108

RTCs designated as non-tradable/non-usable pursuant to this subparagraph shall be held, but shall not be used or traded. The adjustment factors in this subparagraph are subject to change pursuant to paragraph (i)(5).

(B) The Executive Officer will adjust NOx RTC holdings, as of (Date of Amendment) for compliance years 2016 and thereafter by multiplying the amount of RTC holdings by the following adjustment factors for the relevant compliance year, to obtain tradable/usable and non-tradable/non-usable holdings:

Compliance Year	Tradable/Usable NOx RTC Adjustment Factor	Non-tradable/ Non-usable NOx RTC Adjustment Factor
2016	0.925	0
2017	0.849	0.031
2018	0.774	0.063
2019	0.698	0.094
2020	0.623	0.126
2021	0.547	0.157
2022 and after	0.512	0.189

RTCs designated as non-tradable/non-usable pursuant to this subparagraph shall be held, but shall not be used or traded. The adjustment factors in this subparagraph are subject to change pursuant to paragraph (i)(5).

(~~B~~C) Commencing on January 1, 2008 with NOx RTC prices averaged from January 1, 2007 through December 31, 2007, the Executive Officer will calculate the 12-month rolling average RTC price for all trades for the current compliance year. The Executive Officer will update the 12-month rolling average once per month. The computation of the rolling average prices will not include RTC transactions reported at no price or RTC swap transactions.

(~~C~~D) ~~Notwithstanding the requirements of non-tradable/non-usable credits specified in subparagraphs (f)(1)(A), i~~In the event that the NOx RTC prices exceed $15,000 per ton based on the 12-month rolling average calculated pursuant to subparagraph (f)(1)(~~B~~C), the Executive Officer will report to the Governing Board. Notwithstanding the requirements of non-tradable/non-usable credits specified in subparagraphs (f)(1)(B) and ~~I~~if the Governing Board finds that the 12-month rolling average RTC price exceeds $15,000 per ton, then the incremental NOx reductions as specified in subparagraph (f)(1)(~~D~~E) shall be converted to Tradable/Usable NOx RTCs upon Governing

Board concurrence. The Executive Officer's report to the Board will be made at a public hearing at the earliest possible regularly scheduled Board Meeting, but no more than 60 days from Executive Officer determination.

(~~D~~E) The incremental NOx RTCs restored shall be the difference between the Non-tradable/Non-usable Adjustment Factors, as specified in subparagraph ~~(f)(1)(A)~~(f)(1)(B), of the current compliance year and the most recent prior year the adjustment factor was implemented.

(~~E~~F) RTC conversion pursuant to subparagraph (f)(1)(~~C~~D) shall~~-~~ only occur in the compliance year in which Cycle 1 facilities are operating.

(~~F~~G) Notwithstanding the adjustment factors required pursuant to subparagraph ~~(f)(1)(A)~~ (f)(1)(B), beginning with the following December and each year thereafter that the Governing Board finds the $15,000 per ton NOx RTC price is exceeded pursuant to subparagraph (f)(1)(~~C~~D), the Executive Officer will publish the applicable adjustment factors for the next compliance year beginning January 1. The adjustment factors will be published at a public hearing during a regularly scheduled Board Meeting. The adjustment factors will be determined as follows:

(i) If the 12-month rolling average falls below $15,000 per ton for at least 6 consecutive months, then the emission adjustment factors for the following compliance year shall equal the next more stringent adjustment factors listed in subparagraph ~~(f)(1)(A)~~ (f)(1)(B) than the factors currently in effect; otherwise;

(ii) The next compliance year adjustment factors shall equal the compliance year adjustment factors currently in place.

The Executive Officer need no longer comply with the annual public hearing requirement once the adjustment factors for the 2022~~10~~ compliance year have been implemented for a 12-month period.

(~~G~~H) The NOx RTC adjustment factors for compliance years 20~~08~~19 through 20~~10~~21 shall not be submitted for inclusion into the State Implementation Plan until the adjustments have been in effect for one full compliance year. The 2022~~11~~ NOx RTC adjustment factors shall not be submitted for inclusion into the State Implementation Plan until 12-months after the adjustments have been in effect for one full compliance year.

(~~H~~I) NOx Allocations for facilities that enter RECLAIM after January 7, 2005 for compliance years 2007 and after shall be determined by applying the Tradable/Usable and Non-tradable/Non-usable NOx RTC Adjustment Factors under subparagraph (f)(1)(A) to the facility's Compliance Year 2006 Allocation and under subparagraph (f)(1)(B) to the facility's Compliance Year 2015 Allocation.

(~~I~~J) SOx RTC Holdings as of November 5, 2010, for compliance years 2013 and after shall be adjusted to achieve an overall reduction in the following amounts:

Compliance Year	Minimum emission reductions (lbs.)
2013	2,190,000
2014	2,920,000
2015	2,920,000
2016	2,920,000
2017	3,650,000
2018	3,650,000
2019 and after	4,161,000

(~~J~~K) The Executive Officer shall determine Tradable/usable SOx RTC Adjustment Factors for each compliance years after 2012 as follows:

$$F_{\text{compliance year i}} = 1 - [Xi / (Ai + Bi + Ci)]$$

Where:

$F_{\text{compliance year i}}$ = Tradable/usable SOx RTC Adjustment Factor for compliance year i starting with 2013

A_i = Total SOx RTCs for compliance year i held as of November ~~11~~5, 2010, by all RTC holders, except those listed in Table 5

B_i = Total SOx RTCs for compliance year i credited to any facilities listed in Table 5 between August 29, 2009 and ~~(rule adoption date)~~November 5, 2010, and not includes in C_i

C_i = Total SOx RTCs held as of (rule adoption date) by facilities listed in Table 5 for compliance year i in excess of allocations as determined pursuant to subdivision (e).

X_i = Amount to be reduced for compliance year i starting with 2013 as listed in subparagraph (f)(1)(~~I~~J).

(~~K~~L) The Executive Officer shall determine Non-tradable/Non-usable SOx RTC Adjustment Factors for compliance years 2017 through 2019 as follows:

$$N_{\text{compliance year j}} = F_{\text{compliance year 2016}} - F_{\text{compliance year j}}$$

Where:

$N_{\text{compliance year j}}$ = Non-tradable/Non-usable SOx RTC Adjustment Factor for compliance year j

$F_{\text{compliance year j}}$ = Tradable/Usable SOx RTC Adjustment Factor for compliance year j as determined pursuant to subparagraph (f)(1)(~~J~~K)

j = 2017 through 2019

Fcompliance year 2016 = Tradable/usable SOx RTC Adjustment Factor for compliance year 2016 as determined pursuant to subparagraph (f)(1)(~~J~~K)

Non-tradable/Non-usable SOx RTC Adjustment Factors for compliance years 2013, 2014, 2020, and all years after 2020 shall be 0.0.

(~~L~~M) The Executive Officer shall adjust the SOx RTC holdings as of November 5, 2010, for compliance years 2013 and after as follows:

(i) Apply the Tradable/Usable SOx RTC Adjustment Factor ($F_{\text{compliance year i}}$) and Non-tradable/Non-usable SOx RTC Adjustment Factor ($N_{\text{compliance year j}}$) for the corresponding compliance year as published under subparagraph (f)(1)(~~M~~N) to SOx RTC holdings held by any RTC holder except those listed in Table 5;

(ii) Apply no adjustment to SOx RTC holdings that are held as of August 29, 2009 by a facility listed in Table 5, and that are less than or equal to the facility's allocations as determined pursuant to subdivision (e), and that were not credited between August 29, 2009 and November 5, 2010;

(iii) Apply the Tradable/Usable SOx RTC Adjustment Factor ($F_{compliance\ year\ i}$) and Non-tradable/Non-usable SOx RTC Adjustment Factor ($N_{compliance\ year\ j}$) for the corresponding compliance year as published under subparagraph (f)(1)(~~M~~N) to any SOx RTC holding as of ~~(~~November 5, 2010~~)~~, that is held by a facility that is listed in Table 5, and that is over the facility's allocations as determined pursuant to subdivision (e); and

(iv) Apply the Tradable/Usable SOx RTC Adjustment Factor ($F_{compliance\ year\ i}$) and Non-tradable/non-usable SOx RTC Adjustment Factor ($N_{compliance\ year\ j}$) for the corresponding compliance year as published under subparagraph (f)(1)(~~M~~N) to any SOx RTC holding that was acquired between August 29, 2009 and November 5, 2010, by a facility that is listed in Table 5.

No SOx RTC holding shall be subject to the SOx RTC adjustments as published under subparagraph (f)(1)(~~M~~N) more than once.

(~~M~~N) The Executive Officer shall publish the SOx RTC Adjustment Factors determined according to subparagraphs (f)(1)(~~J~~K) and (f)(1)(~~K~~L) within 30 days after November 5, 2010.

(~~N~~O) Commencing on January 1, 2017 and ending on February 1, 2020, the Executive Officer will calculate the 12-month rolling average SOx RTC price for all trades during the preceding 12 months for the current compliance year. The Executive Officer will update the 12-month rolling average once per month. The computation of the rolling average prices will not include RTC transactions reported at no price or RTC swap transactions.

(~~O~~P) In the event that the SOx RTC prices exceed $50,000 per ton based on the 12-month rolling average calculated pursuant to subparagraph (f)(1)(~~N~~O), the Executive Officer will report to the Governing Board at a duly noticed public hearing to be held no more than 60 days from Executive Officer determination. The Executive Officer will announce that determination on the SCAQMD website. At the public hearing, the Governing Board will decide whether or not to convert any portion of the Non-tradable/Non-usable RTCs, as determined pursuant to subparagraphs (f)(1)(~~K~~L) and (f)(1)(~~L~~M), and how much to convert if any, to Tradable/Usable RTCs. The portion of Non-tradable/Non-usable RTCs available for conversion to Tradable/Usable RTCs shall not include any portion of Non-tradable/Non-usable RTCs that are designated for previous compliance years and has not already been converted by the Governing Board, or that has been otherwise included in the State Implementation Plan pursuant to subparagraph (f)(1)(~~P~~Q).

(~~P~~Q) The Executive Officer will not submit the emission reductions obtained through subparagraph (f)(1)(~~I~~J) for compliance years 2017 through 2019 for inclusion into the State Implementation Plan until the adjustments for the RTC Holdings have been in effect for one full compliance year.

(~~Q~~R) SOx Allocations for compliance years 2013 and after, for facilities that enter RECLAIM after November 5, 2010, and for basic equipment listed in Table 4 shall be determined according to the BARCT level listed in Table 4 or the permitted emission limits, whichever is lower.

(2) New facilities initially totally permitted, on and after October 15, 1993, but prior to January 7, 2005, and entering the RECLAIM program after January 7, 2005 shall not have a rate of reduction until 2001. Reductions from 2001 to 2003, inclusive, shall be implemented pursuant to subdivision (e). New facilities initially totally permitted on or after January 7, 2005 using external offsets shall have a rate of reduction for such offsets pursuant to subparagraph (c)(5)(C). New facilities initially totally permitted on or after January 7, 2005 using RTCs shall have no rate of reduction for such RTCs, provided that RTCs obtained have been adjusted according to paragraph (f)(1), as applicable. The Facility Permit for such facilities will require the Facility Permit holder to, at the commencement of each compliance year, hold RTCs equal to the amount of RTCs provided as offsets pursuant to Rule 2005.

(3) Increases to Allocations for permits issued for Clean Fuel adjustments pursuant to paragraph (c)(12), shall be added to each year's Allocation.

(g) High Employment/Low Emissions (HILO) Facility

The Executive Officer or designee will establish a HILO bank funded with the following maximum total annual emission Allocations:

(1) 91 tons per year of NO_X

(2) 91 tons per year of So_X

(3) After January 1, 1997, new facilities may apply to the HILO bank in order to obtain non-tradable RTCs. Requests will be processed on a first-come, first-served basis, pending qualification.

(4) When credits are available, annual Allocations will be granted for the year of application and all subsequent years.

(5) HILO facilities receiving such Allocations from the HILO bank must verify their HILO status on an annual basis through their APEP report.

(6) Failure to qualify will result in all subsequent years' credits being returned to the HILO bank.

(7) Facilities failing to qualify for the HILO bank Allocations may reapply at any time during the next or subsequent compliance year when credits are available.

(h) Non-Tradable Allocation Credits

(1) Any existing RECLAIM facility with reported emissions pursuant to Rule 301 - Permit Fees, in either 1987, 1988, or 1993, greater than its starting Allocation, shall be assigned non-tradable credits for the first three years of the program which shall be determined according to the following methodology:

Non-tradable credit for NO_X and SO_X:

Year 1 = $(\Sigma [A \text{ X } B_1])$ - 1994 Allocation;

Where:

A	=	the throughput for each NO_X or SO_X source or process unit in the facility from the single maximum throughput year from 1987, 1988, or 1993; and
B_1	=	the applicable starting emission factor, as specified in Table 1 or Table 2.
Year 2	=	Year 1 non-tradable credits X 0.667
Year 3	=	Year 1 non-tradable credits X 0.333
Year 4 and subsequent years	=	Zero non-tradable credit.

(2) The use of non-tradable credits shall be subject to the following requirements:

(A) Non-tradable credits may only be used for an increase in throughput over that used to determine the facility's starting Allocation. Non-tradable credits may not be used for emissions increases associated with equipment modifications, change in feedstock or raw materials, or any other changes except increases in throughput. The Executive Officer or designee may impose Facility Permit conditions necessary to ensure compliance with this subparagraph.

(B) The use of activated non-tradable credits shall be subject to a non-tradable RTC mitigation fee, as specified in Rule 301 subdivision (n).

(C) In order to utilize non-tradable credits, the Facility Permit holder shall submit a request to the Executive Officer or designee in writing, including a demonstration that the use of the non-tradable credits complies with all requirements of this paragraph, pay any fees required pursuant to Rule 301 - Fees, and have received written approval from the Executive Officer or designee for their use. The Executive Officer or designee shall deny the request unless the Facility Permit holder demonstrates compliance with all requirements of this paragraph. The Executive Officer or designee shall, in writing, approve or deny the request within three business days of submittal of a complete request and notify the Facility Permit holder of the decision. If the request is denied, the Executive Officer or designee will refund the mitigation fee.

(D) In the event that a facility transfers any RTCs for the year in which non-tradable credits have been issued, the non-tradable credit Allocation shall be invalid, and is no longer available to the facility.

(i) RTC Reduction Exemption

(1) A facility may file an application for Executive Officer approval to be exempted from all or a portion of the requirements pursuant to subparagraph (f)(1)(~~A~~B) with the exception of RTC holdings as of ~~January 7, 2005 for compliance year 2007~~ (Date of Amendment) for compliance year 2016 and thereafter in excess of the initial allocation. For the purposes of this rule, initial allocation refers to the RTCs issued by the District to a facility upon entering the RECLAIM program. The

application shall contain sufficient data to demonstrate to the satisfaction of the Executive Officer that the facility meets the following criteria:

(A) the facility has been in the program since the start of RECLAIM, or existed prior to 1994, but subsequently entered RECLAIM pursuant to Rule 2001 because facility emissions exceeded 4 tons per year;

(B) at least 99 percent of the facility's emissions reported for ~~the most recent completed c~~Compliance ~~y~~Year 2013 ~~prior to the date of filing an application~~ is from equipment not listed in Table 3 or Table 6 and the achieved emission rates for each and every piece of equipment at the facility is less than or equal to the 2000 (Tier I) Ending Emission Factor listed in Table 1 or the emission factor listed in Table 3, whichever is lower, for the corresponding equipment type;

(C) RTCs that were part of the total initial allocation for the facility have never been transferred or sold by the facility for Compliance Year~~year~~ 2016~~07~~ or later~~ compliance years~~; and

(D) the cumulative NOx compliance costs incurred by the facility up to the submittal date of the application as specified in paragraph (i)(3) to comply with the RECLAIM Allocation as required under Rule 2004(b) and (d)(1) exceed the compliance costs that otherwise would have occurred to meet and maintain emission limits specified in Table 1 or 3, whichever is lower, for each and every piece of equipment at the facility. The compliance costs shall be based on the following parameters:

(i) cost of controlling emissions using the parameters and procedures for determining total direct and indirect capital investment and total annual costs as specified in the most recent edition of the Control Cost Manual published by the U.S. EPA Office of Air Quality and Planning Standards, excluding control costs for any equipment listed in Table 3 or Table 6, if any;

(ii) realized and anticipated revenues and expenditures of the Facility Permit holder resulting from buying and selling any RTCs that are or were held by the facility where the contract of sale or purchase was executed prior to the date of application for exemption pursuant to paragraph (i)(1);

(iii) costs associated with compliance with the New Source Review provisions of Rule 2005, Rule 2012(c), or other applicable state or federal requirements shall not be included;

(iv) costs that result only in improving process efficiency or product quality, costs of projects that were initiated before the date the facility was subject to RECLAIM requirements, or legal costs or any other costs that do not directly reduce NOx emissions shall not be included; and

(v) any cost savings that resulted in implementing any NOx emissions strategy, such as fuel savings, increased production or sale; or

(2) A facility may file an application for Executive Officer approval to be exempted from all or a portion of the requirements pursuant to subparagraph (f)(1)(~~A~~B) for the initial allocations portion of a facility's RTC holdings provided that the facility meets all of the following:

(A) The facility's starting and year 2000 Allocations were calculated using the same emission factors that are equal to or lower than the 2000 (Tier 1) emission factors listed in Table 1;

(B) Emission rate achieved for each source at the facility is less than or equal to the emission factors listed in Table 3 for the corresponding equipment type; and

(C) RTCs for ~~2007~~ 2016 or later compliance years for the facility have never been transferred or sold.

(3) A facility shall submit the applications specified pursuant to paragraphs (i)(1) or (i)(2) no later than ~~July 7, 2005~~ six months after adoption of rule amendment ~~or between January 1 and March 31, 2006~~, pay the appropriate evaluation fee pursuant to Rule 306, and accept enforceable permit conditions to ensure compliance with the provisions of this subdivision, in order for the Executive Officer to approve the exemption. If approved, the facility's initial RTC allocation shall be designated as

non-tradable and additional RTCs purchased above the initial allocation shall be subject to the RTC adjustments specified in subparagraph (f)(1)(~~A~~B), as appropriate. The Executive Officer shall deny an application that is not filed within the time periods specified in this paragraph, lacks any information specified under paragraph (i)(7), or fails to demonstrate that it meets the requirements in paragraphs (i)(1) or (i)(2).

(4) Upon approval the exemption shall:

(A) be limited to the adjustment factors specified in subparagraph (f)(1)(~~A~~B);

(B) begin the next compliance year following the exemption approval; and

(C) not apply to reductions resulting from future periodic BARCT review.

(5) RTC adjustments exempted pursuant to this subdivision shall be distributed proportionally among the remainder of the RTC holders and implemented two years from the compliance year of the applicable exemption and are subject to applicable paragraph (f)(1) provisions. Public notification of the distributed reductions shall occur at least one year prior to implementation.

(6) A Facility Permit holder has the right to appeal the denial of the exemption application to the Hearing Board in the same manner as a permit denial as specified in Health and Safety Code Section 42302.

(7) An application submitted to request an exemption from the RTCs reduction pursuant to paragraphs (i)(1) or (i)(2) shall include the following information.

(A) Detailed description of each project and itemized listing of how it relates to meeting the RECLAIM reduction requirements;

(B) Date of start and completion of each project listed in (A);

(C) Detailed calculations or emissions data demonstrating NOx emission reductions resulting from each project or combination of projects directly resulting in reductions. The emission levels achieved shall be based on actual CEMS data or source tests results;

(D) Itemized revenue and expenditures for each RTC trading activity since participation in the RECLAIM program;

(E) Itemized costs for each project and corresponding receipts or other equivalent documentation as approved by the Executive Officer for such expenditures; and

(F) Cost savings resulting from each project(s) (e.g. fuel savings, improved productivity, increased sales, etc.) and documentation of the values of such savings.

(8) A facility qualifying for exemption shall report as part of its Annual Permit Emission Program (APEP) report, submitted pursuant to Rule 2004(b)(4), whether or not emissions from equipment listed in Tables 3 and 6, if any, remain less than or equal to 1 percent of the total facility emissions on an annual basis for the duration of the exemption. If the emissions exceed 1 percent, the facility shall be in violation of the rule for each and every day of the compliance year and the Executive Officer shall reduce the facility's initial allocation for the next compliance year to the emissions level specified for that year pursuant to subparagraph (f)(1)(~~A~~B).

(9) A facility applying for exemption shall have 1 percent of its initial allocations subject to the requirements pursuant to subparagraph (f)(1)(~~A~~B).

(10) Non-tradable RTC allocations designated pursuant to paragraph (i)(3) shall become tradable in the event the facility permanently ceases to operate.

APPENDIX B

PROPOSED AMENDED RULE 2011 APPENDIX A – PROTOCOL FOR MONITORING, REPORTING, AND RECORDKEEPING OXIDES OF SULFUR (SOX) EMISSIONS (ATTACHMENT C – QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES)

RULE 2011 PROTOCOL - ATTACHMENT C

QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES

TABLE OF CONTENTS

ATTACHMENT C - QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES

A. Quality Control Program....................C-1
B. Frequency of Testing....................C-2

ATTACHMENT C

QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES

A. QUALITY CONTROL PROGRAM

Develop and implement a quality control program for the continuous emission monitoring systems and their components. As a minimum, include in each quality control program a written plan that describes in detail complete, step-by-step procedures and operations for each of the following activities:

1. Calibration Error Test Procedures

Identify calibration error test procedures specific to the CEMS that may require variance from the procedures used during certification (for example, how the gases are to be injected, adjustments of flow rates and pressures, introduction of reference values, length of time for injection of calibration gases, steps for obtaining calibration error, determination of interferences, and when calibration adjustments should be made).

2. Calibration and Linearity Adjustments

Explain how each component of the CEMS shall be adjusted to provide correct responses to calibration gases, reference values, and/or indications of interference both initially and after repairs or corrective action. Identify equations, conversion factors, assumed moisture content, and other factors affecting calibration of each CEMS.

3. Preventative Maintenance

Keep a written record of procedures, necessary to maintain the CEMS in proper operating condition and a schedule for those procedures.

4. Audit Procedures

Keep copies of written reports received from testing firms/laboratories of procedures and details specific to the installed CEMS that were to be used by the testing firms/laboratories for relative accuracy test audits, such as sampling and analysis methods. The testing firms/laboratories shall have received approval from the District by going through the District's laboratory approval program.

5. Record Keeping Procedures

Keep a written record describing procedures that shall be used to implement the record keeping and reporting requirements.

Specific provisions of Section A-3 and A-5 above of the quality control programs shall constitute specific guidelines for facility personnel. However, facilities shall be required to take reasonable steps to monitor and assure implementation of such specific guidelines. Such reasonable steps may include periodic audits, issuance of periodic reminders, implementing training classes, discipline of employees as necessary, and other appropriate measures. Steps that a facility commits to take to monitor and assure implementation of the specific guidelines shall be set forth in the written plan and shall be the only elements of Section A-3 and A-5 that constitute enforceable requirements under the written plan, unless other program provisions are independently enforceable pursuant to other requirements of the SOx protocols or District or federal rules or regulations.

B. FREQUENCY OF TESTING

There are three situations which will result in an out-of-control period. These include failure of a calibration error test, failure of a relative accuracy test audit, and failure of a BIAS test, and are detailed in this subdivision. Data collected by a CEMS during an out-of-control period shall not be considered valid.

The frequency at which each quality assurance test must be given is as follows:

1. Periodic Assessments

For each monitor or CEMS, perform the following assessments during each day in which the unit combusts any fuel or processes any material (hereafter referred to as a "unit operating day"), or for a monitor or a CEMS on a bypass stack/duct, during each day that emissions pass through the bypass stack or duct. These requirements are effective as of the date when the monitor or CEMS completes certification testing.

a. Calibration Error Testing Requirements for Pollutant Concentration Monitors, Fuel Gas Sulfur Content Monitors, and O_2 Monitors

Test, record, and compute the calibration error of each SO_2 pollutant concentration monitor, fuel gas sulfur content monitor, if applicable, and O_2 monitor at least once on each unit operating day, or for monitors or monitoring systems on bypass stacks/ducts on each day that emissions pass through the bypass stack or duct. Conduct calibration error checks, to the extent practicable, approximately 24 hours apart. Perform the daily calibration error test according to the procedure in Chapter 2, Subdivision B, Paragraph 1, Subparagraph a, Clause ii of this Attachment.

For units with more than one span range, perform the daily calibration error test on each scale that has been used since the last calibration error test. For example, if the emissions concentration or the fuel gas sulfur content has not exceeded the low-scale span range since the previous calendar day, the calibration error test may be performed on the low-scale only. If, however, the emissions concentration or the fuel gas sulfur content has exceeded the low-scale span range since the previous calibration error test, perform the calibration error test on both the low- and high-scales.

i. Design Requirements for Calibration Error Testing of SO_x Concentration Monitors, the Fuel Gas Sulfur Content Monitors, and O_2 Monitors

Design and equip each SO_x concentration monitor, fuel gas sulfur content monitor, and O_2 monitor with a calibration gas injection port that allows a check of the entire measurement system when calibration gases are introduced. For extractive and dilution type monitors, all monitoring components exposed to the sample gas, (for example, sample lines, filters, scrubbers, conditioners, and as much of the probe as practical) are included in the measurement system. For in situ type monitors, the calibration must check against the injected gas for the performance of all electronic and optical components (for example, transmitter, receiver, analyzer).

Design and equip each pollutant concentration monitor, fuel gas sulfur content and O_2 monitor to allow daily determinations of calibration error (positive or negative) at the zero-level (0 to 20 percent of each span range) and high-level (80 to 100 percent of each span range) concentrations.

ii. Calibration Error Test for SO_x Concentration Monitors, Fuel Gas Sulfur Content Monitors, and O_2 Monitors

Measure the calibration error of each SO_2 concentration analyzer, fuel gas sulfur analyzer, and O_2 monitor once each day according to the following procedures:

If any manual or automatic adjustments to the monitor settings are made, conduct the calibration error test in a way that the magnitude of the adjustments can be determined and recorded.

Perform calibration error tests at two concentrations: (1) zero-level and (2) high level. Zero level is 0 to 20 percent of each span range, and high level is 80 to 100 percent of each span range. All calibration gases used during certification tests and quality assurance and quality control activities shall be NIST/EPA approved standard reference materials (SRM), certified reference materials (CRM), or shall be certified according to "EPA Traceability Protocol for Assay and Certification of Gaseous Calibration Standards," September 1997, EPA 600/R-97/121 or any subsequent version published by EPA.

Introduce the calibration gas at the gas injection port as specified above. Operate each monitor in its normal sampling mode. For extractive and dilution type monitors, pass the audit gas through all filters, scrubbers, conditioners, and other monitor components used during normal sampling and through as much of the sampling probe as practical. For in situ type monitors, perform calibration checking on all active electronic and optical components, including the transmitter, receiver, and analyzer. Challenge the SO_x concentration monitors, the fuel gas sulfur content monitors, and the O_2 monitors once with each gas. Record the monitor response from the data acquisition and handling system. Use the following equation to determine the calibration error at each concentration once each day:

$$CE = \frac{|R - A|}{S} \times 100 \qquad \text{(Eq. C-1)}$$

Where:

CE = Percentage calibration error based on the span range

R = Reference value of zero- or high-level calibration gas introduced into the monitoring system.

A = Actual monitoring system response to the calibration gas.

S = Span range of the instrument

b. Calibration Error Testing Requirements for Stack Flow Monitors

Test, compute, and record the calibration error of each stack flow monitor at least once within every 14 calendar day period during which at anytime emissions flow through the stack; or for monitors or monitoring systems on bypass stacks or ducts, at least once within every 14 calendar day period during which at anytime emissions flow through the bypass stack or duct. Introduce a zero reference value to the transducer or transmitter. Record flow monitor output from the data acquisition and handling systems before and after any adjustments. Calculate the calibration error using the following equation:

$$CE = \frac{|R - A|}{S} \times 100 \qquad \text{(Eq. C-2)}$$

Where:

CE = Percentage calibration error based on the span range

R = Zero reference value introduced into the transducer or transmitter.

A = Actual monitoring system response.

S = Span range of the flow monitor.

c. Interference Check for Stack Flow Monitors

Perform the daily flow monitor interference checks specified in Chapter 2, Subdivision B, Paragraph 1, Subparagraph c of this Attachment at least once per operating day (when the unit(s) operate for any part of the day).

Design Requirements for Flow Monitor Interference Checks

Design and equip each flow monitor with a means to ensure that the moisture expected to occur at the monitoring location does not interfere with the proper functioning of the flow monitoring system. Design and equip each flow monitor with a means to detect, on at least a daily basis, pluggage of each sample line and sensing port, and malfunction of each resistance temperature detector (RTD), transceiver, or equivalent.

Design and equip each differential pressure flow monitor to provide (1) an automatic, periodic backpurging (simultaneously on both sides of the probe) or equivalent method of sufficient force and frequency to keep the probe and lines sufficiently free of obstructions on at least a daily basis to prevent sensing interference, and (2) a means to detecting leaks in the system at least on a quarterly basis (a manual check is acceptable).

Design and equip each thermal flow monitor with a means to ensure on at least a daily basis that the probe remains sufficiently clean to prevent velocity sensing interference.

Design and equip each ultrasonic flow monitor with a means to ensure on at least a daily basis that the transceivers remain sufficiently clean (for example, backpurging the system) to prevent velocity sensing interference.

d. Recalibration

Adjust the calibration, at a minimum, whenever the calibration error exceeds the limits of the applicable performance specification for the SOx monitor, O_2 monitor or stack flow monitor to meet such specifications. Repeat the calibration error test procedure following the adjustment or repair to demonstrate that the corrective actions were effective. Document the adjustments made.

e. Out-of-Control Period – Calibration Test

An out-of-control period occurs when the calibration error of an SO_2 concentration monitor or a fuel gas sulfur content monitor exceeds 5.0 percent based upon the span range value, when the calibration error of an O_2 monitor exceeds 1.0 percent O_2, or when the calibration error of a flow monitor exceeds 6.0 percent based upon the span range value, which is twice the applicable specification. The out-of-control period begins with the hour of completion of the failed calibration error test and ends with the hour of completion of following an effective recalibration. Whenever the failed calibration, corrective action, and effective recalibration occur within the same hour, the hour is not out-of-control if 2 or more valid readings are obtained during that hour as required by Chapter 2, Subdivision B, Paragraph 5, Subparagraph a.

An out-of-control period also occurs whenever interference of a flow monitor is identified. The out-of-control period begins with the hour of the failed interference check and ends with the hour of completion of an interference check that is passed.

f. Data Recording

Record and tabulate all calibration error test data according to the month, day, clock-hour, and magnitude in ppm, dscfh, and percent volume. Program monitors that automatically adjust data to the calibrated corrected calibration values (for example, microprocessor control) to record either: (1) the unadjusted concentration or flow rate measured in the calibration error test prior to resetting the calibration, or (2) the magnitude of any adjustment. Record the following applicable flow monitor interference check data: (1) sample line/sensing port pluggage, and (2) malfunction of each RTD, transceiver, or equivalent.

2. Semi-annual Assessments

a. For each CEMS, perform the following assessments once semi-annually thereafter, as specified below for the type of test. These semi-annual assessments shall be completed within six months of the end of the calendar quarter in which the CEMS was last tested for certification purposes (initial and recertification) or within three months of the end of the calendar quarter in which the District sent notice of a provisional approval for a CEMS, whichever is later. Thereafter, the semi-annual tests shall be completed within six months of the end of the calendar quarter in which the CEMS was last tested. For CEMS on bypass stacks/ducts, the assessments shall be performed once every two successive operating quarters in which the bypass stacks/ducts were operated. These tests shall be performed after the calendar quarter in which the CEMS was last tested as part of the CEMS certification, as specified below for the type of test.

Relative accuracy tests may be performed on an annual basis rather than on a semi-annual basis if the relative accuracies during the previous audit for the SO_X pollutant concentration monitor, flow monitoring system, and SOx emission rate measurement system is 7.5 percent or less.

b. For CEMS on any stack or duct through which no emissions have passed in two or more successive quarters, the semi-annual assessments must be performed within 14 unit operating days after emissions pass through the stack/duct.

c. The due date for a semi-annual or annual assessment of a major source may be postponed to within 14 unit operating days from the first re-firing of the major source if the major source is physically incapable of being operated and all of the following are met:

i. All fuel feed lines to the major source are disconnected and flanges are placed at both ends of the disconnected lines, and

ii. The fuel meter(s) for the disconnected fuel feed lines are maintained and operated and associated fuel records showing no fuel flow are maintained on site.

For any hour that fuel flow records are not available to verify no fuel flow, SOx emissions shall be calculated using the maximum valid hourly emissions from the last 30 days of operation.

Prior to re-starting operation of the major source, the Facility Permit Holder shall: (1) provide written notification to the District no later than 72 hours prior to starting up the source, (2) start the CEMS no later than 24 hours prior to the start-up of the major source, and (3) conduct and pass a Cylinder Gas Analysis (CGA) prior to the start-up of the major source. The emissions data from the CEMS after the re-start of operations is considered valid only if the Facility Permit Holder passes the CGA test. Otherwise, for a non-passing CGA, the CEMS data is considered invalid until the semi-annual or annual assessment is performed and passed. As such, SOx emissions shall be calculated using the maximum valid hourly emissions from the last 30 days of operation commencing with the hour of start up and continuing through the hour prior to performing and passing the semi-annual or annual assessment.

d. An electrical generating facility that only operates under a California Independent System Operator (Cal ISO) contract may postpone the due date for a semi-annual or annual assessment of a major source to the next calendar quarter provided that the facility shows the semi-annual or annual assessment was scheduled to be performed during the first 45 days of the calendar quarter in which the assessment is due but the assessment was not completed due to lack of adequate operational time, and a CGA is conducted and passed within the calendar quarter when the assessment is due.

~~a.~~e. Relative Accuracy Test Audit

Perform relative accuracy test audits and bias tests semi-annually and no less than 3 months apart for each $S0_2$ pollutant concentration monitor, fuel gas sulfur content monitor, stack gas volumetric flow rate measurement systems, and the $S0_2$ mass emission rate measurement system in accordance with Chapter 2, Subdivision B, Paragraphs 10, 11, and 12 and Attachment B of the Protocol for ~~Proposed~~ Rule 2011. The relative accuracy of the pollutant concentration monitor and the mass emission rate measurement system shall be less than or equal to 20.0 percent, and the relative accuracy of the stack gas volumetric flow rate measurement system shall be less than or equal to 15.0 percent. For monitors on bypass stacks/ducts, perform relative accuracy test audits once every two successive bypass operating quarters in accordance with Chapter 2, Subdivision B, Paragraphs 10, 11, and 12 and Attachment B (bias test) of the ~~Draft~~ Protocol for ~~Proposed~~ Rule 2011.

~~b.~~f. Out-of-Control Period – Relative Accuracy Test Audit

An out-of-control period occurs under any of the following conditions: (1) The relative accuracy of an SO_2 pollutant concentration monitor, a fuel gas sulfur content monitor, or the $S0_2$ emission rate measurement system exceeds 20.0 percent; (2) the relative accuracy of the flow rate monitor exceeds 15.0 percent; or (3) failure to conduct a relative accuracy test audit by the due date for a semi-annual assessment. The out-of-control period begins with the hour of completion of the failed relative accuracy test audit and ends with the hour of completion of a satisfactory relative accuracy test audit.

~~c.~~g. Out-of-Control Period – BIAS Test

An out-of-control period occurs if all the following conditions are met:

i. Failure of a bias test as specified in Attachment B of this Appendix;

ii. The CEMS is biased low relative to the reference method (i.e. Bias Adjustment Factor (BAF), as determined in Attachment B of this Appendix, is greater than 1); and

iii. The Facility Permit holder does not apply the BAF to the CEMS data.

The out-of-control period begins with the hour of completion of the failed bias test audit and ends with the hour of completion of a satisfactory bias test.

~~d.~~h. Alternative Relative Accuracy Test Audit

i. The Facility Permit holder of a major source, that has received written approval from the Executive Officer as an intermittently operated source, may postpone the due date for a semi-annual assessment to the end of the next calendar quarter if the Facility Permit holder:

I. operated the source no more than 240 cumulative operating hours and no more than 72 consecutive hours during the calendar quarter when a semi-annual assessment is due; and

II. conducted a relative accuracy test audit on the CEMS serving the source during the previous four calendar quarters and meeting the accuracy criteria as set forth under Subparagraph B.2.~~a~~e.; and

III. conducted an ~~alterative~~ alternative relative accuracy test audit on the CEMS serving the source during the calendar quarter when a semi-annual assessment is due and meeting the criteria specified under Clause B.2.~~d~~h.iii.

If any of the requirements under Subclauses B.2.~~d~~h.i.I, II and III is not met and the source did not have passing RATA during the calendar quarter when the semi-annual assessment is due, emissions from the source shall be determined pursuant to the Missing Data Procedures as specified under Rule 2011, Appendix A, Chapter 2, Subdivision E after the semi-annual assessment due date until the hour of completion of a satisfactory relative accuracy test audit.

ii. The Facility Permit holder may submit a written request to designate a major source as an intermittently operated source provided the Facility Permit holder demonstrates that:

I. During any calendar quarter within the previous two compliance years, the source was operated no more than 240 cumulative operating hours and no more than 72 consecutive hours~~.~~; or

II. During any calendar quarter within the next two compliance years, the source will be operated no more than 240 cumulative operating hours and no more than 72 consecutive hours.

iii. An alternative relative accuracy shall consist of a Cylinder Gas Analysis (CGA) method as defined under 40 CFR, Part 60, Appendix F, combined with a flow accuracy verification. For sources equipped with stack flow monitors, the flow accuracy shall be verified by calibrating the transducers and transmitters installed on the stack flow monitors using procedures under Paragraph B.3 of this attachment. For sources equipped with fuel flow meters and no stack flow monitors, the flow accuracy shall be verified by calibrating the fuel flow meters either in-line or offline in accordance with the procedures outlined in 40CFR Part 75, Appendix D. Passing flow accuracy verification results that were obtained within the past 4 quarters may be used in lieu of performing a flow accuracy verification during the calendar quarter when a semi-annual assessment is due. The calculated accuracy for the analyzer responses for NO_x and O_2 concentration shall be within 15 percent or 1 ppm, whichever is greater, as determined by the CGA method as defined under 40 CFR, Part 60, Appendix F. Successive alternative relative accuracy test audits shall be performed no less than 45 days apart.

3. Calibration of Transducers and Transmitters on Stack Flow Monitors

All transducers and transmitters installed on stack flow monitors must be calibrated every two operating calendar quarters, in which an operating calendar quarter is any calendar quarter during which at anytime emissions flow through the stack. Calibration must be done in accordance with Executive Officer approved calibration procedures that employ materials and equipment that are NIST traceable.

When a calibration produces for a transducer and transmitter a percentage accuracy of greater than ± 1%, the Facility Permit holder shall calibrate the transducer and transmitter every calendar operating quarter until a subsequent calibration which shows a percentage accuracy of less than ± 1% is achieved. An out-of-control period occurs when the percentage accuracy exceeds ±2%. If an out-of-control period occurs, the Facility Permit holder shall take corrective measures to obtain a percentage accuracy of less than ±2% prior to performing the next RATA. The out-of-control period begins with the hour of completion of the failed calibration error test and ends with the hour of completion of following an effective recalibration. Whenever the failed calibration, corrective action, and effective recalibration occur within the same hour, the hour is not out-of-control if two or more valid data readings are obtained during that hour as required by Chapter 2, Subdivision B, Paragraph 5, Subparagraph a.

APPENDIX C

PROPOSED AMENDED RULE 2012 APPENDIX A – PROTOCOL FOR MONITORING, REPORTING, AND RECORDKEEPING OXIDES OF NITROGEN (NOX) EMISSIONS (ATTACHMENT C – QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES)

RULE 2012 PROTOCOL - ATTACHMENT C

QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES

TABLE OF CONTENTS

ATTACHMENT C - QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES

A. Quality Control Program..C-1

B. Frequency of Testing C-2

ATTACHMENT C

QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES

A. Quality Control Program

Develop and implement a quality control program for the continuous emission monitoring systems and their components. As a minimum, include in each quality control program a written plan that describes in detail complete, step-by-step procedures and operations for each of the following activities:

1. Calibration Error Test Procedures

   Identify calibration error test procedures specific to the CEMS that may require variance from the procedures used during certification (for example, how the gases are to be injected, adjustments of flow rates and pressures, introduction of reference values, length of time for injection of calibration gases, steps for obtaining calibration error, determination of interferences, and when calibration adjustments should be made).

2. Calibration and Linearity Adjustments

   Explain how each component of the CEMS will be adjusted to provide correct responses to calibration gases, reference values, and/or indications of interference both initially and after repairs or corrective action. Identify equations, conversion factors, assumed moisture content, and other factors affecting calibration of each CEMS.

3. Preventative Maintenance

   Keep a written record of procedures, necessary to maintain the CEMS in proper operating condition and a schedule for those procedures.

4. Audit Procedures

   Keep copies of written reports received from testing firms/laboratories of procedures and details specific to the installed CEMS that were to be used by the testing firms/laboratories for relative accuracy test audits, such as sampling and analysis methods. The testing firms/laboratories shall have received approval from the District by going through the District's laboratory approval program.

5. Record Keeping Procedures

Keep a written record describing procedures that will be used to implement the record keeping and reporting requirements.

Specific provisions of Section A-3 and A-5 above of the quality control programs shall constitute specific guidelines for facility personnel. However facilities shall be required to take reasonable steps to monitor and assure implementation of such specific guidelines. Such reasonable steps may include periodic audits, issuance of periodic reminders, implementing training classes, discipline of employees as necessary, and other appropriate measures. Steps that a facility commits to take to monitor and assure implementation of the specific guidelines shall be set forth in the written plan and shall be the only elements of Section A-3 and A-5 that constitute enforceable requirements under the written plan, unless other program provisions are independently enforceable pursuant to other requirements of the NO_x protocols or District or federal rules or regulations.

B. FREQUENCY OF TESTING

There are three situations which will result in an out-of-control period. These include failure of a calibration error test, failure of a relative accuracy test audit, and failure of a BIAS test, and are detailed in this subdivision. Data collected by a CEMS during an out-of-control period shall not be considered valid.

The frequency at which each quality assurance test must be performed is as follows:

1. Periodic Assessments

For each monitor or CEMS, perform the following assessments on each day during which the unit combusts any fuel or processes any material (hereafter referred to as a "unit operating day"), or for a monitor or a CEMS on a bypass stack/duct, on each day during which emissions pass through the bypass stack or duct. These requirements are effective as of the date when the monitor or CEMS completes certification testing.

a. Calibration Error Testing Requirements for Pollutant Concentration Monitors and O_2 Monitors

Test, record, and compute the calibration error of each NO_x pollutant concentration monitor and O_2 monitor at least once on each unit operating day, or for monitors or monitoring systems on bypass stacks/ducts on each day that emissions pass through the bypass stack or duct. Conduct calibration error checks, to the extent practicable, approximately 24 hours apart. Perform the daily calibration error test according to the procedure in Paragraph B.1.a.ii. of this Attachment.

For units with more than one span range, perform the daily calibration error test on each scale that has been used since the last calibration error test. For example, if the emissions concentration has not exceeded the low-scale span range since the previous calendar day, the calibration error test may be performed on the low-scale only. If, however, the emissions concentration has exceeded the low-scale span range since the previous calibration error test, perform the calibration error test on both the low- and high-scales

i. Design Requirements for Calibration Error Testing of NO_x Concentration Monitors and O_2 Monitors

Design and equip each NO_x concentration monitor and O_2 monitor with a calibration gas injection port that allows a check of the entire measurement system when calibration gases are introduced. For extractive and dilution type monitors, all monitoring components exposed to the sample gas, (for example, sample lines, filters, scrubbers, conditioners, and as much of the probe as practical) are included in the measurement system. For in situ type monitors, the calibration must check against the injected gas for the performance of all electronic and optical components (for example, transmitter, receiver, analyzer).

Design and equip each pollutant concentration monitor and O_2 monitor to allow daily determinations of calibration error (positive or negative) at the zero-level (0 to 20 percent of each span range) and high-level (80 to 100 percent of each span range) concentrations.

ii. Calibration Error Test for NO_x Concentration Monitors and O_2 Monitors

Measure the calibration error of each NO_x concentration analyzer and O_2 monitor once each day according to the following procedures:

If any manual or automatic adjustments to the monitor settings are made, conduct the calibration error test in a way that the magnitude of the adjustments can be determined and recorded.

Perform calibration error tests at two concentrations: (1) zero-level and (2) high level. Zero level is 0 to 20 percent of each span range, and high level is 80 to 100 percent of each span range. All calibration gases used during certification tests and quality assurance and quality control activities shall be NIST/EPA approved standard reference materials (SRM), certified reference materials CRM), or shall be certified according to "EPA Traceability Protocol for Assay and Certification of Gaseous Calibration Standards," September 1997, EPA 600/R-97/121 or any subsequent version published by EPA.

Introduce the calibration gas at the gas injection port as specified above. Operate each monitor in its normal sampling mode. For extractive and dilution type monitors, pass the audit gas through all filters, scrubbers, conditioners, and other monitor components used during normal sampling and through as much of the sampling probe as practical. For in situ type monitors, perform calibration checking all active electronic and optical components, including the transmitter, receiver, and analyzer. Challenge the NO_x concentration monitors and the O_2 monitors once with each gas. Record the monitor response from the data acquisition and handling system. Use the following equation to determine the calibration error at each concentration once each day:

$$CE = \frac{|R-A|}{S} \times 100 \qquad \text{(Eq. C-1)}$$

Where:

CE = The percentage calibration error based on the span range

R = The reference value of zero- or high-level calibration gas introduced into the monitoring system.

A = The actual monitoring system response to the calibration gas.

S = The span range of the instrument

b. Calibration Error Testing Requirements for Stack Flow Monitors

Test, compute, and record the calibration error of each stack flow monitor at least once within every 14 calendar day period during which at anytime emissions flow through the stack; or for monitors or monitoring systems on bypass stacks or ducts, at least once within every 14 calendar day period during which at anytime emissions flow through the bypass stack or duct. Introduce a zero reference value to the transducer or transmitter. Record flow monitor output from the data acquisition and handling systems before and after any adjustments. Calculate the calibration error using the following equation :

$$CE = \frac{|R - A|}{S} \times 100 \qquad \text{(Eq. C-2)}$$

Where:

CE = Percentage calibration error based on the span range

R = Zero reference value introduced into the. transducer or transmitter.

A = Actual monitoring system response.

S = Span range of the flow monitor.

c. Interference Check for Stack Flow Monitors

Perform the daily flow monitor interference checks specified in Paragraph B.1.c.i. of this Attachment at least once per operating day (when the unit(s) operate for any part of the day).

i. Design Requirements for Flow Monitor Interference Checks

Design and equip each flow monitor with a means to ensure that the moisture expected to occur at the monitoring location does not interfere with the proper functioning of the flow monitoring system. Design and equip each flow monitor with a means to detect, on at least a daily basis, pluggage of each sample line and sensing port, and malfunction of each resistance temperature detector (RTD), transceiver, or equivalent.

Design and equip each differential pressure flow monitor to provide (1) an automatic, periodic backpurging (simultaneously on both sides of the probe) or equivalent method of sufficient force and frequency to keep the probe and lines sufficiently free of obstructions on at least a daily basis to prevent sensing interference, and (2) a means to detecting leaks in the system at least on a quarterly basis (a manual check is acceptable).

Design and equip each thermal flow monitor with a means to ensure on at least a daily basis that the probe remains sufficiently clean to prevent velocity sensing interference.

Design and equip each ultrasonic flow monitor with a means to ensure on at least a daily basis that the transceivers remain sufficiently clean (for example, backpurging the system) to prevent velocity sensing interference.

d. Recalibration

Adjust the calibration, at a minimum, whenever the calibration error exceeds the limits of the applicable performance specification for the NO_x monitor, O_2 monitor or stack flow monitor to meet such specifications. Repeat the calibration error test procedure following the adjustment or repair to demonstrate that the corrective actions were effective. Document the adjustments made.

e. Out-of-Control Period – Calibration Test

An out-of-control period occurs when the calibration error of an NO_x concentration monitor exceeds 5.0 percent based upon the span range value, when the calibration error of an O_2 monitor exceeds 1.0 percent O_2, or when the calibration error of a flow monitor exceeds 6.0 percent based upon the span range value, which is twice the applicable specification. The out-of-control period begins with the hour of completion of the failed calibration error test and ends with the hour of completion following an effective recalibration. Whenever the failed calibration, corrective action, and effective recalibration occur within the same hour, the hour is not out-of-control if 2 or more valid readings are obtained during that hour as required by Chapter 2, Subdivision B, Paragraph 5.

An out-of-control period also occurs whenever interference of a flow monitor is identified. The out-of-control period begins with the hour of the failed interference check and ends with the hour of completion of an interference check that is passed.

f. Data Recording

Record and tabulate all calibration error test data according to the month, day, clock-hour, and magnitude in ppm, DSCFH, and percent volume. Program monitors that automatically adjust data to the calibrated corrected calibration values (for example, microprocessor control) to record either: (1) the unadjusted concentration or flow rate measured in the calibration error test prior to resetting the calibration, or (2) the magnitude of any adjustment. Record the following applicable flow monitor interference check data: (1) sample line/sensing port pluggage, and (2) malfunction of each RTD, transceiver, or equivalent.

2. Semi-annual Assessments

a. For each CEMS, perform the following assessments once semi-annually thereafter, as specified below for the type of test. These semi-annual assessments shall be completed within six months of the end of the calendar quarter in which the CEMS was last tested for certification purposes (initial and recertification) or within three months of the end of the calendar quarter in which the District sent notice of a provisional approval for a CEMS, whichever is later. Thereafter, the semi-annual tests shall be completed within six months of the end of the calendar quarter in which the CEMS was last tested. For CEMS on bypass stacks/ducts, the assessments shall be performed once every two successive operating quarters in which the bypass stacks/ducts were operated. These tests shall be performed after the calendar quarter in which the CEMS was last tested as part of the CEMS certification, as specified below for the type of test.

Relative accuracy tests may be performed on an annual basis rather than on a semi-annual basis if the relative accuracies during the previous audit for the NO_X pollutant concentration monitor, flow monitoring system, and NOx emission rate measurement system is 7.5 percent or less.

b. For CEMS on any stack or duct through which no emissions have passed in two or more successive quarters, the semi-annual assessments must be performed within 14 unit operating days after emissions pass through the stack/duct.

c. The due date for a semi-annual or annual assessment of a major source may be postponed to within 14 unit operating days from the first re-firing of the major source if the major source is physically incapable of being operated and all of the following are met:

i. All fuel feed lines to the major source are disconnected and flanges are placed at both ends of the disconnected lines, and

ii. The fuel meter(s) for the disconnected fuel feed lines are maintained and operated and associated fuel records showing no fuel flow are maintained on site.

For any hour that fuel flow records are not available to verify no fuel flow, NOx emissions shall be calculated using the maximum valid hourly emissions from the last 30 days of operation.

Prior to re-starting operation of the major source, the Facility Permit Holder shall: (1) provide written notification to the District no later than 72 hours prior to starting up the source, (2) start the CEMS no later than 24 hours prior to the start-up of the major source, and (3) conduct and pass a Cylinder Gas Analysis (CGA) prior to the start-up of the major source. The emissions data from the CEMS after the re-start of operations is considered valid only if the Facility Permit Holder passes the CGA test. Otherwise, for a non-passing CGA, the CEMS data is considered invalid until the semi-annual or annual assessment is performed and passed. As such, NOx emissions shall be calculated using the maximum valid hourly emissions from the last 30 days of operation commencing with the hour of start up and continuing through the hour prior to performing and passing the semi-annual or annual assessment.

d. An electrical generating facility that only operates under a California Independent System Operator (Cal ISO) contract may postpone the due date for a semi-annual or annual assessment of a major source to the next calendar quarter provided that the facility shows the semi-annual or annual assessment was scheduled to be performed during the first 45 days of the calendar quarter in which the assessment is due but the assessment was not completed due to lack of adequate operational time, and a CGA is conducted and passed within the calendar quarter when the assessment is due.

~~a.~~e. Relative Accuracy Test Audit

Perform relative accuracy test audits and bias tests semi-annually and no less than 3 months apart for each NO_X pollutant concentration monitor, stack gas volumetric flow rate measurement systems, and the NO_X mass emission rate measurement system in accordance with Chapter 2, Subdivision B, Paragraph 10, Chapter 2, Subdivision B, Paragraph 11, and Chapter 2, Subdivision B, Paragraph 12. The relative accuracy of the pollutant concentration monitor and the mass emission rate measurement system shall be less than or equal to 20.0 percent, and the relative accuracy of the stack gas volumetric flow rate measurement system shall be less than or equal to 15.0 percent. For monitors on bypass stacks/ducts, perform relative accuracy test audits once every two successive bypass operating quarters in accordance with Paragraphs 2.B.10, 2.B.11, and 2.B.12.

~~b.~~f. Out-of-Control Period – Relative Accuracy Test Audit

An out-of-control period occurs under any of the following conditions: (1) The relative accuracy of an NO_X pollutant concentration monitor or the NO_X emission rate measurement system exceeds 20.0 percent; (2) the relative accuracy of the flow rate monitor exceeds 15.0 percent; or (3) failure to conduct a relative accuracy test audit by the due date for a semi-annual assessment. The out-of-control period begins with the hour of completion of the failed relative accuracy test audit and ends with the hour of completion of a satisfactory relative accuracy test audit.

~~c.~~g. Out-of-Control Period – BIAS Test

An out-of-control period occurs if all the following conditions are met:

i. Failure of a bias test as specified in Attachment B of this Appendix;

ii. The CEMS is biased low relative to the reference method (i.e. Bias Adjustment Factor (BAF), as determined in Attachment B of this Appendix, is greater than 1); and

iii. The Facility Permit holder does not apply the BAF to the CEMS data.

The out-of-control period begins with the hour of completion of the failed bias test audit and ends with the hour of completion of a satisfactory bias test.

~~d.~~h. Alternative Relative Accuracy Test Audit

i. The Facility Permit holder of a major source, that has received written approval from the Executive Officer as an intermittently operated source, may postpone the due date for a semi-annual assessment to the end of the next calendar quarter if the Facility Permit holder:

I. operated the source no more than 240 cumulative operating hours and no more than 72 consecutive hours during the calendar quarter when a semi-annual assessment is due; and

II. conducted a relative accuracy test audit on the CEMS serving the source during the previous four calendar quarters and meeting the accuracy criteria as set forth under Subparagraph B.2.~~a~~e.; and

III. conducted an alterative relative accuracy test audit on the CEMS serving the source during the calendar quarter when a semi-annual assessment is due and meeting the criteria specified under Clause B.2.~~d~~h.iii

If any of the requirements under Subclauses B.2.~~d~~h.i.I, II and III is not met and the source did not have passing RATA during the calendar quarter when the semi-annual assessment is due, emissions from the source shall be determined pursuant to the Missing Data Procedures as specified under Rule 2012, Appendix A, Chapter 2, Subdivision E after the semi-annual assessment due date until the hour of completion of a satisfactory relative accuracy test audit.

ii. The Facility Permit holder may submit a written request to designate a major source as an intermittently operated source provided the Facility Permit holder demonstrates that:

I. During any calendar quarter within the previous two compliance years, the source was operated no more than 240 cumulative operating hours and no more than 72 consecutive hours ; or

II. During any calendar quarter within the next two compliance years, the source will be operated no more than 240 cumulative operating hours and no more than 72 consecutive hours.

iii. An alternative relative accuracy shall consist of a Cylinder Gas Analysis (CGA) method as defined under 40 CFR, Part 60, Appendix F, combined with a flow accuracy verification. For sources equipped with stack flow monitors, the flow accuracy shall be verified by calibrating the transducers and transmitters installed on the stack flow monitors using procedures under Paragraph B.3 of this attachment. For sources equipped with fuel flow meters and no stack flow monitors, the flow accuracy shall be verified by calibrating the fuel flow meters either in-line or offline in accordance with the procedures outlined in 40CFR Part 75, Appendix D. Passing flow accuracy verification results that were obtained within the past 4 quarters may be used in lieu of performing a flow accuracy verification during the calendar quarter when a semi-annual assessment is due. The calculated accuracy for the analyzer responses for NO_x and O_2 concentration shall be within 15 percent or 1 ppm, whichever is greater, as determined by the CGA method as defined under 40 CFR, Part 60, Appendix F. Successive alternative relative accuracy test audits shall be performed no less than 45 days apart.

3. Calibration of Transducers and Transmitters on Stack Flow Monitors

All transducers and transmitters installed on stack flow monitors must be calibrated every two operating calendar quarters, in which an operating calendar quarter is any calendar quarter during which at anytime emissions flow through the stack. Calibration must be done in accordance with Executive Officer approved calibration procedures that employ materials and equipment that are NIST traceable.

When a calibration produces for a transducer and transmitter a percentage accuracy of greater than ± 1%, the Facility Permit holder shall calibrate the transducer and transmitter every calendar operating quarter until a subsequent calibration which shows a percentage accuracy of less than ± 1% is achieved. An out-of-control period occurs when the percentage accuracy exceeds ±2%. If an out-of-control period occurs, the Facility Permit holder shall take corrective measures to obtain a percentage accuracy of less than ±2% prior to performing the next RATA. The out-of-control period begins with the hour of completion of the failed calibration error test and ends with the hour of completion of following an effective recalibration. Whenever the failed calibration, corrective action, and effective recalibration occur within the same hour, the hour is not out-of-control if two or more valid data readings are obtained during that hour as required by Chapter 2, Subdivision B, Paragraph 5, Subparagraph a.

APPENDIX G

COMMENT LETTERS RECEIVED ON THE NOP/IS AND RESPONSES TO COMMENTS

INTRODUCTION

A Notice of Preparation/Initial Study (NOP/IS) was released for a 57-day public review and comment period from December 5, 2014 to January 30, 2015 which identified the environmental topics of aesthetics; air quality and greenhouse gas emissions; energy; hydrology and water quality; hazards and hazardous materials; solid and hazardous waste; and, transportation and traffic, as potentially being significantly adversely affected by the project. The SCAQMD received eight comment letters regarding the preliminary analysis in the NOP/IS during the public comment period.

The comment letters have been numbered (see Table G-1 below) and individual comments within each letter have been bracketed and numbered. Following each comment letter is SCAQMD staff's responses to the individual comments.

Comment Letter #1

January 29, 2015

South Coast Air Quality Management District
21865 Copley Drive
Diamond Bar, CA 91765
Attn: Barbara Radlein

Re: Comments on "Draft Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM)"

Ms. Radlein:

SCAQMD has recognized that a small percentage of facilities are responsible for a majority of NOx emissions in the South Coast air basin. These high-producing NOx facilities, owned by major corporations and utility companies, have the resources available to invest in the technologies outlined in the BARCT analysis and achieve substantial reductions in their NOx emissions. However, SCAQMD is proposing a shave of nearly half of all RECLAIM Trading Credits (RTCs) from both large and small facilities alike. Baker Commodities ("Baker") does not feel that small companies such as ours should be punished for the emissions of a select few large facilities. 1-1

Baker is not a major source of NOx amongst RECLAIM facilities, cannot achieve significant emission reductions by implementing any control technology, and does not have the resources available to invest in them. Moreover, at current RTC prices, purchasing additional RTCs to make up for a reduced allocation will place an equally onerous burden on Baker's operations. 1-2

The proposed RTC shave translates to a reduction of .015 potential tons of NOx per day for Baker's facility. If Baker were to invest in control technology, such as selective catalytic reduction (costing upwards of $1 million), we are likely to see an actual reduction of approximately .012 tons of NOx per day. In such scenario, Baker is looking at a figure that amounts to less than 0.5% of SCAQMD's 5 tons per day reduction target, per CMB-01. With the currently proposed amendments to Rule 2002 targeting a reduction greater than 5 tons per day, investment by Baker in such technology seems immaterial and like a poor return on the investment. 1-3

Baker requests that only those facilities that are significant contributors of NOx and have the potential for major reductions in their emissions, such as the top emitters that are the focus of the BARCT analysis, be subject to the currently proposed NOx RTC shave. 1-4

Sincerely,

Chris Hassler
Environmental Compliance Specialist, Baker Commodities

RESPONSES TO COMMENT LETTER #1
(Baker Commodities - January 29, 2015)

1-1 This comment points out that a small percentage of facilities are responsible for a majority of NOx emissions in the SCAB and these facilities have the resources to invest in the technologies outlined in the BARCT analysis in order to achieve NOx reductions. This comment also claims that a proposed shave of nearly half of all RTCs from both large and small facilities, would disproportionately punish small facilities, including the commentator's facility.

SCAQMD staff conducted a BARCT assessment of the NOx RECLAIM program which resulted in adjusting BARCT levels for both equipment and source categories in the refinery and non-refinery sectors. For the refinery sector, a new level of BARCT is proposed for FCCUs, refinery boilers/heaters rated greater than 40 mmBTU/hr, refinery gas turbines, coke calciners, and SRU/TGUs. For the non-refinery sector, a new BARCT level is proposed for container glass melting furnaces, cement kilns, sodium silicate furnaces, metal melting furnaces rated greater than 150 mmBTU/hr, gas turbines and ICEs not located on the outer continental shelf (OCS). No new BARCT is proposed for power plants. Overall, a total of 14 tpd of NOx RTC reductions from the current RTC holdings of 26.5 tpd is proposed. For the 275 facilities that are in the NOx RECLAIM program, the 14 tpd of NOx RTC reductions will only affect 65 facilities plus the investors that, together, hold 90 percent of the NOx RTC holdings. Investors are included in the refinery sector and treated as one facility. For the remaining 210 facilities that hold 10 percent of the 26.5 tpd of the NOx RTCs, no NOx RTC shave is proposed because no new BARCT was identified for the types of equipment and source categories at these facilities.

Tables 7 and 8 in PAR 2002 list the facilities that would have RTC adjustments. The commentor's facility is not included in either of these tables. This facility is included in the facilities for which there is not a proposed shave.

1-2 The commentator states that their facility is not a major source of NOx emissions among RECLAIM facilities, cannot achieve significant emission reductions by implementing any control technology, and does not have the resources to invest in control technology. This comment claims that the cost of purchasing RTCs will place an onerous burden on the commentator's facility operations.

This facility is considered a major source of NOx emissions because it is a Title V facility with NOx emissions that have ranged over the last decade from 7 to 13 tons per year. The commentator's facility is not included in the categories of facilities that have a proposed RTC reduction, see Tables 6 and 7 in PAR 2002. See also Response 1-1.

1-3 This comment claims that the proposed shave represents 0.015 tons per day NOx RTC reductions for the commentator's facility and if control technology such as SCR were installed at a cost of $1 million, the actual NOx emission reductions would be 0.012 tons per day which amounts to less than 0.5 percent of SCAQMD's NOx emission reduction goal of five tons per day.

The commentator's facility is not included in the categories of facilities that have a proposed RTC reduction, see Tables 7 and 8 in PAR 2002. See also Response 1-1.

1-4 This comment requests that only significant contributors of NOx (e.g., top emitters) with the potential to achieve major reductions in NOx emissions should be subject to the NOx RTC shave.

This comment is a summary of the concerns expressed in Comments 1-1 through 1-3. See Responses 1-1 through 1-3.

Subject: Air Products and Chemicals, Inc. – Comments on Proposed NOx RECLAIM Shave Approach

Dear Ms. Radlein:

On behalf of Air Products and Chemicals, Inc. (Air Products) we appreciate the opportunity to comment on the approach that should be utilized for conducting a NOx RECLAIM shave. Air Products operates two (2) "new" RECLAIM facilities: Carson Hydrogen Plant (Facility ID 3417) and Wilmington Hydrogen Plant (Facility ID 101656). Both facilities' primary RECLAIM equipment are major source reforming furnaces (>750 MMBTU/hr) and both utilize selective catalytic reduction (SCR) for NOx control. 2-1

Our primary concern is regarding our Carson Hydrogen Plant where we had purchased two (2) infinite block streams of RECLAIM Trading Credits (RTCs) well before the 2005 NOx RECLAIM shave. These infinite block streams were acquired to cover facility NOx emissions (reforming furnace is only RECLAIM source at Carson) based on an initial, permitted BACT NOx limit of 5 ppmv @3% O2 (3-hr average). Our understanding, based on any recent/similar permitting projects, is that this level of NOx is still considered BACT at this time for hydrogen reforming furnaces. 2-2

Upon review of District staff draft report "Proposed Amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM)" (December 2004), it does not appear either of Air Products reforming furnaces, as non-refinery heaters >750 MMBTU/hr and not subject to Rule 1146, were evaluated for BARCT. Nonetheless, Carson Hydrogen Plant, like all of the RECLAIM facilities, was subjected to the ~20% across-the-board shave; however, the facility has since been able to continue to cover NOx emissions using the reduced infinite block streams through increased SCR ammonia injection and more frequent SCR catalyst change-outs. 2-3

Fast forward to the currently proposed across-the-board shave of ~50% and it appears that still neither of Air Products reforming furnaces was evaluated for BARCT. Based on the cumulative effect (~60%) of the 2005 reduction (~20%) and currently proposed reduction (~50%), the District is essentially forcing the Carson Hydrogen Plant, as a source where no BARCT limit has been identified and no more stringent BACT limit exists, to either operate at ≤2 ppmv NOx levels (which would likely not be possible without significant and expensive SCR equipment modifications due to current system limitations and/or taking into account NH3 slip limit) or purchase RTCs on the market whose cost, as an infinite block stream, could easily exceed $1 million. 2-4

-2-

We feel that the most fair and equitable manner is to apply the shave such that it is only impacting facilities where actual reductions have been identified through new 2014 BARCT limits. By applying the shave across the board there can be, as described above for example, significant financial impacts to sites and sources that were not evaluated and may already be operating at levels considered as current BACT. While Air Products appreciates the complexity of doing something other than an across the board shave in a free trade market such as RECLAIM; we feel that the District has a responsibility to look closer at possible methods that could exempt sources from a shave where no reductions have been evaluated and identified; such as: 2-5

- Segregating all RTCs into two different types that can be used to cover sources/facility emissions; one type where a 2014 BARCT limit has been identified and one type where a 2014 BARCT limit has not been identified.
- An option to "lock-in" current infinite block stream(s) a facility holds (as of some previous date) for life or until any future RECLAIM shave may occur with an applicable BARCT limit for that facility.

Please feel free to contact me at (310) 847-7300 or by email at reebeljc@airproducts.com if you have any questions or would like to discuss further. Thank you.

Sincerely,

Jim Reebel

RESPONSES TO COMMENT LETTER #2
(Air Products and Chemicals, Inc. - January 30, 2015)

2-1 This comment introduces the commentator's facilities and identifies the primary equipment sources of NOx RECLAIM emissions. No response is necessary.

2-2 This comment inquires as to whether BACT for a hydrogen reforming furnace is going to remain at five ppmv NOx at 3% O_2 because the commentator's facility had previously acquired two infinite block streams of NOx RTCs prior to the 2005 NOx RECLAIM shave to cover emissions from this type of equipment.

SCAQMD staff did not propose a new BARCT for reforming furnaces. SCAQMD staff conducted a BARCT analysis for several source categories among the top emitting facilities for compliance year 2011. The analysis demonstrated that SCR is the preeminent technology for achieving NOx emission levels at two ppm at 3% O_2 for combustion sources. As part of the BARCT analysis, some equipment, such as boilers and engines, were also evaluated for those facilities outside the range of the top emitting facilities. While the process is referred to as hydrogen reforming, the equipment is considered a heater/furnace with a heat rating greater than 50 MMBTU/hr. This is not different from a large boiler/heater or a refinery boiler and heater that would be subject to 2ppm BARCT. While there were many refinery boilers and heaters that were analyzed do have cost-effective BARCT, the analysis of reforming furnaces was based on the vast majority of the boilers and heaters in the non-refinery sector and determined to be not cost effective. Thus, SCAQMD staff did not propose a new BARCT for reforming furnaces.

2-3 This comment states that the staff report for the 2005 NOx RECLAIM amendments did not conduct a BARCT evaluation of reforming furnaces or non-refinery heaters rated greater than 750 MMBTU/hr and not subject to Rule 1146. This comment also states that in response to the 20 percent shave applicable to all NOx RECLAIM facilities as part of the 2005 NOx RECLAIM amendments, the commentator's facility, in response to that shave, increased ammonia injection into the SCR and implemented more frequent SCR catalyst change outs in addition to applying the purchased infinite block streams to cover the emissions.

For any gaseous fueled heater that is rated above five MMBTU/hr and is operated at a facility that is not subject to the RECLAIM program, the requirements in Rule 1146 would apply. Thus, contrary to the comment, RECLAIM heaters were subject to BARCT as part of the 2005 NOx RECLAIM amendments. Since the shave for that rule amendment was an across the board approach, all facilities in NOx RECLAIM had their RTCs reduced.

2-4 This comment claims that the current proposal of a 50 percent shave also does not include a BARCT evaluation of reforming furnaces. This comment states that the cumulative effect of the 2005 NOx shave, when combined with the current proposed 50 percent shave, will have an overall effect of reducing RTCs at the commentator's facility by 60 percent. The comment also claims that the commentator's facility will either need to operate at less than or equal to two ppmv NOx levels by making expensive modifications to existing SCR equipment or by purchasing over $1 million of RTCs.

As explained in Response 2-2, SCAQMD staff did not propose a new BARCT for reforming furnaces. The commentator is correct that no BARCT analysis was conducted for reforming furnaces. The staff proposal does not shave offsets at the commentator's facility; the emission reduction calculations and associated costs are not germane to the current staff proposal. The current staff proposal, in addition to relying on a BARCT analysis, also proposes to shave excess RTCs in the market since unused RTCS can be used to emit at levels exceeding BARCT.

2-5 This comment suggests that the shave be applied only to facilities where actual reductions have been identified via new 2014 BARCT limits to avoid significant financial impacts to sites and sources that were not evaluated and that may already be operating at current BACT levels. This comment suggests exempting sources/facilities from the RTC shave if no 2014 BARCT limit has been identified. This comment also suggests that the proposed amendments include a provision that would segregate RTCs into two categories – one for equipment with BARCT and one without or allow an option to "lock in" current infinite block streams that a facility holds, until such time that a future BARCT limit would apply specifically to that facility's equipment.

Certain facilities are included in the shave even though there may be no new 2014 BARCT because they hold large amounts of RTCs that are not needed. See also Response 2-4 regarding the proposed RTC shave. CEQA alternatives which would have an across the board reduction have been included due to comments from some industry representatives. However, the staff proposal has the reductions described in previous responses.

Regarding the suggestion to have different classifications for RTCs, doing so would introduce significant complexity to the program and create uncertainties in the market, which staff does not support.

Comment Letter #3

CALPORTLAND

January 30, 2015

1.0 Summary of Key Comments

After a thorough review of the Draft Program Environmental Assessment (PEA) for the proposed amendments to SCAQMD Regulation XX, Regional Clean Air Incentives Market (RECLAIM) dated December 2014, and related support documents by ETS, Inc., CalPortland and its consultants Schreiber, Yonley & Associates have identified significant problems with the documents and the process utilized to develop the control options in those documents and the associated emissions reductions contained in these documents. The following comments address these deficiencies:

1.1 The Administrative Process was Flawed

During the public meetings and throughout the rulemaking process, CalPortland Company (CalPortland) and their technical consultants were given no opportunities to provide critical process details to either the SCAQMD, its contractors, or the vendors providing proposed control technology options, cost quotations for the proposed controls, or proposed control efficiencies for those control options. Furthermore, although CalPortland began requesting the detailed cost spreadsheets from which the Cost Effectiveness Table for cement kilns was derived as early as July 2014, none of this information was made available to CalPortland until late in the day on January 23, 2015. That information contained only very general spreadsheets (which leave many questions and concerns unanswered). Further, Confidential Appendices A of the ETS, Inc. Final Report, dated November 26, 2014, was not provided to CalPortland until January 20, 2015, ten days before the comment period ended. CalPortland was told that vendor communications, design details, cost details, warranty information and/or clarification information was confidential. We are at a loss as to how vendor information regarding control strategies would be confidential from the affected facility but this is what they were told by District staff.

The failure to provide critical documents related to the cost estimates and control technology design information during the regulatory development process has essentially denied CalPortland a voice in this regulatory process. Further, CalPortland was treated differently in this regard than other regulated industries. Not only does the withholding of critical information during this process deny CalPortland an opportunity to be heard during the process, but also prevents CalPortland from having the ability to thoroughly evaluate the PAE and the ETS, Inc. review of the cost analysis, it further denies CalPortland the ability to determine if the technical basis/design basis for the controls, the proposed control efficiencies and therefore the basis for the proposed emissions reductions in the proposed amendments to the regulation. Essentially, the flawed process prevents CalPortland from making fully informed comments on the proposed amendments.

3

1.2 Inconsistencies Exist Between the PEA and Cost Analysis Control Options

The three control technology options listed in the PEA are not consistent with the control technologies listed and evaluated in the Cost Analysis and the ETS evaluation of the cost analysis.

1.3 There are Significant Technical Concerns with the Control Options in the Cost Analysis

The characteristics of the emissions from cement kilns vary from kiln to kiln due to differences in the type of cement kiln, the fuels utilized, and the chemical characteristics of the raw materials. The vast majority of the raw materials utilized by cement kilns are mined onsite and not only vary from site to site, but also may vary within the onsite quarries. These site specific conditions are critical to the design of emissions control equipment. Critical site-specific characteristics include process information that is not included in reports/documents submitted to regulatory agencies. Critical design parameters include not only the average values, but also the minimums and maximums. The failure to allow CalPortland access to the vendor documents jeopardized the validity of the design basis. Further, based upon knowledge of the differences between the CalPortland kilns and the kiln gas characteristics from the limited number of other kilns which have utilized SCR systems, the CalPortland kilns are significantly different. The SCR systems on other kilns operate at significantly higher gas temperatures. Further, when a low temperature catalyst was pilot tested on a cement kiln at similar gas temperature and which also experiences SO_2 spikes similar to CalPortland, the catalyst was poisoned within less than three months. The Ultracat option to our knowledge has not had any long term application on a cement kiln.

Finally, the SO_2 control options proposed to control the SO_2 spikes will have little to no impact on typical SO_2 emissions levels at CalPortland. This is because the average SO_2 emissions from CalPortland are below concentrations where these controls are effective. While there may be control during the SO_2 spikes, either SO_2 control option proposed by the vendors will have a lag time to react to the increased concentrations during emissions spikes, and therefore the catalyst will not be sufficiently protected from SO_2 poisoning.

4

1.4 Cost Effectiveness Analysis

The estimated costs provided in the cost analysis are impossible to fully evaluate without having the design basis and supporting detailed cost estimation spreadsheets. Nevertheless, the capital and annual costs appear to be too low and it is unclear if they fully address site specific construction conditions, costs for treatment of the wastes generated by the WGS, a realistic frequency for catalyst replacement/reactivation/disposal and other site specific costs. CalPortland acknowledges that even with corrected cost estimates, the cost effectiveness is unlikely to exceed SCAQMD criteria of $50,000 per ton pollutant removed. However, the cost analysis fails to address one way in which CalPortland differs from the majority of the other industry categories impacted by the Proposed Amended Regulation XX. CalPortland will not be able to pass these cost on to customers through increases in the price for cement. The cement industry is highly competitive. The proposed controls would result in an increase of $10 or more per ton of cement. This will not only price CalPortland out of the local market with local competitors that are not subject to SCAQMD RECLAIM program, but for that price difference cement can be imported from Asia at a lower price.

1.5 CalPortland's Emissions Rate

To our knowledge CalPortland's current NO_x emissions limit of 2.73 lb/T clinker (T_c) already represents the lowest emission limitation for long dry cement kilns. Typical long dry kiln emission rates are in the range of 8-12 lb NO_x/T_c, which is represents the uncontrolled emissions rate from the Colton kilns, and the existing limitation is already a 65-77% reduction in NO_x emissions for a typical uncontrolled long dry kiln.

BARCT emissions limits should be essentially the same as BACT. Retrofit controls should not be expected to be more stringent than controls that are designed and integral to a new source. The emissions limit under the New Source Performance Standards for a new cement kiln is 1.5 lb/Tc which was adopted recently by EPA after a very thorough technology review (which included a review of SCR). CalPortland has proposed to add SNCR to the NO_x controls already in place at the plant and believes that an additional reduction in NO_x emissions of 30-40% can be achieved. The result would be an emissions rate in the range of 1.64 -1.91 lb NO_x/T_c. At that emissions rate, it is believed that the emissions from the Colton kilns would be lower than the emissions from the Joppa, IL long dry kiln which utilizes SCR.

2.0 Introduction

In a cement kiln, raw materials containing the necessary ratios of calcium, alumina, silica and iron are blended, ground to the required fineness in the raw mill and pyroprocessed at very high temperatures (material temperatures of 2700F) at which the materials liquefy and react to form a complex mixture of compounds referred to as clinker. **Note that clinker is not "..lumps of limestone and clay)" as stated in paragraph 5, page 1-16, of the PEA.** The chemistry of the raw materials and fuels and the operation of the kiln are critical to making clinker that will meet cement quality specifications. NO_x emissions are the result of the combustion of the nitrogen found in the fuels and the oxidation of the nitrogen in the combustion air due to the high temperatures in the combustion zone. **Note that the statement found in the PEA, Page 1-17, paragraph 3, ..., 2) oxidation of sulfides (e.g. pyrites) in the raw materials entering the cement kiln." is incorrect. The oxidation of sulfides form SO_2 not NO_x.**

There are several types of cement kilns in operation in the United States today, these are: long wet kilns, long dry kilns (CalPortland's Colton, CA kilns are this type), preheater kilns, and preheater/precalciner kilns. All new kilns built today are preheater/precalciner kilns (PH/PC). PH/PC kilns are more energy efficient, minimize waste (significantly reduce or eliminate the generation of cement kiln dust (CKD) requiring landfilling) and are designed to produce lower pollutant emissions, including GHG, than the earlier kiln designs. Pollutant emissions from cement kilns are directly related to the chemistry of the raw materials utilized. Because the vast majority of these raw materials are mined onsite, typically 85 percent or greater, the emissions from each kiln are site-specific. Therefore, the design of emissions controls must also be site-specific as will be the potential reduction in emissions from those controls.

3.0 Comments on Proposed Control Options

The draft PEA, page 1-17, paragraph 4 lists the 3 potential available control technologies for cement kilns as:

1. SCR with or without a WGS;
2. Ultracat; or
3. SNCR

All of the cost effectiveness documents list and evaluate the following three control options:

1. Vendor 1: SCR system installed between waste heat boiler and baghouse
2. Vendor 2: Dry scrubbing and ceramic filter system installed after the waste heat boiler and replacing the baghouse
3. Wet gas scrubber and SCR system with heat exchanger installed after the waste heat boiler and replacing the baghouse.

Note that the cost effectiveness documents do not include analysis of SNCR nor did the PEA discuss the heat exchanger option with SCR. The remaining comments in this section will focus on the three alternatives evaluated in the cost effectiveness documents first focusing on technical concerns with the proposed technologies and then addressing the cost estimates themselves.

The existing gas flow is as follows: the gas exits the kiln and passes through a series of 4 cyclones and a multiclone then is ducted to a waste heat boiler (WHB). Then the gas is ducted back to the inlet to the baghouse and then exits through the kiln stack. The temperature of the gas entering the waste heat boiler is in the 900 - 1200°F range and the temperature exiting the waste heat boiler is around 350°F. Figure 1 below illustrates the existing gas flow.

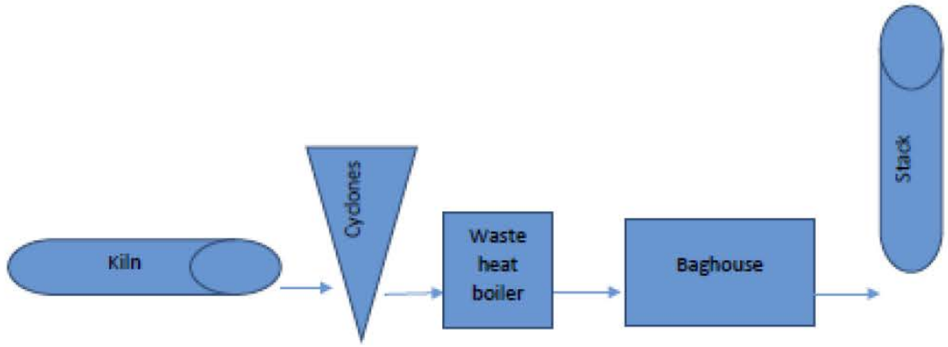

Figure 1: Existing Kiln Gas Flow Diagram

3.1 Vendor 1

Vendor 1 proposed to install a SCR between the waste heat boiler and the baghouse. In reality, the SCR would not physically be located between the waste heat boiler and the baghouse as there is physically no room to install an SCR there on either kiln. Figure 2 is a photograph of the kiln baghouses and stacks and illustrates the physical constraints and physical size of the equipment.

8

Figure 2: Photo of Kilns and Baghouses

9

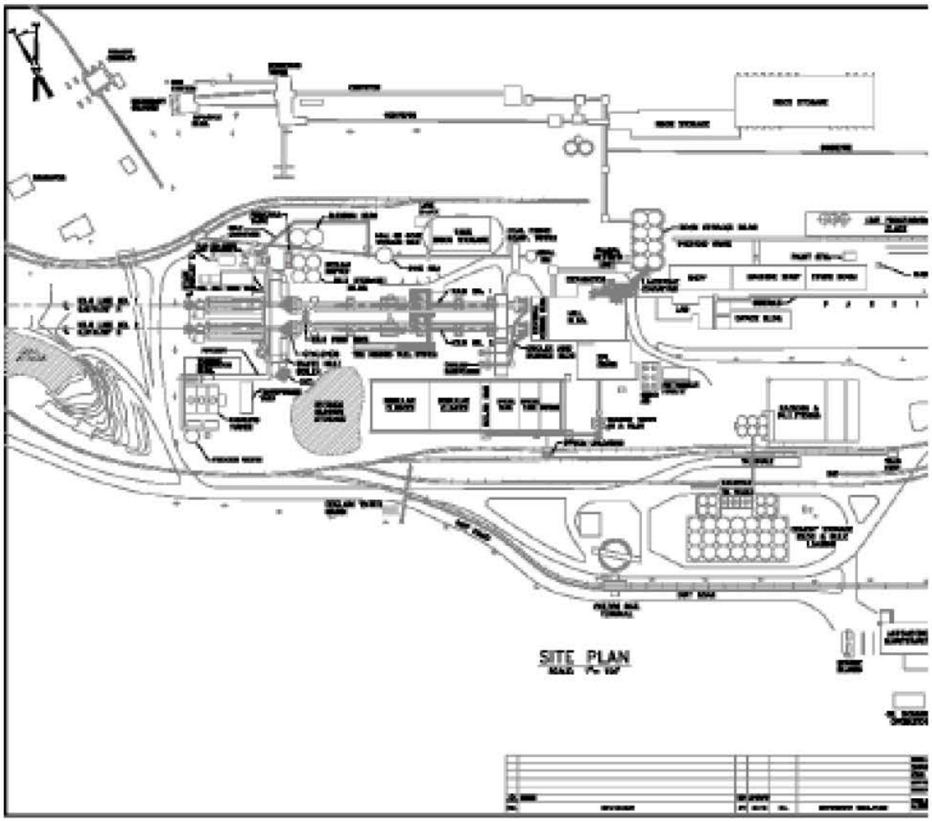

Figure 3: Site Plan

10

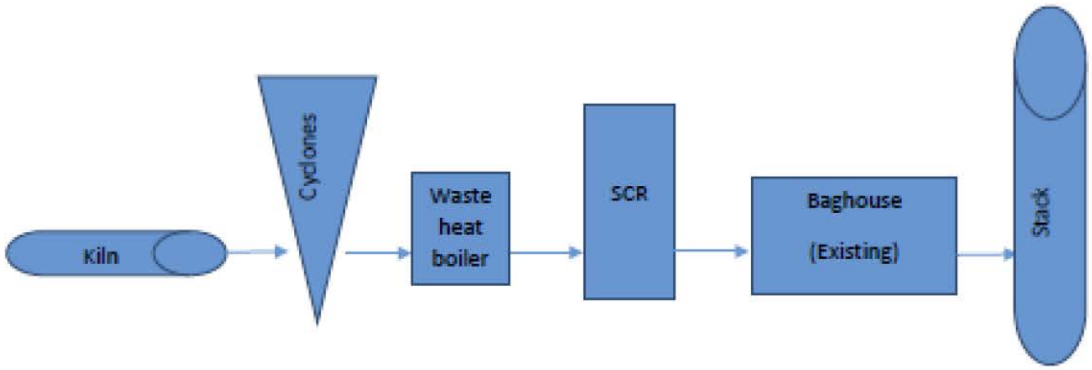

Figure 4: Gas Flow Diagram for Vendor 1 Option

Figure 3 above shows the existing equipment at the site. As is obvious from the site plan and the photo in Figure 2, the SCRs cannot physically be located between the waste heat boilers and the baghouses. The existing coal pile and handling systems are north of the baghouses and cannot be moved due to fugitive emissions constraints as well as proximity to coal unloading and handling equipment. Therefore, the SCRs would need to be located in the area north of the kilns, Co-generation facility or rail lines, requiring the ductwork to go above existing equipment 150-200 feet to the SCR and then back 150 -200 feet to the baghouse inlets. This ductwork would need to be insulated and the SCR and ductwork construction would need to comply with local seismic construction codes. As noted in the initial summary. CalPortland has been denied access to the vendor design basis based on confidentiality of the vendor information and the cost spreadsheets provided on January 23, 2015 do not contain sufficient detail to make a determination. Therefore, it is unknown whether the increased construction costs, potentially 20% or more, to comply with local seismic codes were included in their cost estimates.

ETS noted in their report that there has been conflicting information provided regarding the temperature of the gas returning from the waste heat boilers. Initially 300-350°F, then an indication that it might be 450-500° F and then in October 2014, 350°F. ETS indicated that Vendor 1 indicated that an additional layer of catalyst would be needed at a lower temperature of 450°F. Obviously, since their costs were provided to the SCAQMD prior to that time, and have not been revised by ETS other than to include a 15% contingency, the cost for the SCR both capital and annual would need to be increased to include the costs for installing and operating with an additional catalyst.

11

It is also unclear whether the current ID fan would be adequate to meet the additional pressure loss across the SCR and the lengthy ductwork to and from the SCR, or whether the cost for replacement ID fan was included in the vendor cost estimate. CalPortland believes a new fan would be necessary. Based upon knowledge of costs for other cement SCR systems, even with the ETC contingency adjustment, Vendor 1's costs appear to be significantly low.

However, the greatest concern with the Vendor 1 proposal is the impact of the gas temperature on the efficiency of the catalyst to control NO_x, and more importantly, the impact of the SO_2 emissions on the catalyst when the SO_2 spikes. The catalyst converts SO_2 to SO_3. . Below 450°F, any ammonia injected for the NO_x reaction will react to form ammonium salts, $(NH_4)_2SO_4$ and NH_4HSO_4 , which poison and plug the catalyst (see chart in Appendix A). This is particularly true for the more reactive catalyst formulations required for lower gas temperature applications. A pilot test with a low temperature catalyst on a cement plant with similar gas temperature and which although SO_2 was typically low, experienced occasional spikes in SO_2 was unsuccessful due to sulfur poisoning. Even with duct burners, as suggested by ETS to address temperature loss between the waste heat boiler and SCR, temperatures would not be expected to be above the 450°F necessary to prevent the formation of ammonium salts and catalyst poisoning. Therefore, regardless of the addition of duct burners, which would generate additional combustion emissions including NO_x, the SCR proposed by Vendor 1 is unlikely to be technically feasible.

3.2 Vendor 2

Vendor 2 proposed to place a dry scrubbing system after the waste heat boiler to address concerns with SO_2 emissions then follow that with a ceramic filter system in place of the existing baghouse. Figure 5 below is a diagram of the gas flow for this scenario.

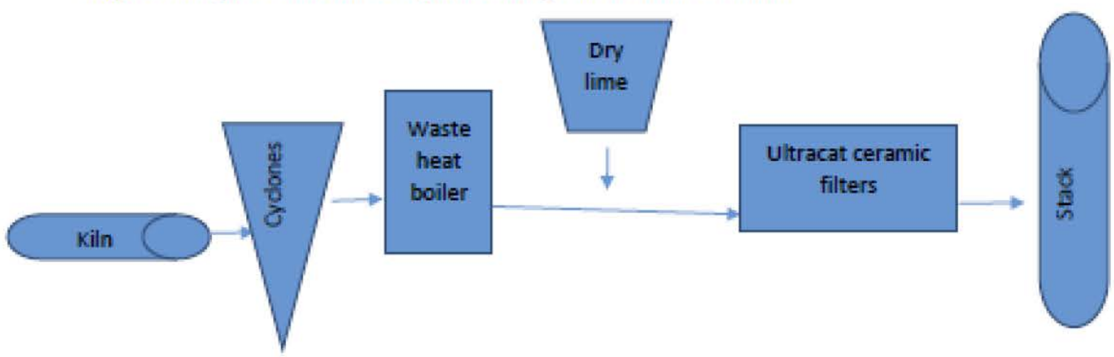

Figure 5: Vendor 2 Proposed Control Gas Flow Diagram

12

It is believed that Vendor 2 included the dry scrubbing system to address concern with catalyst poisoning due to the SO_2 concentrations and the gas temperatures. However, there are two technical concerns with this approach. First, the temperature of the gas stream exiting the waste heat boiler is at or near the temperature for the lowest SO_2 reduction efficiency, perhaps 30% control. Second, because of the high dust loading in the gas stream as well as other factors, a CEMS system to monitor the SO_2 concentration prior to the lime injection location, upstream of the ceramic catalyst (Ultracat) system cannot be used because the sample probe cannot endure the conditions in the gas stream (high dust concentration). Therefore, the stack CEMS would be the first indicator of the SO_2 spike and by this point the catalyst would already have some exposure to the increased SO_2 levels. By the time a spike is noted and the control system increases the lime injection rate, some level of catalyst damage would likely have already occurred.

Ultracat's vendor literature, available from the internet, and conversations with the vendor for a different, but similar application, indicate that NO_x control becomes effective at 350°F but does not achieve high (90%) efficiency until gas temperatures above 400°F.

Without access to the vendor's design basis and more details than the spreadsheets provided on January 23, 2015 include, it is not possible to comment on the proposed cost effectiveness calculations other than to express concerns on whether the costs account for construction compliant with seismic codes and the need for a contingency. Given that, to our knowledge, the Ultracat system has not been installed for full scale, long term application at a cement kiln, a contingency of greater than 15% would be warranted. Further, annual costs are somewhat speculative due to unknown life of the ceramic catalyst filter system in a cement application.

The Ultracat ceramic filter system is untried on a full-scale long-term application for a cement kiln. Given the differences in cement plant applications compared to other applications, CalPortland does not believe that it meets the criteria for a demonstrated control technology for this application especially for a definition of a best available "retrofit" technology. Further, although the vendor literature indicates that their product will control particulate emissions to levels that comply with the 40 CFR Part 63, Subpart LLL (the NESHAPS for portland cement manufacturing), CalPortland is unaware of any long-term application of the technology on a cement kiln and cannot verify that it will comply with the new emissions limitations for PM in routine cement application.

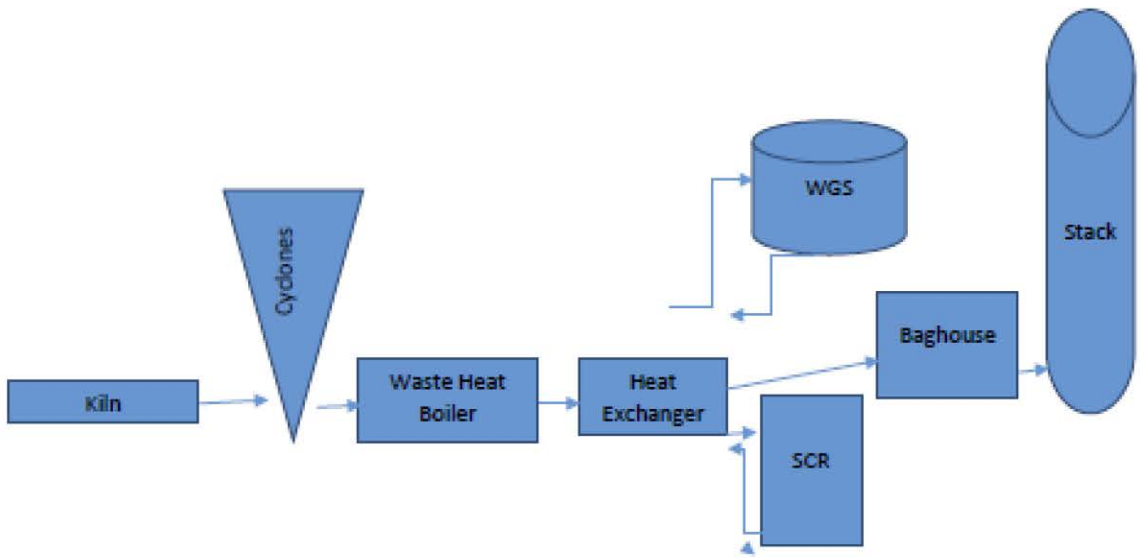

Figure 6: Vendor 3 Proposed Control Gas Flow System

3.3 Vendor 3

Vendor 3 proposes to utilize a wet gas scrubber to address the SO_2 in the gas exiting the waste heat boilers, a heat exchanger to increase the gas temperature for the SCR and then replace the existing baghouse. Figure 6 below illustrates the kiln gas flow through this control system.

The wet gas scrubber is proposed to reduce SO_2 emissions prior to the SCR. However, the typical concentration of SO_2 in the gas stream is between zero and 10 ppm and typically in the 2 ppm range. Discussions with a wet scrubber vendor confirmed that there is a lower limit/concentration that they will guarantee. For a wet lime scrubber, the type currently utilized at the few cement kilns with wet scrubbers, the lower limit for the warranty for the concentration of SO_2 in the scrubber exit gas is 10-12 ppm, a caustic scrubber, as proposed by Vendor 3, might be slightly lower, but still would have no impact on a 2 ppm stream. Therefore, under typical kiln operations the WGS will provide no impact/control of SO_2 because the emissions are below the effectiveness of the technology. Essentially, when a control technology utilizes a reagent which must react with the pollutant in the gas stream, the pollutant molecule and the reagent molecule must come into contact with each other for the reaction to occur. The lower the concentration of the pollutant, the lower the potential for the reaction to occur. Therefore, during typical operations the WGS would be utilizing significant energy, for little to

14

no reduction in SO_2. The same issue exists for a CEMS probe for this control options as existed for the Vendor 2 option in the probe in the WGS inlet duct will not survive. Therefore an alternate mechanism for determining the necessary molar concentration for the regent in the scrubber liquid and the reagent addition rate is needed. The vendor contacted indicated that the control system measures the acidity of the scrubber liquid and when it reaches a set point, additional reagent is added. The control loop takes some time to fully address a spike situation. Like the dry reagent/lime addition proposed by Vendor 2, some damage to the SCR catalyst will occur before the system can react to the spike. It is not clear why the vendor specified a caustic scrubber when lime scrubbers are typically utilized for a cement kiln application. Further, the cost spreadsheets do not appear to include the capital costs for a scrubber wastewater treatment system or the costs for the disposal/discharge of the wastewater after treatment.

It is unclear at what temperature the SCR in this control option would operate. There is no discussion of an additional heat source to raise the gas temperature above the temperature at which it exits the waste heat boiler. Therefore it is assumed that the heat exchanger is proposed to maintain that temperature rather than to increase the temperature to the temperature range of the currently operating SCR systems on cement kilns.

Table 1 below lists the gas inlet temperatures for the cement kiln SCR applications. This information was taken either from the vendor website for a particular plant, or from papers presented by either the vendor or owner of the cement plant.

Location	Operating Temperature (°F)
Solnhofen, Germany	572-608
Monselice, Italy	608-626
Sarche, Italy	666-750
Mergelstetten, Germany	716-750
Rohrdorf, Germany	550-660
Mannersdorf, Austria	570-660
Joppa, Illinois	572
Rezzato, Italy	590-626

Table 1: Operating Temperatures of Existing Cement Kiln SCRs

It is important to note that, whether the SCR is low-dust, semi-dust or high-dust application, the gas inlet temperature to the SCR is between 550°F and 750°F. Only one of these applications reheats the gas stream, and in that instance there are no waste heat boilers utilizing the available waste heat from the process to minimize/eliminate the combustion of additional fuels which would generate combustion emissions.

ETS, in their review indicate that they corresponded with USEPA regarding the SCR on the Joppa, IL cement kiln. The plant has not yet completed their written report on the SCR, but USEPA reported that 70-80% NOx reductions were being achieved. Although the Joppa kiln is also a long dry kiln, it is not equipped with waste heat boilers. In addition, the hot kiln gases are routed through a hot ESP which significantly reduces the dust-loading prior to the gas entering the SCR. Therefore, the Joppa SCR utilizes a typical high temperature catalyst, operating at 572°F versus the 350°F at CalPortland's Colton kilns, the catalyst is not as reactive to SO_2 as the catalyst formulation necessary for CalPortland. The Joppa SCR operates at a temperature well

16

above the temperature below which ammonium salts are a problem (450°F). Further, the dust loading to the catalyst is significantly reduced improving catalyst reliability.

3.4 Summary of Control Technology Evaluation

Due to the temperature of the gas stream exiting the waste heat boilers, there are concerns with the technical feasibility of all three control options evaluated for cost effectiveness. As previously discussed these concerns are directly related to the impact of SO_2 spikes combined with gas temperatures in the range where ammonium salts form (below 450°F). These salts poison the catalyst. The only SCR application which utilized a lower temperature catalyst in a cement plant application that we are aware of, was a pilot test which was a failure due to catalyst poisoning. Of the SCRs listed in Table 1, Sarche and Rohrdorf are low dust applications and therefore have not, and would not be expected to experience problems with dust loading on the catalyst. However all of the others with the exception of Joppa and Rezzato, for which information is not yet publically available, the SCRs experienced significant issues with the catalysts in the first years of operation and replaced and/or regenerated the catalysts multiple times in the first years of operation until catalyst pitch sizing was addressed and dust removal mechanisms were modified and became operational. Each cement kiln has site-specific gas chemistry and characteristics. CalPortland's Colton kilns are not currently operating and thus key design parameters cannot be measured or analyzed.

The current allowable NO_x emissions rate for CalPortland's Colton kilns is 2.73 lb NO_x/T_c. This represents a reduction of approximately 65-77% from uncontrolled emissions rates (uncontrolled NO_x emissions ranged from 8-12 lb/T_c). CalPortland believes that the addition of SNCR to their current controls will reduce NO_x emissions another 30-40% for a final emissions rate between 1.64-1.91 lb NO_x/T_c, which would constitute roughly a 75-85% reduction in emissions below the uncontrolled emissions rate and result in a total control efficiency in the same range as what the Joppa plant is achieving with a high temp, semi-clean, SCR system. At that emissions rate CalPortland believes that their emissions might actually be lower than the emissions rate achieved by Joppa. The emissions level at Joppa will not be available until the Joppa Demonstration Report is submitted. Further, SNCR is not adversely impacted by SO_2 spikes, can be installed and operational on the Colton kilns at or shortly after startup of the kilns. In contrast, the installation of any of the three vendor control options will take at least a year for pilot testing and multiple years to install.

4.0 Flaws in the Administrative Process

4.1 CalPortland Denied Access to Vendor Information

Throughout the rulemaking process, CalPortland repeatedly requested access to the vendors' design basis and the details of the vendors' cost information and requested to meet with the vendors to ensure that they fully understood the kilns system and kiln gas characteristics that impact design, CalPortland has not had any opportunity to discuss vendor information with the District or the vendors and was not provided the detailed design basis or detailed cost spreadsheets necessary to determine the validity of the design or costs. CalPortland was told that the information was confidential. We are at a loss as to how vendor information regarding control strategies would be confidential from the affected facility, but this is what CalPortland was told by SCAQMD staff. The very basic cost spreadsheets provided on January 23, 2015, do not address all of CalPortland's questions or concerns.

Questions not addressed or answered by the vendor cost spreadsheets that were provided are as follows:

1. Were the vendors notified of the updated temperature information for the gas stream after the October 2014 site visit by ETS? Vendor costs were not changed from the summary cost spreadsheet provided in July 2014 to the spreadsheets and costs in the November ETS and December PEA. ETS indicates that Vendor 1 modified their design to include more catalyst after they were notified of a temperature of 450°F. Would additional changes need to be made for the actual temperature of 350°F? Further, given that the actual temperature is well below the temperature for ABS formation, would any of the vendors warranty the designs they quoted at this lower temperature given the additional knowledge that emissions of SO_2 spike up to 1500 ppm?

2. The annual costs for catalyst replacement vary significantly between Vendor 1 and Vendor3 for the same control of the same gas stream. There is no explanation for the discrepancy. Further, although the two vendors are consistent in indicating 3-year catalyst life, this life is questionable given the history of SCR at other kilns. CalPortland has knowledge of a recent SCR catalyst warranty of two years. There is no indication in the spreadsheets provided that pilot testing of a gas slip-stream is planned or included in the costs. Even with pilot testing, previously constructed SCR systems on cement plants have routinely had to change out catalysts multiple times in the first years of operation.

3. There is no mention in the, PEA, the ETS documents or the vendor spreadsheets regarding the need for the controls to operate for the gas stream at both potential operating conditions. While the waste heat boilers operate when the kilns operate under normal conditions, they may not always do so. For example, a malfunction or need for maintenance on the WHB would not result in shutting down the kiln. First, it takes significant amounts of time to safely and properly shut down a cement kiln. Further, some level of thermal shock to the kiln refractory occurs even when kilns are shut down properly. Therefore, the kilns would continue to operate even if the associated WHB needed to be taken offline. The emissions control systems would need to be able to operate at both gas stream conditions, higher temperature (in excess of 900°F) when the WHB is offline and the low 350°F temperature when the WHB are in use.

4. There is no mention or apparent cost included by any of the vendors to replace the existing kiln ID fans. The additional pressure drop resulting from any of the three control scenarios would necessitate the replacement of the kiln ID fans.

5. The reports and the vendor spreadsheets make no mention of the additional construction costs associated with construction to the new stringent seismic codes. It does not appear that the these additional costs, which could be as much as 20% or more, have been included in the vendor costs.

6. As previously noted, it does not appear that Vendors 1 and 3 have included the costs and time required to conduct a slip stream pilot test prior to the design and construction of the full scale control systems. Pilot testing is essential to allow the design to address site-specific conditions.

7. Vendors 2 and 3 propose removal of the existing baghouses and footnote their spreadsheets that they haven't adjusted their costs for any salvage value of the existing baghouses. However, they do not specify whether their costs include the demolition costs for the existing baghouses.

8. Without being provided all of the correspondence related to the gas stream specifications requested by and provided to the vendors, it is not clear whether the vendors are aware of the extremely low typical concentrations of SO_2, 2ppm range, and the magnitude of the spikes which can reach 1500 ppm.

19

9. Vendor 2 proposes a product that to our knowledge has not been in long-term cement plant application. Does the vendor warranty that the system can comply with the particulate limits in 40 CFR Part 60, Subpart LLL? Can this technology even be considered to be demonstrated technology in this application?

10. Vendor 3 proposes a caustic scrubber for SO_2 control. The costs do not appear to include the capital costs for a waste water treatment system or the costs to operate that system or dispose/discharge treatment residues/wastewater. The few existing wet scrubber systems on cement kilns utilize lime rather than caustic for compatibility with the process. No information was included to justify the use of caustic rather than lime in the scrubbers for CalPortland.

Confidential Appendix A of the ETS Final Report, dated November 25, 2014 was not provided to CalPortland until January 20, 2015, only ten days before the close of the comment period. Although ETS notes in Section B, Paragraph number 3 on Page 3 of the Confidential Appendix A that: "Project documentations shows much contact and discussions with some willing vendors on the subjects of potential problems and steps for resolving them. Problems and concerns were presented by the facility were factored into the costing, e.g. adding caustic scrubbers, a heat exchanger system and soot blowers." There was no direct communication between CalPortland and the vendors and CalPortland was never provided the details of the design basis utilized by the vendors. Without an opportunity to speak directly to the vendors to provide site specific information critical to design that was not requested by the SCAQMD nor contained in documents or reports requested or required to be submitted to the District, or at the very least an opportunity to review and comment on the information provided to the vendors and by the vendors CalPortland was denied the opportunity to constructively participate in the control selection and evaluation process. Without access to the design basis details of what equipment is included in the cost estimates, CalPortland cannot fully evaluate the technical feasibility of the proposed control options, the reported costs for those controls or whether those controls can actually achieve the emissions limit contained in the proposed amended Regulation XX.

4.2 Vendor Costs were not revised even though SCAQMD and ETS were made aware Lower Gas Temperatures at least by Mid-October 2014.

CalPortland acknowledges that there were discrepancies in gas stream temperatures discussed with SCAQMD at different points in time. However, the gas temperature for the gas exiting the waste heat boiler/entering the baghouse provided to SCAQMD in February 2014 was 300-350°F and the temperature provided in October 2014 was 350 °F. There was adequate time for the vendors to revise costs estimates to address this lower temperature. In review of ETS's discussion on Page 4 of the Confidential Appendix A, it appears that either the SCAQMD told the vendors initially to utilize the temperature of the gas exiting the kiln, prior to the waste heat

20

boilers, or provided some other temperature. Section C, Paragraph No. 1 on Page 4 as the discussion notes that ""...All vendors offered technical advice as well as costing revisions (if warranted) to account for the lower temperature range of (450-500°F after the WHB)." Paragraph No. 4 on the same page confuses the temperatures even more. Further, after the October 2014 site visit where ETS was informed that the gas temperatures were 350°F, no revisions were made to the costs to address this lower temperature although ETS speculates that duct burners can be utilized. It is unclear whether the vendors were ever made aware of the 350°F gas temperature. This is critical to the validity of the design, costs, technical feasibility of the proposed control options, and the ability of those controls to achieve the proposed amended emissions limit. As noted previously in the discussion of the control options, gas temperatures below 500°F would require a different, more reactive, catalyst formula than systems operating at gas temperatures above 500°F. And, as also previously stated, the only known application of a low temperature catalyst in a cement plant application was a slip-stream pilot test which failed due to catalyst poisoning. None of the operating SCR systems in cement kiln applications operate below 550°F. Further SCAQMD acknowledges on page 1-23 of the PEA, paragraph 2, that: "..., and the presence of sulfur compounds in the exhaust gas , the optimum flue gas temperature of an SCR system is case-by-case and will range between 550 °F and 750°F to limit the occurrence of several undesirable side reactions at certain conditions." CalPortland, does not know if the vendors were made aware of the actual expected gas temperature of around 350°F or whether they would still warranty their systems to perform and achieve the proposed emissions limit at this stack condition.

4.3 Vendors not Adequately Informed Regarding SO_2 Emissions

As also discussed the effectiveness of the SO_2 control technologies proposed by Vendors 2 and 3 are questionable at the actual emissions concentrations of the gas stream. The low temperature of the gas stream, the concentration of the SO_2 in the gas stream, and the humidity/moisture content of the gas stream negatively impact the potential effectiveness of the dry scrubbing technology. First, the low temperature by itself would imply that the control efficiency would be very low. (Reference 1). Consultation with a supplier of hydrated lime indicated that optimum control efficiency for dry lime injection is impacted by both temperature and moisture content. The moisture content is the kiln gas is less than 1-3 %. Further, USEPA in their ACT for cement NO_x controls, acknowledges in Section 8.4.3 that: "Reaction kinetics decrease as the concentration of reactants decreases." In layman's terms, the molecule of pollutant must find and react with a molecule of reagent. The fewer molecules of pollutant in the gas the lower the probability that the pollutant and reagent will find each other and react. During typical operations the concentration of SO_2 in the gas is well below 10 ppm and often around 2 ppm. At these concentrations, reaction kinetics would indicate little to no impact on the SO_2 concentration from injecting dry reagent. Then the question is whether this control system would protect the catalyst during the periods when the SO_2 spikes to 1500 ppm.

21

Discussions with a WGS vendor indicated that at the low typical SO_2 concentrations no reductions in the SO_2 concentration would be achieved. Further, although a WGS will reduce SO_2 down to somewhere between 5 and 12 ppm depending upon the reagent used, there would be a lag between the beginning of the spike and the time the control would effectively control the higher concentration. Discussions between CalPortland and the Vendors, where the actual typical and spike emissions rates and gas temperatures would have identified these concerns. Based upon knowledge of the gas conditions, and the operation of the proposed control technologies, CalPortland questions whether either the SO_2 or NO_x controls will perform as proposed and further questions if the Vendors would warranty them. CalPortland has no way of knowing if the Vendors were ever made aware of the range of pollutant concentrations and gas temperatures when proposing their technologies and costs.

Further, the options as proposed, do not appear to address the fact that although CalPortland would not routinely operate the kilns without operating the waste heat boilers as the boilers provide energy to either the plant or the grid and result in lower emissions, of GHG and other combustion pollutants for the required energy usage. The kilns can operate without the waste heat boilers, and in situations where a waste heat boiler (WHB) needs to be offline for repair or due to a malfunction, the kiln would not be shutdown. First, it takes significant amount of time (days rather than hours) to safely shut the kiln down. Further, because of the high temperatures within the kiln, the refractory is thermally shocked to some degree during startup and shutdown, unnecessary startups and shutdowns result in unnecessary damage to the refractory. Therefore, the NO_x control systems would need to be designed to either operate at the higher temperature when the WHB is not in operation or would need to either bypass the NOx control until gas temperatures are reduced or include mechanism to rapidly cool the gas to the acceptable range to protect the catalyst. There is no indication in either the available PEA or the ETS documents to indicate that this alternate operating scenario was contemplated. Further, from a technical perspective, the catalyst formulations are different for low temperature and the more common higher temperature applications.

4.4 Determination of BARCT

Best Available Retrofit Control Technology (BARCT) is the retrofit of an additional control technology on an existing industrial process. By the very nature of retrofit of a control versus integrating the control into the initial design of a process, and the fact that the uncontrolled emissions rates for existing, older process design are in most cases higher than those from a new process, the control technologies and the achievable emissions reductions/ emissions rates after the installation of BARCT in many instances will not achieve the emissions reductions and ultimate pollutant emissions rates from Best Available Control Technology (BACT) required for new process equipment or major modifications to existing process equipment. Therefore, BARCT should not establish an emissions limit lower, than that which would be achieved by A

22

BACT for a new source. The Proposed emissions limit of 0.5 lb NO_x/T_c is 33% of the new limit established by the New Source Performance Standards (NSPS) for a new PH/PC kiln system, the only new kiln type being constructed which has a limit of 1.5 lb NO_x/Tc. A review of the RBLC indicates that the lowest BACT limit for a new PH/PC kiln is 1.4 lb NO_x/T_c and the lowest/only LAER limit for a cement kiln, also a new PH/PC kiln, is 1.2 lb NO_x/T_c. The NOx limit proposed for BARCT (0.5 lb NO_x/T_c) is approximately 60% lower than for a new kiln constructed in a non-attainment area and for a kiln type with significantly lower uncontrolled emissions rate. Establishing a BARCT limit at this level is inappropriate and not supported by practical application of the technologies or common sense.

4.5 Evaluation of Cost Effectiveness based solely on the cost per ton of pollutant removed is inappropriate for Cement Application.

Cement is a commodity product and as such pricing is competitive with competitors with the general vicinity of the cement plant as well as imports. Particularly in locations with nearby ports for imports from Asia where production costs are lower and environmental controls are less stringent. Unlike other industrial categories the high capital and annual operational costs to implement the controls proposed as necessary to achieve the unrealistic emissions limitation in the proposed amended Regulation XX cannot be recovered by increases in the price of the cement product. While as noted previously, CalPortland has serious concerns about whether the estimated capital and annual operating costs provided by the three vendors, the costs provided will result in an increase in the price of cement from the plant of as much of $10 per ton of cement or more. At this price differential, cement from CalPortland's plant will have no market.

The implementation of SNCR to the existing NO_x controls on CalPortland's Colton kilns will achieve an overall NOx reduction of approximately 75% below the uncontrolled emissions rate., This represents a control efficiency in the same range as the reported control efficiency (70-80% control) of the Joppa kiln, which is the only existing long dry kiln operating an SCR for NO_x control. Further, the resulting emissions rate achieved by the use of SNCR at CalPortland's kilns, 1.64-1.91 lb NO_x/T_c is believed to be at or below the emissions rate of the Joppa kiln.

23

5.0 Conclusions

1. The Administrative Process for the development of the proposed emissions rate in Proposed Amended Regulation XX is flawed and did not provide CalPortland the opportunity for input to the Vendors, thereby potentially and CalPortland believes did indeed compromise the technical feasibility of the proposed control options and emissions limit. Failure to provide, at a minimum, access to the details of the design basis utilized by the vendors and the detailed cost spreadsheets and assumptions denied CalPortland the opportunity to provide fully informed comments on the proposal.
2. CalPortland, based upon knowledge of the process and gas characteristics at the Colton plant and based upon knowledge of the existing cement kiln SCR operations, does not believe that the control technologies are technically feasible or the Colton kilns.
3. CalPortland believes that the proposed emissions limit is unachievable for the long dry kilns at Colton and further that setting a BARCT emissions limit that is one third of the NSPS and BACT limits established for new preheater/precalciner kiln systems and 60% lower than a LAER emissions limit for a new kiln is inappropriate and well beyond the intent of BARCT.
4. The proposed emissions rate is technically unachievable with the proposed controls, and further will result in the inability of CalPortland's cement product to compete in a commodity market.

RESPONSES TO COMMENT LETTER #3
(Cal Portland Company - January 30, 2015)

On April 9, 2015, after the release of the NOP/IS for public review and comment, the Cal Portland Company (CPCC) operators surrendered their operating permits for the Portland cement kilns and have applied for Emission Reduction Credits (ERCs). Thus, because CPCC operators are no longer operating the Portland cement kilns and they no longer hold current SCAQMD operating permits for these units, the existing setting or NOx emissions baseline for the Portland cement kilns at CPCC is zero. Further, if CPCC operators decide to restart the Portland cement kilns in the future, applications for new SCAQMD permits to operate would be required. Further, these permit applications would be subject to an extensive permit review process such that that the Portland cement kilns would be treated as a new installation that would be subject to a new CEQA review and BACT requirements, instead of BARCT. In addition, CPCC would need to purchase RTCs to offset any NOx or SOx emissions as well as ERCS to offset other non-attainment pollutants as required by Regulation XIII. Because of CPCC's current permitting status for these Portland cement kilns, CPCC operators will not be able to retrofit the Portland cement kilns with air pollution control equipment in response to the proposed project without first dealing with the permitting issues for the Portland cement kilns.

Because this comment letter does not contain any CEQA-related comments, and because the CPCC facility is no longer affected by the proposed project, responses to this comment letter have not been prepared.

Comment Letter #4

Los Angeles Department of Water & Power

January 30, 2015

Ms. Barbara Radlein
South Coast Air Quality Management District
21865 Copley Drive
Diamond Bar, CA 91765

Dear Ms. Radlein:

Subject: Los Angeles Department of Water and Power's (LADWP) Comments on Notice of Preparation of a Draft Program Environmental Assessment Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM)

The LADWP appreciates the opportunity to provide comments on the *Notice of Preparation (NOP) of a Draft Program Environmental Assessment on the Proposed Amended Regulation XX – RECLAIM*. The LADWP remains committed to working with South Coast Air Quality Management District (SCAQMD) to further develop efficient and effective policies to reduce NOx emissions from RECLAIM facilities in order to meet the federal Ozone standards in the South Coast Air Basin.

Serving approximately 1.4 million customers in Los Angeles with a generating capacity of over 7,300 megawatts, the LADWP is the largest municipal electric utility in the nation, and the third largest electric utility in California. The LADWP is a vertically integrated utility, owning and operating a diverse portfolio of generation, transmission, and distribution assets spanning several states. As part of its modernization efforts, since the 1990's, the LADWP has been replacing its existing, less efficient utility boilers in the South Coast Air Basin with new, state-of-the-art combined-cycle and simple cycle turbine systems equipped with selective catalytic reduction technology to minimize NOx emissions. During this modernization process, the LADWP's generating facilities have been subject to New Source Review and are equipped with Best Available Control Technology, or BACT which reduces NOx emissions by at least 90 percent. 4-1

The LADWP also continues to make unprecedented investments in renewable energy resources, energy efficiency and transportation electrification to improve the

Los Angeles Aqueduct Centennial Celebrating 100 Years of Water 1913-2013

January 30, 2015

environment. The LADWP is on track to meet 33 percent of its energy sales from renewable energy resources, has a goal to achieve 15 percent energy savings by 2020, and is continuing to implement programs to support the electrification of the transportation sector to reduce greenhouse gases and criteria pollutants, including NOx, and as a potential solution to absorb over-generation from solar renewable sources. 4-1 Concluded

Comments on the Notice of Preparation
Draft Program Environmental Assessment Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM)

1. Project Description Does Not Reflect Language in the Proposed Amended Rule 2002 – Allocations of Oxides of Nitrogen (NOx) and Oxides of Sulfur

   The NOP states that the project will affect the following types of equipment and process of the top NOx emitting facilities in the NOx RECLAIM program:

   - Fluid catalytic cracking units (FCCUs)
   - Refinery boilers and heaters
   - Refinery gas turbines
   - Sulfur recovery units/Tail gas treatment units (SRU/TGUs)
   - Non-refinery/Non-power plant gas turbines
   - Non-refinery sodium silicate furnaces
   - Non-refinery/Non-Power Plant internal combustion engines (ICEs)
   - Container glass melting furnaces
   - Coke calcining
   - Portland cement kilns
   - Metal heat treating furnaces

   The NOP *Technological Overview* section further states that the project will focus on reducing NOx emissions from "the major and large sources of the top emitters of NOx" for which new Best Available Retrofit Control Technology (BARCT) has been identified, but not yet applied. This description is clearly inconsistent with the proposed amendments in Proposed Amended Rule (PAR) 2002, which establishes new NOx RECLAIM Trading Credit (RTC) adjustment factors (reductions) for all affected RECLAIM facilities (including electric generating facilities) starting in year 2016. 4-2

   Notably, the proposed draft regulatory language does not explicitly state that the reductions in NOx RTC holdings would only be applied to the eleven types of equipment and processes listed in the NOP/Initial Study. Rather, the draft regulatory text on the proposed NO_x RTC adjustment is broadly written. This interpretation of the proposed regulatory language is confirmed in the NOP/Initial

Ms. Barbara Radlein
Page 3 of 10
January 30, 2015

Study, which states: "It should be noted that the proposed rule language describes an evenly distributed percent of NOx RTC reductions applicable to *all* RECLAIM facilities. [emphasis added]" Thus, the proposed NOx adjustment factors in PAR 2002 would decrease the NOx RECLAIM Trading Credits (RTCs) for all RECLAIM facilities by 49% by 2020. This reduction in NO_x RTCs would apply across the board to all facilities, regardless of whether the facility operates any of the equipment or processes listed above or not. 4-2 Concluded

If the SCAQMD determines that a NO_x RTC shave is necessary, this adjustment should focus only on the eleven types of equipment or processes with newly identified BARCT and not also apply to electric generating facilities that already have reduced RTC allocations based on most current BARCT performance levels. By contrast, the expanded scope of the RTC adjustment, as proposed in regulatory text of PAR 2002, is inappropriate given that there would likely be significant impacts to other RECLAIM facilities impacted by an across-the-board shave in RTC holdings.

2. Initial Study does not address the impacts of an across-the-board 49 percent reduction in RTC holdings on energy supply

Because SCAQMD, in the NOP, did not consider the across-the-board NOx RTC reductions as proposed in PAR 2002, it did not address the potential impacts on energy supply. Reduction in allocations will create significant impacts on energy supply by restricting power generation operations. LADWP's in-basin generating facilities' would be faced with the following operational constraints and needs: 4-3

- Transmission constraints – The LADWP is currently reaching its maximum transmission system capability. As the LADWP integrates renewables in the generation mix, increased frequency of ramp-ups to mitigate variable output from renewables would lead to corresponding increases in the in-basin NOx emissions from electric generating facilities regulated under RECLAIM program. Limiting internal generation capability by the shave would require the LADWP to import power from out-of-basin generation, which could further strain the transmission system. 4-4

- Need for local generation to support local renewables - Local renewables are not reliable sources of sustained electricity and are significantly less reliable than Photovoltaic (PV) and wind projects, especially during peak periods. Due to the nature of the connection between local solar sources (*i.e.*, roof-top PV panels) and the local grid, the connection automatically disconnects during unstable voltages due to high demands by heat waves. As a result, local, dispatchable generation is very important to support local renewables. 4-5

Ms. Barbara Radlein
Page 4 of 10
January 30, 2015

- Certain minimum amounts of inertia in-basin are required to import out-of-basin generation - This is a location specific requirement to maintain the stability of in-basin local transmission system as well as the entire transmission system and to smooth out the fluctuation of import of out-of-basin generation. The paradox of this requirement is as follows. The fewer generating units that are online in the basin, the less inertia (rotating mass of turbine and generator) is online. The less inertia that is online, the less transiently stable the local system will be following typical disturbances, such as transmission line short circuits that are normally cleared by very fast-acting relays and circuit breakers. The remedy for the lack of local inertia is to decrease imports into the basin from external sources. The physical paradox is the fewer generators that are on in the basin, the less one can import into the basin due to limits on imports due to transient instability. If the LADWP decreases local generation, it only decreases its ability to import. 4-6

- "Reliability Must-Run" Generation is needed in-basin - LADWP's local transmission system was never intended to be reliably operated without some local generation online. This generation is called "Reliability-Must-Run" (RMR) generation because the local transmission system can be operated in compliance with Federal and WECC reliability standards only when location-specific RMR units are in operation at minimum load levels. If the RMR generation is decreased due to lack of NOx credits, the only way to meet reliability standards under high load conditions would be to shed customer load, which is contrary to the LADWP's obligations to provide reliable supplies of electricity to our customers. 4-7

- Increased vehicle electrification will increase electricity demand – Although the LADWP's Integrated Resource Plan analyses show that LADWP's in-basin generating facility NOx emissions are projected to increase due to increased vehicle electrification, there would be a *net decrease* in NOx emissions in the South Coast Air Basin. LADWP urges SCAQMD to consider the potential net NOx reductions from transportation electrification in the design of the NOx RECLAIM program. Furthermore, the Clean Air Act (CAA or Act) allows SCAQMD to consider the offsetting NOx emission reductions from transportation electrification in developing an approvable implementation plan for the attainment and maintenance of the ozone standard. As SCAQMD has acknowledged, reaching the 2032 ozone attainment goal would require nearly complete transformation of passenger vehicles to zero-emission technologies, about 80 percent of the truck fleet to zero- to near-zero technology, and nearly all locomotives operating in the South Coast Air Basin to be using some form of zero-emission technology. In addition, Governor Brown's State of the State speech includes reducing today's petroleum use in cars and trucks by up 4-8

Ms. Barbara Radlein
Page 5 of 10
January 30, 2015

to 50 percent. This means that the only way for the State to achieve the Governor's goal, as well as the air goal goals under the CAA, is for SCAQMD to develop regulatory policies that allow for increased generation (and thereby emissions) from electric generating facilities in order to supply the necessary energy for electrifying the transportation sector. 4-8 Concluded

Alternative Regulatory Approaches

In the event that SCAQMD decides to impose an across-the-board RTC reduction on all affected RECLAIM facilities (including electric generating facilities), LADWP urges the SCAQMD alternatives to minimize the regulatory impacts of that RTC adjustment on the electric power sector. The development of such a regulatory alternative is appropriate given that affected electric generating units already meet the proposed BARCT based on SCAQMD's own analysis. Furthermore, additional reduction in NOx emissions at in-basin plants may not be feasible due to the fact that the only way to achieve additional reductions from these well-controlled plants is by reducing their generation output. As discussed above, reducing the utilization of in-basin gas-fired generation is not a viable option given the essential role these units play in ensuring a reliable supply of electricity in the basin. 4-9

The LADWP has identified a possible regulatory credit mechanism that could be developed to ensure that affected power plant facilities would not be penalized for increased NOx emissions resulting from an increased demand in electricity due to native load needs and increased transportation electrification. Such a crediting mechanism would incentivize the development and implementation of renewable energy and transportation electrification. This approach would be consistent with SCAQMD's position as described in its comment letter to U.S. Environmental Protection Agency (EPA), which states that "It is important that the 111(d) regulation recognizes California's unique situation and does not hinder the introduction of additional renewable energy generation." "The proposed regulation must be structured to support clean generation and renewable energy."[1] 4-10

The policy to be addressed is similar to the Clean Fuels Adjustment provision in that "Allocation adjustments are warranted because of the significant emission decreases that will be realized from mobile sources."[2] Thus, there is a precedent where SCAQMD has allowed RECLAIM affected entities to have sufficient RTCs for increased NOx emissions in the South Coast Air Basin decrease in order to

[1] November 26, 2014 letter to EPA regarding *Carbon Pollution Emission Guidelines for Existing Stationary Sources: Electric Utility Generating Units – Proposed Rule*

[2] RECLAIM Rules staff report, October 1993, p. 2-19

Ms. Barbara Radlein
Page 6 of 10
January 30, 2015

ensure attainment and maintenance of the ozone and other ambient air quality standards. Similarly, the purpose of this alternative approach would be to ensure sufficient RTCs are available for affected electric generating facilities to support the planned levels of transportation electrification that are necessary for achieving the air quality standards, as well as operate its in-basin generating stations to meet native load needs.

The California Air Resource Board's (CARB) Phase II reformulated gasoline production and federal Clean Fuel requirements adopted in the early 1990s require that cleaner burning fuel for automobiles be sold in California. The SCAQMD determined that the modifications to the refining facilities in California would be necessary to produce the reformulated gasoline. These plant modifications would result in emissions increases but the emissions increases would be offset more by mobile source reductions from the use of cleaner fuels by vehicles in the same air shed. As a result, SCAQMD developed criteria to allow for the emission increases while providing an upper bound of RTC allocations. Refinery owners could request an increase in RTC allocations when submitting an application for a permit amendment.

4-10 Continued

The Clean Fuels Adjustment provision establishes helpful precedent for SCAQMD providing flexibility in the implementation of the RECLAIM Program. The discussion below describes how a similar credit mechanism might be developed to ensure affected electric generating facilities had sufficient RTCs in the event that SCAQMD decides to impose an across-the-board RTC reduction on all affected RECLAIM facilities.

1. <u>Quantify the amount of RTCs needed to support native load and transportation electrification.</u>

The first step of the process would involve each affected electric utility quantifying the amount of NOx RTCs that it would need to cover its projected NOx emissions. The process for calculating each unit's generation level would be based on the amount of electricity that the utility would need to generate in order to meet its native load, along with the expected electricity demand increase resulting from the transportation electrification. This determination would likely be based on the Integrated Resource Plan (IRP) or similar process for estimating the utility's native load and the expected transportation electrification for the next 10 to 15 years. With respect to transportation electrification, the utility would need to work with the SCAQMD and CARB to estimate the expected number of electric vehicles (EVs) in the basin in order to determine the increased electricity demand resulting from electrification of the transportation sector.

Based on this quantification of future electricity demand and NOx emissions (which could be updated on an annual basis), the SCAQMD would allow the

Ms. Barbara Radlein
Page 7 of 10
January 30, 2015

affected electric utilities to hold in their accounts sufficient number of NOx RTCs to cover their emissions on a system-wide basis. This amount of each utility's RTCs would not be deducted from its RECLAIM account and consequently remain available for use in meeting its RECLAIM credit-holding requirements.

2. Determine the amount of RTCs used for transportation electrification.

   Each utility sector would quantify the number of RTCs that are actually used to generate electricity for vehicle electrification. This quantification would be performed for each compliance year based on a method similar to CARB's Low Carbon Fuel Standard approach. A combination of meter kWh data and estimated kWh data applied to the number of EVs that a utility reports would be used to quantify the emissions due to the increase in electricity demand from electric transportation.

3. Label unused RTCs designated to cover transportation electrification as non-tradable.

   The RTCs that an electric utility retains based on the quantification of future electricity demand due to transportation electrification would be put into a utility's account and labeled non-tradable. The non-tradable RTCs could be used for compliance purposes only and allocated tradable RTCs would be used first for compliance. Thus, if a utility has NOx emissions that are lower than expected such that its non-tradable RTCs are unused, the utility would not be able to sell them to entities outside of the utility's system. At the end of the reconciliation period, the utility would surrender unused non-tradable RTCs to SCAQMD for credit toward reducing NOx emissions through the RECLAIM program and meeting attainment of the ozone standard. 4-10 concluded

State Implementation Plan crediting with respect to design of the NOx RECLAIM program to accommodate transportation electrification

There are uncertainties with respect to the level of transportation electrification and the level of in-basin generation needed to support future renewables which creates uncertainties as to the number of RTCs that electric generating facilities would need. LADWP believes that SCAQMD has the discretion to develop its NOx RECLAIM program to accommodate such uncertainties without having to determine the exact amount of the NOx reductions upfront for SIP credit purposes. LADWP is ready and willing to work with SCAQMD, CARB, and EPA to explore opportunities in creating an approach to include the benefits of transportation electrification as well as support clean generation and renewable energy.

Comments of Proposed Amended Rule 2012 – Appendix A: Protocol for Monitoring, Reporting and Recordkeeping of Oxides of Nitrogen (NOx) – Attachment C – Quality Assurance and Quality Control Procedures

Section (B)(2) – LADWP supports SCAQMD's efforts to allow postponement of a RATA when a major source is physically incapable of being operated.

Section (B)(2) requires that a relative accuracy test audit (RATA) be performed on a major source on a semi-annual or annual basis within a specified time period. For example, the semi-annual assessment is required to be completed within six months of the end of the calendar quarter in which the continuous emission monitoring system (CEMS) was last tested for certification purposes or within three months of the end of the calendar quarter in which SCAQMD sent notice of a provisional approval for a CEMS, whichever is later. This requirement currently does not provide NOx RECLAIM facilities with the flexibility to reschedule a RATA when a unit is inoperable due to unexpected unit shutdowns or delays in completing unit's scheduled maintenance and repair. When this happens, the RECLAIM operator must seek a variance from the SCAQMD Hearing Board. LADWP supports SCAQMD's efforts to address these situations in Section (B)(2) to allow postponement of a RATA when the major source "is physically incapable of being operated."

The LADWP has experienced situations where its generating units were shut down due to unit damage or unexpected delays encountered during scheduled maintenance and repair of a unit. In such situations, LADWP's generating units were incapable of being operated at the time of the mandated RATA test. For example, in October 2013, LADWP's Haynes Unit 9 combustion turbine was operating at full generation capacity when it came to an abrupt stop; it was determined that the compressor section of the turbine was damaged such that procurement of replacement components and repair required several months. The unit's RATA was scheduled for early November 2013 to meet the December 31, 2014 regulatory deadline but could not be performed due to the length of time required to repair the unit. Although SCAQMD does allow postponement of a RATA for an "intermittently operated source" under Section (B)(2)(h), the provision is narrowly defined. In LADWP's case as described above, SCAQMD's regulatory requirements did not allow reschedule of the RATA. Because of the inflexibility with respect to reschedule of the RATA, LADWP needed to seek a variance from the SCAQMD Hearing Board. Thus, SCAQMD's efforts to postpone a RATA to address the situation where the major source is physically incapable of being operated would allow facilities to focus on bringing the unit back in operation rather than spending significant

4-11

staff and Hearing Board time in the variance process for situations where there are no adverse air quality impacts. 4-11 Concluded

Section (B)(2)(c) and (B)(2)(d) Due Date for RATAs

The LADWP has the following concerns with the proposed language in this section:

- With respect to rescheduling of a RATA, there is inconsistent treatment between electrical generating facilities that only operate under a California Independent System Operator (Cal ISO) contract and those generating facilities such as LADWP's that do not. Generating facilities only operating under a Cal ISO contract would be able to postpone the due date for a RATA to the next calendar quarter whereas LADWP's generating facilities would not. If LADWP encountered a situation as described above where the unit is physically incapable of being operated, it would be able to postpone the RATA only to within 14 unit operating days from the first re-firing of the unit. It is unclear why there is inconsistent treatment when electrical generating facilities, whether they have a Cal ISO contract or not, face similar operational issues. 4-12
- The proposed 14 unit operating day window of time for conducting a RATA in the case where a major source is physically incapable of being operated is insufficient at LADWP generating facilities when a unit is inoperable for an extended period of time. Before a RATA can be performed, the LADWP must perform a series of tests to ensure reliable and safe operation of the unit. Tests to balance the turbine rotor and generator rotor must be performed when there is a repair that lasts longer than several months to ensure that the unit operates within the Original Equipment Manufacturer vibration limits. It may take several sets of these "balance shot" tests before the unit is operating within vibration limits and each balance shot typically takes several days to a week to complete. Based on LADWP's experience, we recommend that SCAQMD allow postponement of the due date for a RATA to the next calendar quarter similar to Section (B)(2)(d) or 30 unit operating days in order to safely conduct the tests and operate the unit and avoid the risk of damaging the unit. This 30-day extension is similar to the provision in 40 CFR Part 75, Appendix B. Section 2.3.3 in which EPA provides a 720-operating hour grace period if RATA cannot be performed on the due date. 4-13

Ms. Barbara Radlein
Page 10 of 10
January 30, 2015

Section (B)(2)(c)(i) and (ii) – Proposed requirement to disconnect and flange the fuel feed lines when a unit is physically incapable of operation is unnecessary and costly

The proposed language requires that:

i. All fuel lines to the major source are disconnected and flanges are placed at both ends of the disconnected lines, and
ii. The fuel meter(s) for the disconnected fuel feed lines are maintained and operated and associated fuel records showing no fuel flow are maintained on site.

The proposed requirement to disconnect and flange the fuel feed lines would be costly and a significant task requiring scaffolding, crane support, procurement of equipment, and staff/labor time from pipefitters, welders, maintenance mechanics, pressure vessel group inspectors, engineering, drafting and operations. This requirement would unnecessarily create a significant health and safety risk if the fuel lines are insulated with asbestos-containing materials (ACM). The intact ACM would have to be removed to gain access to the fuel pipelines which would be against the general plant operating and maintenance best practices to leave intact ACM alone. This requirement would also take several weeks in order to procure the necessary materials and to complete construction. Since the fuel meters would be required to be maintained and associated fuel records be kept, SCAQMD would already have two sources of data as a check that the source is not operating. Thus, LADWP urges SCAQMD to delete Section (B)(2)(c)(i). 4-14

Again, the LADWP appreciates the opportunity to provide comments on the NOP. We would urge that LADWP and other stakeholders be provided a reasonable schedule for further development of any rule changes to RTC allocations that is consistent with the regulatory requirements and provides a reasonable opportunity for stakeholder review and comment. 4-15

RESPONSES TO COMMENT LETTER #4
(Los Angeles Department of Water and Power - January 30, 2015)

4-1 This introductory comment summarizes the commentator's facilities, customer base, generating capacity, and control equipment and explains that this comment letter has been submitted in response to the proposed amendments to Regulation XX and the associated NOP/IS. Responses to specific concerns are presented in Responses to Comments 4-2 through 4-21.

4-2 This comment states that there is an inconsistency between the project description in the NOP/IS which focuses on achieving NOx emission reductions from the top emitting NOx RECLAIM facilities compared to the proposed rule language which shows a 50 percent shave across all NOx RECLAIM facilities. Further, this comment claims that the proposed rule language does not explicitly state that reductions in RTC holdings would only be applied to the 11 types of equipment/processes that are identified in the NOP/IS. This comment requests the shave, if determined by the SCAQMD to be necessary, to only focus on the 11 types of equipment/processes that are identified in the NOP/IS and not apply to electric generating facilities that already have reduced RTC allocations based on the most current BARCT performance levels.

Since the release of the NOP/IS, the proposed project has been modified to apply a shave to the holders of the top 90 percent of RTCs. However, it is likely that the required reductions will be obtained from the installation of NOx control equipment at 20 facilities, as well as from RTCs that are in the program but are being used for compliance purposes. Since only the installation and operation of NOx control equipment would have environmental impacts, the CEQA analysis focuses on these impacts. If some facilities purchase RTCs to meet their allocation targets, this will not have an additional environmental impact but will be considered in the socioeconomic analysis.

4-3 This comment claims that because the NOP does not consider an across the board shave that would affect more than 11 categories of equipment/processes as is proposed in PAR 2002, the NOP did not address the potential impacts on energy supply and the operational constraints on in-basin electrical generating facilities.

Contrary to the comment, the NOP/IS identified energy, including impacts on energy supply, as one of the environmental topic areas that may be adversely affected by the proposed project. PAR 2002 has been revised and the project description in the Draft PEA now correlates to the rule language. The proposal includes an adjustment account specifically for power generating facilities. The RTCs in this account could be accessed in the event of a power generation emergency declared by the Governor.

4-4 This comment states that the commentator's facilities are reaching the maximum transmission capability and limiting the internal generation capability as a result of the NOx shave would require power to be imported from out-of-basin generation, which could further strain the transmission system. This comment also claims that the increased reliance on renewable sources of energy with variable outputs will cause an increased frequency of ramp-ups and increased in-basin NOx emissions from electric generating facilities.

SCAQMD staff acknowledges that during times when maximum transmission capability is reached, there will be a need for peaker plants to ramp-up and there will be increases in emissions as a result. Staff does not believe transmission limitations will be significantly affected because the rule proposal provides a mechanism for access to additional RTCs if needed by power plants.

4-5 This comment maintains that local renewables are not reliable sources of sustained electricity and local, dispatchable generation is very important to support local renewables. For example, the connection between local solar sources and the local grid is automatically disconnected when there are unstable voltages due to high demand during heat waves.

SCAQMD staff acknowledges that there is a need to access local renewable sources of energy. The rule proposal has been modified to help generators ensure this availability.

4-6 This comment claims that there are certain minimum amounts of inertia in-basin that are required to import out-of-basin generation such that when fewer generators are operating in the basin, a lesser amount of electricity can be imported into the basin.

The staff proposal has been modified to allow needed generation for local inertia requirements.

4-7 This comment claims that if local electricity generation or "Reliability-Must-Run (RMR) is decreased due to a lack of NOx credits, the only way electricity demand can be met under high load condition would be shed customer load, which is contrary to the LADWP's obligations to provide reliable supplies of electricity to its customers.

The staff proposal has been modified to allow meeting electricity demand under high load conditions.

4-8 This comment claims that because increased vehicle electrification will increase electricity demand causing an increase in NOx created for electricity generation but decreasing overall NOx because electric vehicles will no longer be combusting fuel. This comment also claims that the SCAQMD should develop regulatory policies that allow for increased generation and increased emissions from generation in order to supply the necessary energy for electrifying the transportation sector.

Increased demand due to transportation electrification will occur gradually and will be monitored by staff. If such demand requires rule amendments, there will be time to implement them.

4-9 This comment requests the alternatives in the PEA minimize the regulatory impacts of the RTC shave on the electric power sector if there is an across the board shave for all facilities in the program.

The staff proposal does not recommend an across the board reduction for all facilities. The proposal contains a 47 percent NOx RTC shave on power plants and an adjustment account that could be accessed by power plants if the Governor declares an emergency that would require additional power generation. In addition, the PEA analyzes multiple alternatives, each with a varying NOx RTC shave on power plants. For example, Alternative 1 proposes a 53 percent NOx RTC shave on power plants and Alternative 2 proposes a 60 percent NOx RTC shave on power plants. In addition, of the shaves proposed, Alternative 3 contains the smallest shave percentage for power plants at 36 percent. In addition, the No Project alternative, Alternative 4, does not propose a NOx RTC shave on any facility, including power plants.

4-10 This comment suggests that a credit mechanism should be developed to ensure that affected electric generating facilities have sufficient RTCs if the SCAQMD proposes an across the board RTC shave. The example cited is the Clean Fuel Adjustment credits that have been available to refineries for the production of reformulated gasoline.

In response to the comment, the staff proposal would not be an across the board shave. The staff proposal would establish a separate adjustment account to hold RTCs for power plants to meet their NSR holding obligations. Many newer, peaking plants are required to hold RTCs at the potential to emit level each year even though their actual emissions are far below this level. The adjustment account would relieve power producing facilities from the obligation of purchasing RTCs in order to meet the NSR holding requirements of Rule 2005. RTCs either held or purchased by a facility would be for the purpose of reconciling annual emissions. Furthermore, if the demand for power results in a severe shortage that would lead to the state Governor declaring a state of emergency, a power producing facility would be able to access the adjustment account for non-tradable credits for offsetting annual emissions. The adjustment account would take the shaved RTC amount for the given compliance year according to the implementation schedule in the rule; each year would be an increment of the overall 47 percent shave.

The comment states that there would be increased demand due to increased transportation electrification and renewable power. If this power demand translates into an RTC demand, these credits would be purchased from the NOx RECLAIM market. If there is a shortage of credits which would result in an increase in the RTC price, a safety valve in the rule would provide access to non-usable, non-tradable credits in the event that the market price for discrete year credits rises above $15,000 per ton.

4-11 The comment expresses support regarding SCAQMD’s efforts to allow a postponement of a RATA when a major source is physically incapable of being operated.

SCAQMD staff acknowledges your support for the proposed amendments in Rule 2012.

4-12 This comment claims that there are inconsistencies in how electrical generating facilities that only operate under a California Independent System Operator (Cal ISO) and how generating facilities operated by the commentator are treated when rescheduling a RATA.

Staff has revised the proposed rule language to include power plants operated by municipalities.

4-13 This comment claims that the proposed 14 unit operating day window of time for conducting a RATA where a major source is physically incapable of being operated is insufficient at the commentator's generating facilities when a unit is inoperable for an extended period of time. This comment recommends a postponement of the due date for a RATA to the next calendar quarter or 30 unit operating days.

Discussion with the commenter revealed that the concern here has to do with the potential for sequential equipment failures. However, the 14 unit operating day RATA extension being proposed would apply separately for each independent failure. That is, if equipment operating under the 14 operating day RATA postponement provision should experience an unrelated failure prior to successfully completing a RATA, the 14 day clock would restart. The staff report provides clarification on this point. Furthermore, an extension duration of 14 operating days is consistent with the existing provisions pertaining to the timing of RATA for CEMS on a stack or duct through which no emissions have passed in two or more successive quarters in Attachments C to Rules 2011 and 2012 and with variance conditions established by the SCAQMD Hearing Board in previous cases. Conversations between SCAQMD staff and facility operators also indicate that fourteen operating days provide sufficient time to conduct a RATA in such cases.

4-14 This comment requests deletion of the proposal to disconnect and flange the fuel feed lines because it would be a costly and a significant task involving construction workers and equipment and would create significant health and safety risks if fuel lines are insulated with asbestos-containing materials.

RECLAIM has existing provisions that address non-operated major SOx and NOx sources in Rule 2011 (c)(10) and Rule 2012 (c)(9), respectively. These requirements are imposes when the period of non-operability is relatively long. These provisions both require the operator to "disconnect fuel feed lines and place flanges at both ends of the disconnected lines." Similarly, Rule 2011 (c)(9) addresses infrequently-operated major SOx sources. One of the requirements with which a source must comply to be eligible to be an infrequently-operated major SOx source is that the "Facility Permit holder shall disconnect fuel or process feed line(s) and install, maintain, and operate a monitoring device, which has been approved by the Executive Officer, to provide a continuous positive indicator of the operation status of the source to the remote terminal unit (RTU) for the purposes of demonstrating the source is not operating and for preparing emissions reports." Collectively, the requirements of Rule 2011 (c)(9), Rule 2011 (c)(10), and Rule 2012 (c)(9) establish the appropriate precedents for the steps a facility must take to qualify for a reduced level of emissions monitoring of a major source that is out of operation for an extended period. In addition, the comments have not included any examples to demonstrate cases where disconnecting sections of fuel line is infeasible. Therefore, the proposed rule language's eligibility requirements for delaying RATA testing to the end of the next quarter of both disconnecting fuel lines and maintaining and operating the fuel meters are appropriate and consistent with existing, related provisions.

4-15 This comment expresses appreciation for the opportunity to provide comments on the NOP and requests a reasonable schedule and an opportunity to comment on rule development changes to RTC allocations.

SCAQMD staff appreciates the comments and input. All affected stakeholders will be notified of any changes and SCAQMD staff will continue to meet regularly with the stakeholders, which includes the commentator, to solicit input.

Re: Comment Letter on Notice of Preparation of a Draft Program Environmental Assessment--Proposed Amended Regulation XX; City of Burbank, Department of Water and Power

Dear Ms. Radlein:

The City of Burbank, Department of Water and Power ("the City") appreciates the opportunity to present the following comments on the Notice of Preparation ("NOP") of a Draft Program Environmental Assessment on Proposed Amended Regulation XX. The comments address the need to evaluate potential adverse impacts of a proposed reduction of approximately 50% of each facility's NOx RECLAIM Trading Credits ("RTCs") ("NOx Shave"). The City operates two facilities regulated under the RECLAIM: its own power plant operated by its Department of Water and Power ("BWP") and the Magnolia Power Plant ("MPP"), a facility owned by the Southern California Public Power Authority ("SCPPA") but also operated by BWP. 5-1

SUMMARY

If power plants are subject to a 50% NOx Shave, as set forth in the draft rule attached to the NOP, then they may be operated less frequently due to the higher costs that the shave imposes. Their electricity production may be shifted to other, more polluting power plants, with adverse air quality impacts where those other power plants are located. The District must evaluate these potential adverse air quality impacts in the Environmental Assessment for the 5-2

Barbara Radlein
January 30, 2015
Page 2

proposed NOx RTC shave, whether those impacts occur inside or outside the South Coast Air Basin. In addition, the District should analyze two alternative projects that may mitigate or eliminate these potential adverse impacts but still allow the project to achieve its basic objectives: (1) the alternative of no reduction of NOx RTCs for any power plant that already operates with either Best Available Control Technology ("BACT") or Best Available Retrofit Control Technology ("BARCT") installed, and (2) the alternative of a smaller reduction of, for example, 25% of each such power plant's NOx RTCs. 5-2 Concluded

ADDITIONAL DETAIL

Most of the power plants that would be subject to a 50% NOx shave are gas-fired peaking plants with BACT or BARCT already installed and NOx emissions in the range of 2-5 ppm. These power plants could not achieve cost-effective reductions of NOx emissions in response to a NOx shave. Instead, they would have to purchase more RTCs to maintain or increase their electricity production. If they are facilities that were newly-constructed under RECLAIM (Rule 2005), they also would have to purchase RTCs to cover their PTE at the start of each compliance year. 5-3

RTC purchases in response to the shave would increase the operating costs of these power plants. The increased costs may make it economical for the operators of these power plants to reduce their level of operation and purchase replacement power from other facilities outside the South Coast Air Basin. These other facilities likely have NOx emissions rates higher than the emissions rates of the power plants subject to the NOx shave. Therefore, NOx emissions per MWhr, and overall NOx emissions from power plants, may actually increase due to the shave. But these increased NOx emissions would occur mostly in areas outside of the South Coast Air Basin. The District must evaluate these potential adverse air quality impacts. 5-4

For example, we estimate that, in response to a 50% NOx RTC shave, MPP may have to spend as much as $17 million between 2018 and 2023 to maintain its NOx RTC allocation and cover its PTE at the beginning of the compliance year, assuming no increase in capacity factor. This cost could be reduced somewhat if the District made RTCs available to MPP on a temporary basis to cover its PTE at the beginning of the compliance year, thus making it unnecessary for MPP to purchase these RTCs. These costs assume that RTC prices rise to a level comparable to the last time there was a NOx shave, in 2005 ($250/lb of so-called "perpetuity RTC"). This increase in MPP's operating costs could result in a shift of production to power plants outside of the South Coast Air Basin that do not bear these same increased costs.

In addition to evaluating these potential adverse air quality impacts in areas where emissions would increase under the proposal in the NOP, the District should also evaluate two alternatives that may reduce any potential adverse air quality impacts identified in the environmental assessment but still allow the project to achieve its basic objectives. One alternative is no reduction in RTC allocation for any power plant that already operates with either BACT or BARCT installed. A second alternative is to reduce each such power plant's RTC 5-5

Barbara Radlein
January 30, 2015
Page 3

allocation by a smaller amount than the amount proposed in the NOP, such as a 25% reduction. Under both of these alternatives, facilities that have not yet achieved BARCT could have their NOx RTCs shaved by whatever percentage is needed to achieve the emissions reductions in the proposal, without asking power plants to help pay for those reductions by having their own RTC allocations shaved. 5-5 Concluded

We appreciate your consideration of our comments. Please let us know if you have any questions.

Sincerely,

Charles F. Timms, Jr.

RESPONSES TO COMMENT LETTER #5
(Charles F. Timms, Jr. on behalf of
City of Burbank Department of Water and Power - January 30, 2015)

5-1 This introductory comment explains that this comment letter has been submitted on behalf of the City of Burbank Department of Water and Power in response to the CEQA document and proposed shave for the proposed project. Thus, responses to the specific concerns are presented in Responses 5-2 through 5-5.

5-2 This comment suggests that the Draft PEA should evaluate the adverse environmental effects that the 50 percent NOx shave will have on power plants due to higher costs that will cause electricity production to drop and the possible shift to producing electricity from other, more polluting power plants, located either inside or outside the South Coast Air Basin (SCAB). This comment also suggests that the Draft PEA should analyze at two alternatives, as follows: 1) not imposing a shave on any power plant that already operates with BACT or BARCT; and, 2) a smaller reduction than a 50 percent shave, such as a 25 percent shave, on power plant NOx RTCs.

Regarding the comment relative to increased costs that would cause production to drop, SCAQMD staff understands that the power producers can pass costs on to consumers, so there would be no need to reduce local generation.

With regard to comment relative to alternatives, a full range of alternatives have been developed and analyzed in Chapter 5 of the PEA. Alternative 4, the no project alternative, does not impose a NOx RTC shave on any RTCs held by power plants. The proposed project would apply a 47 percent NOx RTC shave to power plant RTC holdings. When compared to the proposed project, Alternative 3 contemplates a lesser NOx RTC shave to power plant holdings of 33 percent. The two alternatives suggested by the commentator are within the range of the existing alternatives of this PEA, so specific additional alternatives are not necessary.

5-3 This comment claims that most of the power plants that would be subject to the shave are gas-fired peaking plants with BACT or BARCT already installed. This comment further claims that power plants would need to purchase more RTCs to maintain or increase electricity production levels.

SCAQMD staff acknowledges the unique situation that power generators have with regard to operating at BARCT or BACT and the requirement for RTC holdings for New Source Review (NSR) purposes. The project now contains a proposal which establishes an adjustment account which would contain the shaved RTCs from new power producing facilities for the purposes of satisfying the NSR requirements. Most power plants emissions are much less than their potential to emit, so this provision will help reduce the amount of RTCs that power plants will need to hold.

5-4 This comment claims that RTC purchases in response to the shave would increase power plant operation costs and would reduce local generation but increase NOx emissions from other power plants transmitted to the municipal utilities. The comment claims that the increase in power plant NOx emissions would be generated outside of the South Coast Air Basin and that the District should evaluate these impacts.

A sector-specific approach has been proposed with the establishment of an adjustment account. Power producing facilities would meet the NSR holding requirements without purchasing credits with this adjustment account. RTCs in this account would only be made usable for compliance with annual emissions if California's governor declares a state of emergency.

In the Draft PEA, an energy analysis was conducted and an estimated increase of electricity demand was provided in Subchapter 4.3 – Energy of this PEA. From the estimated increased electricity demand, increases in both criteria pollutants and GHG emissions were quantified for the affected facilities in Subchapter 4.2 – Air Quality and Greenhouse Gases in this PEA.

5-5 This comment duplicates the suggestions expressed in Comment 5-2. See Response 5-2.

Comment Letter #6

California Council for Environmental and Economic Balance

Southern California Air Quality Alliance

Regulatory Flexibility Group

WSPA Western States Petroleum Association

30 January 2015

Dr. Elaine Chang
Deputy Executive Officer, Planning, Rule Development & Area Sources
South Coast Air Quality Management District
21865 Copley Drive
Diamond Bar, CA 91765

SUBJECT: INDUSTRY COMMENTS ON THE NOTICE OF PREPARATION (NOP) OF A DRAFT PROGRAM ENVIRONMENTAL ASSESSMENT FOR PROPOSED AMENDED REGULATION XX – REGIONAL CLEAN AIR INCENTIVES MARKET (RECLAIM)

Dear Dr. Chang:

These comments are presented on behalf of the members of leading Southern California businesses represented by the California Council for Environmental and Economic Balance ("CCEEB"), the Regulatory Flexibility Group ("RegFlex"), the Southern California Air Quality Alliance ("SCAQA"), and Western States Petroleum Association ("WSPA"). The members of these business groups are major Southern California employers who own and operate facilities in the Regional CLean Air Incentives Market ("RECLAIM") program. 6-1

This "Industry RECLAIM Coalition" formally offers the following comments on the Notice of Preparation and Initial Study for the Draft Program Environmental Assessment ("PEA") for Proposed Amended Regulation XX ("NOP/IS"). [1]

1. *The PEA Project Description should specify the potential shave as a range since neither the Proposed Amended Rule nor the Staff's Technical Report is complete.*

The Project Description presented in the NOP and Initial Study ("NOP/IS") incorporates Proposed Amended Rule (PAR) 2002 language as presented in Appendix A of the NOP/IS. At the time of the NOP/IS release, the AQMD had not completed technical work on this rulemaking, with the third-party consultant reviews having not even been released. The cover page for NOP/IS Appendix A did include the following disclaimer: 6-2

> *"The BARCT evaluation and the RTC shaving methodology are ongoing, so a RECLAIM industry's required RTC shave may change due to the public review process. The*

[1] SCAQMD, Notice of Preparation (NOP) of a Draft Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), 4 December 2014.

Dr. Elaine Chang, SCAQMD
30 January 2015

programmatic RTC shave could range from five to 14 tons per day. To provide a worst case scenario of adverse environmental impacts, the adjustment factors and the Non-tradable/Non-usable NOx RTC adjustment factors in Proposed Amended Rule 2002 subparagraph (f)(1)(B) reflect an RTC shave at the higher end of the range to capture a conservative estimate of potential control technologies needed that could generate secondary environmental impacts. As the staff proposal is being refined, if a lesser RTC shave is proposed, the adverse environmental impacts would be less and the Draft PEA and its alternatives will also be further defined."[2]

Now that the third-party contractor reviews have been released, we expect changes are needed to the technical analysis which would alter the technical calculations. Members of this coalition have unresolved questions and concerns about those reviews and the current analysis from AQMD staff. But these reviews and additional inputs from industry stakeholders will necessitate revisions to the draft PAR 2002 language, and more changes will undoubtedly be needed as the rulemaking process progresses. 6-2 Concluded

For this reason, we recommend that the PEA Project Description should explicitly specify the potential shave under this rulemaking as a range. This could be accomplished using language similar to that which was presented on the NOP/IS Appendix A cover page, however this disclosure should be noted in the Project Description section of the main PEA document; not left only in an Appendix.

2. *The PEA should explicitly address at least two project Alternatives: (1) AQMP control measure CMB-01 as approved by the Governing Board (i.e., shave of 3-5 tpd); and (2) the Industry RECLAIM Coalition proposal.*

Under the 2012 Air Quality Management Plan ("AQMP"), the Governing Board approved control measure CMB-01 which authorized further reductions from the NOx RECLAIM program. The control measure authorized by the Governing Board was based on a range of 3-5 tons per day ("TPD") of RECLAIM Trading Credits ("RTCs") being removed from the program. While stakeholders understood the eventual rulemaking could differ, the current Staff proposal as presented in the NOP/IS would be substantially larger at nearly 13 TPD. 6-3

This Industry RECLAIM Coalition has presented an alternative methodology for demonstrating command-and-control equivalency. The Industry proposal would reduce the program's quantity of RTCs by limiting the "shave" to only those reductions that can be directly attributed to the advancement of Best Available Retrofit Control Technology ("BARCT"). This Industry proposal could also result in RTC reductions greater than the approved AQMP control measure, but less than those which have been presented by the AQMD Staff.

We recommend that both of these alternatives should be fully considered as project Alternatives in the PEA, at a minimum.

[2] SCAQMD, NOP/IS for Proposed Amended Regulation XX, Appendix A, 4 December 2014.

Dr. Elaine Chang, SCAQMD
30 January 2015

3. *Public stakeholders should be provided a schedule that is consistent with regulatory requirements while providing reasonable opportunity for stakeholder review and comment.*

The proposed rulemaking could potentially result in significant economic impacts to Southern California businesses and the regional economy. The technical analysis for this rulemaking is not yet complete, and the potential impacts have not yet been fully analyzed or considered. To date, only preliminary technical data has been made available to stakeholders. As such, thorough review and input by the RECLAIM Working Group or other stakeholders has not been possible. 6-4

This Industry RECLAIM Coalition respectfully requests that stakeholders be provided with a rulemaking schedule, including this PEA and the socioeconomic analysis, that is consistent with applicable regulatory requirements but also provides stakeholders a reasonable opportunity for review and comment of the technical bases.

The RECLAIM program remains vitally important to the health of Southern California's economy and environment. The members of this coalition have actively participated in this rulemaking through the NOx RECLAIM Working Group over these last two years, and we look forward to continuing to work with you and the District's Staff on the significant rulemaking. 6-5

Very truly yours,

Bill Quinn
California Council for Environmental and Economic Balance

Michael Carroll

RESPONSES TO COMMENT LETTER #6
(California Council for Environmental and Economic Balance et al - January 30, 2015)

6-1 This introductory comment explains that this comment letter has been submitted on behalf of multiple business groups that own and operate RECLAIM facilities in response to the CEQA document for the proposed project. Thus, responses to the specific concerns are presented in Responses 6-2 through 6-5.

6-2 This comment suggests that the project description in the Draft PEA should specifically describe the potential shave as a range in the same manner as the disclosure language inserted in Appendix A before PAR 2002. Since the proposed amended rule language and corresponding staff report were not complete at the time the NOP/IS was released for public review due to pending third-party consultant reviews and now that the third-party consultant reviews have been released, the technical analysis along with the proposed rule language is expected to change and as such, the Draft PEA should also reflect these changes.

The contractor's assessments were considered in the staff proposal in the Preliminary Draft Staff Report, which is the project analyzed in this PEA. The alternatives in the PEA include a No Project alternative and other alternatives that include a range of emission reductions.

6-3 This comment suggests that the Draft PEA should analyze at least two alternatives to the project. The first alternative should analyze a shave ranging from three to five tons per day in accordance with AQMP control measure CMB-01. The second alternative should analyze the "Industry RECLAIM Coalition" proposal which would limit the shave to only reductions that can be directly attributed to BARCT.

It is not necessary to add these specific alternatives because the ranges are included within the alternatives for the PEA. SCAQMD staff has included Alternative 3, the Industry Proposal, in the Draft PEA analysis. Staff did not explicitly analyze a three to five ton shave alternative as this would be between Alternative 3 and the No Project alternative (Alternative 4).

6-4 This comment is requesting a rule development schedule, to include the PEA and socioeconomic analysis, in order for public stakeholders to provide a reasonable opportunity for review and comment. This comment claims that the technical analysis for this rulemaking is not complete and only preliminary technical data has been made available to stakeholders. This comment claims that stakeholders have not been able to provide a thorough review and input. This comment claims that potential impacts have not been fully analyzed or considered.

Rule development efforts for the proposed project were initiated over two and a half years ago when staff presented basic concepts to the NOx RECLAIM Working Group on January 31, 2013. Since the January 31, 2013 Working Group Meeting, staff has held 11 additional Working Group meetings at which members were given multiple and ample opportunities to provide comments. For example, in March 2013, equipment with the highest potential for achieving NOx emission reductions was presented to Working Group members. Then, in September 2013, a preliminary assessment quantified potential NOx emission reductions and detailed survey results. In October 2013, third party contractors conducted site visits and reviewed staff's technical analysis and their results were released in December 2014 and presented at the January 7, 2015 Working Group meeting.

In addition to Working Group meetings, staff has met frequently with the members of the Industry RECLAIM Coalition and other stakeholders throughout this rule-making to answer questions and discuss any concerns related to this proposed amendment. Also, staff has presented an update on the progress of this rule development to the Stationary Source Committee on March 21, 2014 and July 24, 2015. During the entire rulemaking process, staff has kept the public and stakeholders adequately informed on all upcoming milestones. Based on concerns that have been raised by the regulated community, the rulemaking schedule has been adjusted. At the earliest practical time staff will continue to apprise stakeholders of any future scheduling changes. To date there have not been any scheduling changes that would have given stakeholders less time to provide comments.

While it is true that the technical analysis for this rulemaking effort was not complete at the time the NOP/IS was released for public review and comment, the technical analysis for this proposed amendment is currently well-developed. The Draft PEA reflects the staff proposal for a 14 ton per day shave of NOx RTC holdings which is consistent with the project as described in the NOP/IS. In fact, the Draft PEA fully analyzes the potential environmental impacts that were identified in the NOP/IS as having potentially significant adverse effects.

The public hearing for these proposed rule amendments is currently scheduled for November. As the rule development process continues, there will be subsequent opportunities for the public and stakeholders to provide comments on staff's technical analysis, such as the 45-day public review and comment period provided for this Draft PEA.

6-5 This comment expresses the desire for commentators to continue to work with the SCAQMD on this rulemaking. SCAQMD staff appreciates the input of all stakeholders and looks forward to future discussions regarding the proposed changes to the NOx RECLAIM program.

Re: Comments on Proposed RECLAIM Regulation XX Amendment and associated CEQA Notice of Preparation and Initial Study (NOP/IS)

Dear Ms. Radlein and Mr. Cassmassi:

Paramount Petroleum Corporation (Paramount) appreciates the opportunity to comment on the District's proposed amendments to Regulation XX, and the associated CEQA document. In particular, Paramount's comments will focus on the Project Description contained in the CEQA document and the clear inconsistency between the Project Description and how the proposed rule changes will impact Paramount's refinery. These comments are being addressed to both the District's CEQA section and the Rule Development Division. We would like to begin our comments by stating that we were gratified that the District undertook efforts to visit the various refineries in the District and look at the cost effectiveness of various controls strategies. 7-1

The current Nitrogen Oxide (NOx) RECLAIM universe consists of approximately 276 facilities. The objective of the Proposed Project is to achieve additional NOx emission reductions on the top 39 RECLAIM facilities. However, the reduction allocation distribution currently being analyzed in the CEQA document is a single cut across the board of fifty percent shave to all RECLAIM facilities as a worse-case scenario. Paramount believes that there is clear discrepancy between the project's objectives and the scenario that is being analyzed. Thus we believe that the Project Description is flawed and the District cannot undertake a proper CEQA analysis. To demonstrate how the proposed project would adversely impact affected facilities, Paramount will use itself as an example. 7-2

The CEQA Project Description provided in the CEQA document identifies six refineries owned by five companies (Tesoro, Phillips 66, Chevron, Exxon/Mobile, and Ultramar (Valero)) that operate FCCUs (fluid catalytic cracking units), boilers and heaters, gas turbines, and SRU/TGU (sulfur recovery unit/tail gas unit), and proposes selective catalytic reduction (SCR) as BARCT for these process units and concludes that the proposed reduction is achievable and cost effective. Paramount does not dispute the 7-3

PARAMOUNT PETROLEUM

a subsidiary of ALON USA

14700 Downey Avenue
P.O. Box 1418
Paramount, CA 90723-1418
(562) 531-2060

District's analysis with respect to these facilities. But conspicuously absent from the Project Description's analysis is any mention of the Paramount Refinery. 7-3 Concluded

The top 39 facilities primarily consist of refineries and power plants. Paramount is twenty- ninth on this "top emitters" with aforementioned refineries taking the top seven spots. The average refinery NOx emissions excluding Paramount during the 2011 to 2013 time period was approximately 1.1 million pounds. Paramount's emissions averaged about 80,000 pounds or approximately 7 percent of the other refineries' average emissions. There is a clear size difference between Paramount and other refiners. 7-4

The District's proposed shave, which is based upon a BARCT of SCR, fails to take into account the equipment differences between complex fuel producing refineries and less complex refineries like Paramount. More importantly it fails to take into account that since the last shave in 2005, Paramount has accounted for third of SCR's installed and one-half of the sources controlled by SCR's at refineries. 7-5

If the rules proposed reductions were cost effective Paramount would not be preparing these comments. The District's own staff concluded that there is only one source at Paramount that meets the BARCT cost effectiveness criteria and the independent consultant hired by the District to review the cost effectiveness determinations concluded that none of the sources at Paramount meet the BARCT cost effectiveness criteria. 7-6

Paramount understands that there is a need to reduce NOx emissions within the Basin and therefore we are not asking to be excluded from the shave.[1] Instead we believe that the District needs to recognize, that not all refineries are the same and revises the Project Description and the rule to acknowledge that there is a distinct line between Paramount and other major refineries that justifies a separate shave percentage. 7-7

Paramount does not operate a FCCU or Coker, has a lower throughput and different product mix than most if not all of the other refineries in the Basin, and has installed more SCRs on its sources since 2005 than any other refineries. Therefore our opportunities to control sources are significantly more limited than the majors. The across the board fifty percent shave would impose a severe and unjustified burden on Paramount when compared to other refineries. 7-8

Moreover, Paramount is a Low Complexity-Low Energy refinery as defined in the proposed California Air Resources Board (CARB) Low Carbon Fuel Standard. The CARB Low Complexity-Low Energy means that Paramount is more fuel efficient in its processing operations on a per barrel bases than larger more complex refiners. It also means that Paramount is a lower NOx emitter on a per barrel bases than other refineries in the Basin. Attached to this letter is a bubble chart showing the 2013 Green House Gas 7-9

---

[1] Paramount is opposed to making any RECLAIM credits non-tradable and believes that doing so is contrary to the spirit and purpose of the RECLAIM Program.

PARAMOUNT PETROLEUM
a subsidiary of ALON USA
14700 Downey Avenue
P.O. Box 1418
Paramount, CA 90723-1418
(562) 531-2060

(GHG) emissions for the various refineries in the Basin. GHG emissions are a surrogate for fuel combustion. The Chart clearly demonstrates that there is a distinct line between us and the other refineries. Looking at average refinery NOx emissions of the subject refineries (excluding Paramount), the average mass of NOx emitted on a per barrel bases was 6.52 pounds per barrel of name plate capacity during the 2011 to 2013 time period. Paramount emitted approximately 3 pounds of NOx per barrel of name plate capacity using the highest annual NOx emissions from the past 10 years. Even if other refiners reduced their NOx emissions by fifty percent on a per barrel bases, their emissions would still be more than of Paramount. 7-9 Concluded

Since the necessitated AQMP emission reductions do not require that the District imposes a fifty percent shave across the board, Paramount believes that the District should use this flexibility to allow for subsets of facilities within the universe of facilities to be shaved and apply a different shave percentage to these facilities. In the case of the refining sector, refineries that do not have Cokers and FCCUs and/or meet the CARB definition of a Low Complexity-Low Energy refinery could be considered a separate subset of the refining sector subject to a lower shave percentage. Paramount would be happy to work with the District to craft appropriate language to define this subset. 7-10

Please feel free to contact me with any questions you may have.

Sincerely,

Matthew Jalali

RESPONSES TO COMMENT LETTER #7
(Paramount Petroleum - January 30, 2015)

7-1 This introductory comment explains that this comment letter has been submitted in response to the proposed amendments to Regulation XX and the associated CEQA document and focuses on an alleged an inconsistency between the project description and project implementation. This comment also expresses appreciation for efforts made by SCAQMD staff to visit various refineries and to examine the cost effectiveness of various control strategies. Thus, responses to the specific concerns are presented in Responses 7-2 through 7-10.

7-2 This comment explains that there is a discrepancy between the objective of the proposed project (e.g., to achieve NOx emission reductions from the top 39 RECLAIM facilities out of a total of 276) versus the worst-case analysis in the CEQA document (e.g., a 50 percent shave across all 276 facilities). This comment asserts that the project description in the CEQA analysis is flawed and because of this flaw, a proper CEQA analysis cannot be done.

Since the release of the NOP/IS, the proposed project has been modified to apply a shave to the holders of the top 90 percent of RTCs. However, based on feasibility and cost-effectiveness, NOx controls would be installed at only 20 facilities. The remainder would surrender RTCs or purchase RTCs in order to comply with the proposed project. The environmental impacts would only be associated with the installation and operation of NOx control equipment.

7-3 This comment agrees that SCR is BARCT for FCCUs, boilers and heaters, gas turbines, and SRU/TGUs that are operated by six refineries owned by five companies and that the proposed reductions are achievable and cost-effective. This comment also points out that project description in the CEQA document does not mention the commentator's facility (e.g., Paramount Petroleum).

SCAQMD staff is pleased that you agree with its BARCT analysis related to the larger refiners. The proposed project was designed to apply BARCT to various types of equipment and processes operated by a multitude of industries, including but not limited to refineries. The equipment/processes for which BARCT was identified are as follows: 1) FCCUs; 2) refinery boilers and heaters; 3) refinery gas turbines; 4) SRU/TGUs; 5) non-refinery/non-power plant gas turbines; 6) non-refinery sodium silicate furnaces; 7) non-refinery/non-power plant ICEs; 8) container glass melting furnaces; 9) coke calcining; 10) Portland cement kilns, and, 11) metal heat treating furnaces. While Paramount Petroleum is considered a refinery that is part of the NOx RECLAIM program, Paramount Petroleum does not operate a FCCU or SRU/TGU. Paramount Petroleum operates refinery boilers and heaters that were analyzed for BARCT, but these units were found to be already at BARCT. For the proposed RTC shave calculation, Paramount has been included as part of the non-major refinery category that would be subject to a lesser shave than the major refineries. See Table 8 in PAR 2002.

7-4 This comment identifies Paramount Petroleum as being a relatively small emitter in the NOx RECLAIM program by being ranked 29th out of the top 39 emitters when compared to the other refiners that take the top seven spots.

SCAQMD staff agrees that there is a difference in NOx emissions between Paramount Petroleum and the other larger refiners operating in the District. However, because the Basin is designated as an "extreme" nonattainment area for the 8-hour ozone standard under federal law, and because NOx is a precursor to ozone formation, NOx emission reductions are being sought from a large variety of RECLAIM sources as part of this rulemaking as well as from non-RECLAIM facilities that emit considerably less emissions than Paramount (as part of other rulemaking activities in accordance with control measures in the Final 2012 AQMP).

7-5 This comment claims that the proposed shave does not take into account the equipment differences between complex fuel producing refineries and less complex refineries like Paramount Petroleum. This comment also claims that the proposed shave does not take into account that one-third of the SCRs that were installed in response to the 2005 NOx RECLAIM shave were installed at Paramount Petroleum.

The task of achieving RECLAIM NOx emission reductions has historically been approached in a programmatic manner. The size of a particular facility or the number of sources within a facility with potential emission reduction opportunities has not always been a determining factor as to whether a particular facility would be subject to a shave. As explained in Response 7-3, Paramount Petroleum operates refinery boilers and heaters that were analyzed for BARCT, but these units were found to be already at BARCT. For the proposed RTC shave calculation, Paramount has been included as part of the non-major refinery category that would be subject to a smaller shave than the major refineries.

7-6 This comment expresses disagreement with SCAQMD's position that the proposed BARCT that would only apply to one source at Paramount Petroleum is cost-effective. This comment claims that the consultant hired by the SCAQMD did not identify any sources at this facility that meets the BARCT cost-effectiveness criteria.

As explained in Response 7-3, Paramount Petroleum operates refinery boilers and heaters that were analyzed for BARCT, but these units were found to be already at BARCT. The proposed shave would affect those facilities that are among the top 90% of NOx RTC holders. For the proposed RTC shave calculation, Paramount has been included as part of the non-major refinery category that would be subject to a smaller shave than the major refineries at 47 percent. There is an opportunity within the current proposed rule that would exempt a facility from the requirements of the shave if the facility can demonstrate that their equipment is at BARCT, in addition to other criteria. The requirements to qualify for this exemption are outlined in Proposed Amended Rule 2002 (i).

7-7 This comment is requesting the SCAQMD to revise the project description to include a separate shave percentage for Paramount Petroleum.

Staff has not established an individual shave for Paramount Petroleum but this facility is included in the non-major refinery category and the NOx RTCs for this category would be subject to a 47 percent shave.

7-8 This comment claims that the opportunities to further control NOx emissions at the Paramount Petroleum facility are significantly limited and an across the board 50 percent shave would impose a "severe and unjustified" burden on this facility.

SCAQMD staff agrees that this facility is different than the major refineries based on the equipment they operate. The proposed project would apply a NOx RTC shave of 67 percent to the major refineries, while for non-major refining facilities, a NOx RTC shave of 47 percent would be applied.

SCAQMD staff is aware of Paramount Petroleum's concern about severe or unjustified burdens and have attempted to minimize the impact to this facility by applying a sector-based shave approach that excludes Paramount Petroleum from the major refineries category. In addition, there is a safety valve in the rule that may alleviate the burden of the shave to a facility's RTC allocation in the event of a shortage of RTCs in the market. If there is a shortage of credits which would result in an increase in the RTC price, the safety valve in the rule would provide access to non-usable, non-tradable credits in the event that the 12-month rolling average market price for discrete year credits rises above $15,000 per ton. Furthermore, as stated Response 7-6, a facility whose equipment is already at BARCT may apply to be exempted from the shave requirements if it meets the criteria in Rule 2002 (i).

7-9 This comment claims that Paramount Petroleum qualifies as a "Low Complexity-Low Energy" refinery as defined in CARB's Low Carbon Fuel Standard because of high fuel efficiency operations, lower NOx emissions per barrel and lower GHG emissions when compared to the other, larger refineries.

The commentator's assessment of NOx emissions on a per barrel bases appears to be correct. The proposed rule would reduce RTCs from this facility using a smaller percentage than applied to the other, larger refineries.

7-10 This comment claims that NOx emission reductions required by the AQMP do not require a 50 percent shave across the board and instead flexibility should be allowed to account for facility differences.

The staff proposal is the result of a much more rigorous and in-depth analysis as compared to the analysis that supported control measure CMB-01. For a market-based incentive program, SCAQMD staff is required by the California Health and Safety Code to conduct periodic BARCT assessments and demonstrate equivalency with command-and-control rules which would otherwise be developed as a result of BARCT assessment. CMB-01 anticipated this BARCT assessment but could not predict the results of the assessment, and therefore made commitments for a more modest reduction. This staff proposal recommends a reasonably available 14 tpd of NOx RTC reductions, based on

BARCT, as required by state law, and which are needed to help the Basin achieve the PM2.5 standards by 2019 and 2025 and the ozone standards by 2024 and 2032.

Also, as explained in Responses 7-6 and 7-8, this refinery will be excluded from the major refinery category and will be subject to a smaller shave percentage because of the differences in equipment operated.

1.0 Introduction

The electrical output of a solar thermal electric plant is inherently in a state of change, being dictated by both predictable and unpredictable variations—the influences of time and weather. In either event, utility system needs may require a fully functional storage system to mitigate the changes in solar radiation or to meet demand peaks.

A distinct advantage of solar thermal power plants compared with other renewable energies, such as photovoltaics (PV) and wind, is the possibility of using relatively cheap storage systems. That is, storing the thermal energy itself. Storing electricity is much more expensive.

A thermal energy storage (TES) option can collect energy in order to shift its delivery to a later time, or to smooth out the plant output during intermittently cloudy weather conditions. Hence, the operation of a solar thermal power plant can be extended beyond periods of no solar radiation without the need to burn fossil fuel. Times of mismatch between energy supply by the sun and energy demand can be reduced.

When used with Integrated Solar Combined Cycle Systems (ISCCS), energy storage could provide another important advantage. If the plant operates at baseload, it will operate at full load only when enough solar energy is available. At part load, the turbine efficiency can decrease considerably. If fossil energy is used to augment turbine load (through the use of duct firing, a heat transfer fluid [HTF] heater, or a backup boiler) when solar is not available, the plant converts that fossil fuel at a substantially lower efficiency than if it had been used directly in the combined cycle. Using thermal energy storage instead of a fossil burner can help to overcome this problem.

Economic thermal storage is a key technological issue for the future success of solar thermal technologies.

1.1 Scope of this Report

The purpose of this report is to identify and selectively review previous work done on the evaluation and use of thermal energy storage systems applied to parabolic trough power plants. Appropriate storage concepts and technical options are first discussed, followed by a review of previous work. This review is divided into two parts: work done before 1990 and work done after that date. This division was chosen because much of the work currently cited in this field was carried out and reported prior to 1990, and a key objective of the review was to highlight more recent results though they are less plentiful. Finally, observations and conclusions on the status of TES systems for trough plants are put forward, based on the body of literature covered.

1.2 Storage Concepts for Solar Thermal Systems

The principle options for using TES in a solar thermal system highly depend on the daily and yearly variation of radiation and on the electricity demand profile. As noted above, the main options are:

- Buffering
- Delivery period displacement

- Delivery period extension
- Yearly averaging

The goal of a buffer is to smooth out transients in the solar input caused by passing clouds, which can significantly affect operation of a solar electric generating system (SEGS) plant. The efficiency of electrical production will degrade with intermittent insolation, largely because the turbine-generator will frequently operate at partial load and in a transient mode. If regular and substantial cloudiness occurs over a short period, turbine steam conditions and/or flow can degrade enough to force turbine trips if there is no supplementary thermal source to "ride through" the disturbance. Buffer TES systems would typically require small storage capacities (maximum 1 hour full load).

Delivery period displacement requires the use of a larger storage capacity. The storage shifts some or all of the energy collected during periods with sunshine to a later period with higher electricity demand or tariffs (electricity tariffs can be a function of hour of the day, day of the week, and the season). This type of TES does not necessarily increase either the solar fraction or the required collection area. The typical size ranges from 3 to 6 hours of full load operation.

The size of a TES for delivery period extension will be of similar size (3 to 12 hours of full load). However, the purpose is to extend the period of power plant operation with solar energy. This TES increases the solar fraction and requires larger solar fields than a system without storage.

Yearly averaging of electricity production requires much larger TES and solar fields. In general, these are very expensive systems and have not been given serious consideration in the literature, nor will they be considered here.

Definitive selection of storage capacity is site- and system-dependent. Therefore, detailed statistical analysis of system electrical demand and weather patterns at a given site, along with a comprehensive economic tradeoff analysis, are desirable in a feasibility study to select the best storage capacity for a specific application.

1.3 Design Criteria

A key issue in the design of a thermal energy storage system is its thermal capacity - the amount of energy that it can store and provide. However selection of the appropriate system depends on many cost-benefit considerations.

The cost of a TES system mainly depends on the following items:

- The storage material itself
- The heat exchanger for charging and discharging the system
- The cost for the space and/or enclosure for the TES

From the technical point of view, the crucial requirements are:

- High energy density (per-unit mass or per-unit volume) in the storage material
- Good heat transfer between heat transfer fluid (HTF) and the storage medium

- Mechanical and chemical stability of storage material
- Compatibility between HTF, heat exchanger and/or storage medium
- Complete reversibility for a large number of charging/discharging cycles
- Thermal losses
- Ease of control

The most important design criteria are:

- Nominal temperature and specific enthalpy drop in load
- Maximum load
- Operational strategy
- Integration into the power plant

All these facts have to be considered when deciding on the type and the design of thermal storage. This review focuses on thermal energy storage for parabolic trough power plants, which operate under certain temperature limits. TES capacities up to 8 hours full load will be considered, which could significantly increase the solar share of a hybrid power plant, such as an ISCCS.

2.0 Technical Storage Options

Thermal energy storage can be classified by storage mechanism (sensible, latent, chemical) and by storage concept (active or passive).

2.1 Storage Media

Thermal storage can utilize sensible or latent heat mechanisms or heat coming from chemical reactions.

Sensible heat is the means of storing energy by increasing the temperature of a solid or liquid. Latent heat, on the other hand, is the means of storing energy via the heat of transition from a solid to liquid state. For example, molten salt has more energy per unit mass than solid salt.

Table 1 shows the characteristics of candidate solid and liquid sensible heat storage materials and potential phase change (latent) heat storage media for a SEGS plant.

For each material, the low and high temperature limits are given these limits, combined with the average mass density and heat capacity, lead to a volume-specific heat capacity in kWh_t per cubic meter. The table also presents the approximate costs of the storage media in dollars per kilogram, finally arriving at unit costs in $\$/kWh_t$.

The average thermal (heat) conductivity given in the table has a strong influence on the heat transfer design and heat transfer surface requirements of the storage system, particularly for solid media (high conductivity is preferable). High volumetric heat capacity is desirable because it leads to lower storage system size, reducing external piping and structural costs. Low unit costs obviously mean lower overall costs for a given thermal capacity.

2.1.1 Sensible Heat Storage

Thermal energy can be stored in the sensible heat (temperature change) of substances that experience a change in internal energy. The stored energy is calculated by the product of its mass, the average specific heat, and the temperature change. Besides the density and the specific heat of the storage material, other properties are important for sensible heat storage: operational temperatures, thermal conductivity and diffusivity, vapor pressure, compatibility among materials, stability, heat loss coefficient as a function of the surface areas to volume ratio, and cost.

Table 1. Candidate Storage Media for SEGS Plants (Geyer 1991)

Storage Medium	Temperature Cold (°C)	Temperature Hot (°C)	Average density (kg/m³)	Average heat conductivity (W/mK)	Average heat capacity (kJ/kgK)	Volume specific heat capacity (kWh$_t$/m³)	Media costs per kg ($/kg)	Media costs per kWh$_t$ ($/kWh$_t$)

2.1.1.1 Solid Media

For thermal storage, solid media usually are used in packed beds, requiring a fluid to exchange heat. When the fluid heat capacity is very low (e.g., when using air) the solid is the only storage material; but when the fluid is a liquid, its capacity is not negligible, and the system is called a dual storage system. Packed beds favor thermal stratification, which has advantages. Stored energy can easily be extracted from the warmer strata, and cold fluid can be taken from the colder strata and fed into the collector field.

An advantage of a dual system is the use of inexpensive solids such as rock, sand, or concrete for storage materials in conjunction with more expensive heat transfer fluids like thermal oil. However, pressure drop and, thus, parasitic energy consumption may be high in a dual system. This has to be considered in the storage design.

The cold-to-hot temperature limits of some solid media in Table 2 are greater than could be utilized in a SEGS plant because parabolic trough solar fields are limited to maximum outlet temperatures of about 400°C. Table 2 shows the effect on solid media by imposing this temperature limit on the storage medium temperature range, the unit heat capacities, and media costs.

Table 2. Solid Storage Media for SEGS Plants

Storage Medium	Heat Capacity kWh_t/m^3	Media Cost $\$/kWh_t$
Reinforced concrete	100	1
NaCl (solid)	100	2
Cast iron	160	32
Cast steel	180	150
Silica fire bricks	60	18
Magnesia fire bricks	120	30

Using these values and judging the options against the guidelines discussed above, the sand-rock-oil combination is eliminated because it is limited to 300°C. Reinforced concrete and salt have low cost and acceptable heat capacity but very low thermal conductivity. Silica and magnesia fire bricks, usually identified with high temperature thermal storage, offer no advantages over concrete and salt at these lower temperatures. Cast steel is too expensive, but cast iron offers a very high heat capacity and thermal conductivity at moderate cost.

2.1.1.2 Liquid Media

Liquid media maintain natural thermal stratification because of density differences between hot and cold fluid. To use this characteristic requires that the hot fluid be supplied to the upper part of a storage system during charging and the cold fluid be extracted from the bottom part during discharging, or using another mechanism to ensure that the fluid enters the storage at the appropriate level in accordance with its temperature (density) in order to avoid mixing. This can be done by some stratification devices (floating entry, mantle heat exchange, etc.).

The heat transfer fluid in a SEGS plant operates between the temperatures of 300°C and 400°C, approximately. Applying these limitations on temperature, and dropping mineral oil because it cannot operate at the upper temperature requirement gives the results shown in Table 3.

Table 3. Liquid Storage Media for SEGS Plants

Storage Medium	Heat Capacity kWh_t/m^3	Media Cost $\$/kWh_t$
Synthetic oil	57	43
Silicone oil	52	80
Nitrite salts	76	24
Nitrate salts	83	16
Carbonate salts	108	44
Liquid sodium	31	55

Both the oils and salts are feasible. The salts, however, generally have a higher melting point and parasitic heating is required to keep them liquid at night, during low insolation periods, or during plant shutdowns. Silicone oil is quite expensive, though it does have environmental benefits because it is a non-hazardous material, whereas synthetic oils may be classified as hazardous materials. Nitrites in salts present potential corrosion problems, though these are probably acceptable at the temperatures required here. (The U.S. Solar Two project has selected a eutectic of nitrate salts because of the corrosivity of nitrite salts at central receiver system temperature levels.)

2.1.2 Latent Heat Storage

Thermal energy can be stored nearly isothermally in some substances as the latent heat of phase change, that is, as heat of fusion (solid-liquid transition), heat of vaporization (liquid-vapor), or heat of solid-solid crystalline phase transformation. All substances with these characteristics are called phase change materials (PCMs). Because the latent heat of fusion between the liquid and solid states of materials is rather high compared to the sensible heat, storage systems utilizing PCMs can be reduced in size compared to single-phase sensible heating systems. However, heat transfer design and media selection are more difficult, and experience with low-temperature salts has shown that the performance of the materials can degrade after a moderate number of freeze-melt cycles. LUZ International Ltd. proposed evaluation of an innovative phase-change salt concept to the solar community that used a series of salts in a "cascade" design (to be discussed later).

Table 1 showed, for a number of potential salts, the temperature at which the phase change takes place as well as the heat capacity (heat of fusion). Data for the salts shown in that table that are applicable to SEGS plants are shown in Table 4 below. It can be seen that the heat capacities, at least for the nitrites, are high and unit costs are comparatively low.

Table 4. Latent Heat Storage Media for SEGS Plants

Storage Medium	Heat Capacity kWh_t/m^3	Media Cost $/kWh_t$
$NaNO_3$	125	4
KNO_3	156	4
KOH	85	24

2.1.3 Chemical Storage

A third storage mechanism is by means of chemical reactions. For this type of storage it is necessary that the chemical reactions involved are completely reversible. The heat produced by the solar receiver is used to excite an endothermic chemical reaction. If this reaction is completely reversible the heat can be recovered completely by the reversed reaction. Often catalysts are necessary to release the heat. This is even more advantageous as the reaction can then be controlled by the catalyst.

Commonly cited advantages of TES in a reversible thermochemical reaction (RTR) are high storage energy densities, indefinitely long storage duration at near ambient temperature, and heat-pumping capability. Drawbacks may include complexity, uncertainties in the thermodynamic properties of the reaction components and of the reaction's kinetics under the wide range of operating conditions, high cost, toxicity, and flammability.

Although RTRs have several advantages concerning their thermodynamic characteristics, development is at a very early stage. To date, no viable prototype plant has been built.

2.2 Storage Concepts

Storage concepts can be classified as active or passive systems. Active storage is mainly characterized by forced convection heat transfer into the storage material. The storage medium itself circulates through a heat exchanger. This heat exchanger can also be a solar receiver or a steam generator.

The main characteristic of a passive system is that a heat transfer medium passes through storage only for charging and discharging. The heat transfer medium itself does not circulate.

2.2.1 Active Thermal Energy Storage

Active thermal systems typically utilize tank storage. They can be designed as one tank or two tank systems.

Active storage is again subdivided into direct and indirect systems. In a direct system the heat transfer fluid, which collects the solar heat, serves also as the storage medium, while in an indirect system, a second medium is used for storing the heat.

Two prominent examples of two-tank systems for solar electric applications are the storage systems of the SEGS I (Kroizer 1984) and Solar Two plants (Kelly and Lessly 1994, Pacheco and Gilbert 1999, and Valenti 1995). Figure 1 shows a schematic flow diagram of SEGS I. An initial experience with a small-scale two-tank molten salt system has already been described (Chinen et al. 1983).

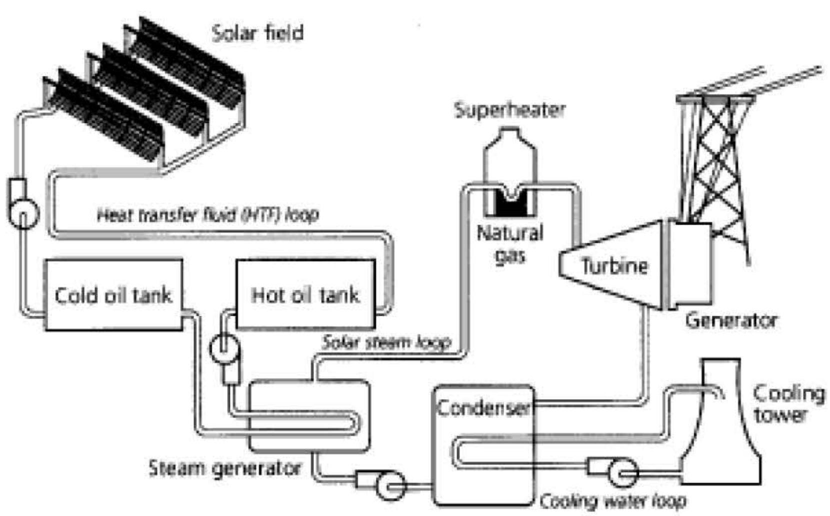

Figure 1. Schematic flow diagram of SEGS I plant

A two-tank system uses one tank for cold HTF coming from the steam generator and one tank for the hot HTF coming directly out of the solar receiver before it is fed to the steam generator. The advantage of this system is that cold and hot HTF are stored separately. The main disadvantage is the need for a second tank. In this type of system, the storage tanks are directly coupled to the HTF pressure levels (which is not necessarily a disadvantage).

The single-tank system reduces storage volume and cost by eliminating a second tank. However, in a single-tank system it is more difficult to separate the hot and cold HTF. Because of the density difference between hot and cold fluid, the HTF naturally stratifies in the tank, from coolest layers at the bottom to warmest layers at the top. These systems are called thermocline storage. Experience with thermocline storage was described by Castro et al. 1992, Dinter et al. 1990, Dugan 1980, and Kandari 1990. Maintaining the thermal stratification requires a controlled charging and discharging procedure, and appropriate methods or devices to avoid mixing. Filling the storage tank with a second solid storage material (rock, iron, sand etc.) can help to achieve the stratification.

2.2.2 Passive Thermal Energy Storage

Passive systems are generally dual medium storage systems. The HTF carries energy received from the energy source to the storage medium during charging and receives energy from the storage material when discharging. These systems are also called regenerators.

The storage medium can be a solid, liquid, or PCM. In general, a chemical storage system employs at least two media.

The main disadvantage of regenerators is that the HTF temperature decreases during discharging as the storage material cools down. Another problem is the internal heat transfer. Especially for solid materials, the heat transfer is rather low, and there is usually no direct contact between the HTF and the storage material as the heat is transferred via a heat exchanger.

3.0 State of the Art

3.1 Existing TES Systems in Solar Thermal Plants

Of eight installed thermal energy storage systems in solar thermal electric plants, seven have been of an experimental or prototype nature and one has been a commercial unit. Table 5 gives the characteristics of the existing units. All have been sensible heat storage systems: two single-tank oil thermocline systems, four single medium two-tank systems (one with oil and three with salt) and two dual medium single-tank systems. To put the size of these systems in perspective, a 30-MWe SEGS plant with a plant efficiency of 35% would require about 260 MWh_t for a 3-hour storage capability. This is considerably larger than any other solar thermal electric storage system built up to now.

All of these systems were successful to varying degrees, recognizing that most were development units that were expected to reveal design flaws or issues as a basis for future design improvements.

Two important characterizations of storage systems are the "round-trip efficiency" and the cost per unit of thermal energy delivery ($\$/kW_t$). The round-trip efficiency is, simply, the ratio of the useful energy recovered from the storage system to the amount of energy initially extracted from the heat source. This efficiency is affected by the laws of thermodynamics and by heat losses in the tanks, piping, and heat exchangers in the system; electric parasitic losses needed to circulate storage system fluids constitute additional losses.

Efficiency and cost experience from existing systems are informative but of limited relevancy to commercial plants because most of the existing facilities were one-of-a-kind development projects. Nevertheless, round-trip efficiencies of more than 90% were measured in many of the systems listed in Table 5, though some systems were as low as 70%. Both the oil systems and molten salt systems were shown to be technically feasible. While various problems arose due to mistakes in design, construction or operation, no fundamental issues surfaced for these approaches.

The SEGS I storage system cost $\$25/kW_t$ in 1984 dollars, with the oil representing 42% of the investment cost. The oil used in the later SEGS plants for operation up to 400°C costs approximately eight times more than the SEGS I oil. This was reason enough that a storage system similar to the SEGS I storage concept was not repeated in later SEGS plants. However, there were other important considerations, such as total system investment, very large tank size requirements, and inflexibility compared to a back-up system.

Table 5. Existing TES Systems

Project	Type	Storage Medium	Cooling Loop	Nominal Temperature Cold (°C)	Hot (°C)	Storage Concept	Tank Volume (m³)	Thermal Capacity (MWh)

3.2 Summary of Work Performed Before 1990

This section reviews the most relevant investigations and evaluations carried out prior to about 1990. Selected literature from this period has been listed in the References, but only selected works are explicitly discussed here. A valuable overview of the applicability of thermal storage to solar power plants was provided by Geyer 1991. Table 6 shows the storage systems initially considered there, though of these only a few were investigated in detail. The final systems are listed in the following paragraphs.

Dual medium sensible heat systems

Two single-tank alternatives were analyzed, one in which HTF oil flows through a storage medium of concrete and another in which the storage medium is solid salt. Cast iron and cast steel were eliminated as storage media due to high cost, even though they offered thermodynamic advantages.

Table 6. Candidate Storage Concepts for SEGS Plants

TES Concepts	Storage Type	Status*	Assessment
Sensible Active	Two-Tank Oil	T	Basic concept, state-of-the-art
	HITEC	T	2 variants analyzed based on existing PSA/THEMIS designs
	Thermocline	T	Proved on pilot scale, no advantages over basic two tank system
Sensible DMS	Oil/Cast Iron	T	Proved on pilot scale, no advantages over basic two tank system
	Oil/Steel	LR	Used in chipboard presses
	Oil/Concrete	MR	Several variants analyzed
	Oil/Solid Salt	MR	Several variants analyzed
PCM	Oil/PC Salts	HR	Several cascade arrangements analyzed
Chemical	Oil/Metal Hybrids	HR	Early state of development, no lead concepts, no cost data

* Nomenclature: **T**: Tested / **LR**: Low Risk / **MR**: Medium Risk / **HR**: High Risk

Sensible heat molten salt system

A two-tank system (similar to SEGS I) utilizing the HITEC salt was chosen. HITEC is a eutectic mixture of 40% $NaNO_2$, 7% $NaNO_3$ and 53% KNO_3 with a 142°C melt-freeze point.

Phase-change systems

These higher-risk systems were judged to have high uncertainty in technical feasibility and cost, but were evaluated for their potential in this application. Three different phase-change concepts were evaluated. The first was a LUZ design using five PCMs in a series, or cascade, design (SERI 1989); the second was a design by the Spanish company INITEC, which also used five PCMs but in a different heat exchanger configuration; the third design originated with the German companies Siempelkamp and Gertec (SGR) and used three commercially available PCMs along with concrete for the higher temperatures.

3.2.1 Overview of Results

Storage system designs for the SEGS conditions based on these five concepts were developed in Dinter et al. 1990. Summary results are presented here giving overall system volume, thermal storage capacity and utilization, and specific costs in $/kWh$_t$ of capacity.

The utilization measure is an interesting aspect of storage systems. Earlier discussion described some of the aspects of temperature differences within the HTF fluid and between the HTF and a solid storage medium. Another aspect of storage design is the temperature difference within the medium itself. In a two-tank liquid system, for example, the entire fluid is heated to a charged temperature and hence the entire storage medium is utilized. PCM systems theoretically also have very high utilization factors. In a solid system, however, temperature gradients required for thermal conduction through the media itself prevent full utilization of the material. In this case, 100% utilization would be achieved if the entire solid medium were heated to the full charging temperature. Hence, the "potential" storage capacity might be two or three times higher than the practical storage capacity. Detailed heat transfer calculations on specific designs provide this type of information.

Figure 2 gives results on the total volume, storage capacity and utilization, and specific cost of the six candidate systems analyzed for SEGS plants. For comparison purposes, we will select the INITEC PCM design as representative of the PCM class, with the qualifier that there is much more uncertainty and technical risk in the PCM results than in the sensible heat oil-solid systems or in the sensible heat HITEC molten salt system.

With regard to volume, the concrete and salt media fill about 6,900 and 5,200 m^3 of space, respectively, whereas the molten salt and PCM system need 2,600 m^3. If the cross-sectional area perpendicular to the flow measured 13m by 13m, the length of the concrete system would be 41 m compared to a 15-m length for the PCM system. A major reason for the larger sizes of the concrete and solid salt systems is the poor volume utilization. The concrete system, for example, is utilized at 36% of its full potential capacity. The molten salt and PCM systems, on the other hand, have utilization factors up to 100%. The concrete system does, however, have cost advantages due to the very low cost of concrete, which results in a low system cost even though there is more structure required for this larger volume system.

Generally, the storage costs developed in this assessment vary from \$25–\$50/kWh_t (on the order of \$65–\$130/kWh_e). At the low end, TES units of 270 and 450 MWh_t capacity would have a capital cost of 6.8 MUSD and 11.3 MUSD, respectively.

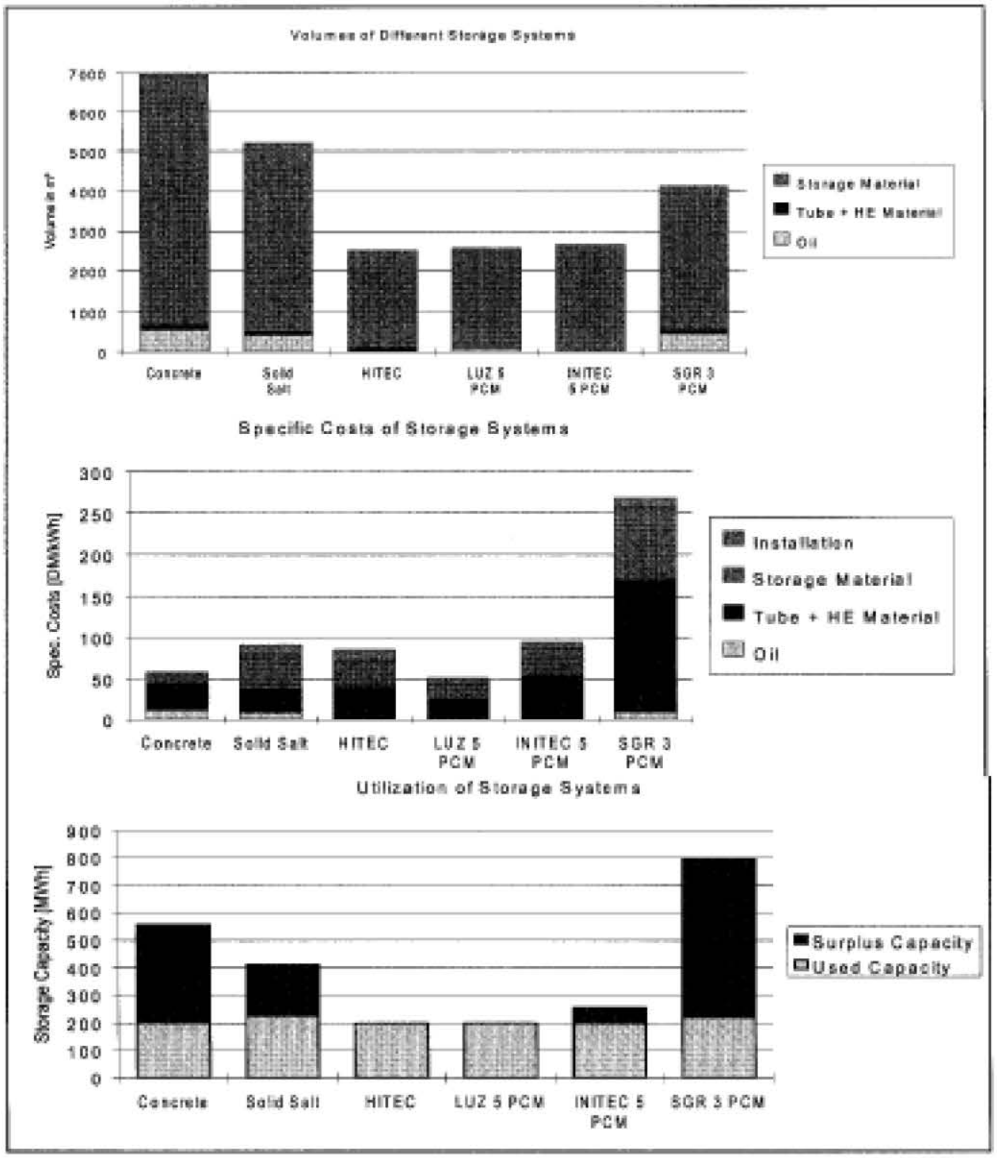

Figure 2. Results of TES evaluations for reference SEGS plant (Dinter et al. 1990)

3.2.2 SEGS TES Workshop

A symposium workshop (SERI 1989) on TES systems for SEGS plants, held in 1989 and sponsored by the Solar Energy Research Institute (SERI—now the National Renewable Energy Laboratory—NREL), discussed several of the options presented above. While the workshop focused on phase-change material concepts, both sensible heat storage and chemical storage were also included in the agenda. The more detailed evaluations reported in Dinter et al. 1990 were completed subsequent to the workshop.

With respect to sensible heat storage, the workshop concluded that this approach could result in a cost-effective system. While no new research would be required, thorough and careful engineering development and small-scale testing would be necessary. Issues such as thermal expansion, potential leakage, heat transfer configuration, and heat exchange optimization require more detailed design within the context of a design concept.

Latent heat (or phase-change) storage was considered to be in a more primitive state of development. While the concept is promising, considerable research, system development, and proof-of-concept testing would be required. Concerns on heat transfer characteristics and heat exchange configuration were expressed. Of several possible configurations, it was concluded that both shell-and-tube heat exchangers and a system of encapsulated particles of phase-change salts were worthy of exploration, with the latter approach having both more potential for cost-effectiveness and a lower probability of success.

3.3 Experience and Research on TES since 1990

To analyze the work that has been done since 1990 on thermal storage for troughs, a thorough literature review was carried out. This review included a computerized literature search in the Energy Technology Data Exchange (ETDE) Energy database.

The ETDE Energy Database contains more than 3.8 million bibliographic records with abstracts for energy research and technology information from around the world. The EDTE, a multilateral information exchange program, was established in 1987 under the auspices of the International Energy Agency (IEA). Member countries share their energy research and technology information through the Energy Database. The database covers journal articles, research reports, conference papers, books, dissertations, computer software, and other miscellaneous types. Of all the records, 7.1% are devoted to energy storage and conservation.

Appendix A gives the report of the database search including the keywords used to identify the records of interest.

Sixty-five references that met the criteria defined through the keywords were identified. After evaluating the 65 abstracts, a lesser number (21) were applicable to TES systems in parabolic trough technology, and this group was added to the reference list given in Chapter 5. The abstracts for this group are included in Appendix B.

Table 7, summarizing the literature analysis, lists all identified works that may help in the selection of a candidate storage concept. The main results for the most promising options are discussed below.

Table 7. Results from Literature Review (after 1999)

Author	Year	Storage Concept	Type of Work*	Temperature Range	Capacity
M. Mitzel et al.	1990	Hydrid/Magnesium Thermochemical Storage	TH	?	-
Brown et al.	1991	Oxide/Hydroxide chemical storage	TH	300°C–400°C	-
D.Steiner, M. Groll	1995	MgH2/Mg Chemical Storage	EX-LS	280°C–480°C	14 kWh
K. Lovegrove A. Luzzi et al.	1999	Ammonia Based Thermochemical Storage	EX-LS	450°C–650°C	?
B.Beine, F. Dinter, R. Ratzesberger et al.	1992	Concrete	EX-LS	290°C–400°C	50 kWh
J. Pacheco, D.B. Kelly et al.	1999	Molten-Salt 2-Tank	EX-FS	290°C–566°C	114 MWh
H. Michels, E. Hahne	1996	Cascaded PCM	EX-LS	250°C–450°C	8.5 kWh

* TH theoretical work
EX-LS experimental work in lab scale
EX-FS experimental work in full scale

In addition to the experimental works listed in Table 7, more theoretical works on TES were performed by Brower 1992, Lund 1994, Meier and Winkler 1993, Steel and Wen 1981, and Steinfeld et al. 1991.

3.3.1 Overview of Progress

3.3.1.1 Experience at Solar Two

The most significant recent work on molten salt storage comes from the experience in the Solar Two Project. This prototype facility, decommissioned in 1999, was a 10-MW power tower system using a nitrate eutectic molten salt as the HTF. A schematic of the system is shown in Figure 3. Molten salt is pumped from the cold storage tank through the tower receiver and then to the hot storage tank. When dictated by the operation, the hot salt is pumped through the steam generation system and then back to the cold tank. Solar Two is capable of producing 10 MWe net electricity. A number of lessons on the equipment design, material selection, and operation of molten salt systems were learned during the 1-1/2 years of testing and evaluation.

Solar Two used an efficient, molten nitrate-salt thermal-storage system (Pacheco and Gilbert 1999). It consisted of an 11.6-m-diameter by 7.8-m-high cold-salt storage tank, a 4.3-m-diameter by 3.4-m-high cold-salt receiver sump, an 11.6-m-diameter by 8.4-m-high hot-salt storage tank, and a 4.3-m-diameter by 2.4-m-high hot-salt steam generator sump. The design thermal storage capacity of the Solar Two molten salt system was 105 MWh_t—enough to run the turbine at full output for 3 hours. The measured gross conversion efficiency of the 12-MWe (10-MWe-net) Solar Two turbine was 33%. Actual thermal storage capacity based on the mass of salt in the tanks, accounting for (subtracting) the 3-foot heels in each tank, and with design temperatures—1050°F hot salt, 550°F cold salt—was 114 MWh_t.

The system contained 1.5 million kilograms of nitrate salt composed of a mixture of 60% $NaNO_3$ and 40% KNO_3, provided by Chilean Nitrate Corporation (New York). This salt melted at 220°C and was thermally stable to about 600°C.

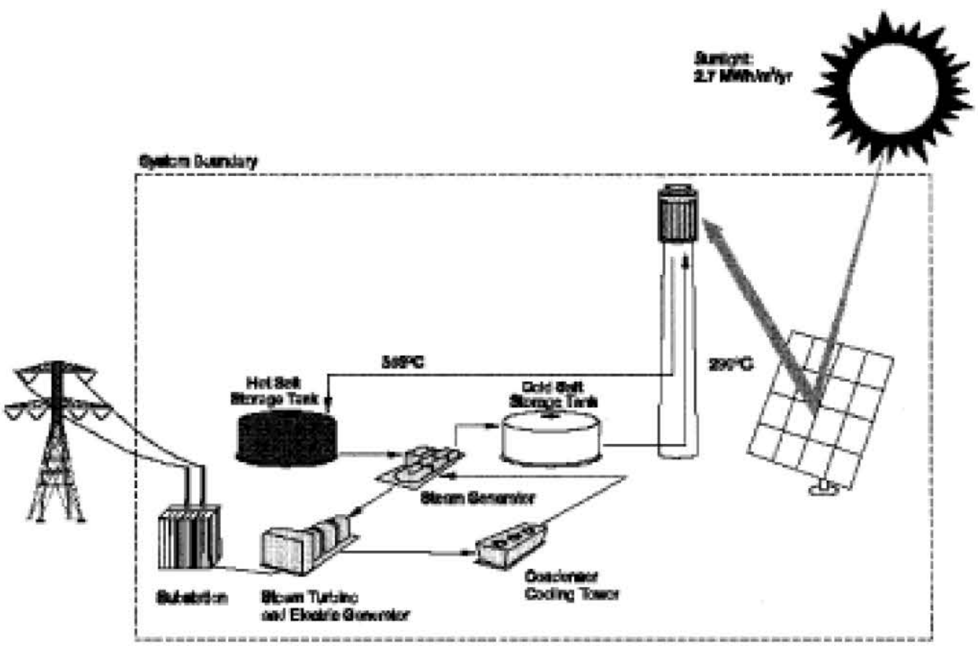

Figure 3. Molten salt power tower system schematic

<u>Heat Losses</u>

Several tests were conducted to quantify the thermal losses of major pieces of equipment throughout the plant and to compare the values to calculated estimates. The major pieces of equipment evaluated were the hot tank, cold tank, steam generator sump, and receiver sump. There were two methods of measuring the thermal losses in the tanks and sumps. One method was to turn off all auxiliary heaters and track the rate of decay of the average tank or sump temperature. By knowing the salt level, and thus the volume of salt in the vessel, an estimate of the heat loss could be made. Another method was to have the heaters energized and regulate the inventory at a set temperature. Once the vessel was at steady state, the power consumption of the heaters was measured over a long period of time. The electrical power consumption was assumed to be equal to the heat loss rate.

A summary of the measured and calculated thermal losses is shown in Table 8. The thermal losses for the tanks and sumps were equal to the calculated values within experimental error, except for the steam generator sump heat loss rate. The losses for the steam generator sump were higher than predicted, possibly because the insulation may have degraded significantly since it was installed. Salt had leaked out of the sump through flanges and into the insulation, which adversely affected its insulating properties. Based on the measured heat loss rates, the total energy lost to the environment over the course of a typical operating year corresponds to a 98% annual thermal efficiency.

Table 8. Measured and Actual Thermal Losses of Major Equipment

Major Equipment	Calculated Thermal Loss, kW	Measured Thermal Loss, kW
Hot Tank	98	102
Cold Tank	45	44
Steam Generator Sump	14	29
Receiver Sump	13	9.5

Operating Experience[1]

The capacity of the system is a function of the hot and cold salt temperatures. Hot salt temperatures at the bottom of the downcomer were typically only 1025°F because some of the isolation ball valves between the riser and downcomer leaked, attemperating the salt coming out of the receiver (which typically exited at 1050°F). The lower salt temperature derated the capacity of the thermal storage system by 5% to 108 MWht.

The fractional amount of the energy sent to thermal storage that was later discharged to the steam generator to make electricity is nearly 1, but is a function of the availability. The thermal losses are basically a fixed loss to the environment. When the plant availability is high, the collected energy increases and the losses are a smaller fraction of the total energy sent to storage. For example, on Dec. 2, 1997, on a sunny winter day, the receiver collected 217 MWh, which was sent to the steam generator system to make electricity. Based on a constant thermal loss of 185 kW from the hot and cold tanks, and the receiver and steam generator sumps, the total energy lost to the environment that day was 185kW x 24 h = 4.43 MWh or 2.0% of the collected energy. In contrast, on a sunny summer day—June 18, 1998—the receiver collected 334 MWht

[1] Comments provided by James Pacheco, Sandia National Laboratories Albuquerque, December 15, 1999.

and the thermal losses were 1.3% of the collected energy. Even with the very prototypical nature of Solar Two (i.e., poor availability, frequent outages, first year operation, etc.), over several months the fractional amount lost to the environment was only 6% of collected energy. If the plant ran with higher availability, i.e., typical mature operation, the factional amount of stored energy lost to the environment would only be about 2% of collected energy.

There were no major operational problems with the thermal storage system and, in general terms, the system ran satisfactorily. Typically, the plant started using the stored energy within an hour or two after the receiver began collecting energy. Scenarios were also run, however, to demonstrate dispatching energy several times or to demonstrate the production of a constant output of electricity at night and through clouds. A number of practical lessons were learned, and no barriers to future implementation were evident.

3.3.1.2 Concrete

Limited prototype testing has been done on the concrete-steel thermal storage concept. Between 1991 and 1994, two concrete storage modules were tested at the storage test facility at the Center for Solar Energy and Hydrogen Research (ZSW) in Stuttgart, Germany (Ratzesberger et al. 1994). Figure 4 shows the prototype concrete module installed in the center's laboratory.

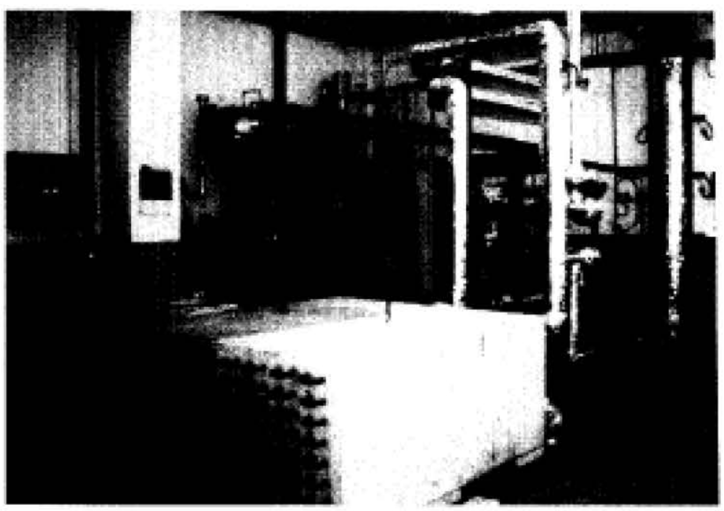

Figure 4. Test Facility for TES with two concrete storage modules at ZSW

The test results gained at ZSW in principle confirm the performance predictions given by Baddruddin, Dinter et al. 1992. Based on these tests, a numerical calculation model for concrete storage was developed by Ratzesberger 1995. He also proposed a slightly different design that results in the same performance but with considerably lower pressure loss in the storage module. According to his results, the pressure loss in a

200-MWh module can be reduced from 4.3 to 1.9 bar. The integration of a sensible heat storage system like concrete storage into a SEGS plant is depicted in Figure 5.

Ratzesberger recalculated the cost for storage and obtained a price of $40/kWh in 1994 U.S. dollars. This is slightly higher than the number given by Dinter. As a next step in the development of concrete storage, a project has recently been proposed to the EU (European Union) by a European team (CONTEST 1999). The proposed project consists of a prototype module with a capacity of 1–2 MWh to be erected at the PSA and connected to a parabolic trough solar field. The project, if funded, will be led by the German company Siempelkamp Giesserei GmbH & CO KG. In the company's proposal, it is projected that storage costs of $26/MWh in commercial scale can be realized.

Summarizing the work performed on concrete storage up to now, it can be concluded that this concept presents a relatively cheap option of thermal storage. The feasibility has already been proven in laboratory tests. The highest uncertainty still remains in the long-term stability of the concrete material itself after thousands of charging cycles. Special tests in a climatic chamber dedicated to investigation of this potential problem are included in the aforementioned EU proposal.

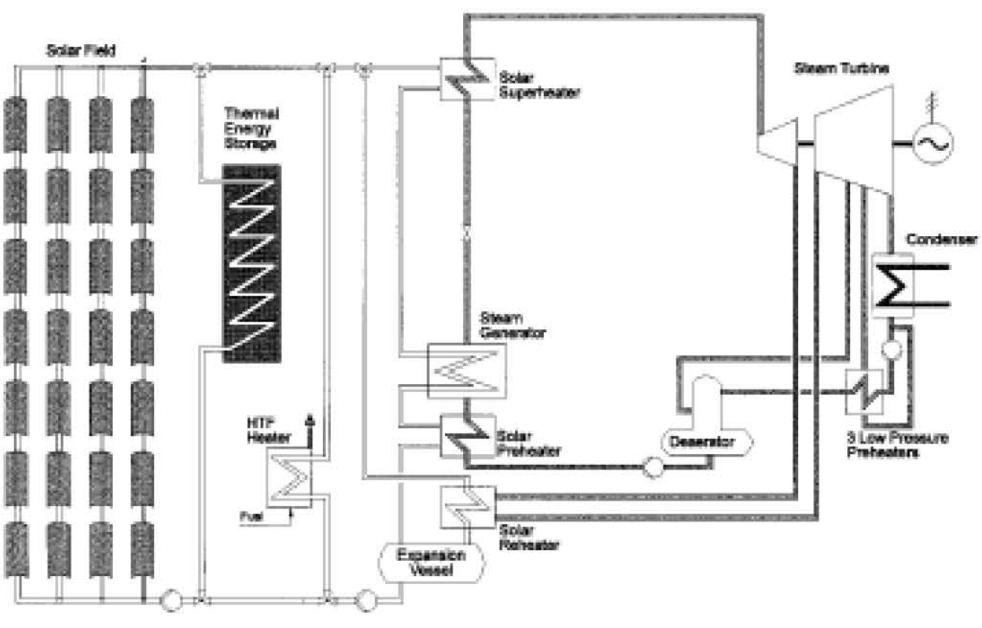

Figure 5. Schematic diagram of a SEGS plant with TES

3.3.1.3 Phase Change Material

Following the recommendations of the SERI workshop held in 1988 (SERI 1989), the ZSW, Germany, started to investigate storage using PCM. It was found by Dinter et al.

1990 that PCM storage has a relatively high heat capacity per volume and offers the lowest cost of all concepts investigated in this study (see also Figure 2).

A storage test facility has been set up in ZSW's laboratory allowing the investigation of various storage concepts independent from the sun. Electrical heating is the heat source, and a cooling tower is the heat sink. Figure 6 shows the flow diagram of the test loop with three PCM modules connected to the system. The modules can be charged by the HTF flow separately or connected to each other in series or in parallel.

A major objective was to investigate the heat transfer mechanism of different PCM salts during phase change and of liquid salts (Hunold et al. 1994, 1992, 1992, and 1994). In the work of Hunold, only one storage module filled with one salt was investigated in each case. Hunold showed that phase change storage is technically feasible and proposed a storage design built out of a shell and tube heat exchanger in a vertical orientation. By adjusting the vertical orientation of the tubes, natural convection and heat transfer can be improved. He selected the nitrate $NaNO_3$, with a melting point at 305°C, as appropriate storage material for the SEGS-type power plants.

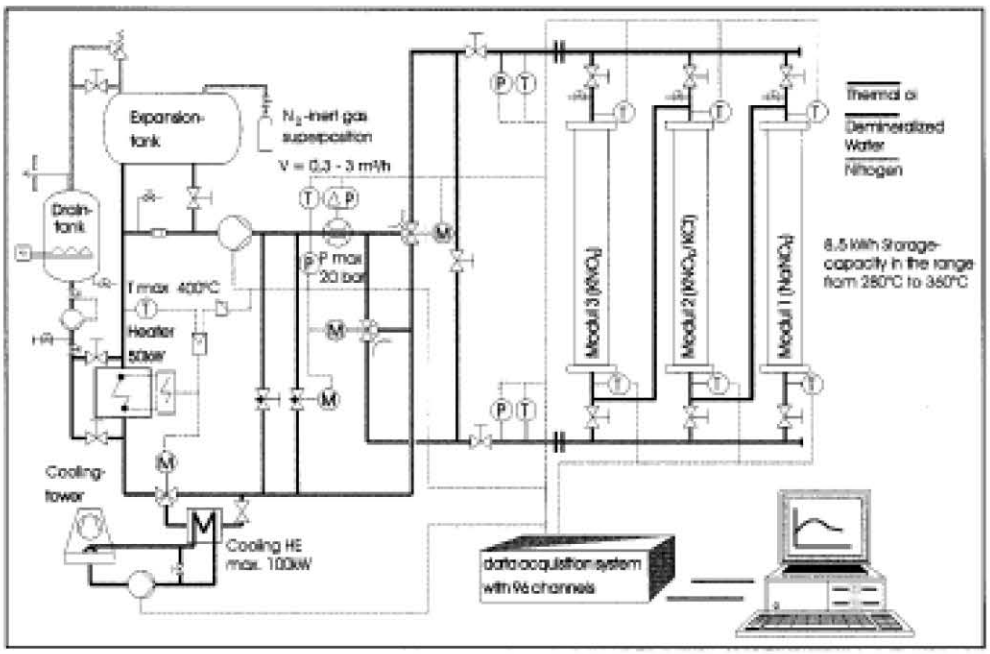

Figure 6. Flow diagram of storage test loop at ZSW (Michels and Hahne 1996)

However, one can only take full advantage of PCM storage by connecting several modules with different salts and different melting points in series as shown in Figure 7. Michels 1996 explained, by means of Figure 8, the reason for this. The left diagram shows the HTF temperature at the end of charging and discharging and the melting temperature of a single-stage salt storage as investigated by Hunold. During discharging the HTF temperature in the biggest part of the storage module is higher than the melting temperature of the salt. This means that a major portion of the salt

20

would not freeze during discharging and the high latent portion of the stored heat can not be extracted from the storage. Consequently, the utilization factor of the system would be relatively low.

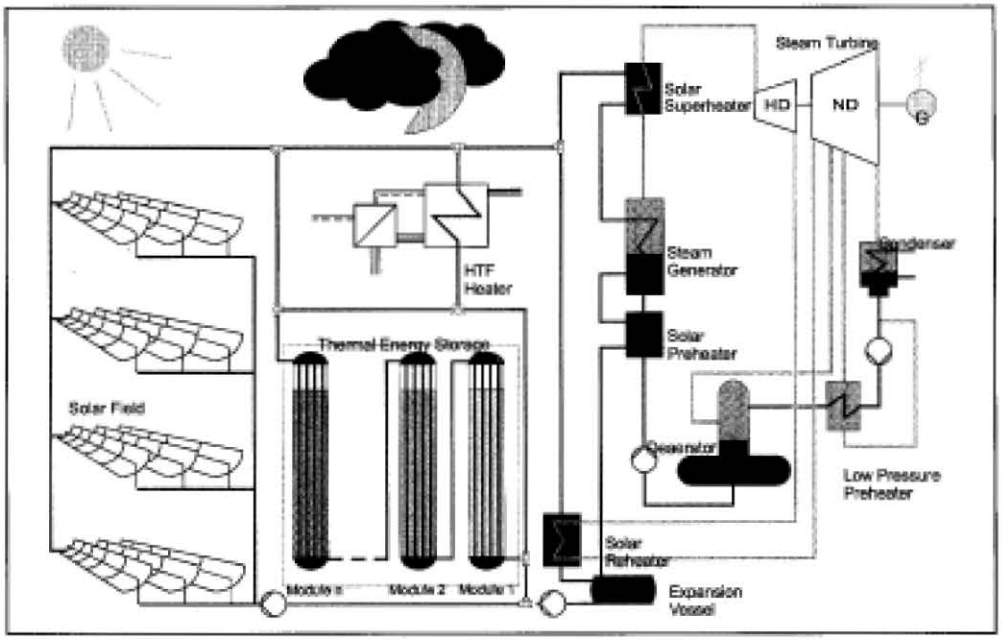

Figure 7. Possible process scheme of a SEGS with integrated PCM-TES (Michels and Hahne 1996)

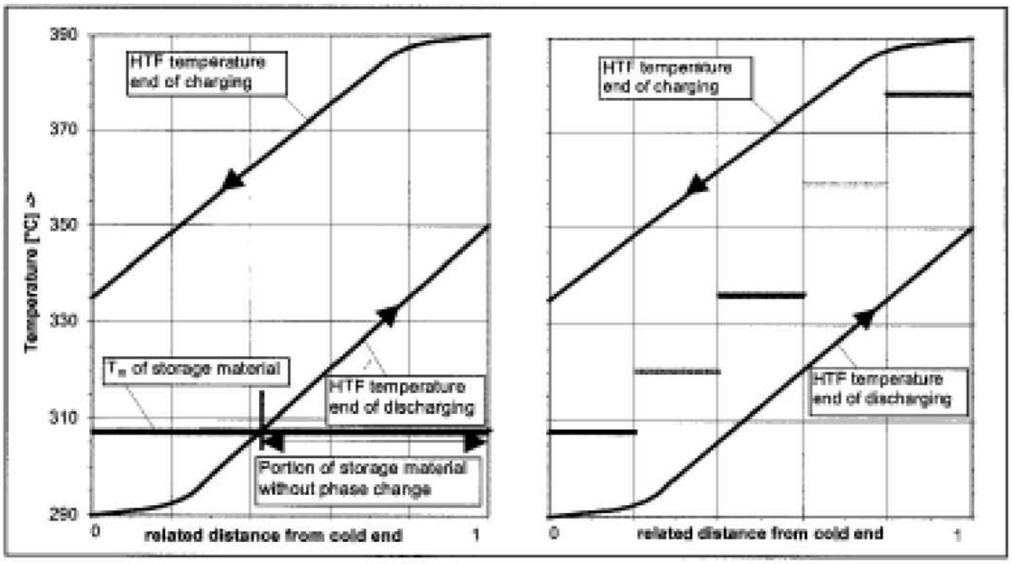

Figure 8. Theoretical temperature distribution in a PCM-TES for SEGS

The latent heat can only be used completely if, during charging, the temperature of the HTF is always higher than the melting point of the storage medium and, during discharging, always lower. This is shown in the right-hand diagram of Figure 8. According to Michels, five different PCMs have to be used for an optimized storage operating in the temperature range of a SEGS plant.

Michels experimentally investigated a configuration of three different modules connected in series (Michels and Hahne 1996). He used the nitrates KNO_3, KNO_3/KCl and $NaNO_3$. Figure 9 shows the measured temperature distribution in the test modules during charging.

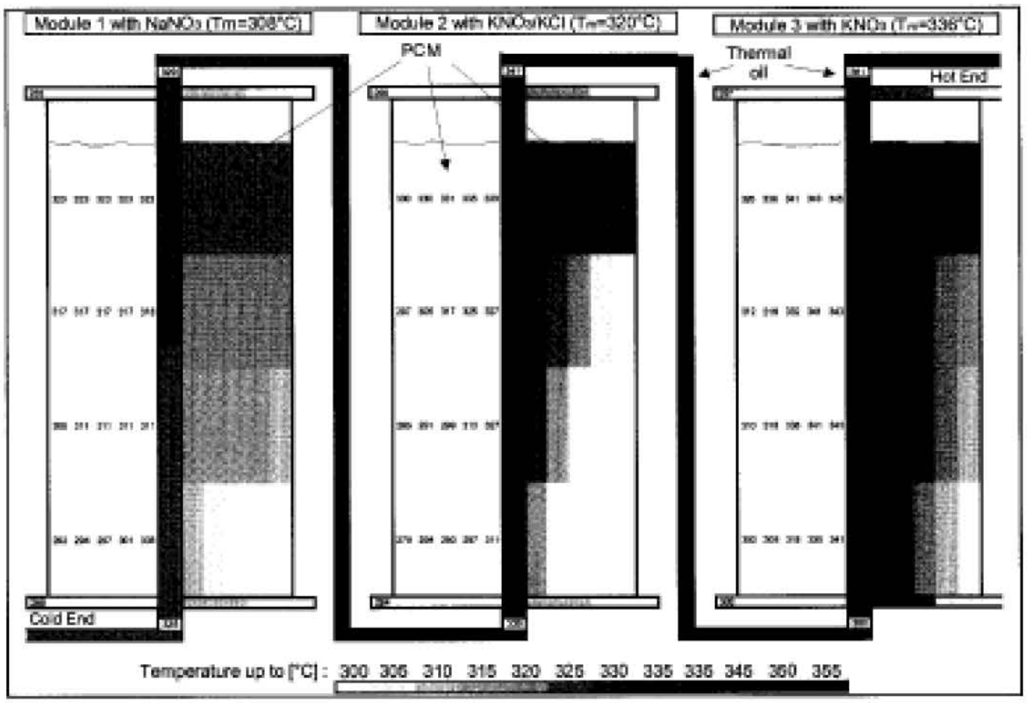

Figure 9. Temperature distribution inside the cascaded PCM test modules during charging

In his experiments, Michels proved the high utilization factor of a cascaded PCM storage. However additional experiments are required to verify the feasibility of a five-stage cascaded storage. Also additional design studies have to be performed to optimize the sizes of each stage, to select the appropriate material for the storage tank for each salt and to evaluate the cost.

Further works are concerned with PCM as storage material for parabolic troughs with Direct Steam Generation (Solomon 1991) and with the development of special measurement devices to observe the phase-change (Jaworske 1991).

A combined configuration of one sensible heat storage module, like concrete, and of two PCM modules at each end as proposed by Ratzesberger et al. (1994) seems to be a reasonable approach as a next step in the development of PCM storage.

3.3.1.4 Chemical Energy Storage

In the SERI workshop it was concluded that chemical energy storage is an attractive option in longer term and may offer relatively low cost. Based on a preliminary cost assessment the hydroxide/oxide reaction between CaO and H_2O was mentioned as one possibility (NASA 1979).

Subsequently, the Pacific Northwest Laboratory (PNL—now the Pacific Northwest National Laboratory—PNNL) conducted a study funded by the U.S. Department of

Energy to investigate the potential feasibility for a chemical energy storage based on this reaction. The report (Brown et al. 1991) concluded that this type of storage is, in principle, applicable under the SEGS temperature conditions. However, the study was based only on theoretical analysis and basic experimental investigations, and information was somewhat limited due to proprietary restrictions. The authors could not determine if the dynamics of the reaction fit to the requirements of storage for solar power plants, and also concluded that the question of proper integration into the solar power system remained unsolved. Costs were roughly estimated to be about $45/kWh. No further development of this type of storage could be identified through the literature review, and it appears that considerable work is required to develop a chemical energy storage system with hydroxide/oxide reaction for commercial application.

Development of another type of chemical storage seems to be much advanced, namely the solar ammonia energy storage developed by the Australian National University (Kreetz and Lovegrove 1999, Lovegrove et al. 1999, and Luzzi et al.). In this system, liquid ammonia is dissociated in a solar reactor into hydrogen and nitrogen. The energy is recovered in an ammonia synthesis reactor. The ammonia system was developed for use with parabolic dishes, but theoretically can also be used in the temperature range of parabolic trough collectors.

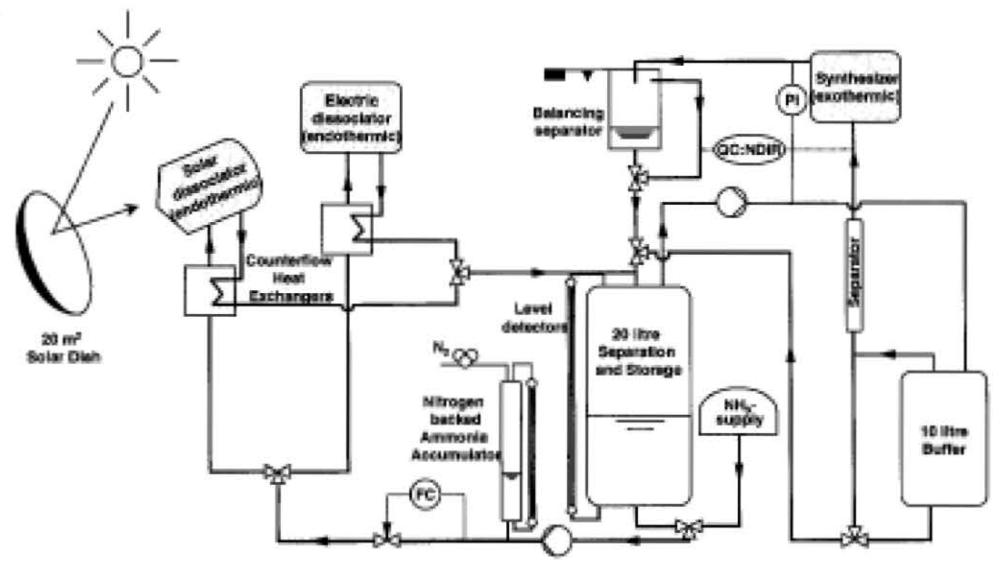

Figure 10. Test loop set up for solar ammonia energy storage (Lovegrove et al. 1999)

The first small-scale solar test facility was set up and has been operating for more than a year. Figure 10 shows the flow diagram of the test installation. The nominal solar input into the system is 1 kW. At this scale, it is clear that potential scale-up to a multi-megawatt system would be a significant undertaking.

24

Current estimates are that a 10-MW plant built largely from industry standard or proven components will cost about $100 million (U.S. 1999) (Luzzi et al.).

4.0 Observations and Recommendations

Based on the body of literature examined in this survey, we come to the following observations:

- There have been no *major* bold developments in the field of thermal energy storage systems for trough power plants in the 1990s compared to prior work. However, there have been important contributions furthering work on candidate systems previously identified.
- Within the context of the Solar Two project, a prototype two-tank molten salt system containing a nitrate salt eutectic was successfully tested over a 11/2 year testing period.
- Molten salt systems with lower melting points should be explored for trough applications. The two-tank system as implemented at Solar Two is a relatively low-risk approach. A one-tank thermocline system is riskier with respect to performance, but offers the promise of important cost reductions.
- Useful laboratory-scale testing on several PCM modules was carried out by ZSW. The results substantiate the prior conclusion that these systems offer promise, and further work appears warranted.
- A proposal for prototype construction and testing of 1–2-MWh prototype concrete-steel storage system was submitted to the European Union in the summer of 1999. Present indications at the issuance of this report are that funding for this project will not be granted in the current round of accepted projects, and resubmission in early 2000 is anticipated.
- We found no evidence that the design and development of chemical storage for parabolic trough applications has been *significantly* advanced in the last decade, though some further useful evaluations have been carried out.

These observations lead us to the following recommendations:

1. On the basis of current progress and cost estimates, molten salts and concrete systems merit priority as candidates for near-term deployment. PCM systems are the additional system of choice for longer-term development.
2. The focus of near-term research should be prototype system development and field implementation to refine designs and provide the bases for valid performance and cost estimates.

AB Within the frame of two projects funded by the German Federal Ministry for Research and Technology (BMFR) a thermochemical energy storage system for solar application and a sensible/latent hybrid storage system for industrial application were investigated. The thermochemical energy storage system utilizes the heat of reaction of the reversible reaction of magnesium and hydrogen. The operation temperature range is between 280 C and 480 C.
The storage capacity amounts to about 54 MJ. The combination of the MgH_2/Mg system with an appropriate low-temperature alloy/hydride offers the option of producing cold below 0 C in the heat retrieval cycle. The hybrid storage system uses a salt/ceramic which consists of a micro-porous MgO matrix, the pores of which are filled with a salt (85 wt% $NaNO_3$, 15 wt% $NaNO_2$). The sensible heat of both the ceramic and the salt and the phase change enthalpy of the salt in the temperature range 250 C to 290 C can be utilized. The experimental storage bed was operated in the temperature range of 150 C to 450 C, the storage capacity was about 400 MJ. Air was used as the heating and cooling heat transfer medium

AB This article describes the world's largest power tower incorporating one of the newest commercial solar energy systems and being build in California's Mojave Desert. The project — sponsored by the Department of Energy (DOE) and a consortium of western utilities, municipalities, and associations — is called Solar Two, and it will use molten salt to absorb solar energy and store that energy until it is needed to generate electricity. Construction will be completed on Solar Two in September. Solar thermal systems convert the sun's rays into electricity by using a thousand or more dual-axis, sun-tracking mirrors, called heliostats, to focus optimum sunlight on the solar receiver of a power tower containing a working fluid. The fluid is heated to a desired temperature and sent to a storage facility. During periods of peak demand, the fluid is circulating through heat exchangers to generate steam used to drive a turbine

AB Conceptual designs, cost estimates, and warranty provisions were developed for nitrate salt steam generators and thermal storage system hot salt tanks in the initial 100 MWe commercial central receiver power plants. All of the steam generator designs, including the U-tube/U-shell, straight tube/straight shell, and U-tube/kettle boiler, offered comparable steady state and transient performance and competitive cost estimates. The hot salt tank designs included <1) a stainless steel tank with external insulation and (2) a carbon steel tank with
internal refractory insulation and a corrugated Incoloy liner to isolate the salt from the refractory. The stainless steel tank designs had both lower heat losses and lower capital costs

AB Solar dynamic receiver designs are investigated and evaluated for possible use with sensible energy storage in single-phase materials. The designs are similar to previous receivers having axial distribution of concentrated solar input flux, but differ in utilizing axial conduction in the storage material for attenuation of the solar flux "signal", and in having convective beat removal at the base of the receiver. One-dimensional, time-dependent heat transfer equations are formulated for the storage material temperature field, including radiative tosses to the environment, and a general heat exchange effectiveness boundary condition at the base. The orbital periodic input solar flux is represented as the sum of steady and oscillating components, with the steady component solved numerically subject to specified receiver thermal efficiency. For the oscillating components the Fast Fourier Transform algorithm (FFT) is applied, and the complex transfer function of the receiver is obtained and evaluated as a filter for the input flux spectrum. Inverse transformation, result in the amplitudes and mode shapes of the oscillating temperatures. By adjustment of design parameters, the amplitude of the oscillating component of the outlet gas temperature is limited to an acceptable magnitude. The overall result of the investigation is the dependence of the receiver M×c product (mass times specific beat) on the conduction transfer units, which leads to lower weight designs than comparable previous single and two phase designs, when all constraints are included. As these designs also offer improvements in cost reduction and reliability they warrant further detailed investigation

AB The current R and D activities in the field of medium and high temperature storage are presented and the storage test facilities of ZSW and DLR briefly described. The R and D activities include studies on heat transfer processes in alkali metal nitrates used as phase-change storage material for the medium temperature range with different geometries of the heat exchanger, as well as investigations of different salt ceramic hybrid materials for high temperature applications. The state of development of medium and high temperature
storage systems is shown, possible constructions of storage systems are presented, and an outlook on further studies is provided. (orig.)

AB Based on a mathematical-physical model for the description of sensible heat storage in packed beds, the simulation program PACKBED has been developed, which is intended to serve as a decision base for the assessment of packed bed storage systems used in solar high temperature applications. For the validation of the theoretical model, the thermodynamic behaviour of packed beds consisting of sensible heat storage material has been investigated in the experimental store ARIANE. using air as heat transfer medium. Different material tests in the temperature range up to 800oC have been carried out. The short-time storage in large scale solar thermal power plants has been simulated under real operating conditions, as they are expected for the planned 30 MWe PHOEBUS solar tower power plant. For the same storage, it has been shown that the pressure drop, and therefore the required pumping power of the fan, can be reduced significantly by introducing an air bypass system. For the characterization of the storage performance, a storage quality factor has been introduced, which allows to compare different sensible heat storage systems and to describe the degradation of such storage systems during consecutive charging/discharging cycles. In the field of latent heat storage, a thorough literature research has been performed. With a new simulation program for large scale latent heat storage systems, parameter studies have been performed in order to clarify the suitability of latent storage material for storing solar high temperature heat in packed beds. (author) 22 figs., 7 tabs., 88 refs.

AB The heart of a solar-energy based electricity generation approach is a direct steam generation (DSG) unit consisting of tube banks, embedded in a phase changing material (PCM). During times of high solar energy availability steam is pumped through the tubes, releasing heat to the PCM which takes it up as the latent heat of melting and undergoes a phase change to its liquid phase. This period is referred to as the charging period. The discharge period is marked by water being pumped through the tubes; now heat is transferred from the PCM to the water which, under appropriate conditions, will boil and emerge as steam. The process of heat exchange between the water or steam in the tube (during charge and discharge) and the PCM is a complex one governed by a variety of factors including tube size, pressure drops, quality of the two phase flow region, extent of this region, and flow rates. In order to examine the performance of such a DSG unit a computer code simulating two phase flow, heat exchange between tube and PCM, and heat transfer and phase change in the PCM has been prepared. The code permits the user to vary all major geometric and thermophysical parameters; options include variable tube diameter, angle of inclination and different flow directions during charge and discharge. In this paper the author describes the above code, examining its underlying assumptions and algorithms. Among points raised are the role of natural convection in the melt. Results shown include sample runs and simple analytical approximations for key performance factors. In addition he describes preliminary experimental work being done to verify the computer model.

AB Molten salts are attractive candidates for thermal energy storage in solar dynamic power systems owing to their high latent heat of fusion. This paper reports that, to gain direct observation of the molten salt phase change, a novel containerless technique was developed where the high surface tension of lithium fluoride was used to suspend a bead of the molten salt inside a specially designed wire cage. By varying the current passing through the wire, the cage also served as a variable heat source. In this way, the freeze/thaw performance of the lithium fluoride could be photographed by motion picture photography without the influence of container walls. The motion picture photography of the lithium fluoride sample revealed several zones during the phase change, a solid zone and a liquid zone, as expected, and a slush zone that was predicted by thermal analysis modeling.

AB This article describes a comparison and evaluation of the Solar One and CESA-I receiver and thermal storage systems. The evaluation is based on operating data from Solar One, the MWe experimental solar central receiver plant located near Barstow, California, USA and CESA-I, the 1.2 MWe experimental solar central receiver plant located near Almeria, Spain. This study was sponsored by the US-Spain Joint Committee for Scientific and Technological Cooperation. Significant differences exist in the design and operation of the receiver and thermal storage systems for the two experimental plants. An evaluation of their performance has increased our understanding of the plant design variables and provides useful information to improve the designs of future central receiver plants.

AB The objective of the study was to find a thermal energy storage unit for a medium-temperature solar power station in the temperature range between 200deg C and 400deg C requiring investment cost of less than 25 US Dollar/kWh of exploitable thermal energy. The following storage types were compared: Hot-tank and cold-tank liquid salt storage unit with pumps and heat exchangers; thermal oil storage unit; concrete storage unit with cast-in pipes; solid salt slab storage unit with cast-in pipes, and liquid salt storage unit in cascade connection. A concrete storage unit will have to be preferred none the least for reasons of technical risks and fast erectibility. (BWI).

This experimental investigation was conducted as a support activity for the development at Sulaibiyah, which has a 22 m3 stratified tank to act as a buffer reservoir between the paraboloid-dish solar collector and the toluence turbine energy-conversion device. The results show that the disturbed zone is 1500 mm thick (i.e. nearly 30% of the usable tank height). Based on these results, an experimental model (1/25th scale by volume) was constructed to study the effect of using improved distributor header geometry and a settling mesh for reducing the buffer-zone thickness. Using the new header configuration, extraction efficiencies of 85% could be achieved, (author).

AB	For the parabolic dish solar powerstations of the solar electric generating system (SEGS) type, regenerators are designed which use the thermal oil used for solar collectors as heat carrier. Alternative concepts with concrete and/or phase change material as storage material are compared. The design for a compound regenerator with a capacity of 200 MWhth is discussed. Using quasi steady state thermodynamic process calculations, the interaction between the regenerator and powerstation operation is measured and the use of the store is thus quantified. From annual energy balances, the effect of solar field size and store capacity on the duration of annual powerstation operation is determined. Finally, from an economy calculation, one can prove that the additional investment in an enlarged solar field and a thermal energy store reduces the electricity generating costs of the plant, (orig.)

AB	The solar power plant design characteristics and system description at Daggett California are presented. The solar collector assembly (SCA) is the primary building block of this modular system. A single SCA consists of a row of eight parabolic trough collectors, a single drive motor, and a local microprocessor control unit. The basic components of the parabolic trough collector are a mirrored glass reflector, a unique and high-efficiency heat collection element, and a positioning system. The heat collection element includes a stainless steel absorber tube coated with a black chrome selective surface, which is contained within a unique and high-efficiency evacuated cylindrical glass envelope. The SCA is designed to have an operating efficiency of 67% at 265 deg C under a direct normal insolation of 3500 kJ/m2. The operation of the system is discussed.

AB The IMWe solar thermal power generation pilot plant featuring plane-parabolic type concentrators and molten salt heat storages succeeded to generate IMWe power and operated about 2 years. Thermal simulation of the plant predicted the plant operation well and confirmed designed performance of the heat storage system. Optical performance of concentrator was evaluated and led to the following results. 1. The optical performance of the evaporator was satisfactory, and the measured error of parabolic mirror and collecting pipe bending had negligible effect on evaporator concentrator. 2. The banding of collecting pipe produced slight leakage in superheater concentrator, that is about 3%. 3. Adjustment were needed to some sun tracking mechanism due to the friction in sliding parts of it after about 2 years operation.

The cost of storage systems which can compete with the use of fuel in hybrid parabolic dish solar power plants is identified for one set of specific assumptions. The hybrid plants burn fuel to increase the hours of usage each day. The cost and performance characteristics of concentrators, receivers and power conversion units are based on estimates by the contractors developing this hardware under the direction of the Department of Energy and the Jet Propulsion Laboratory (JPL). Thermal storage systems are not yet designed and only the cost goal which would make them competitive is known. 12 refs.

RESPONSES TO COMMENT LETTER #8
(Public Solar Power Coalition - January 30, 2015)

Comment Letter #8 was hand-delivered to SCAQMD staff in the form of a poor image quality photocopy of handwritten materials with reference materials attached. Because this comment letter contains several patches that are either difficult to decipher or are illegible, wherever the difficulty occurs, SCAQMD staff has attempted to either summarize or transcribe the text to assist the reader with understanding the nature of the comment and the context of the responses provided.

8-1 Because this comment may appear difficult to decipher, SCAQMD staff has attempted to transcribe the text, as follows:

> *"Solar Energy is BARCT and should have been submitted as the Best Available Retrofit Technology [illegible] with the backup options cited by staff but solar thermal system with line focus concentrator within 100 miles of the District supplying 354 MW (Megawatts) have been operating for 30 to 20 years. See Power Point printout 9 pages on SEGS solar energy electric generating systems (9 in all – 1x14 MW, 6x30 MW, and 280 MW). These have been the largest operation solar thermal at moderate temperature 500 - 700 °F and higher temps can be operated for use with point double axis solar [illegible] of 1000 °F +++ plus storage. (9 see the 9 page power point print out provided by PSPC/HE."*

SCAQMD staff is aware of the types of solar technologies available and their capabilities. Companies may choose to make use of solar technologies to provide heat and/or power for their facilities. However, for existing and new fuel-fired equipment, the SCAQMD regulates combustion sources through several SCAQMD Regulations (e.g., Regulations IX, X, XI, XIII, and XIV). While solar energy has merits for providing an alternative source of energy on a smaller scale (e.g., residential or commercial applications) or at the utility level, solar energy has not been identified as a feasible replacement source of energy to fulfill the extensive electrical demand and reliability needs of individual, heavy industrial facilities in the NOx RECLAIM program.

In addition, the reference materials linked to this comment as "Attachment A" (e.g., "An Overview of the Kramer Junction SEGS Recent Performance" and the National Renewable Energy Laboratory report "Survey of Thermal Storage for Parabolic Trough Power Plants") do not provide evidence to support the suggestion that solar energy be considered BARCT for any specific source category involved in this rule amendment.

8-2 Because this comment may appear difficult to decipher, SCAQMD staff has attempted to transcribe the text, as follows:

> *"PSPC/HE should be hired as [a] consultant to show the solar options [from] both solar thermal and P.V photovoltaics and hybrids as soon as possible. This can form the center of on, near and further solar thermal SCHP, combines solar combined heating and cooling. District heating and cooling system (absorption vis a vis Dr. Bercum etc. as well as electricity). The repair of sewage and water systems will be*

planned at the same time as well as replacing old nat[ural] gas system a la San Bruno explosion in PG&E territory [illegible].

BARCT is a "technology forcing" control measure cite 2012 California Supreme Court Decision on VOC in American Coatings Association vs. SCAQMD. The law is clear and as pointed out in the current litigation [illegible] the commenter has with the District (with a Draft Amended [illegible] and now federal EPA etc. You can pay now for the construction at a lower costs [sic] or pay more later. A recent study by the [illegible] Economic Advisory says and demonstrated that climate change implementation will cost 40 percent+ each 10 years that we wait."

With regard to the suggestion that the commenter should be hired as a consultant, the commenter is invited to submit a proposal to the SCAQMD Technology Advancement Office with a description of the proposed project, budget and proposed deliverables. In addition, the commenter should periodically review the requests for proposals from the SCAQMD that may be of interest and submit proposals accordingly.

With regard to the remark that BARCT is a technology forcing control measure, see Response 8-1 for why the SCAQMD believes that solar energy, while a very beneficial alternative energy source that we support, does not qualify as BARCT.

8-3 Because this comment may appear difficult to decipher, SCAQMD staff has attempted to transcribe the text, as follows:

"The SEGS plants were brought to the SCP decades by the [illegible]/consultant. This information was [illegible] between early 1991 AQMP Draft and the final adopted in mid year July 1991. Our litigation followed but without a follow through – the time to act is now if not yesterday."

The commenter has not provided a correlation that explains how the SEGS plants and the 1991 AQMP are linked to the currently proposed amendments to the NOx RECLAIM program. As such, SCAQMD staff is unable and not required to prepare a response to this comment.

8-4 This comment requests a full Environmental Impact Report (EIR) to be prepared for the proposed project.

The SCAQMD is not required to prepare an EIR for the proposed project, but is required to prepare a full environmental analysis and has done so. Public Resources Code §21080.5 allows public agencies with regulatory programs to prepare a plan or other written documents in lieu of an EIR once the Secretary of the Resources Agency has certified the regulatory program. The SCAQMD operates pursuant to a regulatory program that was certified by the Secretary of the Resources Agency on March 1, 1989 in accordance with CEQA Guidelines §15251 (l) and as codified in SCAQMD Rule 110 - Rule Adoption Procedures to Assure Protection and Enhancement of the Environment. Thus, in accordance with the SCAQMD's certified regulatory program, a Program Environmental Assessment (PEA) has been prepared for the proposed project. The PEA is a substitute CEQA document that has been prepared in lieu of an EIR as allowed by

CEQA Guidelines §15252. Nonetheless, the PEA provides the same quality of analysis and will afford the public the same amount of time for comment and review on the Draft PEA as would be provided for under a Draft EIR (e.g., 45 days).

8-5 Because this comment may appear difficult to decipher, SCAQMD staff has attempted to transcribe the text, as follows:

> *"In reference to the December 5, 2014 document, at least solar energy must be studied as an alternative. The areas covered are energy, GHG green house [sic] gases, transportation and traffic as well as water (even the fact that over 20 percent of the District's state energy is used to move water.)"*

As explained in Response 8-1, SCAQMD does not believe that solar energy qualifies as BARCT for sources involved in this rule amendment. (Utilities are already required to source 33 percent of their power from renewable sources, including solar energy, by 2020.) While solar energy has merits for providing an alternative source of energy on a smaller scale (e.g., residential or commercial applications) or at the utility level, solar energy has not been identified as a feasible replacement source of energy to fulfill the extensive electrical demand and reliability needs of individual, heavy industrial facilities in the NOx RECLAIM program. Further, in accordance with CEQA Guidelines §15126.6, the Draft PEA shall describe a range of reasonable alternatives to the project which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project, and evaluate the comparative merits of the alternatives. However, the Draft PEA is not required to consider alternatives which are infeasible. For these reasons, solar energy as "BARCT" for all sources was not considered as an alternative in the Draft PEA.

8-6 Because this comment may appear difficult to decipher, SCAQMD staff has attempted to transcribe the text, as follows:

> *"Immediate total solar conversion means now or yester year. Climate change etc. was addressed in the 1992 BC cases that are in the record in the Superior and Appeals Courts in the state as well as the Federal 9th Circuit Appeal Court. This time with a plethora of environmental and community groups joining us HE/PSPC in litigation. The drought continues."*

There are no substantive remarks on the currently proposed amendments to the NOx RECLAIM program or the associated CEQA document in the legible portions of this comment. As such, SCAQMD staff is unable and not required to prepare a response to this comment.

8-7 Because this comment may appear difficult to decipher, SCAQMD staff has attempted to transcribe the text, as follows:

> *"The fact that almost two years ago the District had all of the information in hand prior litigation with us from the sunshot initial draft incorporated by reference herein as well as the complete sections of solar thermal and solar photovoltaic technology. Sunshot is a play on words for Kennedy's moon shot in the 1960's. Over 60 percent*

on it [sic] was for air grip parity as of last year with only 40 percent of this passing. This is for everywhere in the U.S.A. All other [illegible] in SC119641 Eder vs. SCAQMD as well as B251627 [illegible] as the Federal Record and Federal Register September 3, 2014 and all information submitted to date as well as in the future are incorporated here into the record."

Of the legible words, the sentences and phrasing structure do not raise, in the context presented, any substantive remarks on CEQA or on the NOP/IS. In addition, the attachments to Comment Letter #8, "An Overview of the Kramer Junction SEGS Recent Performance" and the National Renewable Energy Laboratory report "Survey of Thermal Storage for Parabolic Trough Power Plants" also do not correlate to the text in this comment. As such, SCAQMD staff is unable and not required to prepare a response to this comment.

8-8 Because this comment may appear difficult to decipher, SCAQMD staff has attempted to transcribe the text, as follows:

"At the January 7 GB meeting, Eder/PSIC stated that (as is part of the record [sic]) no consultant was hired to study solar energy as BARCT which has been before the District and CARB for decades!"

Because the comment does not specify the year when the January 7th Governing Board (GB) meeting occurred, it is unclear if the commentator meant to say the January 9, 2015 GB meeting, or the January 7, 2011 GB meeting. These are the only two recent GB meetings that fell on January 7. In any event, for both of these GB meetings, the minutes do not mention the topic of solar energy or BARCT. The following is the link to the minutes for the January 9, 2015 GB meeting: http://www.aqmd.gov/docs/default-source/Agendas/Governing-Board/2015/2015-feb6-001.pdf?sfvrsn=2. The following is the link to the minutes for the January 9, 2015 GB meeting: http://www.aqmd.gov/docs/default-source/Agendas/Governing-Board/2011/2011-feb4-001.pdf?sfvrsn=2. In addition, the comment does not mention any source category for which solar energy would be BARCT.

With regard to the suggestion that the SCAQMD should hire a solar energy consultant, see Response 8-2.

8-9 Because this comment may appear difficult to decipher, SCAQMD staff has attempted to transcribe the text, as follows:

"As the cover article in this week's Economist says carpe diem of sieze [sic] the day. Gov. Brown set 50 percent solar renewables by 2030 of [illegible] but his off by 100 percent in February and 100 percent/50 percent [illegible] by EPA for 2023!"

Of the legible words, the sentences and phrasing structure do not raise, in the context presented, any substantive remarks on CEQA or on the NOP/IS. As such, SCAQMD staff is unable and not required to prepare a response to this "CEQA" comment.

APPENDIX H (OF THE DRAFT PEA)

CEQA SCOPING MEETING COMMENTS AND RESPONSES TO COMMENTS

INTRODUCTION

The NOP/IS for the proposed project was circulated for a 57-day public review and comment period, which started on December 5, 2014, and ended on January 30, 2015. During this public comment and review period, the SCAQMD held a CEQA Scoping Meeting at the SCAQMD's headquarters on January 8, 2015. The CEQA Scoping Meeting was held in accordance with the requirements in Public Resources Code §21083.9 (a)(2) for any project that may have statewide, regional or areawide significance.

CEQA SCOPING MEETING COMMENTS AND RESPONSES TO COMMENTS

At the CEQA Scoping Meeting, oral public testimony was received relative to the rule development process and the CEQA process. The following is a summary of the CEQA-specific comments that were made at this meeting and the responses to the comments.

1. Comment: Since SCR technology is being considered for BARCT, there could be an increase in the need to transport, store and use ammonia as part of operating SCR equipment. The Draft PEA should contain an analysis of ammonia.

   Response: As explained in the NOP/IS, both SCR and SNCR technologies utilize ammonia, a toxic air contaminant (TAC) and acutely hazardous material. Because hazard and hazardous materials impacts could occur as a result of the increased use, transport and storage of ammonia as well as the potential for an accidental release of ammonia into the environment, the NOP/IS identified ammonia as a source of potentially significant hazards and hazardous materials impacts and these impacts were analyzed in the Draft PEA.

2. Comment: A different approach to tackling the NOx RECLAIM RTC shave via an "incremental BARCT analysis shave" is currently being developed by industry groups and will be submitted to SCAQMD as a recommendation for consideration as part of the rule development process. As such, the Draft PEA should include and analyze the potential environmental impacts of the "incremental BARCT analysis shave" as one of the alternatives.

   Response: A Draft PEA is being prepared for the proposed project and several alternatives to the proposed project will be analyzed in accordance with the requirements in CEQA Guidelines §15126.6. The purpose of analyzing alternatives is to find project components that minimize impacts while still attaining the project's objectives. Alternatives were developed by altering specific components of the proposed project. One of the alternatives analyzed in the Draft PEA is an alternative based on the industry proposal.

3. Comment: The CEQA Scoping presentation states that all equipment subject to the proposed BARCT will install the most cost-effective control technology to meet proposed reductions. Does this mean that the CEQA document will analyze the environmental impacts of installing SCR technology now, even if SCR technology was not installed as a result of the NOx RTC shave in 2005?

Response: The Draft PEA analyzes a wide assortment of cost-effective BARCT options, including SCR technology. The analysis in the Draft PEA examines the potential environmental impacts of installing SCR technology in response to the currently proposed project, regardless of whether SCRs were installed in response to the previous NOx RTC shave that was implemented in 2005.

4. Comment: In addition to analyzing an alternative comprised of the industry's proposed "incremental BARCT analysis shave," the Draft PEA should also analyze an alternative that focuses on meeting the minimum NOx emission reduction goals in the 2012 AQMP per Control Measure #CMB-01 (e.g., at least three to five tons per day of NOx reductions by 2023).

Response: As required per CEQA Guidelines §15126.6 (e), the Draft PEA contains a "No Project" alternative that analyzes what would reasonably be expected to occur in the foreseeable future in the event the proposed project is not approved. A specific alternative limited to three to five tons per day of NOx RTC reductions was not analyzed because its impacts would likely fall between those resulting from the industry proposal (Alternative 3) and the No Project alternative (Alternative 4). The Draft PEA thus provides a range of potential impacts for these alternatives.

5. Comment: While the proposed revisions to the semi-annual assessment procedures in protocols for Rule 2011 and Rule 2012 will cause affected facilities difficulties to implement, it is not clear whether these proposed revisions would cause an adverse environmental effect.

Response: SCAQMD staff invites the commentator to provide more specific information regarding the implementation difficulties. Even if there are implementation difficulties, SCAQMD believes that the proposed revisions to the semi-annual assessment procedures are administrative in nature and as such, no physical environmental effects requiring a CEQA evaluation would be expected from implementing this portion of the proposed project.

APPENDIX I

COMMENT LETTERS RECEIVED ON THE DRAFT PEA AND RESPONSES TO COMMENTS

INTRODUCTION

A Draft Program Environmental Assessment (PEA) was released for a 53-day public review and comment period from August 14, 2015 to October 6, 2015 which identified the environmental topics of aesthetics; air quality and greenhouse gas emissions; energy; hydrology and water quality; hazards and hazardous materials; solid and hazardous waste; and, transportation and traffic, as potentially being significantly adversely affected by the project. The SCAQMD received eight comment letters regarding the analysis in the Draft PEA during the public comment period.

The comment letters have been numbered (see Table I-1 below) and individual comments within each letter have been bracketed and numbered. Following each comment letter is SCAQMD staff's responses to the individual comments.

Re: **DRAFT PROGRAM ENVIRONMENTAL ASSESSMENT FOR PROPOSED AMENDMENTS TO REGULATION XX**

Dear Ms. Radlein:

On behalf of the Regulatory Flexibility Group (RFG), we are submitting the following comments on the Draft Program Environmental Assessment (Draft PEA) prepared to support the proposed amendments to South Coast Air Quality Management District (SCAQMD) Regulation XX- NOx RECLAIM. These comments are limited to the legal adequacy of one of the alternatives analyzed in Chapter 5 of the Draft PEA (Alternative 3 – Industry Approach). The RFG also endorses the comments submitted on behalf of the NOx RECLAIM Industry Coalition and the Western States Petroleum Association. 1-1

During its presentation at the September 23, 2015 Special Stationary Source Committee meeting, SCAQMD staff expressed the view that the industry proposal to reduce current NOx RECLAIM allocations by 8.79[1] tons per day (tpd) fails to meet minimum legal requirements because it fails to attain "maximum reductions achievable," as required by California Health & Safety Code § 40406, and is not equivalent to levels that would be achieved under command and control. 1-2

[1] The industry proposal is to reduce allocations by the level of emission reduction determined to be achievable through deployment of 2015 best available retrofit control technology (BARCT). This level of emission reductions is referred to herein as "BARCT-equivalent emission reductions." 8.79 tpd is the SCAQMD staff's calculated BARCT-equivalent emission reductions. Industry believes that if certain necessary corrections were made to the staff's analysis, the actual figure would be 6.6 tpd. For the purposes of this discussion, we will assume that the staff's figure is correct.

OC\2046820.1

LATHAM&WATKINS LLP

SCAQMD staff is correct that Health & Safety Code § 40440(b)(1) requires adoption of rules and regulations that "require the use of . . . best available retrofit control technology for existing sources." Best available retrofit control technology (BARCT) is defined in Health & Safety Code § 40406 as "an emission limitation that is based on the maximum degree of reduction achievable, taking into account environmental, energy, and economic impacts by each class or category of source." 1-3

Having determined that BARCT-equivalent emission reductions equate to 8.79 tpd, the SCAQMD staff must adopt amendments to the RECLAIM program necessary to achieve that level of reductions in order to meet the legal requirements identified above. Assuming that there is no dispute that 8.79 tpd is the correct level of BARCT-equivalent emission reductions (see footnote 1), then there is no dispute that achieving this level of emission reductions will satisfy applicable legal requirements. 1-4

By applying what it refers to as its "remaining emissions methodology," staff has concluded that it is necessary to reduce allocations by 14 tpd in order to achieve the desired 8.79 tpd in emission reductions. In other words, the reduction in allocations must be 63% higher than the desired reduction in emissions in order to achieve the desired reductions. According to staff, a reduction in allocations of anything less than 14 tpd will not achieve the minimum required emission reductions, and therefore will not satisfy applicable legal requirements. It is on this basis that the staff concludes that the industry proposal to reduce allocations by 8.79 tpd fails to satisfy minimum legal requirements. Thus, staff's legal critique of the industry proposal is entirely dependent on the premise that one must reduce allocations by 14 tpd in order to achieve 8.79 tpd in emission reductions. 1-5

The problem with the staff's analysis, is that there is nothing to support the underlying premise that 14 tpd in allocations must be eliminated in order to achieve 8.79 tpd in emission reductions. In fact, the SCAQMD's own historical data indicate that a much more modest reduction in allocations would achieve the desired emission reductions. The SCAQMD previously adopted amendments to achieve BARCT equivalency in 2005. In that case, allocations were reduced from 34.2 tpd to 26.5 tpd between 2005 and 2011, a reduction of 7.7 tpd. Over that same period of time, emissions were reduced from 26.4 tpd to 20 tpd, a reduction of 6.4 tpd. What this past experience demonstrates is that for every tpd that allocations are reduced, 0.83 tpd of emission reductions will occur. Put another way, the level of reduction in allocations should be no more than 17% higher than the desired level of emission reductions. 1-6

Thus, past experience indicates that the reduction in allocations necessary to achieve 8.79 tpd in emission reductions is 10.3 tpd (17% higher than the desired reductions); not 14 tpd (63% higher than the desired reductions). The drastic reduction in allocations proposed by SCAQMD staff will require overall reductions of greater than 8.79 tpd in order to bring actual emissions in line with remaining allocations. Thus, RECLAIM sources will be required to achieve emission reductions that are greater than what the SCAQMD staff has determined to be BARCT. In other words, RECLAIM sources will be required to achieve reductions above and beyond the BARCT levels that would be required under a command and control regime. 1-7

OC\2046820.1

LATHAM & WATKINS LLP

Not cited by the staff in is presentation, but also relevant to this discussion is Health & Safety Code § 39616. Health & Safety Code § 39616(c)(1) requires that a market-based incentive program adopted in lieu of command and control regulations "result in an equivalent or greater reduction in emissions at equivalent or less cost compared with . . . measures that would have otherwise been adopted [command and control] . . ." (emphasis added). Similarly, Health & Safety Code § 39616(c)(7) requires that the market based program "not result in disproportionate impacts measured on an aggregate basis, on those stationary sources included in the program compared to other permitted stationary sources . . ." 1-8

By requiring emission reductions in excess of what has been determined to be achievable with BARCT, the SCAQMD staff proposal imposes costs on RECLAIM sources that are greater than those that would be imposed under a command and control regime, and imposes disproportionate impacts on RECLAIM sources relative to other stationary sources, in violation of Health & Safety Code § 39616. Thus, it is the SCAQMD staff proposal that runs afoul of applicable legal requirements; not the industry proposal. 1-9

During the September 29, 2015 Public Consultation Meeting on the proposed amendments, SCAQMD staff indicated that it had been suggested that Health & Safety Code § 39616(c) did not apply to the proposed action of the Governing Board to amend the RECLAIM program. Section 39616(c) provides as follows:

> (c) In adopting rules and regulations to implement a market-based incentive program, a district board shall, at the time that the rules and regulations are adopted, make express findings, and shall, at the time that the rules and regulations are submitted to the state board, submit appropriate information, to substantiate the basis for making the findings that each of the following conditions is met on an overall districtwide basis:

Presumably, the party suggesting that this section does not apply to the proposed amendments is focusing on the phrases "at the time that the rules and regulations are adopted" and "at the time that the rules and regulations are submitted to the state board" and arguing that the findings specified later in the section need only be made upon initial adoption of the program and not upon its subsequent amendment. Such an interpretation is nonsensical. First, amendments to rules and regulations are "adopted" by the Governing Board and "submitted to the state board" in the same manner as initial adoption. Second, the specified findings go to the implementation of the program and were clearly intended to survive and apply beyond the date that the rules are adopted and submitted to the California Air Resources Board. Under the proffered interpretation, the Governing Board could make the required findings and adopt the program one day, and then amend it the next with complete disregard for the findings. Clearly, the legislature did not intend to create the possibility of such an absurd outcome. The only reasonable interpretation is that Health & Safety Code § 39616(c) applies to the proposed action of the Governing Board and the specified findings must be made. 1-10

OC\2046820.1

For the reasons set forth above, Alternative 3 analyzed in the Draft PEA, or any other alternative designed to achieve the necessary BARCT-equivalent emission reductions, would meet applicable legal requirements. 1-10 Con't

Best regards,

Michael J. Carroll
of LATHAM & WATKINS LLP

OC\2046820.1

RESPONSES TO COMMENT LETTER #1
(Latham & Watkins on behalf of the Regulatory Flexibility Group – October 6, 2015)

1-1 This comment begins by introducing the parties represented by the letter; no response to this part of the comment is necessary. Relative to comment about the adequacy of Alternative 3 in the Draft PEA, see Responses 1-2 through 1-10. Relative to the comment expressing support for two letters submitted by the Western States Petroleum Association and the NOx RECLAIM Industry Coalition, which are referred to herein as Comment Letter #2 and Comment Letter #6, respectively, see Responses to Comment Letters #2 and #6.

1-2 The comment states that staff's presentation at the September 23, 2015 Special Stationary Source Committee Meeting expressed that the industry proposal fails to meet legal requirements and is not equivalent to levels that would be achieved under command-and-control. Staff continues to stand by that statement as further explained in the following responses to this letter. This issue is also raised in Comment Letter #2. See Responses 2-33, 2-34 and 2-35.

1-3 The comment acknowledges staff's determination that Health and Safety Code §40440 (b)(1) requires the use of BARCT, as defined, for existing sources.

1-4 The comment states that the BARCT-equivalent emission reductions of 8.79 tons per day meet the legal requirements in the Health and Safety Code. Staff disagrees that this amount is the level of reductions necessary to meet the legal requirements for the RECLAIM program. Based on staff's analysis, a reduction of 14 tpd of NOx RTCs is needed to induce actual emission reductions equivalent to BARCT. The 2015 BARCT analysis demonstrated that there would be an actual NOx emission reduction of 8.77 tpd from the 2011-2012 activity levels at 2015 BARCT compared to the same activity levels at 2005 BARCT. This represents 8.77 tpd of NOx reductions in actual emissions. If the overall NOx RTC holdings had closely matched the total amount of actual NOx emissions from the NOx universe, the removal of 8.77 tpd of NOx RTCs would likely induce an equivalent amount of actual NOx emission reductions. However, over the past five years, actual NOx emissions from RECLAIM facilities fell below the overall NOx RTC holdings by 21-30%, resulting in approximately 5.45-8.41 tpd of unused NOx RTCs (unused for compliance purposes). In addition, if the years 2007-2011 are considered (implementation of the 2005 NOx shave), RTCs were reduced by 7.66 tpd, while emissions were reduced only 4.09 tpd, for a ratio of 0.53 ton of emissions reduced for every ton of RTCs reduced. The Draft PEA accounted for the fact that if RTCs are not significantly reduced, there will be enough excess RTCs in the market that facilities can simply surrender unused RTCs, without making significant real emission reductions. Therefore, the removal of 8.77 tpd of NOx RTCs would initially eliminate some, if not all, of these excess NOx RTCs from the market and only thereafter would result in actual emissions reductions. As a result, RTC reductions of 8.77 tpd would be less than the BARCT-equivalent level of actual NOx emission reductions.

1-5 The comment makes reference to the remaining emissions methodology that staff used which concludes that it is necessary to reduce allocations by 14 tpd in order to achieve the desired 8.77 tpd in emission reductions and that anything less than a 14 tpd reduction would not meet the applicable legal requirements. Staff agrees with this statement and the reasons are explained in Response 1-4.

1-6 The comment states that there is nothing to support the premise that 14 tpd must be removed from the RECLAIM program in order to achieve 8.79 tpd in emission reductions. The commenter makes reference to the 2005 amendments which reduced allocations by 7.7 tpd, while emissions were reduced by 6.4 tpd. This comment also suggests that between 2005 and 2011, a comparison of 0.83 tpd emission reductions to 1 tpd RTC reductions would result in a ratio of 0.83 such that the level of reduced allocations should be no more than 17 % higher than the desired level of emission reductions.

Staff disagrees with the commenter's claim for the reasons previously explained in Response 1-4. Also, staff acknowledges that the previous RECLAIM amendment resulted in an allocation reduction of 7.7 tpd from 2007 to 2011, but the emission reductions in that same time frame actually amounted to 4.1 tpd. Also, it is important to note that a large portion (almost two thirds) of these reductions were actually due to shutdowns, so the staff proposal must remove more RTCs from the market to achieve the required amount of emission reductions.

To examine past shaves to determine the ratio between the amount shaved and the amount of actual emission reductions that occurred from the RECLAIM universe (presumably to derive an alternative shave amount) is a flawed approach because there is no fixed ratio between actual emissions reductions and RTCs shaved. Between 2005 and 2011, a comparison of 0.83 tpd emission reductions to 1 tpd RTC reductions would result in a ratio of 0.83, but that included only two years (2005 - 2006) worth of data when there were actual emission reductions, but no RTC shave. If the analysis looks at the actual shave years (2007 through 2011), the ratio would actually be a comparison between 4.09 tpd reductions to 7.66 tpd RTCs reduced, or 0.53 instead of 0.83. Moreover, if there were a larger amount of available unneeded RTCs, such as the 73 percent projected to occur with the Industry Approach (or even more if the Industry Approach used the 6.6 tpd target) it is likely that facilities would not significantly reduce actual emissions but would simply surrender unneeded RTCs. Thus, no fixed ratio can be determined to allow the suggested alternative approach.

1-7 The commenter claims that the level of reduction of allocations should be 17% higher than the desired emission reductions, which would result in a 10.3 tpd shave instead of a 14 tpd shave, and that the staff proposal would require reductions greater than what staff has determined as BARCT.

Staff disagrees with the commenter's claim. As explained in Responses 1-4 and 1-6, a large portion of the reductions from the previous amendments to the NOx RECLAIM program were the result of shutdowns and not from the installation of BARCT. Also, as explained in Response 1-4, the staff proposal would achieve the BARCT reductions necessary to meet the applicable legal requirements.

1-8 The comment refers to Health and Safety Code §39616, which states that a market program will result in equivalent or greater emission reductions at equivalent or less cost than command-and-control and that the program would not result in disproportionate impacts. The comment states that staff has not cited this section and feels that it is relevant.

Although staff is not legally required to make the findings in accordance with Health and Safety Code §39616 because the proposed project consists of an amendment to existing rules, staff has demonstrated that the findings could be made anyway. With the exception of the 2000-2001 period when the California energy crisis took place, the historical discrete NOx RTC prices ($5,500 or lower per ton) have consistently been at the lower end of or below the cost- effectiveness range of pollution controls. As a result, many RECLAIM facilities have accrued substantial cost-savings over the years by being able to delay or forego the installation of pollution control equipment that would have been required at different points in time by command-and-control regulations. Further, if findings need to be made in accordance with Health and Safety Code §39616 (c)(1) for the currently proposed shave alone, the proposed shave is expected to only reduce the future stream of this cost-savings. Even so, a reduced cost-saving is still a cost-savings when compared to command-and-control regulations. Thus, the currently proposed amendments to the NOx RECLAIM program will clearly not cost more than the projected costs that would occur under command-and-control.

1-9 The comment claims that the staff proposal does not meet the legal requirements of Health and Safety Code §39616 because it imposes costs on RECLAIM sources that are greater than those that would be imposed under a command-and-control regime.

Staff disagrees with this claim and refers the commenter to the Response 1-8 as well as the Socioeconomic Report. Staff has never considered the “cost” of the shaved RTCs to be recognized as a “cost” for determining equivalency with command-and-control. At the outset of the RECLAIM program in 1993, RTCs were allocated to RECLAIM facilities free of charge, yet they now have value to the facilities as a commodity that can be bought and sold. While RTCs have value, they are not a property right. The currently proposed amendments to the RECLAIM program will reduce the number of RTCs. Since there was no cost associated with allocated RTCs for a facility, the proposed reduction of RTCs would not create a financial loss to the RECLAIM universe. Any additional purchase of RTCs executed by a facility is made in lieu of controlling emissions. The choice between purchasing RTCs and installing or modifying air pollution control equipment or making other changes to reduce emissions is solely a business decision that is made to generate an expected stream of cost-savings afforded only by the RECLAIM program; this choice is not available to facilities under command-and-control. Therefore, any RTC investment loss should not be considered as a compliance cost to be compared to the compliance cost under command-and-control regulations. Moreover, this loss may be offset by any potential increase in RTC price due to a decreased RTC supply, which would subsequently raise the market value of a facility's remaining RTC holdings. Finally, any loss of "value" of shaved RTCs cannot be compared to command-and-control, because in that case, there would be no RTCs and thus, no similar "value" would be created. Staff acknowledges that, for a portion of the smaller emitters that have no identified cost-effective ways to control emissions further, these smaller emitters may have been affected by past RTC price spikes and could potentially be impacted by future price fluctuations, either due to their RTC holdings or their limited financial capacity to hedge against price volatilities. However, their potential losses incurred as buyers would be concurrent economic gains for the RTC sellers; therefore, the resulting net cost, if any, is expected to be zero or negligible to the entire RECLAIM program, particularly when compared with the program's cost savings. While individual facilities may experience different costs or savings depending on whether they are a buyer or seller, Health and Safety Code §39616 applies to the RECLAIM universe as a whole. Finally, the regulatory history pertaining to Health and Safety Code §39616 is explained in the Socioeconomic Report (see pp. 4-6).

1-10 The commenter expresses disagreement with staff's position that the requirements in Health and Safety Code §39616 do not apply because the findings need to be made at the time of program adoption and not for an amendment. The commenter also states that the industry proposal would achieve the necessary BARCT-equivalent reductions and would meet the applicable legal requirements

Health and Safety Code §39616 does not require a BARCT assessment. As explained in Responses 1-8 and 1-9, analyses were conducted anyway that demonstrate the findings of Health and Safety Code §39616 could be made. Staff believes that the proposal to shave 14 tpd of allocations would achieve the necessary BARCT-equivalent reductions and would meet the applicable legal requirements.

Re: Draft Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market

Dear Ms. Radlein:

We respectfully submit, on behalf of the Western States Petroleum Association ("WSPA") and its members, these comments on the draft Program Environmental Assessment ("PEA") for Proposed Amended Regulation XX – Regional Clean Air Incentives Market ("RECLAIM"). WSPA is a non-profit trade association that represents oil and gas exploration, production, refining and marketing companies, some of whom own and operate facilities in the RECLAIM program. 2-1

The draft PEA suffers from fundamental problems that undermine the entire environmental analysis. The draft PEA purports to consider a project to implement the Air Quality Management Plan ("AQMP") and to evaluate best available retrofit control technology ("BARCT"), but narrowly focuses on construction activities associated with the replacement NOx emissions control equipment for selected facilities to achieve 14 tons per day ("TPD") in NOx reductions. Further, the construction activities that are evaluated in the draft PEA have not been confirmed by the District's independent expert, resulting in a proposed project that is likely infeasible. The District's improper focus on 14 TPD in NOx reductions is particularly apparent in the alternatives analyses where the majority of the alternatives require 14 TPD or more of NOx reductions – a skewed selection of alternatives which fails to meet the "reasonable range of alternatives" requirement. Aside from these fundamental problems, the draft PEA lacks adequate analysis in several individual resource areas. 2-2

Page 2

Attachment 1 to this letter provides more detailed comments on this draft PEA from WSPA's technical consultant, and are hereby incorporated by reference. ("Attachment 1"). 2-3

WSPA has previously submitted numerous comments on the proposed regulation itself, as well as the notice of preparation and initial study ("NOP/IS") for the draft PEA, but these comments have received insufficient attention from the District in its environmental analyses.[1] The District responds to the NOP/IS Letter by claiming that technical analyses have been considered, when an in-depth evaluation of the industry's technical concerns has not been performed. 2-4

WSPA has serious concerns with both the proposed rule amendments and the draft PEA, and believe that the requirements under the California Environmental Quality Act ("CEQA") have not been satisfied. Furthermore, both the proposed amendments and the draft PEA must be revised and recirculated to address the comments raised by WSPA and the numerous other commenters in order to correct errors, disclose all significant impacts, and allow the consideration of feasible mitigation measures or project alternatives to reduce or avoid these impacts. 2-5

I. Fundamental Problems With The Draft PEA Undermine The Environmental Analysis

Under CEQA, an EIR is an informational document designed to provide public agencies and the public with detailed information about the impacts that a proposed project is likely to have on the environment, analyze the ways in which the significant effects of a project might be minimized, and identify alternatives to the project.[2] The District's draft PEA, as a substitute EIR under its certified regulatory program, is also subject to the substantive provisions of CEQA.[3] 2-6

Fundamental flaws in the draft PEA's project description and objectives, the scope of review, and the selection and analysis of alternatives, pervade the document, ultimately resulting in a misleading document in specific resource areas as well. Many of the errors in the draft PEA are related to problems with the methodology, assumptions,

which WSPA described in detail in its August 21 Letter and which are reiterated here as they also relate to inadequacies under CEQA. WSPA believes that the draft PEA must be revised and recirculated for further public review and comment, all in compliance with CEQA. 2-6 Con't

A. The Project Description is Flawed, Misleading and Hinders Analysis

"An accurate, stable and finite project description is the *sine qua non* of an informative and legally sufficient EIR."[4] An accurate project description is an essential requirement because an EIR must be "prepared with a sufficient degree of analysis to provide decisionmakers with information which enables them to make a decision which intelligently takes account of environmental consequences."[5] If the project description contains inaccurate or misleading information, the entire analysis may be tainted. "A curtailed, enigmatic or unstable project description draws a red herring across the path of public input."[6] 2-7

1. The project description includes amendments to Regulation XX, but the draft PEA evaluates only environmental effects of BARCT construction activities

The proposed project is described as "amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM) to achieve additional NOx emission reductions to address best available retrofit control technology (BARCT) requirements and to modify the RECLAIM trading credit (RTC) 'shaving' methodology."[7] However, the draft PEA examines only the construction activities that purportedly achieve a reduction of 14 TPD of NOx emissions, and fails to evaluate in any manner the potential environmental effects of effectively eliminating the NOx RTC market.

The RECLAIM program is a cap and trade program, and it is misleading for the District to characterize the proposed severe changes to this program as merely a series of construction projects to achieve BARCT requirements. Depending on how they are implemented, changes to the marketplace can have wide-ranging impacts that are not limited to BARCT construction, but also to the operation of the RECLAIM facilities subject to the District's proposed severe shave. The District's focus on NOx emissions reduction – and the PEA's correspondingly limited analysis – has resulted in foreseeable consequences that are neither considered in the District's rulemaking nor analyzed in its environmental assessment in the form of the draft PEA. 2-8

Page 4

While the District certainly has the authority to prepare a CEQA document solely for BARCT requirements, and if that is the District's intention with the draft PEA, then the draft PEA needs to clearly state that intention in the project description. "[I]ncessant shifts among different project descriptions" undermines the CEQA process "as a vehicle for public participation."[8] However, the project description purports to include an RTC "shave," and the CEQA document needs to evaluate it. For this reason alone, the draft PEA must be revised and recirculated for further public review and comment. 2-8 Con't

2. The draft PEA does not substantiate the fundamental assumptions that form the basis of the BARCT construction activities

As explained above, the draft PEA improperly focuses solely on BARCT construction activities for its analysis, but the viability of those construction activities being adequately represented and analyzed in the draft PEA cannot be substantiated, creating further uncertainty for the project description. "An EIR may not define a purpose for a project and then remove from consideration those matters necessary to the assessment of whether the purpose can be achieved."[9] Given that the District has narrowly defined the purpose of the project as implementing BARCT, it still must be able to substantiate that those BARCT construction activities can actually be performed. 2-9

The District erroneously assumes all its proposed BARCT requirements are not only technologically feasible but can be achieved unilaterally despite evidence suggesting the proposed BARCT levels may not be cost effective or feasible for all RECLAIM facilities subject to the District's proposed severe shave. As WSPA has explained previously, most recently in its August 21 Letter, this is not the case. In November 2014, Norton Engineering Consultants ("NEC"), the third party expert hired by the District to "ground truth" the District's technical analysis in this rulemaking, presented findings in its BARCT Feasibility and Analysis Review.[10] However, when the preliminary draft staff report for the proposed amendments was released on July 21, 2015, it was apparent that many of NEC's findings were ignored, misunderstood, or misstated by the District. As described in WSPA's August 21 Letter, failure to correct some of the assumptions and errors in the staff report for this rulemaking skews the analysis for nearly 40 operating units (i.e., RECLAIM NOx sources). 2-10

Page 5

Moreover, there is no support for the District's assumption that certain NOx sources subject to this rulemaking can achieve 2 ppm NOx levels using new or upgrade selective catalytic reduction systems ("SCR"). This 2 ppm NOx level assumption is an integral component of the District's calculus justifying the currently proposed severe shave. While CEQA provides that disagreements among experts does not make an EIR inadequate, that is not the case here with the draft PEA.[11] As a threshold matter, the District cannot claim to be an expert in specific applications unique to the refining and petrochemical industry; indeed that is apparently the reason for its hiring of an outside third party expert to verify (i.e., "ground truth") the District's technical assumptions. Importantly, the District has been presented with a highly technical analysis from its own third party expert on the ability – or inability – of certain types of NOx sources to achieve 2 ppm NOx levels using SCR, and effectively dismissed this information in favor of unsubstantiated assertions that certain equipment can, indeed, meet such NOx levels and reductions.[12] 2-11

The District also assumes that the installation of the BARCT can and will be implemented in the specified timeframe, which is fairly aggressive. This aggressive time frame is unrealistic and again, has not been substantiated. A number of internal and external factors influence when a company can and will undertake a construction project. WSPA members report that completion of all needed projects to implement the proposed NOx reductions would likely require at least eight (8) years. (Attachment 1, p. 13).[13] It is also a possibility that, depending on the economic climate and incentives, a project would not be implemented at all. In the current economic climate for the oil and gas industry, a more realistic schedule is required for an adequate CEQA review. 2-12

The draft PEA also purports to conduct a site-specific analysis for certain resource areas, but makes unsubstantiated conclusions to eliminate further environmental analysis. For example, the PEA determines noise impacts will not occur from the project because any increase in noise levels will be within the thresholds of the industrial facilities. The PEA makes similar extrapolations from a site specific review of the aesthetics, taking a specific example of a facility where a wet gas scrubber ("WGS") had been installed, resulting in a characteristic steam plume. The PEA essentially states that because these refineries are in industrial areas, additional WGS plumes would not have an aesthetic impact.[14] The PEA's assumptions and extrapolations make an informed analysis difficult. 2-13

[11] See, e.g., *Karlson v. City of Camarillo*, 100 Cal.App.3d 789, 805 (1980).

[12] See letter from NEC to the District dated August 10, 2015, and included as Attachment 2 to WSPA's August 21 Letter, attached to this letter as Attachment 2.

[13] WSPA also recommended that the shave implementation schedule be "back-loaded" to accommodate a longer, more realistic project implementation period with at least 2 of the proposed 4 TPD (currently being proposed for 2016) being moved to 2019 or later. WSPA's August 21 Letter, p. 3, attached to this letter as Attachment 2.

[14] Draft PEA, p. 4.1-4.

Ms. Barbara Radlein
October 6, 2015
Page 6

The draft PEA should identify realistic assumptions based on facts to properly evaluate potential environmental effects of construction activities, and a one-size fits all approach that dismisses the potential for environmental effects based on the industrial locations of the facilities is not sufficient. 2-14

In short, the PEA makes unsubstantiated industry-wide generalizations in determining that technology is feasible, implementation timeframes are reasonable, the site specific impacts will be negligible, and the individual businesses will perform as expected. These generalizations cannot support the PEA's assumptions, particularly in light of the District's own third party expert's efforts to correct the errors in its technical analysis. If an EIR is "so fundamentally and basically inadequate and conclusory in nature" that public comment on the draft is essentially meaningless, or if significant new information is added to an EIR, it must be recirculated for further public review.[15] The PEA should be revised to substantiate its assumptions and reevaluate its conclusions accordingly, and should then be recirculated for further public review and comment. 2-15

B. The PEA Purports To Be A Program-Level Document, But Construction Activities Generally Require Project-Level Review

The draft PEA is described as a "program CEQA document" ostensibly because it consists of proposed amendments to Regulation XX.[16] As noted above, however, the draft PEA appears to evaluate BARCT construction activities, and specific construction projects generally require a project-level analysis. This distinction is important because a program-level review can be more abbreviated and the District apparently seeks to utilize that approach, but it has now embarked on a partial project-level review of BARCT construction activities. As noted above, noise is dismissed in the PEA and not evaluated at all, even though noise is an environmental topic commonly reviewed in a project level EIR for a construction project. If the District seeks to transform a rule-making into a construction project, it needs to do so in compliance with CEQA. 2-16

Furthermore, the draft PEA, which is a "substitute CEQA document" pursuant to the District's certified regulatory program, states that the "program" CEQA document may be used by other agencies for "future related actions." Section 15253 of the CEQA Guidelines addresses use of a substitute CEQA document by responsible agencies, and the District should clarify how the provisions of that Section have been satisfied. 2-17

The draft PEA's insufficient project level analysis for BARCT construction activities reinforces WSPA's main critique of the District's proposed amendments to Regulation XX—the technical analysis to support the proposed amendments is 2-18

inadequate.[17] If these construction activities had been properly evaluated in the CEQA document at a project level, the infeasibility of the proposed BARCT would have become apparent. 2-18 Con't

C. The PEA Overlooks Impacts From the "Whole Of The Project"

An EIR must consider the whole of an action.[18] "Project" means the whole of an action, which has a potential for resulting in either a direct physical change in the environment, or a reasonably foreseeable indirect physical change in the environment, and that is an activity directly undertaken by any public agency.[19] An "indirect physical change" may be one resulting from any economic and social effects of a project, and that change too must be evaluated.[20] The CEQA Guidelines provide: "Where a physical change is caused by economic or social effects of a project, the physical change may be regarded as a significant effect in the same manner as any other physical change resulting from the project."[21] While not all projects evaluated under CEQA have sufficient economic and social effects to warrant further analysis regarding consequential physical effects, this project is unique in that it consists of amendments to a market system – economic consequences are integral to RECLAIM operations. 2-19

1. The Draft PEA fails to consider the physical effects resulting from reasonably foreseeable economic and social effects

The draft PEA summarily asserts: "No indirect or indirect physical changes resulting from economic or social effects have been identified as a result of implementing the proposed project."[22] No citation is provided for this conclusion, and no analysis was performed to support this conclusion. As a result and the clear fact that the draft PEA proposes such a severe RTC "shave" that it could potentially eliminate the NOx RTC market, an analysis must be performed to evaluate the potential physical changes that might result from the reasonably foreseeable economic and social effects of the project. 2-20

[17] *See also* WSPA's August 21 Letter.

[18] Because the District has adopted a Certified Regulatory Program under California Public Resources Code §21080.5, an environmental assessment ("EA") may be prepared instead of an EIR or negative declaration. An EA is the equivalent of an EIR under the Certified Regulatory Program.

[19] Cal. Code Regs. § 15378(a)(1).

[20] CEQA Guidelines Section 15131. See, e.g., *Bakersfield Citizens for Local Control v. City of Bakersfield*, 124 Cal.App.4th 1184 (2004) (holding that CEQA requires consideration of social or economic impacts if they may lead to adverse changes in the physical environment such as "urban decay").

[21] 14 Cal. Code Regs. §15064(e).

[22] Draft PEA, p. 1-16.

Ms. Barbara Radlein
October 6, 2015
Page 8

More specifically, the draft PEA fails to consider the physical impacts of an analysis in which the economic consequences of the rule result in reasonably foreseeable changes in the regulated sectors. The District is well aware of the statistic it cites in its staff report and PEA: since the start of the RECLAIM program, the number of facilities in the program has shrunk by approximately 30 percent.[23] Where there were once 392 RECLAIM facilities in the South Coast Air Basin, there are now only 276. While the District cites this statistic, it makes no effort to analyze or consider the significance of it, or to examine the physical changes in the environment that resulted in the PEA. 2-21

This reduction in RECLAIM facilities means that some productivity within the Basin has been lost, and the draft PEA should evaluate the potential for future loss of productivity from sources within the RECLAIM system, particularly those RECLAIM facilities subject to the District's proposed severe shave. This analysis in the PEA should evaluate the Basin's energy needs and assess whether there would be adequate sources of reliable power if the proposed project were to result in lowered productivity within RECLAIM facilities and the businesses that support and supply these facilities. It should also consider whether lowered production of the affected products could result in adverse environmental impacts within or outside of the Basin. It should consider the environmental impacts of leakage, which is a well-known, and thus, foreseeable consequence of sub-regional cap and trade schemes. CEQA provides that "[a]ny emissions or discharges that would have a significant effect on the environment in this state" are subject to CEQA.[24] Accordingly, the District is obligated to analyze whether potential changes in operations resulting from the imposition of this aggressive RTC shave would result in potential environmental impacts, including increased emissions due to needing to source products from outside the South Coast Air Basin where the RECLAIM program applies. 2-22

The District's incomplete and selective approach neglects to consider potential environmental impacts beyond the narrow scope of construction associated with installation of the anticipated BARCT required by the proposed project. In the District's own words, RECLAIM is a market-based program which was "designed to use the power 2-23

[23] Draft PEA, p. 2-2.

[24] Cal. Pub. Resources Code § 21080. In certain instances, the mandate of CEQA to ensure a high level of environmental protection extended to considering out of state activities as part of the project due to resulting in-state impacts. (See 58 Ops. Cal. Atty. Gen. 614 (1975), opining that where California cities were joining forces with Utah cities to construct a coal plant in Utah that would provide power to California, and related transmission lines would have to be built from Utah into California, any project-related EIRs had to examine the environmental consequences of the project as a whole. Additionally, because the project area spanned multiple states, local California agencies were required to look at the impacts of the project as a whole.)

Ms. Barbara Radlein
October 6, 2015
Page 9

of the marketplace" to reduce air emissions from stationary sources.[25] A proposed shave effectively manipulates that marketplace. It stands to reason that an aggressive, deep manipulation – like the one proposed by the District – will impact RECLAIM facilities differently than one that is less drastic. The District is proposing a massive change in the marketplace designed to change behavior and cause reactions, yet the District assumes that the only reaction will be small scale construction projects involving installation of NOx control equipment to meet shave requirements. The District is proposing a massive change that will cause RECLAIM facilities and the businesses that support and supply these facilities to *react* in ways that are reasonably foreseeable by the District. These reactions, in turn, will have environmental impacts, which should have been analyzed in the PEA. 2-23 Con't

The RECLAIM program was introduced as an alternative to traditional command and control requirements, and was intended to provide business within the South Coast Air Basin with greater flexibility and financial incentive to reduce air pollution. As set forth in WSPA's August 21 Letter, the District has accomplished the substantial NOx emissions reductions achieved to date by reducing RTCs across the board. With the present project, not only is the District proposing deep cuts to the remaining RTCs, but it is imposing these cuts in a targeted, uneven manner. This is a significant manipulation of the marketplace, with foreseeable consequences that the PEA has neglected to analyze. The likely impacts resulting from the District's chosen methodology occur in various resource areas, as described further in this letter. However, by not recognizing the market-driven business considerations, the PEA has neglected to analyze and disclose the "whole of the project," in violation of CEQA. 2-24

CEQA prohibits segmenting a project into separate actions in order to: avoid environmental review of the "whole of the action"[26]; defer environmental analysis; ignore the foreseeable environmental impacts of the end result of a project; or, avoid considering potential cumulative impacts. Thus, a lead agency may not limit environmental disclosure by ignoring other activities that will ultimately result from approval of a particular project. The District's limited focus on technical equipment related to control of NOx emission reductions to achieve the severe RTC shave, to the exclusion of other foreseeable impacts is evidence of the District's failure to consider the entire project and its potential environmental impacts. 2-25

[26] Cal. Pub. Resources Code § 21065.

2. The draft socioeconomic report is deficient, and a revised report should be prepared and recirculated concurrently with a revised draft PEA

The draft Socioeconomic Report for the RECLAIM amendments provides little assistance in evaluating this issue as it considers only a limited number of potential economic and social issues, based solely on BARCT construction activities, and does not delve into the potential for physical effects resulting from the severe RTC "shave." WSPA will be submitting comments on the draft Socioeconomic Report, and once those comments have been considered and addressed, the draft PEA should be revised and recirculated for public review and comment to reflect the District's analysis of the potential environmental effects of any physical changes resulting from these economic and social effects. 2-26

Furthermore, the Draft Socioeconomic Report was only circulated on September 7, 2015 – weeks after the completion of the PEA. Failure to consider socioeconomic impacts in conjunction with the environmental review hampers the environmental review of the whole of the project. A proper socioeconomic analysis should have been completed in advance of, or at minimum in conjunction with, the draft PEA, and the draft PEA should have analyzed the resulting physical changes based on the socioeconomic effects of the RECLAIM amendments.

For example, the socioeconomic analysis with respect to the BARCT cost effectiveness could well have environmental impacts which were not adequately analyzed in the PEA. Health and Safety Code §39616 requires RECLAIM to achieve emissions reductions "at equivalent or less cost" than otherwise applicable command and control regulations. The project proposes cost effectiveness of $50,000/ton threshold, above which the District assumes, for purposes of CEQA analysis, that a facility would decline to install the given air pollution control technology. However, as discussed in greater detail below, this $50,000 is more than twice the AQMD's cost effectiveness threshold for command-and-control programs. The socioeconomic impacts of adopting new BARCT threshold, and setting such a high cost effectiveness figure, could result in operational changes which have physical impacts on the environment. In order to comply with CEQA, the PEA must analyze the foreseeable impacts of this component of the project. 2-27

D. The Project Objectives Are Disconnected From The Project Evaluated In The Draft PEA 2-28

An EIR is required to have a "statement of objectives sought by the proposed project."[27] The statement of objectives should include the underlying purpose of the project, and it should be clearly written to guide the selection of alternatives to be

[27] 14 Cal. Code Regs. §15124(b).

Ms. Barbara Radlein
October 6, 2015
Page 11

evaluated in the EIR.[28] Here, however, the objectives do not appear to inform the alternatives; instead, they appear to be independent of the proposed project. In fact, the Alternatives section of the draft PEA contains little analysis of whether the project objectives can be satisfied because they have become irrelevant, thereby infecting the Alternative analysis in its entirety (as discussed below). 2-28 Con't

The draft PEA appears instead to apply an unstated objective – reduce NOx RTCs by 14 TPD or more – which actually creates inconsistencies with the District's own plans and with the Health & Safety Code provisions with which it purports to comply. The District's 2012 Air Quality Management Plan ("AQMP") included NOx reduction control measure CMB-01. This control measure provided that additional reductions of NOx RTCs in the range of 3 to 5 tons per day ("TPD") would occur. The PEA states that one of the project objectives is to "[a]chieve the proposed NOx emission reduction commitments" of CMB-01. Yet the current project's proposal to reduce NOx RTCs by 14 TPD goes far beyond the control measure's initial recommendation of 3 to 5 TPD target. 2-29

WSPA and the Industry RECLAIM Coalition commented on this issue in their NOP/IS Letter. The District's response is that the current project "is the result of a much more rigorous and in-depth analysis as compared to the analysis that supported control measure CMB-01."[29] However, it is apparent that the analysis conducted by the District focused primarily on assessing the maximum number of remaining NOx emissions that could be reduced, to the exclusion of other analyses. As described above, the proposed project has the potential to trigger unintended consequences that were not considered in the draft PEA. The new, aggressive reduction in NOx RTCs, combined with the ambitious timeframe and questionable assumptions about facility performance suggest that the District did not undertake the same holistic view of the RECLAIM program and market as it did when it adopted the 2012 AQMP. Again, it appears that in its zeal to reduce NOx emissions by as much as possible, the District has ignored the potential repercussions of such a severe reduction. 2-30

Another unstated, but unsubstantiated, objective is the establishment of a $50,000/ton cost effectiveness threshold that justifies its severe shave. However, this is inconsistent with the stated District's objective: to "[c]omply with the requirements in Health and Safety Code …§39616 by conducting a BARCT assessment of the NOx RECLAIM program and reducing the amount of available NOx RTCs to reflect emission reductions equivalent to implementing available BARCT."[30] Compliance with that provision of the Health and Safety Code requires that the market-based emissions program should result in (1) emissions reductions equivalent to or greater than reductions that would have resulted under command and control, **and** (2) "***at equivalent or less cost*** 2-31

[28] 14 Cal. Code Regs. §15124(b).

[29] Draft PEA, p. 1-15.

Page 12

compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the District's plan for attainment."[31] The currently proposed emissions reductions may well provide greater reductions of NOx than would occur under traditional command and control regulation. However, this comes at a cost which far exceeds what implementation of BARCT would cost under command and control.

More specifically, the project proposes a $50,000/ton cost effectiveness threshold, above which the District assumes, for purposes of a CEQA analysis, a facility would decline to install a given NOx air pollution control technology to meet the severe shave requirements.[32] However, this $50,000 is more than twice the District's cost effectiveness threshold for command-and-control programs. As WSPA explains in its August 21 Letter, the 2012 AQMP used a cost threshold for NOx control measures of $22,500 per ton.[33] As another point of reference, the District's current Best Available Control Technology ("BACT") guidance document presents a discounted cash flow ("DCF") cost effectiveness threshold of only $19,100 per ton.[34] 2-31 Con't

The District, in its preliminary draft staff report for the NOx shave rulemaking, has also made misleading cost analysis assumptions which have the effect of making the overall costs for the severe shave look lower than actual. For example, in its staff report, the District proposed a 25-year Useful Life when calculating equipment cost effectiveness. This is misleading because the District rulemaking – which is often technology forcing – occurs on a more frequent basis. For example, the District last amended the NOx RECLAIM rules only 10 years ago. As WSPA explains in its August 21 Letter, assuming a 25-year project life dilutes the capital cost over a longer period of time than what the company is likely to actually realize. 2-32

As discussed below, Alternative 3 (the Industry Approach) meets project objectives, with fewer impacts. Thus, the project, as currently proposed, does not meet CEQA's requirements, and the PEA must be revised and recirculated for public review and comment. 2-33

E. The Alternatives Analysis Is Flawed

1. The analysis of alternatives is inadequate to allow for informed comparison

The alternatives analysis is critical to the integrity of an EIR.[35] Under CEQA, an EIR must describe a reasonable range of alternatives to the proposed project, or to its location, that would feasibly attain most of the project's basic objectives while reducing or avoiding any of its significant effects, and must evaluate the comparative merits of those alternatives.[36] The alternatives analysis has been described as "the core of an EIR."[37]

An EIR's analysis of alternatives and mitigation measures must focus on those alternatives with the potential to avoid or lessen a project's significant environmental effects.[38] The alternatives discussed in an EIR should be ones that offer substantial environmental advantages over the proposed project.[39]

Here, the PEA evaluates 5 alternatives, and except for the Alternative 4 (No Project) and Alternative 3 (Industry Approach), all other alternatives propose 14 TPD or more of NOx emission reductions. Given that the proposed project has remaining significant environmental effects with the proposed project at 14 TPD, the failure to include any additional alternatives other than Alternative 3 (Industry Approach) at a lesser reduction of NOx emissions does not satisfy CEQA's requirement for a "reasonable range of alternatives." Furthermore, CEQA generally prohibits a selection of "straw man" alternatives which are intended to be knocked down in favor of the proposed project.[40] The majority of the alternatives require 14 TPD or more of NOx reductions, including an alternative for 15.87 TPD, suggesting that the District's selection of alternatives was guided not by the ability to reduce environmental effects, but by an effort to support the proposed project. 2-34

Page 14

2. Alternative 3 is the environmentally superior alternative

The PEA's alternatives analysis is flawed because it appears to reject alternatives based solely on the total TPD of emissions reduced, rather than a more comprehensive analysis that evaluates the remaining significant effects associated with the proposed project. The CEQA Guidelines provide that "the discussion of alternatives shall focus on alternatives to the project or its location which are capable of avoiding or substantially lessening any significant effects of the project, even if these alternatives would impede to some degree the attainment of the project objectives,…"[41] Alternative 3 achieves the project objectives and is the environmentally superior alternative. As such, the District should adopt Alternative 3 rather than the proposed project.

Here, the District has chosen, as the proposed project, to employ a methodology that has significantly greater potential environmental impacts than Alternative 3. Specifically, the District proposes that NOx RTC holdings for major refineries be "shaved" by 67 percent; NOx RTC holdings for non-major refineries and other facilities among the top 90 percent of RTC holders be shaved by 47 percent. This aggressive "shaving" method would remove nearly all of the unused NOx RTCs from the RECLAIM market, ostensibly to reduce NOx emissions from RECLAIM facilities. However, the PEA suffers from a narrow view of the RECLAIM universe: by focusing almost exclusively on potential benefits from NOx emissions, the District fails to analyze the environmental impacts that such a drastic NOx RTC reduction is likely to have. 2-35

On the other hand, the Industry Approach (Alternative 3) to NOx reduction would take a more measured and holistic approach, resulting in fewer environmental impacts while still achieving a reduction in NOx emissions. More specifically, the Industry Approach proposes to reduce the unused RTCs in an amount equivalent to those reductions that could be directly attributable to an appropriate and valid BARCT.[42] The Industry Approach would result in an across the board reduction of 33 percent of the unused NOx RTCs – a significant reduction of RTCs and advancement of BARCT – without many of the environmental impacts resulting from the District's methodology.

The draft PEA downplays that Scenario 3 (Industry Alternative) will require less operational use of ammonia, by claiming that it is "not quantifiable."[43] However, no evidence is provided to support that conclusion. In the alternatives air quality analysis, the District asserts that if Alternative 3 were implemented, it would be too difficult to 2-36

[41] 14 Cal. Code Regs. § 1526.6(a).

[42] The Industry Approach is described in section 5.3.2.4 of the draft PEA, as well as in the January 30, 2015 letter to the District regarding the NOP/IS, submitted by WSPA and the other members of the Industry RECLAIM Coalition.

[43] Draft PEA, Table 1-4.

Ms. Barbara Radlein

Page 15

predict the number of facilities that would install NOx control equipment.[44] First, the District should have acknowledged the unpredictability of facilities implementing the proposed project, which is more aggressive and could trigger correspondingly more drastic business reactions. Instead, the District assumes there that all facilities will fall in line to install NOx control equipment as it predicts. Second, the likely NOx control equipment installation projects can be quantified. 2-36 Con't

Furthermore, the alternatives analysis in the PEA fails to explain why the proposed project will only reduce NOx emissions 8.72 TPD when history suggests a 1:1 relationship between RTC reductions and program emissions.[45] If the project objective is to meet BARCT at 8.7 TPD, Alternative 3 meets that objective with fewer environmental impacts, and thus, should be the environmentally preferred alternative. 2-37

The lead agency has the flexibility to approve an alternative to the proposed project if that alternative better addresses the agency's environmental concerns.[46] An EIR's failure to analyze an adequate range of alternatives deprives the lead agency of the ability to provide this sort of meaningful review and selection. Recirculation of a new draft PEA will be required by CEQA because the current PEA has not considered alternatives that have not been previously adequately analyzed but must be analyzed as part of a reasonable range of alternatives. 2-38

II. Specific Resource Areas Lack Adequate Analysis

A. Energy Reliability Impacts Were Not Considered

The District's proposal will dramatically increase the costs for the facilities it has selected to be regulated and the businesses that support and supply these facilities. The PEA acknowledges that if the BARCT is implemented at these selected facilities, there will be an increase in the amount of energy used both during construction, and more significantly, during operation of the facilities. But the PEA only considered whether there would be sufficient energy when all the facilities installed and implemented the BARCT. Given that 100 facilities have ceased to exist in the District's RECLAIM market since its inception, the District needs to consider not only whether there will be sufficient energy to power the BARCT NOx control equipment, but whether important energy reliability needs of the region and State can be met or whether they will be impacted by the District's proposal. 2-39

Page 16

There is a complete absence of any analysis of electricity or fuel supply impacts. The potential for outages, interruptions and severe price spikes should be considered and analyzed. Also, the future growth in energy demand should be assessed and the impact of this proposed project on the ability to maintain adequate energy supply. This analysis should consider proposed population growth and growth in use of power-consuming electronics (e.g., hospital diagnostic and treatment tools such as high proton lasers are replacing lower-energy using tools) and growth in electrification and energy use more generally. 2-40

B. Air Quality Impacts Were Not Fully Addressed

1. Direct impacts of new and expanded ammonia sources are not addressed

The PEA notes that the proposed project will increase operational use of ammonia, a toxic air contaminant, by 39.5 TPD.[47] The increase is due to the large number of new and expanded ammonia emissions sources associated primarily with the larger number of SCRs that would be required to be installed to meet the severe NOx shave requirements. However, the PEA does not address the impacts from a program which results in increased ammonia emissions. Additionally, as the District's other documents acknowledge,[48] ammonia is a precursor to PM2.5. Accordingly, the PEA should have analyzed the regional impacts from increased secondary formation of PM2.5. 2-41

Furthermore, the draft PEA's analysis of ammonia slip depends on physical conditions which are explicitly omitted from the project description (e.g., use of Ammonia Slip Catalysts or ASC) despite recommendations by Norton to use ASC.[49] Without the ASC, the ammonia slip could be as great as 20 ppmv, but the draft PEA underestimates the ammonia slip to be 5 ppmv, ostensibly based on permit conditions for new SCRs. However, existing SCRs are not necessarily subject to those permit conditions, and thus, ammonia slip of up to 20 ppmv should be considered in the health risk assessment for ammonia emissions.[50]

October 6, 2015
Page 17

2. Cumulative impacts from air emissions are not adequately considered

An EIR must discuss the cumulative impacts of a project when its incremental effects are "cumulatively considerable."[51] Moreover, in the specific context of a programmatic EIR, one of the key purposes of the EIR is to "ensure consideration of cumulative impacts that might be slighted in a case-by-case analysis."[52] Programmatic EIRs play an instrumental role in allowing the lead agency to consider broad policy alternatives and program-wide mitigation measures at an early time when the agency has greater flexibility to deal with basic problems in program implementation, or cumulative impacts.[53] Accordingly, the CEQA Guidelines require lead agencies to explain how implementing the particular requirements in the plan, regulation or program under review "ensure[s] that the project's incremental contribution to the cumulative effect is not cumulatively considerable."[54]

Cumulative impacts are defined as "two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts."[55] "Cumulatively considerable" impacts are present when "the incremental effects of an individual project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects" and activities.[56] A lead agency's threshold findings of significance with regard to cumulative impacts must "be supported by substantial evidence"; and, where found, cumulatively considerable impacts must be adequately mitigated.[57] 2-42

As discussed above, there are indirect air impacts from increased ammonia emissions for SCRs. The District also fails to provide substantial evidence that cumulative impacts from increased ammonia emissions for SCRs (which could number in the dozens at a single refinery) will not result in cumulative health risk impact. The PEA makes the conclusory statements that "[e]ven if multiple SCRs are installed at one refinery facility, the locations of all the stacks would not be situated in the same place within the affected facility's property. As such, even with multiple SCR installations, the acute and chronic hazard indices would not be expected exceed the significance

Page 18

threshold."[58] However, no evidence is provided to support this assumption, and the draft PEA should base its analysis on a conservative assumption regarding the locations of SCRs, and not dismiss the potential environmental effect by relying on unsupported and result-driven assumptions. 2-42 Con't

Furthermore, the PEA's conclusions with respect to potential cumulative health impacts are contradicted by recent District statements that recognize a potential need to control SCR ammonia slip. In a presentation on August 26, 2015, the District proposes possible "short-term" implementation for such a control.[59] Although CEQA does not require compliance with rule or programs that have not yet been adopted, the PEA should address, in its air quality analysis, the underlying concerns driving the proposed 2016 AQMP control measure. However, the project appears to value NOx RTC reductions above all other concerns, and accordingly the lopsided analysis does not acknowledge the related potential ammonia issues. 2-43

C. Water Supply Impacts Are Not Adequately Mitigated

The EIR "must assume that all phases of the project will eventually be built and will need water, and must analyze, to the extent reasonably possible, the impacts of providing water to the entire proposed project." (*Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova*, 40 Cal.4th 412, 431 (2007).) Also, "the future water supplies identified and analyzed must bear a likelihood of actually proving available; speculative sources and unrealistic allocations ('paper water') are insufficient bases for decision-making under CEQA." (*Id.* at 432.)

The draft PEA acknowledges "significant adverse water demand impacts from hydrotesting" requiring the imposition of mitigation measures.[60] The mitigation measures consist of a requirement to use recycled water "if available" and if not, a declaration from the water purveyor indicating why the recycled water cannot be supplied to the project.[61] The draft PEA summarily states that "the potential increase in potable water use cannot be fully supplied either with all potable water or with a combination of recycled water and potable water, since some potable water may still be required." The draft PEA also states: "[T]here is no absolute guarantee at the time of this writing that future supplies of potable or recycled water will be available to all of the affected facilities." 2-44

[58] Draft PEA, p. 4.2-23.

[59] Draft Potential Control Measures Concepts for 2016 AQMP August 2015, at p. 9 (link: http://www.aqmd.gov/docs/default-source/Agendas/aqmp/advisory7-item5-attachment.pdf?sfvrsn=2, last accessed September 16, 2015).

[60] Draft PEA, p. 4.5-9.

[61] Draft PEA, pp. 4.5-9 – 4.5-10.

Ms. Barbara Radlein
October 6, 2015
Page 19

CEQA requires a more in-depth evaluation of the availability and reliability of both potable and recycled water for the project.[62] It is insufficient to conclude that a significant impact for water supply exists without providing a more detailed analysis of the amount of water available, the reliability of such water, all of which has become more important as California is facing one of the most serious droughts in history. While the draft PEA identifies the existence of emergency drought regulations, it does not analyze the effect of these regulations – or of local water restrictions – on the facilities subject to the rule.

A similarly deficient analysis was presented in the draft PEA for the water usage associated with the wet gas scrubbers.[63] In that section, the District states that it cannot confirm or verify the use of recycled water and that "it is not known at this time whether water purveyors would be able to supply potable water for those facilities." CEQA requires an actual analysis of the water availability and reliability, and the inability to verify the use of recycled water means that the use of potable water must be evaluated, including an understanding of whether it is available at all. 2-44 Con't

Furthermore, the draft PEA fails to evaluate any further mitigation measures, other than a commitment to use recycled water, if available. Such mitigation measures are speculative, and may be found to be legally inadequate if they are so undefined that it is impossible to gauge their effectiveness.[64] Feasible – and therefore defensible – mitigation could include provisions in the rule that allow for alternative technologies and additional NOx RTCs in the foreseeable event that water supply is increasingly restricted, and the cost of water increases accordingly.

D. Noise Impacts Should Have Been Analyzed

The NOP/IS for the project determined that noise was among the environmental areas which would not be significantly adversely affected by the project. The PEA, in explaining why noise is not considered, states that the facilities are generally industrial in nature, and any increase in noise levels due to construction and installation of BARCT NOx control equipment would be within acceptable limits for an industrial facility. However, this is an example of the District's programmatic review failing to take into account site-specific conditions which could have an adverse impact. Rather than make generalizations about the facilities and extrapolated that there will be no adverse noise levels, the PEA should have undertaken a more conservative analysis to assess whether noise could, in fact, adversely affect receptors in the vicinity of the facilities, including on 2-45

[62] *California Oak Foundation v. City of Santa Clarita*, 133 Cal.App.4th 1219, 1237 (2005) (EIR requires "forthright discussion of a significant factor that could affect water supplies).

Page 20

nearby roadways based on the local noise ordinances or requirements. Noise impacts could occur from the use of large construction equipment to construct and install NOx control equipment and increase in construction traffic, which can include large trucks, trailers and cranes. Additionally, there could be an increase in noise impacts associated with the operation of the NOx control equipment and the ammonia delivery trucks. 2-45 Con't

E. Solid And Hazardous Waste Is Not Adequately Considered

The PEA fails to adequately analyze potential impacts of hazardous waste as a result of the project. The significant NOx RTC reductions necessitate a high degree of BARCT NOx control installation, most of which consists of SCR technology. While SCR technology has been used in a wide variety of applications and industries over the decades, it nonetheless is generates a hazardous wastestream in the form of spent catalyst which, in turn, requires potential on site storage and off-site transport and disposal.[65] Section 4.6 of the PEA acknowledges that the hazards exist and acknowledges that the generation of hazardous waste and materials will increase. The PEA should also evaluate the impact on communities near hazardous waste landfills, such as Kettlemen Hills, where the impacts may be greater without any corresponding benefit from the District's proposed action. Also, as discussed earlier, the emissions implications of the increased ammonia from the SCR have been overlooked in the District's PEA. 2-46

F. Growth-Inducing Impacts Analysis Is Flawed

An EIR must describe any growth-inducing impacts of the proposed project.[66] As part of the analysis, the EIR must discuss ways in which the project could directly or indirectly foster economic or population growth,[67] and should also describe growth-accommodating features of the project that may remove obstacles to population growth. An EIR must discuss growth-inducing effects even though those effects will result only indirectly from the project.[68] A discussion on growth-inducing effects should not necessarily make assumptions about whether the growth is beneficial, detrimental, or inconsequential to the environment.[69] The purpose of the EIR is to act as an informational document. 2-47

Here, not only does the draft PEA fail to consider the significance of the shrinking number of RECLAIM facilities (as discussed in Section I.C. of this letter), but the PEA also fails to consider the possibility that the facilities within the RECLAIM universe

---

Page 21

could grow. In a footnote, the PEA assigns a "growth factor" to different categories of RECLAIM facilities.[70] No explanation is provided about how that growth factor was derived, nor whether it is current or likely to change. The PEA must consider a scenario which allows for more growth of those industries within the RECLAIM universe, and modify the growth-inducing impacts analysis accordingly.[71] 2-47 Con't

III. Conclusion

The District has a very admirable – but narrow – statutorily defined focus: to promulgate rules and regulations which promote air quality in its jurisdiction. Under CEQA, the District is the lead agency for purposes of its own rulemaking. The District must be able to square its obligations as a lead agency to fully analyze and disclose impacts of its discretionary approvals with the narrow focus required of the District's mission to promote air quality within a specific geographic area. The District has failed to adequately balance those obligations here, which has resulted in a PEA that presents a skewed analysis of the potential benefits and impacts of the proposed rule amendments. The District must address the numerous inadequacies of the draft PEA raised in this comment letter, and then, revise and recirculate the draft PEA for public review and comment in order to meet its mandate under CEQA. 2-48

Page 1-1, 3rd paragraph	This paragraph describes the project as "amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM) to achieve additional NOx emission reductions to address best available retrofit control technology (BARCT) requirements and to modify the RECLAIM trading credit (RTC) "shaving" methodology." [emphasis added] This description is not consistent with the project description contained in the AQMD's Notice of Preparation issued 4 December 2014,[1] nor is the description consistent with Project Description contained in the Initial Study.[2] Specifically, neither the NOP Project Description nor the Initial Study Project Description includes any reference to modifying "the RECLAIM trading credit (RTC) "shaving" methodology" in the description of the project or the project objectives.	2-49
Page 1-1, 4th paragraph	The Draft PEA states that "further analysis of the actual BARCT NOx emission control opportunities for the various equipment/process categories demonstrated that the proposed project could achieve 14 tons per day of NOx emission reductions by 2023 which is much higher than estimates provided in the 2012 AQMP." While this value is certainly much higher than contemplated in the 2012 AQMP, it is also not supported by the AQMD Staff's technical analysis.[3] The Staff's analysis does not support a 14 ton per day (TPD) shave as necessary for BARCT equivalency. Rather, the Preliminary Draft Staff Report (PDSR) very clearly demonstrates that not more than 8.79 TPD of emission reductions from the RECLAIM program can be attributed to BARCT advancement; a conclusion that is later echoed in the Draft PEA.[4] Furthermore, a 14 TPD shave reduction of the RECLAIM market may violate the project objectives under the California Health & Safety Code (H&SC). Contrary to H&SC §40406, Staff have failed to take into account the economic impacts for each class or category of source. The Staff analysis only considers costs and cost effectiveness for the BARCT equivalency amount of 8.79 TPD (i.e., advancement from 2005 BARCT to 2015 BARCT). There is absolutely no consideration of the economic impacts which would be incurred by RECLAIM facilities under a 14 TPD market adjustment that goes beyond BARCT.	2-50

1

	And contrary to H&SC §39616(c)(1), AQMD Staff has failed to demonstrate that the RECLAIM program will result in an equivalent or greater reduction in emissions **at equivalent or less cost compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the district's plan for attainment**. Staff has instead applied a cost effectiveness threshold for this RECLAIM rulemaking of $50,000 per ton of NOx reduction which is more than double the cost threshold used for command-and-control rules within the District (i.e., $22,500 per ton[5]). This higher cost threshold clearly imposes a greater cost on RECLAIM sources than would be incurred under command and control regulations. But the Staff proposal to shave 14 TPD, which goes beyond BARCT, exposes RECLAIM facilities to even greater costs than would have been incurred under a command-and-control program. According the Staff's analysis, BARCT equivalency is not more than 8.79 TPD and even that value is overstated since adjustments are needed to account for the findings of the AQMD's third-party refinery expert (Norton Engineering) would reduce the shave for BARCT equivalency to not more than 7.94 TPD.[6] And contrary to H&SC §39616(c)(7), AQMD has failed to demonstrate that the RECLAIM program as amended will not result in disproportionate impacts, measured on an aggregate basis, to those stationary sources included in the program as compared to other permitted stationary sources in the district's plan for attainment. RECLAIM program sources have already reduced NOx emissions by 69% since 1994, whereas command-and-control stationary sources have only reduced NOx emissions by about 44% during that same period.[7] The BARCT levels being proposed by AQMD Staff represent performance levels that have not been demonstrated as broadly achievable for most of the source categories in question. Furthermore, these performance levels go well beyond the command-and-control standards adopted by AQMD under Regulation XI (i.e., the District's command-and-control program), and are well beyond BARCT determinations made by other major California air agencies administering command-and-control programs (e.g., SJVAPCD, BAAQMD, etc.). The resultant impacts would be disproportionate and that is in conflict with H&SC §39616(c)(7). For these reasons, the Draft PEA must be revised to address inconsistencies between the AQMD Staff's proposal and the project objectives, as well as inconsistencies with the Health & Safety Code.	2-50 Con't
Page 1-2, 1st full paragraph	This paragraph suggests that the proposed project will be limited to specific types of equipment/source categories in the RECLAIM program. While these types of equipment/source categories are certainly in the	2-51

[7] "RECLAIM Sources" data is computed from data presented in AQMD's RECLAIM Audit Report (March 2015). Command-and-control stationary sources NOx emissions is computed from data presented in AQMD Air Quality Management Plans (1997, 2003, 2007, 2012) and AQMP NOx RECLAIM Working Group Meeting #5, Agenda Item #3.

2

	RECLAIM program, the program is a market-based program; not a command-and-control program. Furthermore, the stated objectives of Control Measure CMB-01 Phase I and Phase II which this rulemaking intends to implement are for **programmatic equivalency**. Since this is a market-based system, it cannot be assumed that all impacts from the proposed rulemaking will be exclusively borne by specific equipment/source categories even where AQMD Staff have clearly attempted to target those impacts on specific facilities as is clearly the case here. The language in the referenced section needs to be revised to reflect that (a) proposed project is seeking programmatic equivalency <u>within the requirements and limitations of the California Health & Safety Code</u> and (b) acknowledge that there may be impacts on other RECLAIM facilities given the market-based design of the RECLAIM program. Those impacts must be analyzed to the extent practicable.	2-51 Con't
Page 1-2, 2nd full paragraph	As discussed above (see comments on Page 1-1, 4th paragraph), the Draft PEA must be revised to address inconsistencies between the AQMD Staff's proposal and the project objectives.	2-52
Page 1-13, Table 1-1, Areas of Controversy Line 1, Amount of proposed NOx shave and availability of RTCs	Draft PEA claims "The staff analysis shows that after the proposed shave is imposed, there will be sufficient NOx RTCs available to maintain trading within the NOx RECLAIM program given foreseeable opportunities for emissions reductions." This statement is without technical foundation; neither the PEA nor the PDSR includes such a market analysis. On the contrary, the Staff's proposal would reduce the quantity of RECLAIM Trading Credit (RTCs) to levels without historical precedent and that action, according to Staff's own analysis, would result in a level of "unused" RTCs (i.e., RTCs not used to cover facility emissions) for which the only historical precedent was observed during the RECLAIM market collapse during the California power crisis of 2000-2001.[8] WSPA and the Industry RECLAIM Coalition have repeatedly expressed concerns about shaving the RECLAIM program to this level when such action is clearly beyond what is needed for BARCT equivalency and in conflict with California Health & Safety Code requirements. Table 1-1 must be revised to accurately reflect the actual technical record; not assert conclusions without technical foundation.	2-53
Page 1-14, Table 1-1, Areas of Controversy Line 2, Equity of proposed NOx shave	The Draft PEA states that for 210 facilities holding 10% of the available NOx RTCs that "no NOx RTC shave is proposed because no new BARCT (not cost effective and/or infeasible) was identified…for the types of equipment and source categories." This statement is factually incorrect and should be corrected. In actuality, AQMD Staff <u>elected not to review</u> BARCT for these facilities under this RECLAIM rulemaking. And contrary to the statement, AQMD and other California air districts have previously made BARCT determinations that do apply to the types of equipment and operations at those smaller emitting facilities (e.g., boilers, heaters, etc.) were they not under RECLAIM.[9]	2-54

[8] AQMD Annual RECLAIM Audit Report, March 2015.
[9] See SCAQMD Regulation XI for examples.

5

Page 1-14, Table 1-1, Areas of Controversy Line 3, Results of the BARCT analysis	The Draft PEA states "While staff believes the engineering assumptions in the staff BARCT analysis are appropriate, the difference in BARCT reductions attributable to the alternate engineering assumptions suggested by the consultant is relatively small. To account for this difference and to provide a compliance margin, staff is proposing a shave of 14 tpd, reduced from the initial BARCT result of 14.85 tpd." We disagree. There continues to be a significant number of unresolved issues which result in uncertainty in the Staff's BARCT analysis as presented in the PDSR. This includes, but is not limited to the Staff's decision to selectively ignore the findings of the agreed upon third-party expert for the Refinery Sector, Norton Engineering Consultants. These issues are fundamental to the engineering design basis of the Staff's proposed BARCT determinations for most refinery sector source categories. These discrepancies were exhaustively described in Norton Engineering's expert analysis of the AQMD Staff's analysis,[10] as well as reiterated in NEC's letters dated 10 August 2015[11] and 4 September 2015.[12] Norton's comments are incorporated herein by reference. Furthermore, Staff's "after-the-fact" 0.85 TPD adjustment to the overall shave (i.e., reduces proposed shave from 14.85 to 14.0 TPD) is an improper application of the adjustments necessitated by Norton Engineering's expert findings. Such an adjustment, which is necessary, must be applied to the quantity of BARCT equivalency emission reductions attributed to refinery sector source categories. By failing to properly adjust this value, the AQMD Staff have distorted their own methodology to increase the burden of this shave on one sector (i.e., refineries). This is disproportionate and without technical foundation.	2-55

[10] Norton Engineering Consultants (NEC), SCAQMD NOx RECLAIM - BARCT Feasibility and Analysis Review, Non-Confidential Final Report No. 14-045-4, 26 November 2014.
[11] James Norton, NEC, letter to Dr. Phillip Fine, SCAQMD, Comments on Preliminary Draft Staff Report Proposed Amendments to Regulation XX Regional Clean Air Incentives Market (RECLAIM) NOx RECLAIM – SCRs for FCCUs Document No. 14-045-7, 10 August 2015.
[12] James Norton, NEC, letter to Dr. Phillip Fine, SCAQMD, Comments on Preliminary Draft Staff Report Proposed Amendments to Regulation XX Regional Clean Air Incentives Market (RECLAIM) NOx RECLAIM – SCRs for Fired Heaters & Boilers Document No. 14-045-8, 4 September 2015.

Page 1-14, Table 1-1, Areas of Controversy Line 4, Equivalency with command-and-control	The Draft PEA asserts that the proposed shave amount of 14 tpd is consistent with previous RECLAIM rule amendments, the California Health & Safety Code, and the purpose of the program. As noted above (see above comments on Page 1-1, 4th paragraph), the AQMD Staff have not demonstrated that the Staff proposal is consistent with certain provisions of the California Health & Safety Code. Table 1-1, Line 4 must be revised to describe how the Staff proposal will comply with the project objective requiring compliance with all applicable H&SC requirements. The Draft PEA goes on to state "…This approach will result in approximately 8.79 tons per day of BARCT reductions of actual NOx emissions attributable to installing and operating additional controls. Otherwise, actual emissions reductions of only about two tpd over the next seven years would be achieved." WSPA agrees that under the AQMD Staff's analysis, BARCT equivalency as currently presented is not more than 8.79 TPD. And with adjustments needed to fully account for the findings of the AQMD's third-party refinery expert, Norton Engineering, the shave needed for BARCT equivalency is not more than 7.94 TPD.[13] Staff has provided no information to support the assertion that 14 TPD must be shaved to achieve the 8.79 TPD (or 7.94 TPD) required for BARCT equivalency. And RECLAIM program history does not support that conclusion. Under the 2005 Shave, a 23% reduction in RTCs resulted in a 24% reduction in NOx RECLAIM emissions; a nearly 1:1 relationship.[14] The Staff proposal must be revised to reflect the project objective of BARCT equivalency. That has not been demonstrated as any more than 8.79 TPD.	2-56
Page 1-15, Table 1-1, Areas of Controversy Line 5, 2012 AQMP Commitment in the State Implementation Plan (SIP)	The Draft PEA states: "This staff proposal recommends a reasonably available 14 tpd of NOx RTC reductions, based on BARCT, as required by state law." In fact, the PDSR presents BARCT equivalency as not more than 8.79 TPD, and the AQMD Staff have not explained how its proposal will comply with H&SC §40406, since there is no consideration of the economic impacts which would be incurred under a 14 TPD market adjustment that goes beyond BARCT. Furthermore, AQMD Staff's proposal is contrary to H&SC §39616(c)(1), which requires the market to perform at equivalent or less cost compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the District's plan for attainment. The Draft PEA must be revised to fully demonstrated compliance with the project objectives and relevant H&SC requirements.	2-57

[13] AQMD Preliminary Draft Staff Report, Proposed NOx RECLAIM Amendments, July 2015, p. 18.

[14] SCAQMD Annual RECLAIM Audit Report, March 2015. Under the 2005 shave, RTCs were reduced from 34.2 to 26.5 TPD between 2005 and 2011 and emissions declined from 26.4 to 20 TPD over the same period.

5

Page 1-16, Table 1-1, Areas of Controversy Line 6, Availability of RTCs for future power plant needs	The Draft PEA states" The staff proposal would establish a separate adjustment account to hold RTCs for power plants to meet their NSR holding obligations. Many newer peaking plants are required to hold RTCs at the potential to emit level each year even though their actual emissions are far below this level. The adjustment account would relieve power producing facilities from the obligation of holding RTCs in order to meet the NSR holding requirements of Rule 2005." The AQMD Staff proposal for a separate "adjustment account" has not been fully defined, and the Staff proposal and Draft PEA fail to address how such a mechanism would comply with U.S. EPA requirements for New Source Review. The PDSR and Draft PEA must be revised to demonstrate how such a proposed adjustment account would function, and demonstrate that it is approvable by U.S. EPA. Furthermore, Staff's proposal would apparently not apply to new peaking power plants. The California Air Resources Board prepared assessment of electrical grid reliability needs in the South Coast air basin which suggested a significant amount of peaking power plant capacity would be needed to ensure reliability in the future.[15] This report was prepared in conjunction with the California's power sector regulators (i.e., California Public Utilities Commission, California Independent System Operator, and California Energy Commission). Contrary to the CARB report, AQMD Staff's analysis depends on a negative growth rate for power sector emissions and RTC demand. This is a significant difference. The Draft PEA should be revised to clarify that the Staff proposal would provide no relief to any new peaking power plants. The Draft PEA should also be revised to demonstrate how the Staff proposal will accommodate new power sector facilities which may be needed to ensure electric reliability and integration of renewable electricity. 2-58
Page 1-17, 3rd paragraph	The Draft PEA states "For the remaining 210 facilities that hold 10 percent of the 26.5 tpd of the NOx RTCs, no NOx RTC shave is proposed because no new BARCT (not cost effective and/or infeasible) was identified for the types of equipment and source categories at these facilities." This statement is factually incorrect and should be revised. As noted above, AQMD Staff elected not to review BARCT for these smaller facilities for this RECLAIM rulemaking (i.e., no analysis was performed). 2-59

[15] CARB, Assembly Bill 1318: Assessment of Electrical Grid Reliability Needs and Offset Requirements in the South Coast Air Basin, Draft Final Report, October 2013.

Page 1-20, 1st paragraph, 3rd sentence Air Quality and Greenhouse Gases	The Draft PEA states "For the 275 facilities that are in the NOx RECLAIM program, the 14 tpd of NOx RTC reductions will affect 65 facilities plus the investors, who collectively hold 90 percent of the NOx RTC holdings." This paragraph suggests that the proposed project will be limited to specific facilities in the RECLAIM program. While the application of the shave may be limited to these facilities, the impacts of the proposed shave will be broader. RECLAIM is a market-based program; not a command-and-control program. Since this is a market-based system, it cannot be assumed that all impacts from the proposed rulemaking will be exclusively borne by specific equipment/source categories even where AQMD Staff have clearly attempted to target those impacts on specific facilities as is clearly the case here. For example, smaller facilities without Infinite Year Basis (IYB) RTC holdings may incur higher RTC prices to meet their future compliance obligations. Alternatively, such facilities may find themselves unable to purchase RTCs at any price similar to the RTC supply crisis observed during the 2000/2001 power crisis which nearly collapsed the RECLAIM program. Also, Staff has not considered potential impacts to new or expanding facilities which are required to participate in RECLAIM. Or the potential consequences to the regional economy if those facilities are unable to obtain RTC supply. Or the potential environmental impacts of those operations if they are forced to locate outside of the South Coast air basin where they would presumably be subjected to lessor regulation. These are all issues and impacts which have been identified and should be disclosed as potential impacts from the project. The Draft PEA must be revised to clarify that market impacts may be broader than intended or even recognized by Staff, and those impacts must be quantified to the extent possible.	2-60
Page 1-20, 2nd paragraph	The Draft PEA states "…only 44 facilities are expected to comply with the proposed NOx RTC shave through the purchase of RTCs which will have no environmental impact." The Draft PEA should be revised to present supporting analysis demonstrating how this conclusion was reached. RECLAIM is a market-based program; not a command-and-control program. Since this is a market-based system, it cannot be assumed that all impacts from the proposed rulemaking will be exclusively borne by specific equipment/source categories even where AQMD Staff have clearly attempted to target those impacts on specific facilities as is clearly the case here.	2-61
Table 1-3, Summary of Proposed Project & Alternatives Alternative 3	This table reports the NOx Reduction Potential (tons/day) for Alternative 3 at 8.00 TPD. As proposed by the Industry, RECLAIM Coalition, Alternative 3 would result in BARCT equivalent reductions. Using the AQMD Staff's latest BARCT analysis, which needs to be revised downward as discussed earlier herein, the Proposed NOx RTC "Shave" for this alternative should be 8.79 TPD. The Draft PEA should be revised.	2-62

7

Table 1-3, Summary of Proposed Project & Alternatives Proposed Project Page 1-26	This table clearly shows that the AQMD Staff proposal, which would shave 14 TPD, would include removing 5.21 TPD of RTCs from the RECLAIM market that cannot be attributed to BARCT. The table even labels these 5.21 TPD as "NOx RTCs Needed to Fulfill Shave <u>Post-BARCT</u>." [Emphasis Added] This proposal is beyond BARCT. Furthermore, a 14 TPD shave reduction of the RECLAIM market could violate the project objectives under the California Health & Safety Code (H&SC). Contrary to H&SC §40406, Staff have failed to take into account the economic impacts for each class or category of source. The Staff analysis only considers costs and cost effectiveness for the BARCT equivalency amount of 8.79 TPD (i.e., advancement from 2005 BARCT to 2015 BARCT). There is absolutely no consideration of the economic impacts which would be incurred under a 14 TPD market adjustment that goes Beyond BARCT. Contrary to H&SC §39616(c)(1), AQMD Staff has failed to demonstrate that the RECLAIM program will result in an equivalent or greater reduction in emissions **at equivalent or less cost compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the District's plan for attainment**. Staff has instead applied a cost effectiveness threshold for this RECLAIM rulemaking of $50,000 per ton of NOx reduction which is more than double the cost threshold used for command-and-control rules within the District (i.e., $22,500 per ton[16]). This clearly imposing a greater cost on RECLAIM sources than would be incurred under command and control regulations. Furthermore, Staff has proposed a market shave of 14 TPD which goes beyond BARCT. Under AQMD Staff's analysis, BARCT equivalency is currently presented as not more than 8.79 TPD. Even that value is overstated since adjustments needed to fully account for the findings of the AQMD's third-party refinery expert, Norton Engineering, would reduce the shave for BARCT equivalency to not more than 7.94 TPD.[17] Thus, RECLAIM facilities would have greater costs under the Staff proposal than would have been incurred under a command-and-control program. And contrary to H&SC §39616(c)(7), AQMD has failed to demonstrate that the RECLAIM program as amended will not result in disproportionate impacts, measured on an aggregate basis, to those stationary sources included in the program as compared to other permitted stationary sources in the District's plan for attainment. RECLAIM program sources have already reduced NOx emissions by 69% since 1994, whereas command-and-control stationary sources have only reduced NOx emissions by about 44% during that same period.[18] The BARCT levels being proposed by

2-63

[16] AQMD, 2012 Air Quality Management Plan (AQMP), December 2012.

[17] AQMD Preliminary Draft Staff Report, Proposed NOx RECLAIM Amendments, July 2015, p. 18.

[18] "RECLAIM Sources" data is computed from data presented in AQMD's RECLAIM Audit Report (March 2015). Command-and-control stationary sources NOx emissions is computed from data presented in AQMD Air Quality

	AQMD Staff generally represent performance levels that have not been demonstrated as broadly achievable for the source categories in question. Furthermore, these performance levels go well beyond the command-and-control standards adopted by AQMD under Regulation XI (i.e., the District's command-and-control program), and are well beyond BARCT determinations made by other major California air agencies administering command-and-control programs (e.g., SJVAPCD, BAAQMD, etc.). For these reasons, the Draft PEA must be revised to address inconsistencies between the AQMD Staff's proposal and the project objectives.	2-63 Con't
Table 1-4, Comparison of Adverse Environmental Impacts of the Alternatives Row 3: Air Quality & GHGs	This table reports for Alternative 3 "Less operational NOx reductions than proposed project but not quantifiable." As correctly reported in Table 1-3, Alternative 3 would actually reduce emissions by 8.79 TPD so it clearly is quantifiable. Table 1-4 must be revised to correctly report the emission reduction potential for Alternative 3.	2-64
Table 1-4, Comparison of Adverse Environmental Impacts of the Alternatives Row 3: Air Quality & GHGs Page 1-29	For the proposed project, the table reports "Increases operational use of NH3 (a TAC) by 39.5 tpd." But for Alternative 3, the table reports that ammonia (NH3) use is not quantifiable. However, no evidence is provided to support that conclusion. In the alternatives air quality analysis, the District asserts that if Alternative 3 were implemented, it would be too difficult to predict the number of facilities that would install NOx control equipment. First, the District should have acknowledged the unpredictability of facilities implementing the proposed project, which is more aggressive and could trigger correspondingly more drastic business reactions. Instead, the District assumes there that all facilities will fall in line to install equipment as it predicts (i.e., command and control). Second, the likely NOx control installation projects can be quantified at a program level since it is a function of the same stoichiometric relationship used in the Staff's analysis for the proposed project. The Draft PEA should be revised to provide an estimate of the operational ammonia use for Alternative 3. Since this value will be lower than the proposed project, Alternative 3 would have lower ammonia emissions by comparison and would therefore be environmentally preferable on this issue. Is Staff's estimate for increased operational use of ammonia based on 8.79 TPD of NOx emission reductions (i.e., BARCT equivalency)? Since the Staff's 14 TPD proposal would require significantly greater emission reductions (i.e., beyond BARCT), the Draft PEA should be revised to explain the basis for this ammonia use figure to ensure that project's potential environmental impacts are fully disclosed. The ammonia figure also drives traffic and construction impacts which may be greater than disclosed in the Draft PEA. For similar reasons, the Staff's statement that Alternative 3 emissions for construction are "not quantifiable" is not accurate. As reported in Table 1-3, Alternative 3 would require emission controls sufficient to reduce NOx emissions by 8.79 TPD (again, using the Staff's BARCT analysis). The	2-65

Management Plans (1997, 2003, 2007, 2012) and AQMP NOx RECLAIM Working Group Meeting #5, Agenda Item #3.

9

	Draft PEA must be revised to include a quantified estimate of the construction emissions needed to deliver those emissions control using a methodology similar to the Staff's analysis of the proposed project.	2-65 Con't
Table 1-4, Comparison of Adverse Environmental Impacts of the Alternatives Row 3: Air Quality & GHGs Page 1-30	The Alternative 3, the Draft PEA reports impacts are "Less than significant; achieves net NOx emission reductions during operation (less reductions than the proposed project but not quantifiable)." [emphasis added] This is not correct. As reported in Table 1-3, Alternative 3 would require emission controls sufficient to reduce NOx emissions by 8.79 TPD (again, using the Staff's BARCT analysis) so clearly the impacts from Alternative 3 are quantifiable. The Draft PEA must be revised to include a quantified estimate of the NOx emission reductions during operation for Alternative 3.	2-66
Page 2-2, Section 2.2 Project Objectives	The Draft PEA states: "The objectives of the proposed project are to: 1) Comply with the requirements in Health and Safety Code (HSC) §§40440 and 39616 by conducting a BARCT assessment of the NOx RECLAIM program and reducing the amount of available NOx RTCs to reflect emission reductions equivalent to implementing available BARCT; 2) Modify the RTC "shaving" methodology to implement the emission reductions per the BARCT assessment; 3) Ensure that RECLAIM facilities, in aggregate, achieve the same emission reductions that would have occurred under a command-and-control approach; 4) Achieve the proposed NOx emission reduction commitments in the 2012 AQMP Control Measure #CMB-01: Further NOx Reductions from RECLAIM; and, 5) Achieve NOx emission reductions to assist in attaining the NAAQS." This highlights several problems with the Draft PEA and the Staff proposal. WSPA agrees that AQMD has a legal obligation to comply with the requirements in Health and Safety Code (HSC) §§40440 and 39616. However, Staff has oversimplified what those obligations are by suggesting this is entirely about conducting a BARCT assessment. The AQMD Staff's proposed 14 TPD shave reduction from the RECLAIM market could violate the project objectives under the California Health & Safety Code (H&SC). With respect to H&SC §40406, Staff have failed to take into account the economic impacts for each class or category of source. The Staff analysis only considers costs and cost effectiveness for the BARCT equivalency amount of 8.79 TPD (i.e., advancement from 2005 BARCT to 2015 BARCT). There is no consideration of the economic impacts which would be incurred under a larger 14 TPD market adjustment that goes beyond BARCT. With respect to H&SC §39616(c)(1), AQMD Staff has failed to demonstrate that the RECLAIM program will result in an equivalent or greater reduction in emissions **at equivalent or less cost compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the**	2-67

10

	District's plan for attainment. Staff has instead applied a cost effectiveness threshold for this RECLAIM rulemaking of $50,000 per ton of NOx reduction which is more than double the cost threshold used for command-and-control rules within the District (i.e., $22,500 per ton[19]). This clearly imposes a greater cost on RECLAIM sources than would be incurred under command and control regulations. Furthermore, Staff has proposed a market shave of 14 TPD which goes beyond BARCT. Under AQMD Staff's analysis, BARCT equivalency is currently presented as not more than 8.79 TPD. Even that value is overstated since adjustments needed to fully account for the findings of the AQMD's third-party refinery expert, Norton Engineering, would reduce the shave for BARCT equivalency to not more than 7.94 TPD.[20] Thus, RECLAIM facilities would have greater costs under the Staff proposal than would have been incurred under a command-and-control program. And contrary to H&SC §39616(c)(7), AQMD has failed to demonstrate that the RECLAIM program as amended will not result in disproportionate impacts, measured on an aggregate basis, to those stationary sources included in the program as compared to other permitted stationary sources in the District's plan for attainment. RECLAIM program sources have already reduced NOx emissions by 69% since 1994, whereas command-and-control stationary sources have only reduced NOx emissions by about 44% during that same period.[21] The BARCT levels being proposed by AQMD Staff generally represent performance levels that have not been demonstrated as broadly achievable for the source categories in question. Furthermore, these performance levels go well beyond the command-and-control standards adopted by AQMD under Regulation XI (i.e., the District's command-and-control program), and are well beyond BARCT determinations made by other major California air agencies administering command-and-control programs (e.g., SJVAPCD, BAAQMD, etc.).	2-67 Con't

11

Page 2-2, Section 2.2 Project Objectives (continued)	Next, the Draft PEA suggests an objective to "modify the RTC "shaving" methodology to implement the emission reductions per the BARCT assessment."[21] That is not consistent with the project description contained in the Notice of Preparation issued 4 December 2014,[22] nor is it consistent with project description contained in the Initial Study.[23] Specifically, neither the NOP Project Description nor the Initial Study Project Description included any reference to modifying "the RECLAIM trading credit (RTC) "shaving" methodology" in the description of the project or the project objectives. And this is also inconsistent with the objectives approved by the Governing Board under Control Measure CMB-01. For these reasons, all references to "modifying "the RECLAIM trading credit (RTC) "shaving" methodology" should be removed from the Draft PEA.	2-67 Concluded
Page 2-2, Section 2.2 Project Objectives (continued)	This section also suggests an objective "Achieve NOx emission reductions to assist in attaining the NAAQS." This is also not consistent with the Project Description contained in the Notice of Preparation issued 4 December 2014,[24] or the description contained in the Initial Study Project Description.[25]	2-68

12

Page 2-6, 4th paragraph	The Draft PEA states "the proposed project is estimated to reduce four tons per day of NOx emissions starting in 2016 because the amount of unused RTCs in the NOx RECLAIM program over the past five years (e.g., from 2009 to 2013) ranged from five tpd to eight tpd, demonstrating that there is enough cushion to support reduction of four tpd in 2016." While the quantities of "unused" RTCs are a matter of historical record, Staff has provided no evidence to support that supposition that the RECLAIM market has "enough cushion to support reduction of four tpd in 2016." And if this was just a reduction of unused RTCs, that would not equate to an emissions reduction in 4 TPD. The Draft PEA needs to be revised to include a market analysis to support that supposition or this statement should be deleted.	2-69
Page 2-6, 4th paragraph (continued)	The Draft PEA goes on to state "it could take from two to four years for the affected facilities to plan, obtain permits, and install air pollution control equipment or modify existing equipment in response to the proposed project." According to information from WSPA members, this estimate is too short.[26] While some individual projects might be complete able in 2-4 years, the proposed project would require dozens and dozens of emission control projects to be completed. For the refinery sector, such projects would need to be planned, engineered, and sequenced for construction in consideration of unit turnaround schedules. WSPA members report that completion of all needed projects for the proposed project would likely require not less than eight (8) years. The Draft PEA should be revised to reflect this timetable and the Proposed Amended Rules and PDSR should be similarly adjusted.	2-70
Page 2-9, PAR 2005 Requirements for New or Relocated RECLAIM Facilities – Subdivision (b)	The AQMD Staff have yet to provide a complete description of the amendments to this rule. AQMD Staff have also not obtained U.S. EPA approval that such amendments would even be approvable into the State Implementation Plan (SIP). The Draft PEA and PAR 2005 should be revised to reflect these important details <u>after</u> AQMD Staff have obtained the U.S. EPA approval needed for such amendments to be legal.	2-71
Page 2-10, top of page	The Draft PEA states "Further, only 44 facilities are expected to comply with the proposed NOx RTC shave through the purchase of RTCs which will have no environmental impact." The Draft PEA should be revised to present supporting analysis demonstrating how this conclusion was reached.	2-72
Page 3.2-34, 2nd paragraph, GHG Tailoring Rule	This section should be revised to note that the courts vacated significant portions of the GHG Tailoring Rule. The applicability criteria as described in the Draft PEA are not consistent with current regulations.	2-73
Page 4.1-3, Section 4.1.3.1	The Draft PEA states "Because each affected facility is located in heavy industrial areas, the construction equipment is not expected to be substantially discernable from what exists on-site for routine operations and maintenance activities. Further, the construction activities are not expected to adversely impact views and aesthetics resources since most of the heavy equipment and activities are expected to occur within the confines of each existing facility and are expected to introduce only minor visual changes to areas outside each facility, if at all, depending on the location of the construction activities within the facility."	2-74

[26] WSPA/ERM confidential survey of WSPA members concerning refinery heaters/boilers, March 2015.

13

	This statement oversimplifies the range of physical settings existent for RECLAIM facilities. In actuality, some refinery or non-refinery RECLAIM facilities are located areas where additional vertical obstructions from cranes or new emission control structures could be "discernable" and may adversely impact views and aesthetics resources for adjacent communities. The Draft PEA should be revised to clarify the range of settings which would be impacted by the proposed project and acknowledge the range of potential impacts associated with the proposed project.
Page 4.2-2, Table 4.2-1 Estimated Number of NOx Control Devices Per Sector and Equipment/Source Category	As shown in this table, the Draft PEA states that Staff has assumed 74 SCRs would be installed on Refinery Process Heaters and Boilers under the proposed project. Staff does not explain the basis for this value, which conflicts with the Preliminary Draft Staff Report (PDSR). The PDSR suggests that the proposed project would result in 76 SCRs (25 upgraded, 51 new) for refinery heaters and boilers,[27] in which case the Draft PEA would be understating the potential project impacts. It should also be noted that AQMD's third-party refinery sector expert, Norton Engineering, found that only 48 refinery heaters and boilers could be cost effectively retrofit with new or upgraded SCRs.[28] Staff have done nothing to reconcile this discrepancy which is material. The Draft PEA must be revised to clarify the technical basis for the assumed emission controls outcome and associated potential impacts to the environment. The Draft PEA should also explain how emission controls which are not cost effective, according to AQMD's own third-party expert, will be implemented. 2-75
Page 4.2-4, Section 4.2.3.1, first paragraph	The Draft PEA states "Further, operators at each affected facility who construct NOx control equipment that utilize chemicals as part of the NOx control equipment operations, such as a new ammonia or caustic storage tank, may also need to build a containment berm large enough to hold 110 percent of the tank capacity in the event of an accidental release, pursuant to U.S. EPA's spill prevention control and countermeasure regulations." While other regulations and good engineering practices would require containment features for these tanks, the Spill Prevention Control and Countermeasure (SPCC) regulations actually don't apply to ammonia or caustic storage vessels. The Draft PEA should be clarified accordingly. 2-76
Page 4.2-7, last paragraph	The Draft PEA states "if a particular technology was identified as having a cost that exceeds $50,000 per ton, this CEQA analysis assumed that the facility operator would not install this type of air pollution control technology in response to the project." This statement is inconsistent with the project objectives which require compliance with the California Health & Safety Code. The $50,000 threshold fails in this regard. Under H&SC§39616(c)(1), the RECLAIM program is required to result in "an equivalent or greater reduction in emissions **at equivalent or less cost compared with current command and control regulations** and future air quality measures that would otherwise have been adopted as part of the District's plan for attainment." AQMD Staff has failed to demonstrate that the proposed amended RECLAIM program will be **at equivalent or less** 2-77

[27] AQMD Preliminary Draft Staff Report, Proposed NOx RECLAIM Amendments, July 2015, Table B.10.
[28] AQMD Preliminary Draft Staff Report, Proposed NOx RECLAIM Amendments, July 2015, Table B.9.

14

	cost compared with current command and control regulations. On the contrary, Staff's proposed $50,000 cost effectiveness threshold for this RECLAIM rulemaking is more than double the cost threshold used by AQMD for command-and-control rules (i.e., $22,500 per ton[29]). This clearly imposes a greater cost on RECLAIM sources than would be incurred under command and control regulations. The Draft PEA and Proposed Amended Rules must be revised is be consistent with the project objectives and all applicable H&SC requirements.	2-77 Con't
Page 4.2-8, Section 4.2.3.1, first paragraph	The Draft PEA states "In order to operate SCR and UltraCat technology, ammonia is necessary and, as such, tanks to store ammonia would also need to be installed. The size of each ammonia tank needed to operate the SCR units and one UltraCat filtration unit have been estimated to range between 2,000 and 11,000 gallons in capacity." While this statement may be appropriate for characterizing new tanks which are likely to handle aqueous ammonia, it ignores the fact that some existing ammonia tanks are used to store anhydrous ammonia. The PEA should be revised to address this description. Staff should consider whether this condition requires revision of the offsite consequence analysis presented in the Draft PEA.	2-78
Page 4.2-8, Section 4.2.3.1, 5th paragraph	The Draft PEA states "From a construction point of view, the installation of a NOx control technology at a refinery is a complex process. For example, if a facility operator chooses to install NOx control equipment, time will be needed for pre-construction/advance planning activities such as engineering analysis of the affected equipment, engineering design of the potential control equipment, contracting with a vendor, securing financing, ordering and purchasing the equipment, obtaining permits and clearances, and scheduling contractors and workers. The amount of lead time can vary from six months (e.g., for a SCR for refinery/boiler heater or gas turbine) to up to 18 months for a scrubber (either a WGS or DGS)." AQMD permitting for new emission controls can easily take as much as 18 months for Title V facilities. This could easily increase the amount of lead time a company requires to 2-3 years. Some of the pre-construction activities cannot be conducted until the Permit to Construct has been issued.	2-79
Page 4.2-11, top of page	The Draft PEA states "…the analysis also includes an analysis of the overlapping impacts spread out over a five- and seven-year period." According to information from WSPA members, this estimate is too short. While some individual projects might be complete able in 2-4 years, the proposed project would require dozens and dozens of emission control projects to be completed. For the refinery sector, such projects would need to be planned, engineered, and sequenced for construction in consideration of unit turnaround schedules. WSPA members report that completion of all needed projects for the proposed project would likely require not less than eight (8) years.[30] The Draft PEA should be revised to reflect this timetable and the Proposed Amended Rules and PDSR should be similarly adjusted.	2-80

[29] AQMD, 2012 Air Quality Management Plan (AQMP), December 2012.
[30] WSPA/ERM confidential survey of WSPA members concerning refinery heaters/boilers, March 2015.

15

Page 4.2-13, 1st paragraph Combined Construction Emissions From Non-Refinery and Refinery Facilities	The Draft PEA does not disclose the assumed basis for construction impact estimates. Are these impacts based on construction of emission controls to deliver 8.79 TPD (i.e., BARCT equivalency), or has Staff assumed construction sufficient to deliver the proposed 14 TPD of emission reductions (i.e., beyond BARCT equivalency)? The amount of construction activity for modification of existing SCRs will be different than the activity needed for entirely new SCR installations. The Draft PEA must be revised to fully disclose the technical basis of this analysis so the public can understand whether the impacts presented are complete.	2-81
Page 4.2-13, last paragraph Combined Construction Emissions From Non-Refinery and Refinery Facilities	The Draft PEA notes "…it is likely that only minimal, if any, construction activities would occur at any refinery facilities during 2016." This is exactly why the Staff proposal to remove four (4) TPD of RTCs in 2016 is too much, too fast. Staff has provided no evidence to support that supposition that the RECLAIM market has "enough cushion to support reduction of four tpd in 2016."	2-82
Page 4.2-18, 1st paragraph	The Draft PEA states "Implementation of the proposed project is expected to result in direct air quality benefits from the reduction of 14 tons per day of NOx RTCs by 2022. Because of the RECLAIM market system, the actual reduction in NOx emissions each year may be less than the reduction in RTC holdings imposed by the project." This statement conflicts with Page 1-1, 4th paragraph. Please see our comment to that prior statement.	2-83
Page 4.2-20, Refinery Facilities	This section presents impacts from operation of the proposed project for refinery facilities in the South Coast air basin. The Draft PEA does not disclose the assumed basis for these impact estimates. Are these impacts based on operation of emission controls to deliver 8.79 TPD (i.e., BARCT equivalency), or has Staff assumed operations sufficient to deliver the proposed 14 TPD of emission reductions (i.e., beyond BARCT equivalency)? The Draft PEA should be revised to explain the basis of the technical analysis so the public can understand whether the impacts presented are complete.	2-84
Page 4.2-22, 1st paragraph	The Draft PEA states "Ammonia slip is limited to five parts per million (ppm) by permit condition." This is an oversimplification since some existing SCRs are permitted with higher ammonia slip limits. These existing units may not be required to open their permits, in which case they could continue to operate with higher than 5 ppmv ammonia slip performance. Furthermore, the Draft PEA analysis of ammonia slip for new SCR installations depends on physical conditions which the Staff analysis explicitly omitted from the project description (e.g., use of Ammonia Slip Catalysts or ASC) despite recommendations by the AQMD's third-party expert, Norton Engineering, to use ASC.[31] Without the ASC, ammonia slip from individual devices could be as great as 20 ppmv, but the draft PEA underestimates the ammonia slip by assuming it will universally be 5 ppmv. However, existing SCRs are not necessarily subject to those permit	2-85

[31] Draft Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), 15 August 2015. See Table 2-3.

16

	conditions, and thus, ammonia slip of up to 20 ppmv should be considered in the health risk assessment for ammonia emissions.[32] The Draft PEA should be revised to more accurately reflect the range of ammonia slip conditions which could exist. Importantly, the screening Health Risk Assessment results presented in the Draft PEA would need to be revised to reflect that broad range of ammonia slip performance.	2-85 Con't
Section 4.2.4, Cumulative Air Quality Impacts	The Draft PEA does not discuss the potential secondary impacts on air quality associated with increased emissions of ammonia from the numerous SCRs mandated by this rulemaking. Ammonia is a precursor to PM2.5 formation for which the South Coast AQMD is in nonattainment, so the PEA should consider whether additional ammonia emissions would represent a cumulatively considerable impact.	2-86
Page 4.2-26, 1st full paragraph	The Draft PEA states "…based on regional modeling analyses performed for the 2012 AQMP, implementing control measures contained in the 2012 AQMP, in addition to the air quality benefits of the existing rules, is anticipated to bring the District into attainment with all national and most state ambient air quality standards by the year 2023." This statement is at best incorrect. A significant portion of the control strategy presented in the 2012 AQMP was still 182(e) "black box" measures which have not been defined.	2-87
Chapter 5, Alternatives	In this section, the Draft PEA presents 5 alternatives to the proposed project, but except for Alternative 4 (No Project) and Alternative 3 (Industry Approach), all other alternatives propose 14 TPD or more of NOx emission reductions. Given that the proposed project has remaining significant environmental effects with the proposed project at 14 TPD, the failure to include any additional alternatives other than Alternative 3 (Industry Approach) at a lesser reduction of NOx emissions does not satisfy CEQA's requirement for a "reasonable range of alternatives." In addition, the Draft PEA repeatedly claims that the impacts from the alternatives are "not quantifiable" for unspecified reasons. But these figures are not unknowable. In most cases, Staff could have easily made bounding or other technical assumptions to complete the quantification to allow the public to understand how the impacts from the alternatives compare to the Staff's proposed project. The Draft PEA must be revised to include this additional technical detail.	2-88

SUBJECT: WSPA COMMENTS ON APRIL 29, 2015 SCAQMD NOX RECLAIM WORKING GROUP MEETING

Dear Dr. Wallerstein:

The Western States Petroleum Association (WSPA) is a non-profit trade association representing twenty-six companies that explore for, produce, refine, transport and market petroleum, petroleum products, natural gas and other energy supplies in California, Arizona, Nevada, Oregon, and Washington. WSPA-member companies operate petroleum refineries and other facilities in the South Coast Air Basin that are within the purview of the Regional Clean Air Incentives Market (RECLAIM) program.

On May 15, 2015 we submitted a letter specifically focused on the District's shave approaches under consideration and strongly confirmed our support of an equally distributed "across-the board" reduction in RECLAIM NOx credits. This letter provides additional comments on the remaining proposals presented by Staff on April 29, 2015 during the NOx RECLAIM Working Group meeting. We highlight our key issues below.

2-89

Incremental Best Achievable Retrofit Control Technology (BARCT) Method as a CEQA Alternative

WSPA is a part of the Industry RECLAIM Coalition, and we have presented an alternative formula to determine the size of the shave. The Coalition believes our alternative method is consistent with the Health & Safety Code provisions for a market-based system; reflects advances in emission control technology; achieves real emission reductions; more than fulfills the commitments made in the 2012 Air Quality Management Plan (AQMP); preserves the successful RECLAIM program; and achieves all the above in a more cost-efficient manner than the District's Remaining Emissions proposal.

On January 30, 2015, the Coalition submitted comments on the Notice of Preparation and Initial Study (NOP/IS) for a Draft Program Environmental Assessment (PEA) requesting that at least two project alternatives be considered. Based on the information presented at the April 29, 2015 working group meeting, and subsequently with the document released on May 15, 2015 entitled, "SCAQMD NOx RECLAIM Proposed Shave Approaches", WSPA reiterates this request. The May 15th document only addresses how a 14.85 RECLAIM Trading Credits (RTC) reduction could be implemented. WSPA requests that the PEA include alternative emissions reductions, including the proposed Industry alternative approach, currently estimated at 8.8 tpd based on the District's most recent BARCT determinations. We believe the Incremental BARCT method recognizes the importance and economic value of the allowance market and, hence, must be included for an adequate Staff and CEQA analysis.

WSPA requests that the SCAQMD include an analysis of the Industry Coalition's Incremental BARCT method in the Draft PEA when it is published in the coming months. As the Initial Study acknowledges, the Draft PEA must discuss and compare a reasonable range of alternatives, in addition to the proposed project. Alternatives must be feasible as defined by CEQA (CEQA Guidelines § 15364) and must attain the basic objectives of the proposed project and avoid or substantially lessen adverse environmental impacts of the project as proposed (CEQA Guidelines § 15126.6). *See also City of Long Beach v. Los Angeles Unified School Dist.* (2009) 176 Cal.App.4th 889, 920. The lead agency bears the burden of adequately presenting and analyzing alternatives. *See Laurel Heights Improvement Assn. v. Regents of University of California* (1988) 47 Cal.3d 376, 405. The CEQA document must provide an "in-depth discussion of those alternatives identified as at least possibly feasible." *See Preservation Action Council v. City of San Jose* (2006) 141 Cal.App.4th 1336, 1350; *Sierra Club v. County of Napa* (2004) 121 Cal.App.4th 1490.

The Incremental BARCT method would result in RTC reductions greater than the approved SCAQMD control measures, but would lessen significant impacts from compliance with the District's proposed shave methodology. The Initial Study identifies numerous potentially significant impacts associated with the installation and operation of emission control equipment as required by the project as proposed. These include impacts to aesthetics (visual impacts of control equipment), air quality and greenhouse gases (increased construction emissions from NOx control equipment installation; operational emissions from control equipment and its support equipment, and from trucks delivering supplies and hauling waste), energy (energy demand for construction and operation of control equipment), hazards and hazardous materials (use and transport of catalysts and scrubbing agents used by control equipment, in particular use of acutely hazardous ammonia in SCR and SNCR technologies), hydrology and water quality (risk of spills of toxic chemicals including ammonia), solid and hazardous waste (solid and hazardous waste generation from construction activities), and transportation and traffic (from truck trips associated with construction activity). The Incremental BARCT method can achieve basic project objectives while reducing these impacts, and so should be fully evaluated as a reasonable and feasible alternative in the forthcoming PEA.

2-89
Concluded

2

Alternatives also must be feasible, and one of the elements of "feasibility" as defined by CEQA is economic feasibility (CEQA Guidelines § 15364). The Incremental BARCT method constitutes a feasible alternative that would avoid or reduce the excessive costs of the project as proposed. The District's shave methodology not only includes a reduction in allowances due to a BARCT assessment for new technology, it also removes a considerable amount of allowances beyond what is justified by BARCT advancement. Staff's graph entitled, "BARCT Costs for Refinery Sector", estimated BARCT costs for all five categories of refinery equipment to be $741 million for 6.06 tons/day of NO_x reductions with an average cost of $13,200 per ton of NO_x reduced using the discounted cash flow (DCF) method. However, Staff did not include the cost of reductions for the approximately 6 tons of RTCs that are shaved beyond BARCT. WSPA regards this omission as a significant issue that must be addressed by the SCAQMD Staff analysis and in the CEQA analysis of the proposed project in comparison to alternatives. Simply ascribing zero costs to the additional 6 tpd market shave beyond BARCT is not appropriate. On the contrary, given that the cost of achieving the first 6.06 tpd of NOx reductions is $741 million, the cost of an additional 6 tpd increase must be substantial. If the District has data indicating that the additional 6 tpd could be achievable at a reasonable and feasible cost, it is the District's burden to provide that information and incorporate it into both the CEQA alternatives analysis and the analysis of cost effectiveness. 2-90

<u>Shave Methodology and Estimation</u>

Concerns with the District's method and costs estimates include:

- The District's 2023 remaining emissions calculation includes a growth factor for the non-refinery sectors, BARCT adjustments for shutdown glass facilities and from the CPCC (after BARCT adjustment with growth), remaining emissions from new facilities from the 2005 NO_x RECLAIM amendments, and a 10% adjustment factor applied to refinery, non-refinery, and new facility emissions only. WSPA recommends that a more appropriate compliance margin is 30% or 3.08 tpd. This amount is consistent with the historical unused RTC trend that ranged from 5.1 tpd to 9.1 tpd between 2005 and 2013.[1]
- WSPA recommends that the RTCs derived from ERC conversions be exempted from the proposed shave. According to SCAQMD's 1996 annual RECLAIM audit report, the original RTC amount is 2.6 tpd[2]. With the adjustment for the 2005 shave, the amount for the exemption proposed is 2.01 tpd (i.e. 7.6% of the current RTC market).
- The October 2013 AB 1318 Air Resources Board draft final report[3] stated on page 65 (Table II-5) that the estimated offset needs for once-through cooling power plant replacements and new greenfield generation are 8.23 NO_x tons/day. This does not appear to be included in Staff's adjustment factors. How will the District accommodate the 8.23 tons/day requirement with the approximately 2 tons/day allowance shown for power providers?

---

3

Useful Life of Control Equipment

Abt Associates recently conducted a third-party review of the District's socioeconomic assessment process[4] and recommended that AQMD "appropriately consider useful life of pollution control equipment" to "ensure that compliance deadlines are set such that control equipment is not required to be replaced before end of useful life." In response to this finding, SCAQMD Staff committed to consider equipment life on a case-by-case basis, attempt to avoid stranded assets, and in cases of stranded assets, include equipment replacement costs and salvage values in the socioeconomic analysis.[5]

SCAQMD Staff stated at the Working Group meeting[6] their intention to estimate a useful life of 25 years for the BARCT control equipment review for all source categories under this rulemaking (i.e., refinery and all non-refinery sources). While we agree that certain **emission control equipment** may in theory have a useful life of 25 years, we believe that the economic useful life is more appropriately linked to the adoption frequency of new **control measures.** The regularity with which regulations are being promulgated indicates that the appropriate useful life of an SCR is more likely on the order of 10 years. WSPA's analysis also includes review of other Air Districts in California that support our recommendation.

For example, although Staff presented the Bay Area's useful life of 20 years, this is based only on a rule currently in development. The Bay Area's current BACT Guidelines actually recommend 10 years[7]. Additionally, both the San Joaquin Valley[8] and San Diego County[9] use 10 years. In fact, the South Coast's own Best Available Control Technology Guidelines[10] (BACT) recommends a 10 year useful life.

Staff stated that useful life is solely based on actual equipment life and not economic life. The Staff position does not take into consideration the regularity with which new rules are promulgated and the significant impact that using the 25-year period has on the District's cost effectiveness calculation. By using the District's recommendation for useful life, the costs are amortized over 25 years, rather than recognizing the fact that the last shave was in 2005, and control equipment can potentially be required to be replaced well before 25 years. The useful life of the equipment is simply not relevant when AQMD rulemaking necessitates the upgrade or replacement of equipment on an earlier timetable. In fact, both a useful life of 10 years (non-refinery) and a useful life of 25 years (refinery) were used during the 2005 shave. Therefore, WSPA recommends that Staff recommend a 10-year useful life for Selective Catalytic Reduction (SCR) control equipment. Staff should also include in their CEQA analysis the cost 2-91

4

effectiveness evaluation using a 10-year period[11]. Because SCAQMD is ultimately responsible for making findings and determinations as to the proposal's feasibility, as well as the feasibility of other alternatives, this cost-effectiveness analysis is critical to the CEQA analysis. *See Preservation Action Council v. City of San Jose* (2006) 141 Cal.App.4th 1336, 1356; *see also Flanders Foundation v. City of Carmel-by-the-Sea* (2012) 202 Cal.App.4th 603, 618. 2-91 Concluded

Emission Reductions and Remaining Emissions

Staff presented two tables at the April 29, 2015 Working Group that detailed the emission reductions and remaining emissions for the refinery sector, power plants and non-power plants. Minor changes were noted in the refinery sector and non-power plant sector, however, modifications to the growth factor and base year for the power sector significantly reduced the 2023 Emissions at 2015 BARCT for that category. WSPA requests the data supporting these modifications.

BARCT Costs for the Refinery Sector and Cost Effectiveness Summary

- Staff indicated that they disagreed with the cost data and conclusions from their third party engineering consultant, Norton Engineering. Specifically, the SCR equipment costs were based only on one data point from one refinery and the recommendation was for double the SCR catalyst. As a result, Staff indicated that they dismissed the data and instead used their own cost data derived through their own analysis (i.e. field data for SCR installations, discussions with vendors, and literature reviews). WSPA is troubled by the selective dismissal of the third party engineering analysis which is meant to assure a reliable and transparent process during rulemaking. Additionally, while we appreciate the discussion provided at the April 29, 2015 Working Group, there are several unresolved questions. They are:
    - Since the dismissed cost data will impact a specific engineering recommendation (i.e. length of catalyst beds), how will performance be guaranteed to meet the new BARCT levels proposed?
    - What are the specific cost details that were modified and how does that impact cost effectiveness?
    - How will third party evaluations be treated in the future to ensure a transparent process?
- WSPA met with Staff on April 10, 2015 to discuss the BARCT assessment for refinery heaters & boilers and explained that we believe the District has miscalculated the cost effectiveness for a number of refinery heaters. Specifically, there were 10 heaters in the Staff's BARCT analysis tables dated 2 February 2015[12] where the cost effectiveness of proposed BARCT was analyzed based on an inappropriate cost baseline. That cost baseline assumed the presence of SCR technology where prior BARCT determinations had not been based on SCR technology. Correction of this error would render most of these units not cost effective. Furthermore, if the Staff disregard the conclusion from the Norton's third-party

5

expert report (as suggested to WSPA on 10 April), nearly 40 units would be impacted by this analysis error.[13]

- In reviewing the BARCT costs for the Refinery Sector presented at the Working Group, we are unable to discern if Staff considered our request for changes as outlined in our April 22, 2015 letter. Therefore, WSPA requests the data used to compile these costs.
- At the April 10, 2015 SCAQMD – WSPA meeting, we also discussed various other issues we have with the Staff's NOx RECLAIM shave proposal. One of the topics included the Staff's use of the discounted cash flow (DCF) method instead of the levelized cash flow (LCF) method as used by several other Air Districts. Staff did provide the LCF analysis as a comparison to the DCF method at the Working Group. WSPA believes that the LCF method is a better representation of cost effectiveness than the DCF method. Accordingly, WSPA recommends that the LCF method be used for the rule as well as the same cost effectiveness threshold of $50,000/ton (as currently indicated for the DCF method).

<u>Preliminary BARCT Analysis</u>

- WSPA understands that BARCT should represent a level of performance which is technically feasible and cost effective for most units on a retrofit basis in a given source category. Based on the data provided to the Working Group by Staff, it does not appear that 2 ppm is an acceptable BARCT determination for refinery heaters and boilers. The data provided by Staff and confirmed by a confidential WSPA survey[14], conducted by a third party contractor, suggests that less than 6.5% of the existing refinery heaters and boilers which have been retrofitted with SCR technology, are currently performing at or below 2 ppm[15]. This includes a number of units which had been retrofitted in recent years. This does not represent a considerable proportion of the units in this source category. (In fact, only 3.5% of new installations can meet 2 ppm).
- WSPA recommends that 5 ppm is a more appropriate endpoint for refinery boilers/heaters because of the following reasons:
  - Currently, there are 87 installed SCRs of the 212 total boilers and heaters[16]. As noted above, WSPA's confidential survey indicates that only two of the four heaters that SCAQMD identified as performing below 2 ppm NOx are retrofitted units (i.e. with SCR). This represents only 6.5% of the total retrofitted units (31 units). Additionally, only one more retrofitted unit performs between 2 ppm and 5 ppm.
  - As presented by combustion expert, Rich Smirnoff at our April 10, 2015 meeting[17]:
    - Current commercial burner technology typically produces 16-20 ppm NOx @ 3% O2 in ideal furnace conditions, as in burner test furnaces, with single burners. A target NOx reduction of 90% may not be sufficient if the heater produces 30 ppm NOx.

[17] "Refinery Fired Heaters, NOx Emissions Reductions Retrofit Limitations", presented by Rich Smirnoff, April 10, 2015 at WSPA-AQMD meeting.

6

  - When burning natural gas, the fuel heating value is constant and furnace adjustments can be set with minimal difficulties. However, when burning refinery gas, the heating value will vary significantly.
- The NEC report, as represented at the January 2015 SCAQMD NOx RECLAIM Working Group meeting, indicates that 5 to 10 ppm NOx is feasible for calciner sources. However, given that the technology is unproven in a calciner situation, WSPA recommends that even a higher BARCT endpoint than 10 ppm may be warranted.

Energy Efficiency Projects

Staff presented a slide on Energy Efficiency Projects that stated there could be an additional 0.7 tpd NOx reductions from energy efficiency projects completed from 2007, yet not included in the inventory baseline. WSPA opposes any attempt to include this additional tpd as the projects and benefits reported under the energy efficiency and co-benefits reports would have been largely, if not entirely, reflected in the 2011 emissions baseline being used for this rulemaking. In short, any co-benefits contained in those reports are not additive.

Thank you for considering the comments addressed in this letter. We look forward to continuing to work with you and your Staff on this important rulemaking.

Sincerely,

Suzanne E. Bornicki

SUBJECT: WSPA COMMENTS ON PRELIMINARY DRAFT STAFF REPORT (PDSR) FOR NOX RECLAIM AMENDMENTS DATED JULY 21, 2015

Dear Dr. Fine:

The Western States Petroleum Association (WSPA) is a non-profit trade association representing twenty-five companies that explore for, produce, refine, transport and market petroleum, petroleum products, natural gas and other energy supplies in California, Arizona, Nevada, Oregon, and Washington. WSPA-member companies operate petroleum refineries and other facilities in the South Coast Air Basin that are within the purview of the Regional Clean Air Incentives Market (RECLAIM) program.

WSPA and the Industry RECLAIM Coalition (of which we are a member) have submitted several comment letters during this rulemaking process to request changes to the District Staff's proposal that we believe are necessary to preserve a healthy and successful RECLAIM program for all RECLAIM participants, as well as to satisfy the 2012 AQMP commitments to the State Implementation Plan (SIP) and USEPA. We have not yet received written responses to these comments. Nevertheless, we appreciate the opportunity to provide this letter to reiterate our previous concerns, and to discuss new issues arising from the PDSR.

Below are the highlights of our major concerns. More detailed comments are included in Attachment 1, attached hereto and incorporated herein by reference.

I. Shave Methodology and Arbitrary Removal of Unused RECLAIM Trading Credits (RTCs)

The District's Remaining Emissions method for calculation of RTC reductions conflicts with the CMB-01 Phase 1 and Phase 2 Control Measures as approved under the 2012 AQMP. The District's Remaining Emissions method would remove nearly all Unused RTCs from the RECLAIM market even though CMB-01 Phase 1 had explicitly considered and rejected such a reduction, instead determining that a 2 tpd reduction of Unused RTCs was more appropriate.[1] Additionally, the Incremental BARCT method proposed by the Industry RECLAIM Coalition is more consistent with Control Measure CMB-01 Phase 2 as approved under the 2012 AQMP because this method removes only those RTCs directly attributable to technology advancement (i.e., BARCT).[2]

Further, the proposed Compliance Margin of 10% may be inadequate to meet the market's historical need for Unused RTCs. Unused RTCs may be needed for several reasons, including facility-level compliance margins, which vary depending on facility size and/or risk tolerance; RTC holding requirements imposed under Rule 2005; and market liquidity, to name a few. These Unused RTCs have historically averaged in the 15-30% range (approximately 5 to 9 tpd), with the sole exception being the RTC market crisis during the 2000 compliance year. The AQMD Staff's proposal, which includes only a 10% compliance margin, appears to be inadequate for satisfying this market requirement. Hence, WSPA recommends that Staff adopt the Incremental BARCT method as their preferred proposal.

While the proposed, limited RTC adjustment account may help certain Power Sector facilities subject to Rule 2005 New Source Review (NSR) RTC holding limit requirements, it does not resolve the holding requirements applicable to many current and future non-power facilities. It is recommended that any RTC adjustment account be accessible to all RECLAIM participants subject to the Rule 2005 NSR RTC holding requirement. WSPA also recommends that Staff provide technical justification to support the quantity of RTCs set aside to fund any such adjustment account. Finally, WSPA recommends that USEPA approval of the NSR set aside concept be obtained in writing prior to adoption of the rule amendment.

II. Shave Application and Implementation Schedule

Any NOx RECLAIM shave should be applied in an equally distributed "across-the-board" manner consistent with RECLAIM founding principles[3] and the precedent set under the 2005 NOx RECLAIM shave. In addition, the proposed schedule should be consistent with the 2012 AQMP commitment to the State Implementation Plan (SIP) which was 2 tpd in the first year; anything larger may not allow sufficient time for industry to implement emission control projects necessitated by the rulemaking.[4] Since RECLAIM is tied to BARCT (as discussed in more detail below), the lack of sufficient lead time means that the proposed shave goes beyond

[1] SCAQMD, 2012 AQMP. Page 4-9 states: "The control measure will seek further reductions of 2 tpd of NOx allocations if triggered." Appendix A, page IV-A-13 presents rationale for that conclusion.
[2] SCAQMD, 2012 AQMP. Page 4-26 states: "This phase of control is to implement periodic BARCT evaluation as required under the state law." Appendix A, page IV-A-60 presents more detailed discussion for the measure.
[3] SCAQMD, Staff Report for Proposed Amended Regulation XX – RECLAIM, January 2005, Executive Summary.
[4] WSPA-SCAQMD letter, July 14, 2015.

BARCT and that RECLAIM will not achieve equivalent or greater reductions than BARCT at equivalent or lesser cost. Therefore, the shave implementation schedule should be "back-loaded" to accommodate a longer, more realistic project implementation period with at least 2 of the proposed 4 tpd (currently being proposed for 2016) being moved to 2019 or later. We are not recommending additional annual increments at this time, since the final shave amount has not been finalized.

III. Useful Life of Control Equipment

The proposed Useful Life of 25 years is inappropriate because AQMD rulemaking is far more frequent, with the prior major NOx RECLAIM rulemaking occurring only 10 years ago. Use of a 25 year assumption makes the rule costs appear lower than they actually are by diluting the significant capital costs of required projects over a much longer time table than is likely to occur. The Staff analysis should be revised to reflect the 10-year Useful Life assumption, which is more consistent with recent SCAQMD rulemaking schedules and is also consistent with the Useful Life assumption typically used by CARB and other major Air Districts.

IV. BARCT Analysis

There is a statutory requirement that RECLAIM achieve equivalent or greater emission reductions than command and control at equivalent or lesser cost.

Command and Control Regulation Would Require BARCT of the Refining Sources Subject to RECLAIM: The District is required to adopt rules and regulations implementing the AQMP.[5] Among other things, these rules and regulations must require BARCT for existing sources.[6] In rulemaking addressing existing sources outside of RECLAIM, SCAQMD is mandated to require BARCT. Because of the mandate to require BARCT on all existing sources, it is fair to say that current command and control regulations and future measures adopted as part of the plan would at least be equivalent to BARCT. In the absence of a market-based mechanism (cap-and-trade program) such as RECLAIM, SCAQMD would adopt a rule requiring source-specific BARCT for each of the sources covered under RECLAIM.

The Proposed Shave Appears to Include an Additional 5.21 Tons per Day Beyond BARCT: The proposal set forth by the District indicates that the proposed BARCT would result in a reduction of 8.79 tpd of NOx from 2011 emissions at 2000/2005 BARCT. As described above, RECLAIM must achieve emission reductions equivalent to or greater than traditional command and control, or BARCT. Thus, a NOx shave equivalent to BARCT (which the District proposes at 8.79 tpd) would be the level for comparison with the Health and Safety Code provision stating that equivalent or greater reductions would be achieved at "equivalent or less cost compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the District's plan for attainment." Yet, SCAQMD does not seek merely its determined BARCT equivalency level of 8.79 tpd; it seeks 14 tpd of NOx reductions and has not demonstrated that such reductions will be achieved at equivalent or lower cost than

[5] Health & Saf. Code § 40460.
[6] Health & Saf. Code § 40440.

BARCT. The additional 5.21 tpd reduction goes above and beyond BARCT. Such a severe reduction is not essential to compliance with the statute.

SCAQMD Needs to Demonstrate that Achieving This Additional 5.21 Tons per Day Would Be Less Costly than Achieving BARCT on a Source-by-Source Basis in the District: The Health and Safety Code requires RECLAIM to achieve at least equivalent reductions as traditional command and control at an equivalent or lesser cost.[7] While the draft staff report does provide a cost accounting for BARCT, that accounting (which we believe to be understated) only covers 8.79 tons of the 14 ton per day shave. The draft staff report does not even mention, let alone provide detailed discussion of, the costs associated with the additional 5.21 tons per day being required by the proposed rule. Because the Legislature has required RECLAIM to impose costs less than or equal to command and control regulation (i.e., BARCT), and BARCT only makes up a portion of the proposed shave, the remaining reductions which are in excess of BARCT will cost more than BARCT. The costs related solely to BARCT are substantial with refinery costs over $900 million.[8] Costs associated with the additional 5.21 tpd reduction will only increase that figure in a substantial manner. The District must include the cost figures for the additional shave amount and justify imposing these reductions under the statutory standard of achieving command and control levels at equivalent or lower costs. It is simply not reasonable to exclude such a relevant factor from consideration.

V. NEC Study

The BARCT analysis for Refinery Sector categories should be revised to explicitly consider the findings presented in Norton Engineering Consultants' (NEC) BARCT Feasibility and Analysis Review.[9] NEC is a third-party expert hired to confirm the Staff's technical analysis in support of this rulemaking. Following the issuance of the PDSR, however, NEC responded to SCAQMD in an August 10, 2015 letter (see Attachment 2) to "clarify the most glaring misstatements/misunderstandings of the information [NEC] provided to the District." By selectively dismissing the third-party expert's findings, without resolution of the technical issues in dispute, Staff has compromised the process and the results of that process. It is unacceptable to arbitrarily reduce the overall shave by 0.85 tpd to resolve the differences in technical assumptions. For example, if the Staff disregards the conclusion from the NEC's third-party expert report, nearly 40 operating units would be impacted by this analysis error.[10] Furthermore, any adjustment that may be justified on a technical basis should be applied to the sector where the actual BARCT reduction occurs and not to the total shave reduction (i.e., Staff's proposed adjustment of 0.85 tpd should be applied to the Refinery Sector's BARCT reduction).

While WSPA understands that BARCT should represent a level of performance that is technically feasible and cost-effective for most units on a retrofit basis in a given source category, the District's assumptions regarding the feasibility of achieving the BARCT levels are

[7] Health & Saf. Code § 39616(c)(7).
[8] SCAQMD, *Preliminary Draft Staff Report, Proposed Amendments to Regulation XX Regional Clean Air Incentives Market (RECLAIM) NOx RECLAIM* (Draft NOx RECLAIM Staff Report), p. 23. (July 21, 2015)
[9] Norton Engineering Consultants (NEC), SCAQMD NOx RECLAIM – BARCT Feasibility and Analysis Review, Non-Confidential Final Report No. 14-045-4, 26 November 2014.
[10] SCAQMD, Preliminary Analysis – Refinery Boilers/Heaters, July 2014 (posted on AQMD website October 2014).

not supported by evidence that the units in question can achieve 2 ppm NOx. In fact, the data provided by Staff (Appendix B of the PDSR) indicates that only 4 of the 76 installed SCRs in the boiler and heater category are currently performing below 2 ppm. This alone suggests that the proposed BARCT is not representative. Even more, in a confidential WSPA refinery survey,[11] conducted by a third party contractor, only 2 of the 4 are retrofits. This does not represent the necessary proportion of the units in this source category.

The draft staff report proposes 2015 BARCT levels of 2 ppmv of NOx for FCCUs, refinery heaters and boilers greater than 40 mmbtu/hr, gas turbines, and sulfur recovery unit tail gas incinerators. While the District justifies these levels based on an assumption that all refinery equipment can reach such levels, the draft staff report says otherwise. With respect to refinery heaters and boilers, very few of the existing refinery heaters and boilers already equipped with SCR are able to meet 2 ppmv of NOx. In fact, as stated in the draft staff report, of the 212 refinery boilers and heaters classified as major and large NOx sources, 14 heaters using refinery fuel gas have achieved 1.6-3.5 ppmv NOx, two boilers using natural gas have achieved 2-5 ppmv NOx, and a crude heater using refinery fuel gas achieved 3-8 ppmv NOx. Apart from some unknown percentage of the 14 process heaters, none of these sources already employing the control technology on which the BARCT level is based (SCR) have shown an ability to reduce emissions below 2 ppmv NOx. Accordingly, the District has not shown that a BARCT level of 2 ppmv NOx is achievable over the broad spectrum of refinery heaters and boilers subject to the proposed amendments. Therefore, 5 ppm is a more appropriate endpoint for refinery boilers/heaters.

The same is true with respect to FCCUs. The District proposes a 2015 BARCT level of 2 ppm NOx based on the ability of one FCCU achieving the proposed level. As explained by the District's consultant, of the three FCCUs currently operating with SCRs, only one of them achieves less than 2 ppmv NOx.[12] Again, achievability in one unit does not guarantee similar performance in other units, particularly units that have been operating under different conditions for many years. Each refinery has unique circumstances such as equipment type, age, and configuration that factor into its ability to achieve the proposed emission levels. Thus, what may be achievable for one piece of equipment may not be for another. Further, while there may be controls available with the ability to achieve the proposed level of performance, such control may come at a cost that is unreasonable. The District has not shown that the proposed levels can be achieved across the board in a cost effective manner. As a result, and to be consistent with the statutory obligations, the District needs to reconsider and revise the proposed BARCT levels to ensure that they are achievable by a more representative percentage of the sources subject thereto.

VI. Costs and Cost Effectiveness

Exclusion of the NEC cost estimates results in an inappropriate minimization of the estimated Refinery Sector costs presented in the PDSR. It also inflates the presented emission reductions estimate for the Refinery Sector. The BARCT analysis should be revised to explicitly reflect the

[11] WSPA/ERM confidential survey of WSPA members concerning refinery heaters/boilers, March 2015.
[12] Norton Engineering, *Comments on Preliminary Draft Staff Report Proposed Amendments to Regulation XX Regional Clean Air Incentives Market (RECLAIM) NOx RECLAIM-SCRs for FCCUs Document No. 14-045-7* (August 10, 2015).

NEC cost estimates for Refinery Sector categories. Additionally, use of the Discounted Cash Flow (DCF) method along with interest rate and useful life assumptions make estimated costs for this rulemaking appear less expensive than they would be under the Levelized Cash Flow (LCF) method used by CARB and most other major Air Districts. WSPA believes that the LCF method is a better representation of cost effectiveness than the DCF method and recommends it be used. The same cost effectiveness threshold should be used for both DCF and LCF methods. Staff has used a higher cost threshold for LCF in the past than they used for DCF, so that the differences between the two methods are diluted.

The proposed $50,000 cost effectiveness threshold is greater than the AQMD's DCF cost effectiveness threshold for Command-and-Control sources in South Coast. Under the 2012 AQMP, the approved cost threshold for NOx control measures was $22,500 per ton,[13] and AQMD's current Best Available Control Technology (BACT) guidance document presents a cost effectiveness threshold that is only $19,100 per ton.[14] Also, the Health & Safety Code requires that market-based program costs be "equivalent or less compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the district's plan for attainment" and "the program will not result in disproportionate impacts, measured on an aggregate basis, on those stationary sources included in the program compared to other permitted stationary sources in the district's plan for attainment." [H&SC 39616(c)(1) and (7)]. Staff has not demonstrated that these legal obligations are satisfied. Therefore, WSPA recommends that the PDSR analysis be revised with the cost effectiveness threshold not greater than $22,500 (i.e., the cost effectiveness threshold used in the 2012 AQMP).

Further, the draft staff report understates the actual costs associated with meeting the proposed BARCT levels. As the District has done in past rulemakings, it hired NEC to provide reviews and recommendations on the analysis developed by SCAQMD as it relates to the technical feasibility of the control options as well as the cost effectiveness of each option. After gathering information from onsite visits to six of the refineries, NEC provided the District with a comprehensive evaluation of costs of each control option, the size and space needed for the equipment, and the time needed to install the control technologies. The District, however, chose to use different cost estimation approaches, opting to selectively disregard its own consultant's evaluation. This information was site specific and should be considered more credible than the District's generic evaluation of costs. It is a hallmark of reasoned decision-making that an agency use the most accurate available information.

Apart from WSPA's concern relating to the dismissal of NEC's evaluation, the District's estimates do not include all of the costs that are required to be considered, and therefore vastly understate the cost impacts of the BARCT proposed. It appears that installation, design, and engineering costs have not been included properly. Moreover, it is critical to recognize that each refinery is unique such that BARCT levels achievable and cost effective at one refinery may not be at another. Plant configuration, equipment type, equipment age, length of time the SCR must remain in service and consistently achieving emission reduction targets between maintenance opportunities (most FCCUs, heaters, and boilers operate for years at a time, 24 hours per day and

[13] SCAQMD, 2012 AQMP, December 2012, pages 4-43.
[14] SCAQMD, BACT Guidelines, Part C: Policy and Procedures for Non-Major Polluting Facilities, 2006.

7 days per week), and composition of fuel, are a few of the factors in play with determining the costs associated with achieving the proposed levels. For example, some refinery configurations such as processes that utilize dual stacks, may require more than one SCR, and thus greater expenditures (i.e., double), to achieve the proposed level. It does not appear that such a scenario was considered by the District in developing its cost effectiveness determinations.

Accordingly, WSPA believes that the District's cost effectiveness calculations significantly understate the costs associated with achieving the proposed BARCT levels. We believe that even the Norton analysis underestimates actual costs. WSPA is currently developing additional information based on detailed engineering assessments that more accurately represent the costs associated with the proposed BARCT. We will submit this information to the record as it becomes available.

VII. Disproportionate Impacts

Under Health and Safety Code Section 39616(c)(7), the District must show that RECLAIM facilities are not being disproportionately impacted by participating in the program.[15] The draft staff report, noting the emission projections described in the 2012 AQMP, indicates that RECLAIM sources make up 37 percent of the projected NOx emissions for 2023 from stationary sources.[16] Table 2.1 of the draft staff report indicates that non-RECLAIM sources, including waste disposal and miscellaneous processes, will account for 46 tons per day of the annual average NOx emissions for the 2023 base year while RECLAIM sources (pre-shave) will account for 27 tons per day.[17]

In its proposal, the District is seeking substantial reductions from RECLAIM sources, the majority of which come from the nine refineries in the Basin. Nonetheless, there is nothing in the draft staff report or other proposal document that indicates what reductions will be required for non-RECLAIM facilities. In fact, there is no evidence presented that would lead the Board to make a finding that RECLAIM facilities are not taking the brunt of the load when it comes to requiring emission reductions. The District has failed to provide "appropriate information" to "substantiate" a finding of no disproportionate impact.

Indeed, for the Board to make such a finding, there must be evidence indicating that non-RECLAIM facilities are, on an aggregate basis, required to reduce their NOx emissions at the levels required by their RECLAIM counterparts (at least proportionately). Non-RECLAIM facilities represent the majority of the stationary NOx emissions, yet SCAQMD appears to be seeking *no* reductions from such sources. Barring appropriate information showing that non-RECLAIM sources are required to reduce emissions equivalent to what is proposed by these amendments, the Board cannot make the required findings and as a result, the proposed amendments violate the District's statutory mandate.

[15] Health & Saf. Code § 39616(c)(7).

[17] *Id.*

VIII. Energy Efficiency Projects

Staff suggests that there are NOx emission co-benefits available from Refinery Sector sources due to energy efficiency projects that are in addition to the projected emission reductions under this rule. This is essentially an erroneous assumption due to the fact that the AQMD is relying on information that was submitted under the California AB32 Energy Efficiency and Co-Benefits regulation and most of the projects that were presented by Refinery Sector facilities in those 2011 vintage reports were already completed. As such, those emissions benefits were already reflected in the 2011 baseline year emissions presented in the PDSR. AQMD Staff acknowledges as much in PDSR Table 3.2. As such, these co-benefit reductions should not be presented or characterized as a potential additional benefit.

IX. Socioeconomic Impacts

Under Health and Safety Code Section 40728.5, the District is required to perform an analysis of the socioeconomic impacts of the proposed regulation. This assessment is important because it lays out the range of probable economic impacts to the regulated industries as well as the impact on the economy of the region as a whole. Unfortunately, the socioeconomic impacts analysis is not available at this time. WSPA believes that reviewing the analysis is important to its ability to meaningfully comment on these proposed regulatory changes. Accordingly, WSPA may change or supplement its comments on review of the analysis when it is released.

Thank you for considering the comments addressed in this letter. We look forward to continuing to work with you and your Staff on this important rulemaking. WSPA reserves the right to file additional comments or other materials as this rulemaking progresses.

Sincerely,

Suzanne E. Gornick

ADDITIONAL COMMENTS ON PRELIMINARY DRAFT STAFF REPORT (PDSR) FOR NO_X RECLAIM AMENDMENTS

Page/Section	WSPA Comment
Page 2, Current Emissions and RTC Holdings.	AQMD should use 2012 compliance year emissions as the baseline year for "current emissions" for all industrial sectors. WSPA understands the rationale presented by AQMD for use of 2012 data to characterize baseline Power Sector emissions. However, non-Power RECLAIM facilities were also exhibiting lower output levels in 2011 due to the recession that started in 2007. This is shown in attached Figure 1. Looking at certain key industrial sectors yields a similar conclusion. On a sectoral level, publicly reported economic data (see Figure 2A and Figure 2B) shows that economic output and emissions for the cement and textile manufacturing sectors in AQMD were also still recovering from recessionary low points in 2011. For these reasons, WSPA recommends that AQMD revise the Staff Report to use 2012 compliance year emissions as the baseline emissions year for all industrial sectors.
Page 3: Table EX-1, Summary of Proposed BARCT (May 2015).	Table EX-1 presents data for the Refinery Sector which fails to reflect changes necessitated by the findings of the third-party expert hired to confirm the AQMD Staff's Refinery Sector technical analysis for this rulemaking. The Staff's BARCT analysis for the Refinery Sector categories should be revised to explicitly consider the findings presented in Norton Engineering Consultants' (NEC) BARCT Feasibility and Analysis Review.[1] The third-party experts were hired to confirm the AQMD Staff's technical analysis in support of this rulemaking. By selectively dismissing the third-party refinery sector expert's findings without resolution of the technical issues in dispute, AQMD Staff have compromised the rulemaking process. We also note that NEC has raised a significant number of technical issues with the conclusions presented in the PSDR for the Refinery Sector categories.[2] WSPA strongly suggests that these technical issues be resolved before further presentation of emissions reductions attributable to the proposed BARCT analysis.
Page 3. Last paragraph, 3rd sentence. Resolution of Uncertainties	WSPA recommends this section be re-written after the requested and required changes to the Staff's BARCT analysis have been completed. The subject paragraph suggests that Staff has "accounted for uncertainties that arose in the BARCT analysis…." We disagree. There continues to be a significant number of unresolved issues which result in uncertainty in the Staff analysis presented in the PDSR. This includes, but is not limited to the Staff's decision to selectively ignore the findings of the agreed upon third-party expert for the Refinery Sector.

[1] Norton Engineering Consultants (NEC), SCAQMD NOx RECLAIM - BARCT Feasibility and Analysis Review, Non-Confidential Final Report No. 14-045-4, 26 November 2014.
[2] James Norton, NEC, letter to Dr. Philip Fine, SCAQMD, Comments on Preliminary Draft Staff Report Proposed Amendments to Regulation XX Regional Clean Air Incentives Market (RECLAIM) NOx RECLAIM – SCRs for FCCUs Document No. 14-045-7, 10 August 2015.

Page 3. Last paragraph, 3rd sentence. Proposed Adjustment Account	The proposed "Adjustment Account" should be accessible by all RECLAIM facilities subjected to the Rule 2005 NSR RTC holding requirement. Furthermore, AQMD Staff should provide a technical rationale to support the quantity of RTCs set aside to fund any such adjustment account. The PDSR suggests the RTC demand caused by Rule 2005 RTC holding requirements are addressed by the proposed creation of an RTC Adjustment Account for power plants. However, the RTC holding requirements imposed under Rule 2005 are also applicable to many non-Power Sector facilities under RECLAIM New Source Review. The Staff's current proposal does nothing to address the RTC demand associated with these non-Power Sector facilities. This should be resolved.
Page 3. Last paragraph, 3rd sentence. Proposed Adjustment Account	AQMD Staff should provide a regulatory discussion detailing how this proposed Adjustment Account would be managed, and how RTCs in the account would be treated with respect the to the State Implementation Plan (SIP).
Page 3. Last paragraph, 5th sentence. Compliance Margin	WSPA recommends this section be re-written to eliminate potential misstatements concerning the level of "unused RTCs" that might be available under the Staff's proposed shave. The Staff's "Remaining Emissions" approach as presented in the PDSR limits the overall "Compliance Margin" for RECLAIM facilities to 10% of projected 2023 emissions (i.e., not 23%). The Staff's Remaining Emissions estimate excludes some RECLAIM market sectors (i.e., cement) which had reduced emissions in 2011 due to the major recession from which certain sectors were still recovering. Staff has made an adjustment to account for that omission, but this paragraph then suggests that such adjustment is part of the overall market's Compliance Margin. That is incorrect.
Page 4: 1st full paragraph. Application of Shave	The proposed NOx RECLAIM shave should be applied in an equally distributed, "Across the Board" manner consistent with RECLAIM founding principles and the precedent set under the 2005 NOx RECLAIM shave. RECLAIM is a market-based program which was designed to use "the power of the marketplace"[3] to reduce air emissions from stationary sources. This approach was expressly intended not to impose "command-and-control" requirements on specific facilities or specific equipment therein. Rather, RECLAIM was intended to provide Southern California businesses with greater flexibility and a financial incentive to reduce air pollution at least equal to what traditional command-and-control rules would have required. This program has been very successful in reducing NOx emissions with RECLAIM facilities having reduced their overall actual emissions well in excess of the program's current target under Regulation XX.

[3] SCAQMD RECLAIM website, http://www.aqmd.gov/home/programs/business/business-detail?title=reclaim.

	The District has previously considered and rejected targeted shaves as noted in the excerpts below: • Oct 1993, RECLAIM Program Summary: "Throughout the development of RECLAIM, the District evaluated several design options that would have treated some industries differently than others……After evaluating advantages and disadvantages, the District adopted a program that treats all sources consistently for equity and fairness." • 2005 Staff Report, Appendix E: "The Staff proposal is taking the "across-the-board" reduction of NOx RTC holdings approach by looking at the total reductions possible based on BARCT determinations and reducing allocations for all RTC holders by the same percentage…This approach, from a market design standpoint and based on the overall conceptual design of the RECLAIM program to achieve programmatic BARCT, is the most equitable…" The Staff proposal presented in the PDSR is inconsistent with the founding principles of the RECLAIM program that stressed the importance of a market-based program, as well as the precedent established by the SCAQMD in previous NOx regulatory reductions in 1999 and 2005. An equally distributed "across-the board" treatment of all sources, as originally designed and implemented since the program's inception in 1994, is critical to the continued success of the RECLAIM program.
Page 4: 1st full paragraph, 3rd sentence. Small Facilities	This sentence states "The remaining 210 facilities that hold 10% of the 26.5 tpd RTC are not proposed to be shaved because there was no new BARCT for the types of equipment and operation at these facilities." This statement is factually incorrect and should be corrected. AQMD Staff opted not to review BARCT for these facilities under this RECLAIM rulemaking. Additionally, AQMD and other California air districts have previously made BARCT determinations that would apply to the equipment and operations at those smaller emitting facilities (e.g., boilers, heaters, etc.) were they not under RECLAIM.[4]
Page 4: 2nd and 3rd full paragraphs. Implementation Schedule	The proposed Implementation Schedule should be revised to shave not more than 2 tons per day (tpd) from the program in the first year. This is consistent with Governing Board's direction under Control Measure CMB-01 Phase 1. Additionally, the overall schedule should be longer than the proposed seven (7) years to ensure RECLAIM facilities have sufficient time to comply. 2012 Air Quality Management Plan (AQMP) Control Measure CMB-01) Phase 1 was approved by the Governing Board on the basis that 2 tpd would be removed from RECLAIM in the event of the $PM_{2.5}$ contingency measure being triggered.[5] The proposed schedule should be consistent with that 2 tpd State Implementation Plan (SIP) commitment; anything

[4] See SCAQMD Regulation XI for examples.
[5] SCAQMD, 2012 AQMP. Page 4-9 states: "The control measure will seek further reductions of 2 tpd of NOx allocations if triggered." Appendix A, page IV-A-13 presents rationale for that conclusion.

	larger may not allow sufficient time for industry to implement emission control projects necessitated by the rulemaking. Also, the proposed schedule for full implementation by 2022 may be insufficient to achieve the proposed level of NOx emission reductions from RECLAIM facilities. Refinery Sector sources may need 8 years or more to fully engineer, permit, construct and operationalize all the projects needed to comply with the proposed rulemaking.[6]
Page 6: Table EX-2, Summary of Public Process.	To provide ample opportunity for stakeholder review and comment, AQMD Staff should revise this schedule to provide the public with a realistic schedule for this rulemaking that includes the CEQA Program Environmental Assessment (PEA) and the Socioeconomic Analysis.
Page 19: Co-Benefits of Energy Efficiency Projects.	This section should be completely removed from the PDSR or significantly revised to correct factual mischaracterizations. The information submitted by refineries to the California Air Resources Board in 2011 under the AB32 Energy Efficiency and Co-Benefits regulation reflected projects that mostly had been completed by 2011. Thus, those co-benefits were already reflected in the 2011 baseline year emissions presented in the PDSR and cannot be characterized as additional or creditable. Staff have acknowledged as much in PDSR Table 3.2.
Page 29 CEQA Alternatives	The size of the shave approved in the 2012 AQMP should be included in the list of CEQA alternatives.
Chapter 4: Costs and Cost Effectiveness. Cost Thresholds	The cost effectiveness threshold for this rulemaking should not be greater than $22,500 (i.e., the cost effectiveness threshold used in the 2012 AQMP) and the BARCT analysis presented in the PDSR should be revised accordingly. The $50,000 cost effectiveness threshold proposed by AQMD Staff is greater than the AQMD's DCF cost effectiveness threshold for Command-and-Control sources in South Coast. Under the 2012 AQMP, the approved cost threshold for NOx control measures was $22,500 per ton. As an additional data point, AQMD's current Best Available Control Technology (BACT) guidance document presents a DCF cost effectiveness threshold of only $19,100 per ton. Health & Safety Code (H&SC) §39616(c) requires that market-based program costs will be "equivalent or less compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the district's plan for attainment" and also requires "the program will not result in disproportionate impacts, measured on an aggregate basis, on those stationary sources included in the program compared to other permitted stationary sources in the district's plan for attainment."[7] The AQMD Staff analysis presented in the PDSR has not demonstrated that these obligations are satisfied.
Chapter 4: Costs and Cost Effectiveness.	A 10-year "Useful Life" assumption is more appropriate given actual rulemaking timetables; the BARCT analysis presented in the PDSR should be accordingly revised to use a 10-year Useful Life assumption.

[6] Stillwater Associates LLC, RECLAIM Analysis for WSPA, July 2015.
[7] Health & Safety Code §39616(c)(1) and (7).

Useful Life Assumption	The AQMD Staff's proposed 25-year Useful Life is inappropriate because AQMD rulemaking occurs on a far more frequent recurrence. The last major NOx RECLAIM rulemaking was only 10-years ago. Use of a 25-year assumption makes the rule costs appear lower than actual by diluting the significant capital costs of required projects over a much longer time table than is likely to occur. The AQMD Staff analysis should be revised to reflect the 10-year Useful Life assumption which is more consistent with recent AQMD rulemaking schedules and is also consistent with the Useful Life assumption typically used by CARB and other major Air Districts.
Chapter 4: Costs and Cost Effectiveness. DCF Method	The BARCT analysis presented in the PDSR should be revised to utilize the Levelized Cash Flow (LCF) methodology used by CARB and other major air districts. Use of the DCF method, in combination with the proposed interest rate and Useful Life assumptions serves to distort the estimated costs for this AQMD rule by making them appear less expensive than they would be using the Levelized Cash Flow (LCF) method employed by CARB and other major Air Districts. The same threshold should be used for both DCF and LCF.
Chapter 5: RTC Reductions, Remaining Emissions Remaining Emissions Method	The AQMD Staff's "Remaining Emissions" method conflicts with Control Measure CMB-1 Phase 1 as approved under the 2012 AQMP and should be replaced with the Incremental BARCT method proposed by the Industry RECLAIM Coalition. The Remaining Emissions method presented in the PDSR conflicts with Control Measure CMB-1 Phase 1 because it would remove nearly all Unused RTCs (i.e., "surplus") from RECLAIM. CMB-01 Phase 1 explicitly considered and rejected such a reduction; instead arguing that a 2 tpd of reduction for Unused RTCs was more appropriate due to concerns that baseline RECLAIM emissions might reflect the economic downturn.[8] As noted above, many Southern California industry sectors covered by RECLAIM were in fact still under a recessionary hangover in 2011 so such concerns were valid. Furthermore, the "Incremental BARCT" method is more consistent with Control Measure CMB-1 Phase 2 approved under the 2012 AQMP [9] because the method would only remove RTCs in an amount attributable to technology advancement (i.e., BARCT). AQMD Staff's own analysis demonstrates that less than 9 tpd of proposed RTC reductions are attributable to the 2015 BARCT analysis. Yet the Staff proposal proposes to shave 14 tpd. Removing RTCs beyond what is supported by technology advancement may subject facilities in the RECLAIM program to disproportionate impacts, measured on an aggregate basis, compared to other permitted stationary sources in the District's plan for attainment. It may also subject

[8] SCAQMD, 2012 AQMP. Page 4-9 states: "The control measure will seek further reductions of 2 tpd of NOx allocations if triggered." Appendix A, page IV-A-13 presents rationale for that conclusion.
[9] SCAQMD, 2012 AQMP. Page 4-26 states: "This phase of control is to implement periodic BARCT evaluation as required under the state law." Appendix A, page IV-A-60 presents more detailed discussion for the measure.

	RECLAIM facilities to greater costs compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the District's plan for attainment. Either of these outcomes would conflict with H&SC 39616(c). AQMD has not demonstrated that the Staff proposal successfully meets these obligations. Further, under Section 40727, the Legislature has established that regulations must meet the requirements of necessity, authority, clarity, consistency, non-duplication, and reference. The necessity requirement ensures in part that unnecessary costs are not imposed on the economy of California. Accordingly, the District needs to establish that the shave is no more stringent than what is "necessary." Necessity "means that a need exists for the regulation, or for its amendment or repeal, as demonstrated by the record of the rulemaking authority."[10] Through the 2012 AQMP, SCAQMD has described that a need exists for a reduction in NOx emissions. The ceiling of that need was five tons per day. The magnitude of the current shave proposal goes above and beyond what is necessary to meet the requirements of the AQMP or any other statutory or regulatory obligation that SCAQMD faces.

Chapter 5: RTC Reductions, Remaining Emissions Compliance Margin	The proposed Compliance Margin of 10% appears inadequate to meet the market's historical need for Unused RTCs and should be revised to the 20-30% range. The RECLAIM market has exhibited "Unused RTCs" since program inception. This may be for several reasons including facility compliance margins which range in size depending on facility size and/or risk tolerance, RTC holding requirements imposed under Rule 2005, or market trading to name few. These Unused RTCs have historically averaged in the 15-30% range (5 to 9 tpd) with the sole exception being the market crisis during the 2000 compliance year.[11] The AQMD Staff's proposal (with only 10% compliance margin) may be inadequate for satisfying this market requirement. Excessive shaving of Unused RTCs could result in a market which is unable to accommodate the economic activity levels projected in the Staff's analysis. Furthermore, removal of all Unused RTCs would directly conflict with Control Measure CMB-01 Phase 1 as authorized by the Governing Board.
Chapter 5: RTC Reductions, Remaining Emissions Table 5.1 – Remaining Emissions for Refinery Sector (May 2015)	The BARCT analysis for the Refinery Sector categories should be revised to explicitly consider the findings presented in Norton Engineering Consultants' (NEC) BARCT Feasibility and Analysis Review, and Table 5.1 should be accordingly revised. As noted in the PDSR, the Staff analysis fails to account for the technical recommendations from NEC, the third-party Refinery Sector expert hired by the AQMD. NEC's findings have material impacts on the resulting BARCT determinations for certain Refinery Sector categories. Once corrected, the projected "2023 Remaining Emissions at 2015 BARCT" for the Refinery Sector will increase, and the "2023 Emission Reductions Beyond 2000/2005 BARCT" will decrease. These technical corrections are critical to a fair application of the proposed shave.

[10] Health & Saf. Code § 40727.

Appendix A - Refinery Fluid Catalytic Cracking Units (FCCUs) Page 53. Incremental Costs and Cost Effectiveness Cost Effectiveness Calculations	The cost effectiveness analysis presented for FCCUs in Appendix A does not consider the 2000/2005 BARCT emissions or cost baselines. This conflicts with the methodology outlined in Chapter 4. The Staff BARCT analysis should be accordingly revised based on the incremental cost effectiveness approach outlined in Chapter 4. Staff proposes that the cost effectiveness of 2015 BARCT is to be calculated based on the incremental cost of progressing from 2000/2005 BARCT to the proposed 2015 BARCT level, divided by the incremental emissions benefit related to the progression from 2000/2005 BARCT to the proposed 2015 BARCT level (i.e., "2023 Emission Reductions Beyond 2000/2005 BARCT"). For some reason, it was not applied in this manner for the FCCUs. We request that this oversight be corrected.

Appendix A - Refinery Fluid Catalytic Cracking Units (FCCUs) Page 53. Incremental Costs and Cost Effectiveness Consideration of Third-Party Expert's Recommendations on Cost	The Staff's BARCT analysis for the Refinery FCCUs category should be revised to explicitly consider the findings presented in Norton Engineering Consultants' (NEC) BARCT Feasibility and Analysis Review.[12] The third-party experts were hired to confirm the AQMD Staff's technical analysis in support of this rulemaking. By selectively dismissing the third-party refinery sector expert's findings, without resolution of the technical issues in dispute, AQMD Staff have compromised the rulemaking process. We also note that NEC has raised a significant number of technical issues with the conclusions presented in the PSDR for the Refinery FCCUs which have reportedly been discussed with Staff and were reiterated in NEC's letter dated 10 August 2015.[13] Norton's comments are attached hereto and incorporated herein by reference. These technical issues are significant and should be resolved before any further characterization of emissions reductions attributable to proposed BARCT under the Staff's analysis.
Appendix B – Refinery Boilers and Process Heaters Page 60, Achieved-In-Practice NOx Levels for Boilers and Heaters Proposed BARCT	WSPA requests further technical demonstration to support the proposed BARCT level for refinery heaters and boilers; the proposed BARCT level does not appear to represent an achievable level of performance for most refinery heaters/boilers operating on refinery fuel gas. According to the AQMD's figures, fewer than 10% of the heater/boiler units already equipped with SCR technology are able to achieve the proposed BARCT level. This does not suggest the performance level can be broadly achieved with add-on emissions controls. If this level of performance effectively demands basic equipment replacement, the AQMD's BARCT analysis should identify and quantify costs for that demand. WSPA also requests clarification on the number of refinery heaters and boilers reported to that have "very low emissions levels." AQMD Staff have provided conflicting counts to stakeholders, and those counts conflict

[12] Norton Engineering Consultants (NEC), SCAQMD NOx RECLAIM - BARCT Feasibility and Analysis Review, Non-Confidential Final Report No. 14-045-4, 26 November 2014.
[13] James Norton, NEC, letter to Dr. Philip Fine, SCAQMD, Comments on Preliminary Draft Staff Report Proposed Amendments to Regulation XX Regional Clean Air Incentives Market (RECLAIM) NOx RECLAIM – SCRs for FCCUs Document No. 14-045-7, 10 August 2015.

	with information provided to WSPA directly by WSPA member refineries.[14] The PDSR reports fourteen refinery heaters in the AQMD as using refinery fuel gas and achieving NOx concentrations "between 1.6 and 3.5 ppmv" (corrected to 3% O2) using Selective Catalytic Reduction (SCR) technology. AQMD Staff also report that two boilers have achieved NOx emissions between 2 and 5 ppmv using LoTOx scrubbers and natural gas. We understand that AQMD's analysis is based on data collected from Southern California refineries under a 2013 survey.[15] AQMD had previously reported to the RECLAIM Working Group that, based on that same survey, only nine refinery heaters/boilers were achieving below 5 ppmv. WSPA requests clarification on how this count of units with "very low emissions levels" could have changed. Lastly, AQMD should not categorize units between performing "between 1.6 and 3.5 ppmv" as a single group consistent with the proposed BARCT. 3.5 ppmv does not equal 2 ppmv, and some units which achieve 3.5 ppmv may be unable to meet 2 ppmv even with add-on controls. We would suggest this group supports a BARCT determination of 3.5 ppmv; not 2 ppmv.
Appendix B – Refinery Boilers and Process Heaters Page 60, Achieved-In-Practice NOx Levels for Boilers and Heaters Cost Basis for BARCT and Consideration of Third-Party Expert's Recommendations on Cost	The Staff's BARCT analysis for the Refinery heaters and boilers should be revised to explicitly consider the findings presented in Norton Engineering Consultants' (NEC) BARCT Feasibility and Analysis Review, and any subsequent comments from NEC.[16] The third-party experts were hired to confirm the AQMD Staff's technical analysis in support of this rulemaking. By selectively dismissing the third-party refinery sector expert's findings without resolution of the technical issues in dispute, AQMD Staff have compromised the rulemaking process. The AQMD Staff's analysis suggests that the proposed BARCT level of 2 ppmv can be achieved with less equipment (e.g., 1 layer of catalyst) and less cost than suggested by the third-party Refinery expect; a firm that engineers such equipment as its primary business. Counter to the AQMD Staff's assertion that NEC was simply wrong on its design basis is the fact (reported by AQMD)[17] that fewer than 10% of the existing Refinery heaters/boilers with SCR technology are able to meet 2 ppmv. This result includes both new and retrofit installations and suggests that the proposed 2 ppmv NOx performance level may not be as easily achieved as suggested by Staff. Given the material impact of these technical issues on the BARCT analysis, they should be resolved before any further characterization of emissions reductions attributable to proposed BARCT under the Staff's analysis. Specifically, we request that the BARCT analysis presented in Appendix B be revised to consider the cost estimates presented by NEC.
Appendix B – Refinery	The BARCT cost effectiveness analysis presented in this table suggests

[14] WSPA/ERM confidential survey of WSPA members concerning refinery heaters/boilers, Mar 2015.
[15] SCAQMD, Preliminary Draft Staff Report (PDSR) for Proposed Amendments to NOx RECLAIM, 21 July 2015.
[16] Norton Engineering Consultants (NEC), SCAQMD NOx RECLAIM - BARCT Feasibility and Analysis Review, Non-Confidential Final Report No. 14-045-4, 26 November 2014.
[17] SCAQMD, NOX RECLAIM Working Group Meeting, 19 September 2013.

Boilers and Process Heaters Table B.11 - Details of Cost Estimates for Boilers and Heaters (March 2015)	AQMD Staff have selectively applied the methodology outlined in Chapter 4. This is specifically a problem for select heaters which are reportedly already meeting proposed BARCT. In these instances, Staff has claimed emissions reductions relative to the 2000/2005 BARCT level without assigning any programmatic costs for those reductions. This is inconsistent with the programmatic approach outlined in Chapter 4, under which cost effectiveness of 2015 BARCT is to be calculated based on the incremental cost of progressing from a 2000/2005 BARCT level to the proposed 2015 BARCT level, divided by the incremental emissions benefit related to the progression from 2000/2005 BARCT to the proposed 2015 BARCT level (i.e., "2023 Emission Reductions Beyond 2000/2005 BARCT"). WSPA does not believe it appropriate for Staff to selectively "pick and choose" when use the prescribed programmatic approach. The Staff BARCT analysis should be revised accordingly to be fully consistent with the incremental cost effectiveness approach outlined in Chapter 4.
Appendix D - Coke Calciner Staff's Recommendation	WSPA appreciates that AQMD Staff accepted NEC's recommended BARCT level of 10 ppmv and has incorporated it into the BARCT analysis for this source category.
Appendix E - Sulfur Recovery Units/Tail Gas Incinerators Page 110. Costs and Cost Effectiveness Design Basis for BARCT and Consideration of Third-Party Expert's Recommendations	The Staff's BARCT analysis for the Refinery Sulfur Recovery Units/Tail Gas Incinerators (SRU/TG Incinerators) category should be revised to explicitly consider the findings presented in Norton Engineering Consultants' (NEC) BARCT Feasibility and Analysis Review.[18] The third-party experts were hired to confirm the AQMD Staff's technical analysis in support of this rulemaking. As with other categories, the AQMD Staff's analysis suggests that the proposed BARCT level of 2 ppmv can be achieved for SRU/TG Incinerators with less equipment (e.g., fewer layers of catalyst) and less cost than suggested by the third-party Refinery expert; a firm that engineers such equipment as its primary business. By selectively dismissing the third-party refinery sector expert's findings without resolution of the technical issues in dispute, AQMD Staff have compromised the rulemaking process. Given the impact of these technical issues on the projected emissions and costs for this category, these issues should be resolved before any further characterization of emissions reductions attributable to proposed BARCT under the Staff's analysis. Specifically, we request that the BARCT analysis presented in Appendix E be revised to consider the cost estimates presented by NEC. Tables E.1 and E.2 should include NOx concentration levels.
Appendix K – Co-Benefits of Energy Efficiency Projects	This appendix should be completely removed from the PDSR or significantly revised to correct factual mischaracterizations.

[18] Norton Engineering Consultants (NEC), SCAQMD NOx RECLAIM - BARCT Feasibility and Analysis Review, Non-Confidential Final Report No. 14-045-4, 26 November 2014.

	The information submitted by refineries to the California Air Resources Board in 2011 under the AB32 Energy Efficiency and Co-Benefits Regulation reflected projects that had mostly been completed by 2011. Thus, those co-benefits were already reflected in the 2011 baseline year emissions presented in the PDSR and cannot be characterized as additional or creditable. Staff have acknowledged as much in Table K.1 and also PDSR Table 3.2.

Part III – RTC Reduction Approaches Appendix U – Staff's Proposal and CEQA Alternatives	The proposed NOx RECLAIM shave should be applied in an equally distributed, "Across the Board" manner consistent with RECLAIM founding principles and the precedent set under the 2005 NOx RECLAIM shave. RECLAIM is a market-based program which was designed to use "the power of the marketplace"[19] to reduce air emissions from stationary sources. This approach was expressly intended not to impose "command-and-control" requirements on specific facilities or specific equipment therein. Rather, RECLAIM was intended to provide Southern California businesses with greater flexibility and a financial incentive to reduce air pollution at least equal to what traditional command-and-control rules would have required. This program has been very successful in reducing NOx emissions with RECLAIM facilities having reduced their overall actual emissions well in excess of the program's current target under Regulation XX. The District has previously considered and rejected targeted shaves as noted in the excerpts below: • Oct 1993, RECLAIM Program Summary: "Throughout the development of RECLAIM, the District evaluated several design options that would have treated some industries differently than others……After evaluating advantages and disadvantages, the District adopted a program that treats all sources consistently for equity and fairness." • 2005 Staff Report, Appendix E: "The Staff proposal is taking the "across-the-board" reduction of NOx RTC holdings approach by looking at the total reductions possible based on BARCT determinations and reducing allocations for all RTC holders by the same percentage…This approach, from a market design standpoint and based on the overall conceptual design of the RECLAIM program to achieve programmatic BARCT, is the most equitable…" The Staff proposal presented in the PDSR is inconsistent with the founding principles of the RECLAIM program that stressed the importance of a market-based program, as well as the precedent established by the SCAQMD in previous NOx regulatory reductions in 1999 and 2005. An equally distributed "across-the board" treatment of all sources, as originally designed and implemented since the program's inception in

[19] SCAQMD RECLAIM website, http://www.aqmd.gov/home/programs/business/business-detail?title=reclaim.

	1994, is critical to the continued success of the RECLAIM program.

Comments on Preliminary Draft Staff Report
Proposed Amendments to Regulation XX
Regional Clean Air Incentives Market (RECLAIM)
NOx RECLAIM – SCRs for FCCUs
Document No. 14-045-7

Dear Mr. Fine,

We have completed a first pass review of the above captioned report's discussion of SCR applications to district SCRs and have identified several misstatements and/or misunderstandings of the information provided by our company, under contract from SCAQMD, which may have material impact on the conclusions drawn by staff in the report. It is my intent in this letter to clarify the most glaring misstatements/misunderstandings of the information we provided to the district both in our final report (Doc. No. 14-045-4, Nov. 26, 2014) which summarized the data on a non-confidential basis, and the details provided on a confidential basis to the district and individually to each of the refineries.

We stated, quite clearly, in the final report and in subsequent discussions with staff, that we agree that 2 ppmvd (3% O_2) NOx emissions is a justifiable emission level for SCR applications to FCCUs, Fired Heaters, Boilers, Gas Turbines and TGU/SRUs, with caveats. While a few existing units can meet this guideline under current operating conditions, many more, similarly designed units have not demonstrated similar low emissions capabilities. With the exception of Gas Turbine installations (which have an equivalent emission level of 6 ppmv @ 3% O_2) most low emission SCRs in service today, being built today and even those being designed today carry manufacturer's guarantees to meet a NOx limit of 5 vppm @ 3% O_2. In spite of the limited number of units (other than gas turbines) operating at or below 2 vppm NOx, we believe that it is possible to achieve these levels, but to guarantee long term reliable performance (refineries typically operate 24/7 for periods of 4 to 6 years) it is prudent and quite possibly necessary to design future SCRs to increase residence time, improve NH_3 distribution, improve overall flue gas flow distribution, add catalyst, etc. SCAQMD staff agrees with this concept but we have strong disagreement as to how much change from current SCR designs will be required to achieve the sought after NOx reductions not only on day one but at the end of year one and year five and beyond.

NEC's engineers have extensive experience in process development, equipment development and project development for the refining and petrochemical industry in the manufacturing and air pollution control areas. The experience level of the engineers who completed our technology and project cost evaluations is 51, 37 and 8 years. It is exactly this experience base, and past successful work with the district, that caused you to look to NEC to develop "cost guidance" for evaluating the refining sector. We find it very surprising therefore, that staff essentially ignored our recommendations and continued to use what we feel are unrealistically low costs for NOx control projects for district refineries.

Comments on FCCU SCR Costs

Appendix F presents a review of NEC's analysis for FCCU SCR costs by SCAQMD staff. It concludes that NEC's estimated costs for NOx control are excessive and gives the following reasons for this assessment:

- NEC recommends using three catalyst beds and designing for superficial gas velocities of 10 ft/sec vs SCR vendor proposals which have less catalyst and 20% higher superficial velocities.
- NEC conditions budgetary quotations from manufacturers for the accuracy of the quote, the accuracy of the project basis and for the application of refining industry standards for construction of the equipment. This is characterized by staff as: "Adding a "mark-up" factor, or a bid conditioning factor of 1.35 to increase the costs".
- NEC includes the cost of installation of the SCR in its estimate to arrive at a direct material and labor cost for the SCR component of a project at 75% of the equipment cost. Characterized by staff as: "Adding another 75% increase in labor to the costs of the manufacturer's SCR.".
- NEC used incorrect FCCU feed rates in developing comparisons to AQMD PWVs.

The following paragraphs address each of staff's objections and provide additional information and clarifications to address what we perceive as staff's misunderstanding of the information presented in our final report.

**Basis for Catalyst Addition and
Velocity Reductions vs Vendor Budget Quotes**

All FCCU SCR catalyst beds are in the range of 3 - 4' deep, all are prone to plugging by catalyst and/or ABS and all have limitations on allowable pressure drop, so superficial velocity is a good basis for comparison between units. The district has three operating FCCU SCRs. All units have two catalyst beds and operate at superficial gas velocities in the range of 8 to 13 ft/sec. Two of the three units, operating at superficial velocities of 12 and 13 ft/sec do not achieve emissions of 2 vppm @ 3% O_2. The other unit, highlighted in the draft report, achieves less than 2 vppm @ 3% O_2 operating at a superficial velocity of 7.7 ft/sec. The "good" unit is operating with inlet NOx levels which are 50%

of design or lower and at lower than design flue gas flows. There are several ways to bring the two "non-performing" units into compliance with the revised standard, each with different costs and different overall performance impacts. NEC was not commissioned to do an evaluation of individual units and propose improvement options, but rather to make an assessment of what it would take, cost wise, to reliably achieve the 2 ppmv limit for grass roots SCR installations. Based on the experience of operating units in the district, and our direct experience with FCCU units for other clients (due to confidentiality agreements we cannot divulge client identities and specific locations) reliably achieving 2 vppm NOx emissions in an FCCU over a five year run will require the addition of catalyst and will be designed for superficial velocities of 10 ft/sec or less. Considering that SCR catalyst vendors have not developed and guaranteed a specific SCR design for 2 ppmvd @ 3% O_2 NEC feels that it is prudent to assume that a third bed of catalyst (SCR or ASC) and cross section designed to achieve a maximum superficial velocity of 10 ft/sec is sufficient to characterize the most likely cost of a SCR unit capable of achieving 2 ppmvd in a typical refinery FCCU environment. *The impact of the increased cross sectional area and the addition of a third bed of catalyst on the cost of an SCR installation has been overstated by district staff as a 284% increase in catalyst volume over manufacturer's estimates. The increase over manufacturer's budget estimates/proposals is actually 92%, one half of staff's reported delta.*

Staff's SCR Design Comparison Did Not Accurately Reflect NEC's "Typical" FCCU SCR Design

Staff used an incorrect basis for comparing NEC's typical FCCU SCR with district units in Table F.3. A revised comparison, using data from Refineries 1, 5 and 6 is shown below.

Table 1 (F. 3 Showing NEC Typical SCR)
Performance Information of Existing SCRs

	Refinery 1	Refinery 5	Refinery 6	NEC Typical
FCC Feed Rate, kBPD	95	71	84	55
SCR Inlet Flue Gas Flow, ACFS	6,585	5,525	9,685	3,848
SCR Manufacturer	1	3	2	--
No. Catalyst Layers	2	2	2	3
Catalyst Volume, ft^3	6,200	2,975(1)	6,200(5)	4,600
Design Inlet NOx, ppmv	133(2)/40-80(3)	150	35	45
Design Outlet NOx, ppmvd	--	17	6	2
NOx Measured, ppmvd	<2	15-17	5.6 – 6.4	1.5 (Est.)
Superficial Gas Velocity, fps	7.4	13.3	11.6	10.0
Space Velocity, 1/hr	3,823(6)	6,686(4)	5,624(5)	3,011
Removal Efficiency	95 - 97%(3)	89%	83%	97%

Notes:

1. Staff incorrectly stated catalyst volume as 2,391 ft^3 in Table F.3. 2,975 ft^3 catalyst volume confirmed by NEC with Refinery 5 and via review of SCR data provided by Refinery 5 to SCAQMD.
2. Design value reported as 155 ppmv @ 0% O_2. Value presented in table is corrected to 3% O_2.

3. Measured outlet NOx value of <2 ppmv corresponds to operation of unit with inlet NOx in the range indicated. Removal efficiency based on range of actual operation.
4. Staff reports space velocity value of 2,974/hr in table F.3.
5. Confidential data provided by SCAQMD staff is insufficient to calculate the catalyst volume for this unit without making the following assumption on the depth of a catalyst module which we assume to be 45". Staff used ½ of this value in Table F.3 corresponding to catalyst bed depth (catalyst element height) of 22.5". Recommend staff confirm catalyst volume with Refinery 6.
6. Confidential data on unit design and performance, provided by SCAQMD staff, used to calculate inlet volumetric flow and space velocity. Values differ from staff's entries in Table F.3.

In their review, staff is suggesting that NEC's typical SCR is overdesigned and as a result overpriced. Staff's comparisons suggest an overdesign factor of as much as 284%. We do not agree with this assessment. As can be seen in Table 1, NEC's typical SCR should be able to achieve 97% NOx reduction by virtue of the addition of catalyst at higher gas velocities than the SCR operating at Refinery 1. The typical SCR design provides an approximate 21% margin in space velocity over the Refinery 1 SCR design primarily due to the addition of a third catalyst bed. The addition of a third bed has inherent performance advantages in that it provides for partial redistribution of unreacted NH_3 and NOx versus further cross sectional area additions. If it is determined that the incremental cost of specially fabricated catalyst modules (shorter depth) is low, some further optimization may be possible to reduce SCR cost. It is worth noting that the ~21% catalyst margin will have a 12% overall TIC and PWV cost impact.

Basis of the: ***"mark-up" factor, or a bid conditioning factor of 1.35 to increase the costs"***

The following paragraphs provide background for NEC's use of a 35% conditioning factor for vendor equipment quotes at early stages of projects. These concepts were discussed with SCAQMD staff during reviews of our report and in subsequent follow-up phone conversations and e-mails. Due to the extensive discussion around this topic we are mystified by staff's characterization of this "bid conditioning factor" as, and here I paraphrase, 'an undefined and therefore invalid cost increase'.

Obtaining budgetary quotations from vendors for their equipment is part of the process of developing cost estimates for any project. At the early stages of projects, or when general information is sought, vendors are not provided comprehensive design basis information and therefore do not have a complete picture of the operating envelope for their proposed equipment. In these instances, some vendors will use costs from recent projects and "factor" them to the provided process conditions, other vendors may develop estimates based on equipment designed specifically to meet the provided process conditions. In either eventuality, the vendor is providing a quality estimate with reasonable accuracy (about +/- 10%) for the specified process conditions, without providing a performance guarantee and without review of the specific codes and standards applicable to refinery installations.

As project definition improves the process basis becomes fixed, equipment sizes become more reliable, performance guarantees are finalized, and vendor quote accuracy improves. Industry experience shows that at the early stages of a project, basis uncertainty alone, necessitates the addition of a 15 – 25% conditioning factor to a vendor's budget quote, in addition to other bid conditioning factors, to account for the difference seen between early equipment bids and final, full definition, performance guaranteed, equipment bids based on a definitive project basis.

Refineries are built to a more rigorous set of standards than typical air pollution control equipment which makes projects in the refining sector slightly more expensive than typical industrial projects. Standards which will have an impact on either the SCR design, the structural support design, location of equipment, internal and external maintenance access, etc., are likely to increase Direct SCR M&L costs. At this stage of project definition a factor of 10% is added to a vendor's equipment bid to account for the cost of meeting local plant standards.

The 1.35 "mark-up" or bid conditioning factor used in NEC's cost work-up for all SCR projects (FCCU, Heaters/Boilers, etc.) is not an arbitrary factor used to inflate costs, as implied in Appendix F, but is actually the low end of a time tested and proven means to determine the actual cost of a piece of equipment after full project definition is complete, including application of local industry standards to the design of the equipment, performance guarantees are offered and firm pricing for equipment components is provided by the vendor.

Basis for: ***"Adding another 75% increase in labor to the costs of the manufacturer's SCR."***

Another cost factor discussed with SCAQMD staff, and apparently dismissed as a simple adder to make costs appear high, is the cost of actually installing the equipment supplied by the SCR vendor in the plant. The vendor does not do construction and does not quote the cost of field assembly in their quote which only covers fabrication and supply of the equipment, in this case the SCR catalyst, support frames, ammonia injection grid and the carbon steel box.

The labor cost factor used in NEC's development of project costs is applied to the SCR vendor's factored estimate to account for the labor required to install the manufacturer's equipment at the site, transportation, taxes, tie-ins, insulation, access, structural steel, etc. Installation labor for equipment can range from a low of about 30% of the equipment cost to as much as 200% of direct equipment cost depending on the complexity of the equipment, the material it is made of and other equipment specific factors. In general, low cost equipment manufactured of low cost materials have higher installation percentages than highly complex equipment made of high cost materials. As a reference point, "Applied Cost Engineering", Clark F. D. and Lorenzoni A. B.; Marcel Decker Inc., 1978, uses a factor of 2.2 times direct material costs to estimate the direct M&L cost of a fired heater installation, a factor of 3.0 times direct material costs to estimate the direct M&L cost of a pump installation and a factor of 2.9 to estimate the direct M&L cost of a distillation tower. Due to the simplicity of the SCR equipment and its use of low cost materials we have used an installation labor cost factor of 0.75 (75%) to account for physical installation of the SCR, structural steel, fit-up of ducting, connection of piping, foundations, excavation, instrumentation, insulation, equipment storage, etc. This factor does not account for any costs associated with: demolition of existing equipment, modification of existing equipment, labor inefficiencies attributed to working in an operating plant, relocation and/or modification to underground utilities, piping, piping supports, ammonia storage facilities, control system additions, instrumentation wiring, conduit, power wiring, area paving, area lighting, area utilities, safety facilities, sootblowers, etc.. The cost of these items is rolled up into the overall TIC factor applied to escalate SCR M&L costs to a total project cost.

TIC Factor

SCAQMD staff disputes NEC's use of a TIC factor of 4.5 to convert direct M&L costs for the SCR into TIC for the SCR PROJECT. This factor is a reasonable estimate for project items not specifically identified in the direct M&L costs (indirect costs, engineering and owner's costs, labor productivity, ancillary equipment and systems, revamp items, duct work, area paving, lighting, utilities, safety systems, control system connections and programming, instrumentation, sootblowers, etc.) As a point of reference, the TIC factor used by NEC, in this analysis, is 90% of the average TIC factor of 4.9 used to estimate SOx control costs in NEC's SOx RECLAIM report.

NEC Estimated FCCU Feed Rates from
Flue Gas Rate Data Provided by SCAQMD
Correction of NEC PWVs Required

SCAQMD staff is correct in pointing out that NEC used incorrect design capacities in developing the FCCU SCR costs shown in section 1.2 of NEC's non-confidential report (14-045-4, November 26, 2014). NEC back calculated expected FCCU rates from flue gas flow rate data provided by AQMD staff to obtain estimated FCCU sizes. The following table presents a revision to the report table based on corrected FCCU sizes as indicated by district staff. Also included in the table is an update to the cost of a Grass Roots SCR for Refinery 6 based on a comparison of flue gas rates to the SCR versus the typical (base case) SCR. Revised NEC estimates provided in Table 2 do not include any reduction to NEC's original cost estimate model.

Table 2 (Restatement of Table F.2)
Estimates of PWV Correcting NEC Values for FCCU Feed Rates

Facility	FCCU Feed, kBPD	AQMD's Estimate, $M	Revised NEC Estimate, $M	Ratio: NEC/AQMD
5	71	33	43(2)	1.3
6	90	57	62(1)(2)	1.09
7	55	27	37	1.37
4	34/36(3)	16	28	1.75
9	55	19	37	1.95
Total		152	207	1.36

Notes:

1. The PWV shown includes the impact of additional flue gas from a CO boiler but does not include the incremental flue gas from another source which is fed to the existing SCR.
2. Costs shown are for grass roots (new) SCR additions to existing FCCUs. Existing units may be modified to reduce compliance costs below those indicated.
3. Staff report throughput is 34 kBPD. Published unit capacity is 36 kBPD.

Staff Evaluation of NEC PWVs vs. Refinery 1 SCR Costs Does Not Factor In Project Scope Differences

Staff provided a review of NEC's cost estimates based on a comparison to the cost provided for Refinery 1's SCR to demonstrate that NEC's estimating method is overly conservative. In this comparison staff claims that NEC's cost tool over predicts the cost of this installation by $11M (27%). The difficulty in comparing a specific project to a generalized curve is that the project has a specific scope which in most cases is different than the assumed scope of the "typical" project. This is the case for the SCR installation at Refinery 1 which, according to Refinery 1 personnel, did not include the cost for waste heat boiler modifications. Subtracting this component from the TIC for a typical FCCU SCR installation and recalculating PWV yields a cost of $45.45M which is 10.8% higher than staff's cost work-up on this project of $41M, not the 26% difference indicated in Appendix F. Staff had the WHB cost information NEC used in our estimates, we do not understand why they did not make the PWV comparison on the same basis.

Staff Evaluation of NEC PWVs vs. Refinery 9 SCR Costs Misstates Vendor and NEC Information

Staff also provided a review of NEC's cost estimates based on staff's assessment of differences between the data provided by an SCR vendor to staff and NEC for an installation at Refinery 9. In staff's evaluation of the data provided by the vendor they incorrectly calculate the total catalyst volume to be 3,100 ft^3 vs the actual vendor proposal which provided only 2,400 ft^3. Staff also incorrectly calculates NEC's estimated catalyst volume at 12,697 ft^3 vs an actual value of 4,600 ft^3 (1.92 x vendor proposal, see previous discussion on catalyst volumes and specification of a third bed).

Comments on Staff's Determination of PWVs for FCCU SCRs

I would like to take the opportunity to provide a few comments on SCAQMD staff's determination of PWVs for FCCU SCRs.

1. In using the costs provided for Refinery 1's SCR staff is assuming that all district SCRs can be installed without any impact on upstream equipment and that installation of the SCR can be executed in an open, non congested area. Refinery 1's SCR was installed prior to the installation of a large ESP, which occurred around 2006. If the SCR was to be installed today, or at any time after installation of the large ESP, costs would be higher due to productivity debits associated with working in a congested area and quite possibly even higher due to the need to move or modify some equipment to make the installation possible. In the most extreme case the SCR and ducting may have to be field erected from small fabricated assemblies due to access constraints.

2. Staff used a 0.7 power factor to scale the costs for Refinery 1's SCR project to different sizes. Costs for FCCU regenerator flue gas systems scale more accurately when a figure of around 0.6 is used. The effect of using a larger scale factor is a greater reduction in project costs for all projects with the differences getting proportionately greater the further one gets from the base case unit size. In essence using the 0.7 factor instead of 0.6, in this particular evaluation, will decrease costs for all units and will disproportionately decrease the cost of smaller units.

3. In using vendor budget quotes for SCRs, staff needs to add erection labor to the vendor quote. There is no indication that this is done in staff's analysis.

4. Staff does not condition the vendor's quotes to account for operational conditions, including unit upsets, and other project unknowns which will have direct bearing on SCR design details, performance and costs. An allowance must also be made for the accuracy inherent in vendor's budget quotations, which does not appear anywhere.

5. The PWVs provided for Refinery 7 and Refinery 9 are \$27M and \$19M respectively. There is an apparent inconsistency in these numbers as the stated capacity for each of these units is 55 kBPD. Units of the same capacity should have PWVs close to one another not differing by 42%. Staff should check these numbers and ensure that the SCR project scope differences between these two units can explain the large difference in cost.

In the interest in getting our comments into your hands as soon as possible we will provide comments on Staff's review of our SCR estimates for other applications in the district in one or more separate letters.

I am looking forward to discussing the items identified in this letter with SCAQMD staff and invite them to meet with us at our office in Montville, NJ.

Sincerely,

James P. Norton
President & CEO

Comment Letter #6

California Council for Environmental and Economic Balance
Southern California Air Quality Alliance
Regulatory Flexibility Group
WSPA Western States Petroleum Association

30 January 2015

Dr. Elaine Chang
Deputy Executive Officer, Planning, Rule Development & Area Sources
South Coast Air Quality Management District
21865 Copley Drive
Diamond Bar, CA 91765

SUBJECT: INDUSTRY COMMENTS ON THE NOTICE OF PREPARATION (NOP) OF A DRAFT PROGRAM ENVIRONMENTAL ASSESSMENT FOR PROPOSED AMENDED REGULATION XX – REGIONAL CLEAN AIR INCENTIVES MARKET (RECLAIM)

Dear Dr. Chang:

These comments are presented on behalf of the members of leading Southern California businesses represented by the California Council for Environmental and Economic Balance ("CCEEB"), the Regulatory Flexibility Group ("RegFlex"), the Southern California Air Quality Alliance ("SCAQA"), and Western States Petroleum Association ("WSPA"). The members of these business groups are major Southern California employers who own and operate facilities in the Regional CLean Air Incentives Market ("RECLAIM") program. 6-1

This "Industry RECLAIM Coalition" formally offers the following comments on the Notice of Preparation and Initial Study for the Draft Program Environmental Assessment ("PEA") for Proposed Amended Regulation XX ("NOP/IS").[1]

1. *The PEA Project Description should specify the potential shave as a range since neither the Proposed Amended Rule nor the Staff's Technical Report is complete.*

The Project Description presented in the NOP and Initial Study ("NOP/IS") incorporates Proposed Amended Rule (PAR) 2002 language as presented in Appendix A of the NOP/IS. At the time of the NOP/IS release, the AQMD had not completed technical work on this rulemaking, with the third-party consultant reviews having not even been released. The cover page for NOP/IS Appendix A did include the following disclaimer: 6-2

"The BARCT evaluation and the RTC shaving methodology are ongoing, so a RECLAIM industry's required RTC shave may change due to the public review process. The

[1] SCAQMD, Notice of Preparation (NOP) of a Draft Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), 4 December 2014.

programmatic RTC shave could range from five to 14 tons per day. To provide a worst case scenario of adverse environmental impacts, the adjustment factors and the Non-tradable/Non-usable NOx RTC adjustment factors in Proposed Amended Rule 2002 subparagraph (f)(1)(B) reflect an RTC shave at the higher end of the range to capture a conservative estimate of potential control technologies needed that could generate secondary environmental impacts. As the staff proposal is being refined, if a lesser RTC shave is proposed, the adverse environmental impacts would be less and the Draft PEA and its alternatives will also be further defined."[2]

Now that the third-party contractor reviews have been released, we expect changes are needed to the technical analysis which would alter the technical calculations. Members of this coalition have unresolved questions and concerns about those reviews and the current analysis from AQMD staff. But these reviews and additional inputs from industry stakeholders will necessitate revisions to the draft PAR 2002 language, and more changes will undoubtedly be needed as the rulemaking process progresses. 6-2 Concluded

For this reason, we recommend that the PEA Project Description should explicitly specify the potential shave under this rulemaking as a range. This could be accomplished using language similar to that which was presented on the NOP/IS Appendix A cover page, however this disclosure should be noted in the Project Description section of the main PEA document; not left only in an Appendix.

2. *The PEA should explicitly address at least two project Alternatives: (1) AQMP control measure CMB-01 as approved by the Governing Board (i.e., shave of 3-5 tpd); and (2) the Industry RECLAIM Coalition proposal.*

Under the 2012 Air Quality Management Plan ("AQMP"), the Governing Board approved control measure CMB-01 which authorized further reductions from the NOx RECLAIM program. The control measure authorized by the Governing Board was based on a range of 3-5 tons per day ("TPD") of RECLAIM Trading Credits ("RTCs") being removed from the program. While stakeholders understood the eventual rulemaking could differ, the current Staff proposal as presented in the NOP/IS would be substantially larger at nearly 13 TPD.

This Industry RECLAIM Coalition has presented an alternative methodology for demonstrating command-and-control equivalency. The Industry proposal would reduce the program's quantity of RTCs by limiting the "shave" to only those reductions that can be directly attributed to the advancement of Best Available Retrofit Control Technology ("BARCT"). This Industry proposal could also result in RTC reductions greater than the approved AQMP control measure, but less than those which have been presented by the AQMD Staff. 6-3

We recommend that both of these alternatives should be fully considered as project Alternatives in the PEA, at a minimum.

[2] SCAQMD, NOP/IS for Proposed Amended Regulation XX, Appendix A, 4 December 2014.

Dr. Elaine Chang, SCAQMD
30 January 2015

3. *Public stakeholders should be provided a schedule that is consistent with regulatory requirements while providing reasonable opportunity for stakeholder review and comment.*

The proposed rulemaking could potentially result in significant economic impacts to Southern California businesses and the regional economy. The technical analysis for this rulemaking is not yet complete, and the potential impacts have not yet been fully analyzed or considered. To date, only preliminary technical data has been made available to stakeholders. As such, thorough review and input by the RECLAIM Working Group or other stakeholders has not been possible. 6-4

This Industry RECLAIM Coalition respectfully requests that stakeholders be provided with a rulemaking schedule, including this PEA and the socioeconomic analysis, that is consistent with applicable regulatory requirements but also provides stakeholders a reasonable opportunity for review and comment of the technical bases.

The RECLAIM program remains vitally important to the health of Southern California's economy and environment. The members of this coalition have actively participated in this rulemaking through the NOx RECLAIM Working Group over these last two years, and we look forward to continuing to work with you and the District's Staff on the significant rulemaking. 6-5

Very truly yours,

Bill Quinn

RESPONSES TO COMMENT LETTER #2
(Alston & Bird LLP on behalf of the
Western States Petroleum Association – October 6, 2015)

2-1 This introductory comment explains the nature of the commenter's organization. No response is necessary.

2-2 SCAQMD staff disagrees with the comment that analysis in the Draft PEA is undermined and lacks adequate analysis because it "narrowly focuses on construction activities associated with construction activities associated with the replacement of NOx emissions control equipment for selected facilities" without having the construction activities confirmed by the District's expert. . In the first place, the Draft PEA analyzes impacts from the construction and operation of control equipment. As explained in Chapter 4, Subchapter 4.0 of the Draft PEA, the installation and operation of new or modified existing NOx emission control equipment at 20 facilities was identified as the only portion of the entire proposal that is expected to result in physical effects that may affect the environment. According to CEQA Guidelines §15126.2, "An EIR shall identify and focus on the significant environmental effects of the proposed project. In assessing the impact of a proposed project on the environment, the lead agency should normally limit its examination to changes in the existing physical conditions in the affected area as they exist at the time the notice of preparation is published..." For this reason, the analysis in the PEA focuses on the physical effects that may occur as a result of constructing new or modifying existing NOx control equipment and operating the equipment once constructed.

Further, the majority of the data and information relied upon to analyze the environmental impacts for the proposed project was provided by the consultants hired by the SCAQMD. So, it is incorrect to imply that the SCAQMD's consultants would not support the analysis. Additional data and methodologies from previous CEQA documents such as the Final EA for NOx RECLAIM[1] that was certified in January 2005 and the Final PEA for SOx RECLAIM[2] that was certified in November 2010, were also relied upon to prepare this PEA. The same consultants provided data for both this PEA and the Final PEA for SOx RECLAIM. Finally, several other references were used to prepare the extensive PEA. For a complete list of the references relied upon for the preparation of this PEA, see Chapter 6 – References.

The comment also states that the Draft PEA did not examine a reasonable range of alternatives because the majority of alternatives called for a "shave" of 14 tpd or more. However, the Draft PEA specifically considered the Industry Approach (Alternative 3)

[1] SCAQMD, Final Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), December 2004, SCAQMD No. 031104BAR, certified January 7, 2005. http://www.aqmd.gov/home/library/documents-support-material/lead-agency-scaqmd-projects/aqmd-projects---year-2005

[2] SCAQMD, Final Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), October 2010, SCAQMD No. 06182009BAR, SCH No. 2009061088, certified November 5, 2010. http://www.aqmd.gov/docs/default-source/ceqa/documents/aqmd-projects/2010/final-program-environmental-assessment-for-proposed-amended-regulation-xx.pdf?sfvrsn=4

and identified that this alternative would result in fewer impacts during construction and operation than the proposed project. Any alternative with a shave smaller than 14 tpd but larger than the Industry Approach would have environmental impacts in between those identified for the proposed project and the Industry Approach, as it would be expected to result in a lessened need and use of new control equipment. Most of the alternatives included a 14 tpd shave because that is the size of the shave staff believes is necessary to reach BARCT-level emissions from the RECLAIM universe. CEQA does not require consideration of alternatives that do not meet most of the basic project objectives. See CEQA Guidelines §15126.6. Neither this comment letter nor any earlier comment letter identifies another alternative that should have been analyzed that will meet the basic project objective of achieving BARCT levels of emissions. Specific comments raised individual resource areas that are addressed below.

2-3 The comments raised in Attachment 1 have been individually bracketed and numbered as Comments 2-49 through 2-88. See Responses 2-49 through 2-88.

2-4 The three additional letters referenced in this comment were included with Comment Letter #2 and Attachment 1 to Comment Letter #2. The August 21, 2015 letter was primarily written relative to the Preliminary Draft Staff Report for the proposed project and did not raise new or different CEQA issues than what was already raised in the January 30, 2015 letter that was submitted relative to the NOP/IS. The January 30, 2015 letter along with responses were included in the Draft PEA (see Appendix G, Comment Letter #6 and Responses to Comment Letter #6). Because the August 21, 2015 letter was transmitted to the SCAQMD after the Draft PEA was released for public review and comment, separate responses to the August 21, 2015 letter could not have been included or addressed in the Draft PEA. However, responses to the August 21, 2015 letter have been prepared and are included in the Revised Draft Staff Report for NOx RECLAIM as Comment Letter #1 (see Appendix Z, pp. 241-340)[3]. (To avoid confusion, it is important to note that the letter dated August 21, 2015 also contains a document labeled as Attachment 1 which is a different document from Attachment 1 to Comment Letter #2 in this PEA.)

The May 27, 2015 letter was written relative to the NOx RECLAIM Working Group held on April 29, 2015 and contains comments relative to the staff proposal and CEQA. However, the majority of the comments in the May 27, 2015 letter focus on non-CEQA issues that have been superseded by subsequent, more recent letters and corresponding responses that reflect the updated staff proposal (see Appendix Z of the Revised Draft Draft Staff Report). To avoid confusion and repetition of what are now moot comments, only the CEQA-related comments contained in the May 27, 2015 letter have been bracketed (see Comments 2-89, 2-90, and 2-91) and responses have been prepared (see Responses 2-89, 2-90, and 2-91).

[3] SCAQMD, Revised Draft Staff Report, Proposed Amendments to Regulation XX, Regional Clean Air Incentives Market (RECLAIM), NOx RECLAIM, November 4, 2015. http://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/regxx/noxreclaim_dsr_110415.pdf?sfvrsn=4

2-5 This comment neither elaborates on the commenter's concerns with the proposed rule amendments and the Draft PEA nor explains why the commenter believes the requirements under CEQA have not been satisfied. This comment also broadly alleges that the Draft PEA contains errors, does not disclose all significant impacts, and does not allow the consideration of feasible mitigation measures or project alternatives to reduce or avoid impacts without providing any justification or evidence to support revising the proposed rule amendments and the Draft PEA and recirculating the Draft PEA. To the extent that the commenter provides more specificity on the concerns elsewhere in this letter, responses to the more specific concerns have been provided. SCAQMD staff does not agree that the CEQA document needs to be recirculated.

2-6 This comment describes the purpose of an EIR and reiterates earlier statements that the Draft PEA is flawed and includes errors, without providing specific information to support that assertion. As explained in Response 2-4, the August 21, 2015 letter was transmitted to the SCAQMD in response to Preliminary Draft Staff Report for the proposed project and not to the Draft PEA. Further, the August 21, 2015 letter did not raise new or different CEQA issues than what was already raised in the January 30, 2015 letter that was submitted relative to the NOP/IS. Because adequate responses were prepared for the January 30, 2015 letter and included in the Draft PEA, SCAQMD staff does not believe that a revision to the Draft PEA and a recirculation of the document for another public review and comment period is necessary.

2-7 This comment provides multiple quotes from CEQA case law relative to the general content requirements of a project description. SCAQMD staff is well aware of the CEQA requirements for a project description as described in CEQA Guidelines §15124 and the contents of the Draft PEA comply with these requirements.

2-8 As stated in the quote from the Draft PEA found in this comment, the project consists of the proposed amendments to Regulation XX, which includes, among other things, a proposal to reduce NOx RTC holdings by 14 tpd. The project description outlines the entire project and details all of the changes that are proposed to Regulation XX (see Chapter 2, Section 2.3 of the PEA, pp. 2-3 through 2-5). The comment alleges that the Draft PEA fails to evaluate the potential environmental effects of "effectively eliminating the RECLAIM market." However, SCAQMD staff does not believe the amendments would "effectively eliminate" the RECLAIM market as there would still be over 20 percent of unused RTCs even after the shave under SCAQMD's staff proposal and WSPA has admitted that the market has functioned with 15 percent of unused RTCs in the past. Moreover, the comment does not supply substantial evidence that any adverse environmental impacts would result from the elimination of the RECLAIM market, should that occur. State law would still require the identified BARCT to be implemented (Health and Safety Code §§40440 and 40919), which would still require similar construction and operation of control equipment as what was analyzed in the Draft PEA.

The comment also states that it is misleading to characterize the proposed project as merely a series of construction projects to achieve BARCT requirements. As explained above, the project description fully describes the proposed project. Further, as explained in Chapter 4, Subchapter 4.0 of the Draft PEA, the installation and operation of new or modified existing NOx emission control equipment at 20 facilities was identified as the only portion of the entire proposal that is expected to result in physical effects that may affect the environment. According to CEQA Guidelines §15126.2, "An EIR shall identify and focus on the significant environmental effects of the proposed project. In assessing the impact of a proposed project on the environment, the lead agency should normally limit its examination to changes in the existing physical conditions in the affected area as they exist at the time the notice of preparation is published..." For this reason, the analysis in the PEA focuses on the physical effects that may occur as a result of constructing new or modifying existing NOx control equipment and operating the equipment once constructed. Thus, the differences between the general introduction of the proposed project to the reader, what is contained in the project description, and the physical effects of the proposed project and its corresponding analysis in the PEA are not inconsistent with each other and do not represent a shift among different project descriptions that would undermine the CEQA process as a vehicle for public participation.

The comment also states that the amendments can have 'wide ranging impacts" that are not limited to BARCT implementation but also on the operation of the facilities. However, the comment fails to identify any such potential impact. If, for example, a facility were to reduce operations rather than install control technology, adverse environmental impacts beyond those that would result from the construction and operation of controls are not foreseeable. CEQA does not call for an analysis of economic impacts unless they result in adverse environmental impacts, and none have been identified. See CEQA Guidelines §15064 (e).

In addition, the public, stakeholders and interested parties alike were afforded extra time than is required by CEQA for the review and comment periods. For example, the NOP/IS was released for a 57-day public review and comment period when this type of CEQA document is only required to be released to responsible and trustee agencies for their 30-day review and comment period. The Draft PEA was released for a 53-day public review and comment period when this type of CEQA document normally requires a 45-day public review and comment period.

2-9 As explained in Response 2-8, analysis of the potentially significant impacts of the proposed project in the PEA focused on both construction and operation activities, and not just construction activities, as the comment claims. SCAQMD staff's determination that BARCT construction activities as well as operation activities can actually be performed was based on the consultants' reports and previous CEQA documentation for similar projects as described in Response 2-2. RECLAIM does not prescribe that each of these control equipment be installed, as there is flexibility for facility operators to make other changes to reduce emissions or purchase RTCs to meet their requirements. The Draft PEA analyzes the impacts of installation and operation of all of the control equipment, which puts an upper bound on potential environmental impacts. The purpose of the project (e.g., the project objectives) is outlined in Chapter 2, Section 2.2 of the

PEA. Contrary to the comment, all of the project objectives were considered in the analysis of the various components of the proposed project and the alternatives.

2-10 As explained in the responses to Comment Letter #1 in the Revised Draft Staff Report (Appendix Z) released November 4, 2015, after review of the consultants' report, SCAQMD staff and Norton Engineering (NEC) agreed on the proper BARCT levels for all but one of the source categories analyzed (boilers/heaters). Therefore, NEC and SCAQMD staff agreed on which emission reductions were technically feasible and cost-effective for each refinery source category. To address the remaining difference of opinion regarding the refinery boilers/heaters, SCAQMD staff reduced the amount of the proposed shave by 0.79 tpd, substantially more than the equivalent NOx reductions that would be eliminated using the Norton Engineering approach (0.33 tpd). Thus, while disagreeing with NEC's BARCT analysis, the SCAQMD has effectively used the NEC BARCT determination. Regarding WSPA's claim that the BARCT requirements may not be cost-effective, as noted above, Norton Engineering and SCAQMD staff agreed on almost all BARCT levels, including that they were cost-effective, and SCAQMD staff adjusted for the one category of remaining disagreement. While WSPA states that its consultant reached a different cost number, that consultant has declined to provide SCAQMD staff with any of the information that went into its total cost number, so SCAQMD staff has no way of verifying the consultant's work. Since the WSPA cost number is unsubstantiated, it is not substantial evidence. Furthermore, if WSPA were correct, and some of the assumed BARCT measures are not cost-effective, this still would not have foreseeable increased adverse environmental effects beyond those resulting from assuming that all identified BARCT measures would in fact be implemented.

As explained in Response 2-4, the issues raised in the August 27, 2015 letter, including those relative to the technical feasibility of the proposed BARCT requirements which are contained throughout the letter, have been responded to by SCAQMD staff. See Revised Draft Staff Report, Appendix Z, pp. 241-340.

2-11 The claim that the proposed 2 ppm NOx levels using new or modified SCR is unsubstantiated, is a repeat of comments expressed in the August 27, 2015 letter. See Revised Draft Staff Report, Appendix Z, Comments 1-7 and 1-8, p. 246; and Responses to Comments 1-7 and 1-8, pp. 274-277. See also Response 2-10 above. The Norton Engineering letter attached to WSPA's comment letter states "we agree that 2 ppmv (3%02) NOx emissions is a justifiable emission level for SCR applications to FCCUs, Fired Heaters, Boilers, Gas Turbines, and TGUs/SRUs, with caveats." The caveats had to do with design features and the costs it would take to achieve these levels. As explained in Response 2-10, SCAQMD staff adjusted the shave to account for the one area (boilers/heaters) where the cost differences between Norton Engineering's approach and SCAQMD staff's approach would potentially make a difference in cost-effective BARCT levels. Again, this comment does not explain how this issue would result in significantly increased adverse environmental impacts beyond those already analyzed.

2-12 The comment pertaining to implementation schedule is a repeat of the sentiments expressed in the August 27, 2015 letter, Comment 1-21. See Revised Draft Staff Report, Appendix Z, Comments 1-21, pp. 252-253; and Response 1-21, p. 284.

In addition, the PEA recognizes and acknowledges the scheduling difficulties that may occur with regard to implementing construction projects at refineries. Without definitively knowing what each refinery operator will ultimately do and their corresponding schedule, the PEA contains assumptions that represent a worst-case analysis as explained in the air quality and GHG analysis in Chapter 4, Subchapter 4.2, page 4.2-10:

> *"Typically construction projects have staggered construction schedules which take into account design and engineering, ordering, purchasing and delivery of equipment, permitting and environmental review, the availability of construction crews, budgeting, and any other construction projects on site. However, due to wide range of construction time necessary to build the various types of NOx control equipment, the construction activities at other affected facilities could overlap. However, because of widely varying turnaround schedules of affected equipment within any given facility and based on past construction projects involving major construction equipment where the SCAQMD was the lead agency, the analysis in this PEA includes a conservative assumption that all of the refineries will have overlapping construction activities occurring in one year. However, since having all facilities construct all NOx controls within the first year is unlikely, for demonstrative purposes, the analysis also includes an analysis of the overlapping impacts spread out over a five- and seven-year period."*

Thus, if the actual construction activities at the affected refineries are not implemented at all or end up being spread out over eight years, then the environmental impacts on a peak daily basis would be less than what is analyzed in the Draft PEA, but would still likely have significant adverse impacts.

2-13 As explained in Response 2-2, the analysis in the Draft PEA relies on data and methodologies from previous CEQA documents such as the Final EA for NOx RECLAIM that was certified in January 2005 and the Final PEA for SOx RECLAIM that was certified in November 2010, for example. Both of these documents address the potential aesthetics impacts in a similar manner. In addition, both of the NOP/ISs prepared for these projects address the potential noise impacts in a similar manner and conclude that the noise impacts would be less than significant at the NOP/IS stage. In addition, as cited in Chapter 6 of the PEA, the following CEQA documents for other projects that have been certified and for which the SCAQMD was the lead agency also provided excellent source materials for the preparation of this PEA, especially with regards to evaluating the various potential impacts at refinery facilities. Moreover, no noise issues were raised relative to these referenced CEQA documents.

1. SCAQMD, 2001. Final Environmental Impact Report for: ARCO CARB Phase 3/MTBE Phase-Out Project, SCH. No. 2000061074; certified May 2001.

2. SCAQMD, 2001. Final Environmental Impact Report for: Chevron El Segundo CARB Phase 3 Clean Fuels Project, SCH. No. 2000081088; certified November 2001.

3. SCAQMD, 2001. Final Environmental Impact Report for: Proposed Equilon Enterprises LLC CARB Phase 3 Reformulated Gasoline Project, SCH. No. 2000091086; certified October 2001.

4. SCAQMD, 2001. Final Environmental Impact Report for: Mobil CARB Phase 3 Reformulated Gasoline Project, SCH. No. 2000081105; certified October 2001.

5. SCAQMD, 2001. Final Environmental Impact Report for: Proposed Tosco Los Angeles Refinery Phase 3 Reformulated Fuels Project, SCH. No. 2000091056; certified April 2001.

6. SCAQMD, 2001. Final Environmental Impact Report for: Proposed Ultramar Wilmington Refinery – CARB Phase 3 Project, SCH. No. 2000061113; certified December 2001.

7. SCAQMD, 2007. Final Environmental Impact Report for the ConocoPhillips Los Angeles Refinery PM10 and NOx Reduction Projects, SCH No. 2006111138, certified June 2007.

Assuming the comment means that the PEA should have evaluated noise impacts at individual facilities, the commenter did not bring up this issue in their letter submitted relative to the NOP/IS which was released for 57-day public review and comment period from December 5, 2014 to January 30, 2015 (see Appendix G, Comment Letter #6). The NOP/IS concluded that the noise impacts would be less than significant and since the commenter's concern relative to noise was not raised during the NOP/IS comment period, the PEA did not further analyze noise impacts beyond what was contained in the NOP/IS.

The noise analysis in the NOP/IS was based on best available information for a program level analysis, because the SCAQMD is not required to conduct a project level analysis. [CEQA Guidelines § 15187 (e)]. Further, the noise environment at the refineries is dominated by refinery equipment, other heavy industrial activities, and traffic. Construction activities for the proposed project are expected to generate noise associated with the use of heavy construction equipment and construction-related traffic. Noise levels during construction are measured from the center of the construction activity and most of the construction noise sources will be located at or near ground level, so the noise levels are expected to attenuate over distance. If and when each actual construction project is proposed as a result of complying with the proposed project, each individual facility operator will have to comply with the local noise element and ordinances applicable to their facility location during both construction and operation after build-out.

Regarding the topic of aesthetics, this PEA (as well as the Final PEA for SOx RECLAIM in 2010) relied upon the extensive aesthetics analysis conducted for the wet gas scrubber

(WGS) installation as analyzed in the referenced document number 7 above as suitable example of a typical WGS project. The commenter provides no evidence that a different aesthetics conclusion would be reached if a WGS was installed at any of the other refineries. Of course, should an individual refinery operator choose to install a WGS, the project will require a CEQA review to compare their individual project issues with the conclusions reached in this PEA. Should facility-specific circumstances cause a conclusion for the topic of aesthetics, noise, or any other environmental topic for that matter, to be different than what was analyzed in the NOP/IS and PEA, an additional CEQA document may be necessary for that future project.

Finally, it is important to keep in mind that a program CEQA document, by design, provides the basis for future environmental analyses and will allow future project-specific CEQA documents, if necessary, to focus solely on the new effects or detailed environmental issues not previously considered. If an agency finds that no new effects could occur, or no new mitigation measures would be required, the agency can approve the activity as being within the scope of the project covered by the program CEQA document and no new environmental document would be required [CEQA Guidelines §15168 (c)(2)].

2-14 This comment states that the PEA should identify realistic assumptions based on facts but it does not identify what the assumptions should be. The comment also states that the PEA has dismissed the potential for environmental impacts based on the facilities' industrial locations. This comment is inaccurate. The PEA thoroughly analyzes potential impacts in all CEQA topic areas identified in the NOP/IS, and does not "dismiss" such impacts based on the project being in an industrial area. If this comment refers to the analysis of the aesthetic impacts of a plume from a wet-gas scrubber, see Response 2-13 above. If the suggestion that "realistic assumptions" be applied instead of reasonable assumptions means that the PEA should attempt to speculate about what facility operators would actually do (and when) to comply with the proposed project, this is not what CEQA requires. See CEQA Guidelines§§15145 and 15384. Instead, in order to provide a conservative approach, the analysis assumed overlapping construction and operational activities. Adjusting to "realistic assumptions" would likely result in less concentrated, overlapping construction and operation activities, would not represent a conservative, worst-case analysis, and would undermine the PEA's ability to disclose all significant impacts.

In evaluating the proposed project at the beginning of the rule development, SCAQMD staff determined that there is substantial evidence that the project may have a significant effect on the environment, and decided to prepare a PEA as an equivalent CEQA document to an environmental impact report in accordance with the SCAQMD's certified regulatory program. CEQA Guidelines §15384 defines substantial evidence as fact, a reasonable assumption predicated upon fact, or expert opinion supported by fact and further explains that substantial evidence is not argument, speculation, unsubstantiated opinion or narrative, evidence that is clearly inaccurate or erroneous, or evidence of social or economic impacts that do not contribute to, or are not caused by, physical impacts on the environment. The commenter's claims of potential additional impacts are mere speculation and unsubstantiated argument. Thus, the PEA is based on reasonable assumptions supported by facts provided by the consultants and the reference materials listed in Chapter 6 of the PEA.

2-15 SCAQMD staff disagrees that any alteration or recirculation of the PEA is necessary. This comment repeats previous comments and adds the claim that the document should be recirculated. However, this comment does not identify any new significant impacts that would require recirculation nor does it establish that the PEA is "fundamentally and basically inadequate or conclusory." See Responses 2-12 through 2-14.

2-16 The evaluation in the PEA of the various possible physical actions that may be taken by facility operators to comply with the proposed project as well as their associated environmental impacts is based partially on facility-specific information provided either to SCAQMD staff or the consultants. While the analysis is quite extensive, it does not reflect a project-level review because none of the information provided confirms what each facility operator will ultimately do between now and 2022. The PEA is consistent with the criteria in CEQA Guidelines §15187 which requires air quality management districts, when adopting a rule or regulation that requires the installation of pollution control equipment or establishing a performance standard, to perform an environmental analysis of the reasonably foreseeable methods by which compliance with the rule or regulation will be achieved. In particular, the environmental analysis in the PEA includes reasonably foreseeable: 1) environmental impacts of the methods of compliance; 2) mitigation measures relating to those impacts; and, 3) alternative means of compliance which would avoid or eliminate the identified impacts. [CEQA Guidelines § 15187 (c)]. Further, while the SCAQMD may utilize numerical ranges and averages where specific data is not available for preparation of the PEA, the SCAQMD is not required to, nor should it, engage in speculation or conjecture. [CEQA Guidelines § 15187 (d)]. Finally, the SCAQMD is not required to conduct a project level analysis. [CEQA Guidelines § 15187 (e)]. For these reasons, the PEA analysis is in fact a program analysis as it contemplates a combination of potential future activities, without knowing all of the actual details of individual projects that would be undertaken in the future by facility operators.

The same type of analysis was conducted in the Final PEA for SOx RECLAIM, which affected a smaller number of facilities with some overlapping of the NOx RECLAIM universe of sources. While the Draft PEA describes construction impacts that are likely to result from implementing the rule amendments, SCAQMD staff recognizes that additional CEQA review may be necessary as the facilities implement their specific projects to meet the emission reduction requirements. The SCAQMD staff has not sought to transform a rule-making into a construction project but rather has analyzed the expected environmental impacts of implementing the proposed amended regulation, which are the impacts of constructing and operating emission reduction projects. See also Responses 2-2 and 2-8.

Regarding the comment that the topic of noise was not evaluated in the PEA, see Response 2-13.

2-17 This comment requests a clarification as to how CEQA Guidelines §15253 – Use of an EIR Substitute by a Responsible Agency, has been satisfied. In the first place, CEQA Guidelines §15253 does not impose any requirements on an agency having a certified program, such as the SCAQMD. CEQA Guidelines §15253 (c) provides that "certified agencies are not required to adjust their activities to meet the criteria in subdivision (b)." Instead, if those criteria are not met, responsible agencies must "comply with CEQA in the normal manner." CEQA Guidelines §15253 (c)(2). Nevertheless, SCAQMD staff has appropriately consulted with responsible agencies. In accordance with CEQA Guidelines §15082, a NOP, which included a notice of a scoping meeting, was provided to all responsible agencies at the same time the NOP/IS was released for a 57-day public review and comment period. The SCAQMD did not receive any responses to the NOP from any responsible agency. Responsible agencies were also notified of the availability of the Draft PEA at the same time the document was released for a 53-day public review and comment period. Again, the SCAQMD did not receive any comments on the Draft PEA from any responsible agency. Thus, SCAQMD staff is unaware of any responsible agencies that may have concerns about the proposed project.

The Final PEA along with all of the other project documents (e.g., proposed rule language, Staff Report, Socioeconomic Report, et cetera) is scheduled to be presented to the SCAQMD Governing Board for consideration and approval. If the project gets approved and the Final PEA gets certified, only then can a responsible agency use the Final PEA in place of an EIR or Negative Declaration for a future project provided that all of the conditions in CEQA Guidelines §15253 (b) are met.

2-18 This comment contains similar sentiments expressed in more detail in Comments 2-2, 2-8, 2-9, and 2-10. See Responses 2-2, 2-8, 2-9, and 2-10. The comment does not provide any evidence of improper evaluation of construction impacts or infeasibility of the proposed BARCT (best available retrofit control technology).

2-19 SCAQMD staff disagrees that the PEA overlooks the impacts from the whole of the project. See Responses 2-2, 2-8, 2-9, and 2-10.

CEQA Guidelines §15064 (e) provides that the economic or social effects of a project shall <u>not</u> be treated as significant effects on the environment. CEQA Guidelines §15064 (e) further states:

"Economic or social changes may be used, however, to determine that a physical change shall be regarded as a significant effect on the environment. Where a physical change is caused by economic or social effects of a project, the physical change may be regarded as a significant effect in the same manner as any other physical change resulting from the project. Alternatively, economic and social effects of a physical change may be used to determine that the physical change is a significant effect on the environment. If the physical change causes adverse economic or social effects on people, those adverse effects may be used as a factor in determining whether the physical change is significant. For example, if a project would cause overcrowding of a public facility and the overcrowding causes an

adverse effect on people, the overcrowding would be regarded as a significant effect."

Thus, instead of economic or social changes, the focus of the analysis in PEA shall be on the physical changes. [CEQA Guidelines §15131 (a)] For this reason, the analysis in the PEA does not address the costs associated with achieving the proposed NOx emission reductions. Instead, a socioeconomic analysis has been conducted and the analysis and findings are presented in a separate document, Socioeconomic Report For Proposed Amendments to Regulation XX - Regional Clean Air Incentive Market (RECLAIM) that was initially published on September 9, 2015 and subsequently revised on October 6, 2015 and November 4, 2015[4]. The socioeconomic analysis addresses the issues and socioeconomic impacts relating to the availability of RTCs to provide structural buyers a source of credits and to provide for NSR holding required by New Source Review. The socioeconomic analysis also addresses the potential cost impacts that may result from the construction and operation of new or modified NOx emissions control equipment that may be installed as a result of the proposed project.

2-20 As explained in Chapter 4, Subchapter 4.0 of the Draft PEA, the installation and operation of new or modified existing NOx emission control equipment at 20 facilities was identified as the only portion of the entire proposal that is expected to result in physical effects that may affect the environment. This comment claims it is a "clear fact" that the proposed amendments could "potentially eliminate the NOx RTC market" but no evidence or data is given to support this assertion. WSPA has conceded in past submittals that the market has functioned with as little as 15 percent excess unused RTCs. (See Special Stationary Source Committee Presentation, September 23, 2015). Even after the shave is fully implemented in 2023, there are expected to be over 20 percent excess unused RTCs. Thus, SCAQMD staff expects that there will be sufficient RTCs for the market to continue to function. Moreover, the comment fails to identify any physical impacts that might result from a failure of the market to function effectively. See also Response 2-19.

2-21 At the time the NOP/IS was published, SCAQMD staff identified 275 facilities that are currently in the NOx RECLAIM universe of sources and these 275 facilities are considered to be part of the existing environmental setting or baseline. For this reason, the reduction in the number of facilities that participate in the NOx RECLAIM program over the years from 392 to 275 is not a product of the proposed project that would require an analysis in this PEA. Moreover, there is no evidence that RECLAIM was in any way the cause of a significant number of facilities shutting down. Each year, the SCAQMD

[4] SCAQMD, Draft Final Socioeconomic Report for Proposed Amendments to Regulation XX - Regional Clean Air Incentive Market (RECLAIM), November 4, 2015. http://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/regxx/noxreclaim_dfsocio_110415.pdf?sfvrsn=2.
SCAQMD, Revised Draft Socioeconomic Report for Proposed Amendments to Regulation XX - Regional Clean Air Incentive Market (RECLAIM), October 6, 2015. http://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/regxx/reclaim_revisedsociodraft.pdf?sfvrsn=2.
SCAQMD, Draft Socioeconomic Report for Proposed Amendments to Regulation XX - Regional Clean Air Incentive Market (RECLAIM), September 9, 2015. http://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/regxx/reclaim_sociodraft_090915.pdf?sfvrsn=4.

staff prepares a program audit and report to the SCAQMD Governing Board pursuant to Rule 2015 (b) which includes the facilities that have shut down and the reasons given for their shutdown. SCAQMD staff has reviewed all annual program audits and concluded that although about 178 facilities have shut down (while about 50 new facilities have entered the market), only three facilities identified RECLAIM as a reason for their shutdown and only 10 identified environmental regulations other than RECLAIM as a reason for their shutdown. Since SCAQMD staff did not follow up on these shutdowns, it is unclear even for those who identified RECLAIM, that it was the sole reason for shutting down. In any event, since the majority of facilities that shutdown did not identify RECLAIM as the cause, any resulting environmental impacts from the shutdowns are also not caused by RECLAIM. Based on this past history, and the fact that the market will continue to have a comparable level of excess unused RTCs even after the shave is fully implemented as it has had historically, no significant number of facility shutdowns and thus no resulting significant environmental impacts can be predicted.

2-22 As explained in Response 2-21, the reduction in the number of participants in the NOx RECLAIM program is not a consequence of the proposed project. Thus, any loss in productivity due to the reduced number of participants is also not a consequence of the proposed project. Further, it would be speculative to assume that there will continue to be a decline in the number of NOx RECLAIM participants as a result of the proposed project. As also explained in Response 2-21, the majority of past facility shutdowns have not been caused by RECLAIM, and there will be sufficient RTCs for the market to continue to function, so it is not expected that RECLAIM will cause facility shutdowns in the future.

The energy analysis in the PEA evaluated a potential increase in energy demand during both construction and operation activities that may occur as a result of the proposed project. If the number of NOx RECLAIM participants reduces below 275, then that could mean that less energy would be needed for operation of these facilities, so any concerns with energy reliability would be moot. Without knowing what the lowered participation would be, it would be speculative to estimate what the corresponding reduction in energy needs would be. With respect to adequate power supply, the rule includes provisions to address the needs of electricity generating facilities, including a Regional NSR Holding Account that will be taken from the shaved RTCs and not submitted into the SIP, so that facilities can use these RTCs to satisfy their NSR holding requirements. Also, electricity generating facilities will have access to RTCs to offset their emissions in the event of a State of Emergency declared by the Governor. In addition, the proposal now includes an option for EGFs to exit RECLAIM if certain requirements are met. Such facilities will only use this option if it is to their benefit.

This comment further suggests that the PEA should consider the environmental impacts of "leakage" which is a known impact of subregional cap and trade programs. According to the Initial Statement of Reasons for the California Air Resources Board Cap-and-Trade Program for greenhouse gases, requirements to reduce emissions can create a disadvantage for facilities subject to the cap compared to other facilities, which could cause production and the resulting emissions to shift to facilities outside the cap. This is called "leakage" and is most likely to happen in an industry where there are higher levels of emissions per unit of output, and where it is difficult for a particular industry to pass through costs[5]. The theory of leakage, however, assumes that comparable sources outside the cap will not be subject to any restrictions; hence, the competitive disadvantage for capped sources. In this case, BARCT is still a requirement for all air districts that are classified as "moderate" for the state ozone standard or above. [Health and Safety Code §40919.] Thus, there is not likely to be a large competitive disadvantage for RECLAIM sources, at least compared to comparable sources within the state. Finally, the California Air Resources Board chose to ameliorate "leakage" impacts by providing free allocations to industries that are at risk of leakage[6]. In RECLAIM, all facilities except those that were newly-constructed after the inception of the program received free allocations, so the program already includes measures to ameliorate leakage. Based on the foregoing, it would be speculative to predict increased NOx emissions resulting elsewhere from the impact of leakage that need to be analyzed under CEQA.

2-23 The SCAQMD's reasoning about how the environmental impacts were identified and analyzed have been previously addressed in Responses 2-2, 2-8, 2-9, and 2-10.

SCAQMD staff believes that the PEA contains an adequate analysis based on the best facts and evidence available. This comment asserts that the rule amendments will cause facilities to react in ways that are reasonably foreseeable (other than installing BARCT-level controls) and will have environmental impacts, but fails to identify what such reactions would be. The comment is too general to enable further response.

2-24 This response contends that the proposed rule amendments "manipulate" the market and will have foreseeable consequences because they are imposed in a "targeted, uneven manner" rather than "across the board." SCAQMD staff disagrees that the proposed amendments are "uneven." To derive the proposed shave, SCAQMD staff examined what source categories could feasibly further reduce emissions by implementing new BARCT, identifying a total of 11 categories, of which about half were source categories located at refineries. SCAQMD staff then identified the level of reductions that would be achievable for the refinery and non-refinery categories, resulting in proposed reductions of about 66 percent for refinery categories and 49 percent for non-refinery categories. SCAQMD staff then proposed a shave methodology that spread the BARCT reductions among 56 facilities that together account for 90 percent of the NOx RTC holdings in RECLAIM. The percent shave was proportional to the available reductions, i.e., 66 percent for refineries and 49 percent for non-refineries. Approximately 219 facilities holding the remaining 10 percent, for which no BARCT was identified, are not proposed

5 State of California, Air Resources Board, Proposed Regulation to Implement the California Cap-and-Trade Program, Part 1, Volume 1, Staff Report: Initial Statement of Reasons, October 28, 2010, p. II-26. http://www.arb.ca.gov/regact/2010/capandtrade10/capisor.pdf

6 State of California, Air Resources Board, Proposed Regulation to Implement the California Cap-and-Trade Program, Part 1, Volume 1, Staff Report: Initial Statement of Reasons, October 28, 2010, p. II-26. http://www.arb.ca.gov/regact/2010/capandtrade10/capisor.pdf

to be shaved. Thus, the shave is more equitable than an across-the-board shave, which would require substantial reductions (an average of 53 percent) from facilities that do not have such reductions available, while shaving refineries by a percentage that is much less than their available reductions. As a result, SCAQMD staff believes the proposed amendments will have a far less adverse effect on the market than an across-the-board shave would have. This comment alleges that the PEA has not analyzed the "whole of the project" but for the reasons stated, SCAQMD staff believes the proposed amendments would have less impact than an across-the-board shave. For an explanation of how SCAQMD staff determined the environmental impacts of the project, see also Response 2-19.

2-25 This comment asserts that the PEA does not analyze "the whole of the action" and implies that the analysis constitutes "piecemealing." The comment fails to identify what future or other activities will allegedly result from adopting the rule that have not been analyzed. In addition, the preparation of a PEA that contains a program level analysis in anticipation of future activities is not piecemealing because "a showing of improper piecemealing requires evidence of a reasonably definite and concrete plan for future activities.[7]" The PEA acknowledges that implementation of the proposed project may result in the construction and operation activities that may cause environmental impacts for some facilities. However, it is also possible that these same facilities may choose to purchase more NOx RTCs to comply with the proposed project instead of installing new or modifying existing air pollution control equipment. Certainty as to which path will be followed at each affected facility may be provided when, for example, facility operators submit permit applications to construct new or modify existing air pollution control equipment. To date, SCAQMD staff is unaware of any permit applications that have been submitted in anticipation and in advance of the proposed project being considered for adoption by the SCAQMD Governing Board. Facility operators tend to wait to follow up with a permit application until after the SCAQMD Governing Board makes a final decision to approve a rule amendment. Thus, for the purpose of preparing the PEA, uncertainty exists and the analysis in the PEA reflects the understanding that there is currently no reasonably definite and concrete plan for future activities that will occur at the affected facilities.

2-26 This comment asserts that the socioeconomic analysis does not delve into the potential physical effects resulting from the NOx RTC shave. SCAQMD has been unable to identify such effects, nor does the comment identify them.

The comment also asserts that the PEA should be recirculated after WSPA provides its comments on the Socioeconomic Report. SCAQMD staff is only required to recirculate the PEA if any of the conditions identified in CEQA Guidelines §15088.5 occur. See also Response 2-19.

2-27 This comment asserts that the Draft Socioeconomic Report was circulated on September 7, 2015 - weeks after the Draft PEA, and the socioeconomic analysis should have been

[7] Berkeley Keep Jets Over the Bay Committee v. Board of Port Commissioners (2001) 91 Cal. App. 4th 1344, 1360-1362.

prepared before, or at least in conjunction with, the Draft PEA. There is no requirement in CEQA for any socioeconomic analysis to occur, let alone any requirements for the timing of such an analysis. In this case, the Draft Socioeconomic Report was released one month before the close of comments on the Draft PEA on October 6, 2015. Thus, there was ample time and opportunity to take the socioeconomic analysis into consideration when preparing CEQA comments. In addition, in response to comments received, a Revised Draft Socioeconomic Report was released on October 6, 2015 and a Draft Final Socioeconomic Report was released on November 4, 2015. See also Response 2-19.

This comment also claims that the SCAQMD staff proposal used $50,000 per ton as a cost-effectiveness threshold and that such a threshold could result in operational changes which have physical impacts on the environment, which should be analyzed in the Draft PEA. As set forth in the Draft Final Socioeconomic Report as revised on November 4, 2015 (see page 13, Table 7), the average cost-effectiveness for the BARCT measures is $13,615 per ton, not $50,000 per ton. The cost-effectiveness for the refinery measures ranges from $2,000 to $34,000 per ton. Even at the upper end, this is comparable to the upper end of cost-effectiveness for other command-and-control measures for combustion sources, such as SCAQMD Rule 1146.1 - Emissions of Oxides of Nitrogen from Small Industrial, Institutional, and Commercial Boilers, Steam Generators, and Process Heaters and Rule 1110.2 – Emissions from Gaseous- and Liquid-Fueled Engines (up to lower $30,000s). In any event, the Draft PEA assumes that all identified BARCT will be installed, and thus, projects the potential reasonable worst case environmental impacts. If a facility finds a more cost-effective measure to implement instead, or decides to reduce production, this would likely result in fewer, not more, environmental impacts than assumed in the analysis.

2-28 The project objectives were prepared in accordance with CEQA Guidelines §15124 (b) and can be found in Chapter 2, Section 2.2 of the Draft PEA, as follows:

"The objectives of the proposed project are to:

1) *Comply with the requirements in Health and Safety Code (HSC) §§40440 and 39616 by conducting a BARCT assessment of the NOx RECLAIM program and reducing the amount of available NOx RTCs to reflect emission reductions equivalent to implementing available BARCT;*
2) *Modify the RTC "shaving" methodology to implement the emission reductions per the BARCT assessment;*
3) *Ensure that RECLAIM facilities, in aggregate, achieve the same emission reductions that would have occurred under a command-and-control approach;*
4) *Achieve the proposed NOx emission reduction commitments in the 2012 AQMP Control Measure #CMB-01: Further NOx Reductions from RECLAIM; and,*
5) *Achieve NOx emission reductions to assist in attaining the NAAQS."*

The comment that the project objectives do not appear to inform the alternatives and are independent of the proposed project seems to misunderstand the purpose of the project objectives. To repeat line-by-line each element of the project description is not what the project objectives requires. Rather, the project objectives are the foundation upon which the proposed project is based. The proposed project consists of amending the NOx RECLAIM rules in compliance with multiple and complex applicable requirements. The project objectives, cited above, form the framework for crafting the alternatives.

It is important to keep in mind that a CEQA document need not consider an alternative whose effect cannot be reasonably ascertained and whose implementation is remote and speculative. In addition, though the range of alternatives must be sufficient to permit a reasoned choice, they need not include every conceivable project alternative (CEQA Guidelines §15126.6 (a)).

As a result, alternatives to the proposed project were crafted by varying how the NOx RTC shave would be applied to the NOx RECLAIM facilities and RTC investors in order to ascertain if there is a project that could meet the project objectives while having lessened impacts than the proposed project. The initial analysis of the proposed project in the NOP/IS determined that, of the amendments proposed, only the components that pertain to the lowered BARCT NOx emission factors could entail physical modifications to the affected equipment and that these physical modifications could create potential adverse significant impacts. As such, in addition to the no project alternative, three alternatives were developed by identifying and modifying major components of the proposed project. Specifically, the primary components of the proposed alternatives that have been modified are the source categories that may be affected, and the manner in which compliance with the proposed lowered BARCT NOx emission factors may be achieved. In addition, in response to comments made by industry, a fifth alternative, with parameters suggested by industry, was also included.

Finally, it is important to note that the reference to Health and Safety Code §39616 has been deleted because it does not require a BARCT analysis. The RECLAIM program proposed here satisfies the findings set forth in Health and Safety Code §39616, although it is not legally required to do so.

2-29 This comment implies that the project is inconsistent with the 2012 Air Quality Management Plan because it goes beyond that control measure's identified 3 to 5 tpd NOx reductions. As explained in Response 2-28, the project proposal needs to meet all five of the project objectives and not just project objective #5 to comply with the initial NOx emission reduction commitment in CMB-01. Furthermore, control measure CMB-01 expressly states that RECLAIM must implement BARCT, so further reductions will be sought if required to attain BARCT. CMB-01 also states that because substantial NOx reductions are needed by 2023, if more reductions are feasible and cost-effective, then they will be considered. (2012 AQMP, Appendix IV-A, Page IV-A-60.) Nothing in CMB-01 limits the rule development efforts to seeking only 3 to 5 tpd.

2-30 This comment asserts that the SCAQMD staff analysis "focused primarily on assessing the maximum number of remaining NOx emissions that could be reduced, to the exclusion of other analyses." California state law defines BARCT as an emissions limitation based on "the maximum degree of reduction achievable" taking into consideration economic impacts. [Health and Safety Code §40406.] Therefore, SCAQMD staff and its consultants examined what BARCT measures could feasibly be implemented, including consideration of costs. Then, after adding allowances for growth, a compliance margin, and BARCT uncertainty, SCAQMD staff set a "remaining emissions" target, and derived the proposed shave as needed to reach that target. SCAQMD staff also prepared a Socioeconomic Report to fully evaluate and disclose the economic impacts of the proposed amendment, and the Draft PEA to disclose the environmental impacts. The fact that the proposed amendments seek more reductions than projected in CMB-01 does not mean cost was not considered. As explained under Area of Controversy Item 5, "The staff proposal is the result of a much more rigorous and in-depth analysis as compared to the analysis that supported control measure CMB-01. For a market-based incentive program, SCAQMD staff is required by the California Health and Safety Code to conduct periodic BARCT reassessments and demonstrate equivalency with command-and-control rules which would otherwise be developed as a result of BARCT reassessment. CMB-01 anticipated this BARCT assessment but could not predict the results of the assessment, and therefore made commitments for a more modest reduction. This staff proposal recommends a reasonably available 14 tpd of NOx RTC reductions, based on BARCT, as required by state law, and the other aforementioned factors. The reduction is also needed to help the Basin achieve the PM2.5 standards by 2019 and 2025 and the ozone standards by 2024 and 2032." As explained in Responses 2-2 and 2-8, the PEA identifies which parts of the proposed project may result in physical effects and the PEA fully analyzes the environmental effects accordingly. This comment asserts that the project has the potential to trigger "unintended consequences" but there is no explanation of such consequences nor evidence to support such a claim.

2-31 Evaluation of the cost-effectiveness of a project is required as part of the rule development process and not CEQA. The $50,000 per ton cost-effectiveness threshold is a criteria applied during rule development to eliminate types of control devices or the application of control equipment for specific equipment before they ever become part of the project. For this reason, cost-effectiveness is not included as a project objective in the PEA because it is an obligation that has to be met as part of formulating a proposal. This comment asserts that the project has a cost which far exceeds that which implementation of BARCT would cost under command-and-control. SCAQMD staff disagrees. The socioeconomic analysis includes a comparison of the costs of implementing the proposed amendments compared to the costs of implementing BARCT under command-and-control, considered on an aggregate basis. At worst, the cost of implementing BARCT-level controls would be the same under RECLAIM as under command-and-control. Because of the flexibility inherent in RECLAIM, it is possible that less costly means to comply will be found. Moreover, RECLAIM has resulted in very substantial cost savings in the past compared to implementing command-and-control.

This comment also asserts that the SCAQMD used a $50,000 cost-effectiveness threshold for the RECLAIM program, while the AQMP used a threshold of $22,500, and the SCAQMD's BACT (Best Available Control Technology) guidance uses a cost-effectiveness of $19,100 per ton. This comment fails to explain how, even if true, this would result in environmental impacts that have not been analyzed, since the Draft PEA assumed that all the identified BARCT controls would be installed, thus resulting in a reasonable worst-case analysis. Moreover, this response compares apples and oranges. The $22,500 threshold in the 2012 AQMP merely triggers more in-depth analysis; it is not a cut-off barring further controls. In BARCT may be more stringent than BACT. See American Coatings Assoc. v. SCAQMD, 54 Cal.4th (2012). See also Response 2-27.

2-32 This comment asserts that the SCAQMD staff used an erroneous useful life when calculating equipment cost-effectiveness. Even if this were true, the comment does not explain how using a different equipment life would result in greater environmental impacts than have already been analyzed. If a shorter equipment life were used, there is the possibility that some controls that were assumed in the draft PEA would no longer be required, thus reducing the potential environmental impacts of the project. Moreover, the comment asserts that the SCAQMD should not use a 25-year useful life because it may amend the RECLAIM rules again in 10 years. While there is always that possibility, there is no evidence to support the assumption that such an amendment would result in having to entirely replace and discard control equipment after only 10 years. Industry has not identified any control equipment that was required to be installed to implement the 2005 RECLAIM amendments that will be discarded as a result of the currently-proposed amendments. It is unlikely that such a result would occur for future amendments. Instead, if a candidate BARCT were identified that would require discarding equipment, that cost would be included in the cost-effectiveness calculation for the candidate BARCT, likely making it no longer cost-effective. As a result, any impacts from future amendments to RECLAIM are speculative, and not a result of the presently-proposed project.

2-33 SCAQMD staff disagrees that Alternative 3 meets all of the project objectives and that the PEA must be recirculated for public review and comment. The proposed NOx RTC shave under Alternative 3 was shown to be substantially less than the proposed project (e.g., 8.77 tpd compared to 14.0 tpd) and the PEA concluded that the entire 8.77 tpd NOx RTC shave could be addressed with unused RTCs without having any facilities modifying their equipment to achieve actual NOx reductions from installing air pollution control equipment. For this reason, Alternative 3 was concluded to not satisfy project objective #2 "to modify the RTC "shaving" methodology to implement the emission reductions per the BARCT assessment." The Industry Approach (Alternative 3) would not result in achieving the maximum level of reductions achievable and so does not meet the legal requirements under Health and Safety Code §40406, and thus, does not meet all of the project objectives.

2-34 Because of the nature and design of the proposed project, there are multiple criteria with which to comply, as outlined in the project objectives, and the alternatives also must be crafted to attain most of the basic objectives of the project while avoiding or substantially lessening any of the significant effects of the project. In this case, the range of alternatives was constrained by the legal requirement to achieve BARCT-level reductions over the RECLAIM universe in the aggregate. Unlike typical "project objectives" which may be modified at the discretion of the project proponent, the SCAQMD is legally required to implement BARCT for RECLAIM sources. [Health and Safety Code §§40440, 40919.] Therefore, although CEQA allows an alternative to meet "most" project objectives, in this case SCAQMD staff could not consider alternatives that did not at least attain BARCT. While the proposed project, Alternative 1 and Alternative 5 all have the same amount of proposed NOx reductions (e.g., 14 tpd), the distribution of the type of reductions, the manner in which those reductions are achieved, and the type and number of facilities that are affected, are very different. For example, for the proposed project, Alternative 1 and Alternative 5, the 14 tpd reduction would be bifurcated into two parts with: 1) an actual emissions reduction of 8.77 tpd from installing new or modifying existing air pollution control equipment on affected sources as part of the BARCT analysis; and, 2) a reduction of NOx RTC holdings (e.g., a NOx RTC shave) of 5.23 tpd. While the overall total number NOx reductions appear to be the same for each, the facilities in the NOx RECLAIM universe are affected very differently. In particular, for the proposed project, the total 14 tpd of NOx reductions is achieved by applying the NOx RTC shave applied to 90 percent of RTC holders which would only affect 56 facilities. Under Alternative 1, the total 14 tpd of NOx reductions is achieved by applying a 53 percent reduction to all NOx RECLAIM facilities. Finally, under Alternative 5, the total 14 tpd of NOx reductions is achieved by applying a weighted average of the BARCT reduction contribution to all facilities and investors.

As explained in Response 2-8, a CEQA document is not required to consider an alternative whose effect cannot be reasonably ascertained and whose implementation is remote and speculative. In addition, though the range of alternatives must be sufficient to permit a reasoned choice, they need not include every conceivable project alternative (CEQA Guidelines §15126.6 (a)).

By including Alternative 2 with the highest amount of NOx emission reductions and Alternative 3 with the lowest amount of NOx emission reductions, notwithstanding the no project alternative (e.g., Alternative 4), SCAQMD staff believes that a sufficient range of alternatives has been considered and analyzed in the PEA.

2-35 SCAQMD staff disagrees that Alternative 3 is the environmentally superior alternative because even if Alternative 3 has less adverse environmental impacts from construction and operation activities, it achieves much less NOx emission reductions and does not satisfy all of the objectives. This comment claims that the proposed amendments would remove "nearly all of the unused NOx RTCs from the RECLAIM market." This is incorrect. Even after the shave is fully implemented in 2023, there are expected to be over 20 percent of unused RTCs available in the market. Moreover, Alternative 3 does not meet all of the project objectives because it can be almost entirely satisfied by merely surrendering unused RTCs, and not resulting in any substantial actual emission reductions. The Industry Approach, Alternative 3, subtracts 8.77 tpd from the existing number of RTCs, 26.51 tpd, to obtain a remaining emissions amount of 17.72 tpd. This is only 0.51 tpd less than the 18.25 tpd that would have been emitted by RECLAIM facilities at 2005 BARCT, thus gaining only about 0.5 tpd of real emission reductions. While there is the potential that facilities may install some additional controls, and thus, attain some additional reductions, in order to maintain a "compliance margin" of RTCs, there is no reason to assume that the facilities would not give up any of the large amount of excess RTCs under Alternative 3. Therefore, this proposal does not demonstrate why additional reductions are not achievable, and thus, does not meet the legal requirements for implementing BARCT.

By taking into consideration the amount of the shave that would be applied by each of the alternatives as an indicator of how facility operators may respond to the reduced amount of available NOx RTCs in the market, then Alternative 2 would have the greatest chance of ensuring that all control equipment that is contemplated would be installed in order to ensure that the maximum amount of NOx emissions reductions projected would actually occur. For this reason, Alternative 2 was selected by staff as the environmentally superior alternative. Although this alternative would have the greatest amount of impact from construction and operation of control equipment, the overall impact to the environment over the long term is highly beneficial by inducing greater NOx reductions. The comment letter seems to incorrectly assume that a lead agency cannot consider the environmental benefits of a project when identifying the environmentally superior alternative.

2-36 As explained in Response 2-25, the PEA contains a program level analysis of the potential effects of the proposed project but also anticipates future activities. The PEA acknowledges that implementation of the proposed project may result in the construction and operation activities that may cause environmental impacts for some facilities. However, it is also possible that these same facilities may already have sufficient NOx RTCs available or may choose to purchase more NOx RTCs to comply with the proposed project instead of installing new or modifying existing air pollution control equipment. As explained in the alternatives analysis in the Chapter 5 of the PEA, Alternative 3, by only having to achieve 8.77 tpd of RTC reductions instead of 14 tpd, less environmental impacts would be expected to occur because fewer construction projects and corresponding operation activities would be needed to achieve the overall emission reduction goal. Further, with fewer construction and operation activities, the resulting environmental impacts would also be lesser. However, it is not necessarily the case that the projects foregone would always be those which use ammonia. While the comment letter asserts that the likely NOx emission control projects can be quantified, it does not provide any evidence as to which specific projects would be foregone. While cost-effectiveness may provide a reasonably foreseeable projection of potential future compliance activities which were analyzed in the PEA, to determine which construction projects would go forward and which would not in order to further define which specific environmental topic areas would be reduced, would require speculation which is prohibited by CEQA.

2-37 This comment claims that the Draft PEA did not explain why the proposed project will only result in 8.77 tpd emission reductions when history suggests a one-to-one ratio between RTC reductions and program emission reductions. SCAQMD staff disagrees that any such fixed ratio exists. For example, if the years 2007-2011 are considered (implementation of the 2005 NOx shave), RTCs were reduced by 7.66 tpd, while emissions were reduced only 4.09 tpd, for a ratio of 0.53 ton of emissions reduced for every ton of RTCs reduced. The Draft PEA accounted for the fact that if RTCs are not significantly reduced, there will be enough excess RTCs in the market that facilities can simply surrender unused RTCs, without making significant real emission reductions. For a discussion of why the Industry Approach (Alternative 3) does not meet BARCT, see Response 2-35.

This comment claims that Alternative 3 meets 8.77 tpd of emission reductions and attains BARCT, but does so with fewer environmental impacts. SCAQMD staff disagrees. Alternative 3 would not obtain the same emission reductions as the proposed project unless it is assumed that industry would not give up any of the excess unused RTCs in the market, and instead would install exactly the same controls as they would under a 14 tpd shave. Industry has not provided any substantial evidence that facilities would not give up excess unused RTCs, especially since the current value of RTCs (less than $4,000 per ton) is substantially less than the average cost of control for the proposed shave ($13,615 per ton as stated in the Draft Final Socioeconomic Report, Table 7, page 13).

The adverse environmental impacts of Alternative 3 would be equivalent to the proposed project only if all 8.77 tpd of NOx emission reductions are achieved from installing new or modifying NOx air pollution control equipment. As explained in Response 2-36, it is possible that the affected facility operators may already have sufficient NOx RTCs available or may choose to purchase more NOx RTCs to comply with the proposed project instead of installing new or modifying existing air pollution control equipment. Thus, because Alternative 3 has less incentive to reduce actual NOx emissions and instead has a higher likelihood of achieving “paper emission reductions” by relying on unused RTCs rather than having control equipment installed, Alternative 3 does not qualify as the environmentally superior choice. Moreover, even in the highly unlikely event that Alternative 3 resulted in the same actual emission reductions as the proposed project, by installing and operating control equipment, it would have the same environmental impacts as the proposed project and would thus not be environmentally superior.

2-38 See Response 2-28, and Responses 2-35 through 2-37.

2-39 The staff proposal for the rule amendments used established industry-specific growth factors to project RTCs needed for all RECLAIM sectors, including electricity generating facilities (EGFs), and included these needs in the remaining emissions target for the shave. The growth factors used in the analysis were provided by the Southern California Association of Governments and are the same as used in the 2012 AQMP, except for electricity generating facilities which used a growth factor from the 2014 California Gas Report (see Appendix W of the Revised Draft Staff Report, pp. 217-218).

The staff proposal has been refined over recent months to address many of the concerns that stakeholders have raised. The staff proposal contains several safeguards that would provide EGFs with an adequate amount of credits, while concurrently achieving the objective of the proposal, which is to effect the installation of BARCT for the applicable equipment categories identified. The safeguards include access to non-tradable/non-usable RTCs with a faster 3-month trigger. The 12-month trigger remains, but the threshold level is now $22,500 per ton. In the event of a State of Emergency declared by the Governor, EGFs would have access to non-tradable/non-usable credits. If these credits are exhausted, EGFs would also have access to the credits in the Regional NSR Holding Account. Furthermore, EGFs now have the option to exit the RECLAIM program if they meet certain requirements. Under this option, an EGF would no longer be concerned with the possibility of an RTC shortage, even though staff believes that there will not be a shortage if BARCT controls are implemented for those applicable facilities that were analyzed. Finally, the SCAQMD staff will propose a Governing Board Resolution which directs SCAQMD staff to monitor the increased demand for electricity, and the needs of electricity generating facilities in RECLAIM and report to the Governing Board or Stationary Source Committee, as appropriate. With these safeguards in place, no adverse impact on electrical reliability is anticipated, so there would be no resulting adverse environmental impacts. See also Responses 2-21 and 2-22 regarding RECLAIM facilities that are no longer in operation.

2-40 Contrary to the comment, Chapter 4, Subchapter 4.3 of the PEA, contains an energy impact analysis which identifies the net effect on energy resources relating to the construction and operation of new or modified NOx air pollution control equipment that may occur as a result of implementing the proposed project. See also Responses 2-21, 2-22, 2-39, 4-5 and 6-3.

2-41 The projected increased use of ammonia by 39.5 tpd does not mean that 39.5 tpd of ammonia will be emitted into the atmosphere. If that were the case, the injection of ammonia into SCR units would be rendered useless for reducing NOx emissions. Rather, the projected increased use of ammonia by 39.5 tpd represents the amount injected into the flue gas streams by all the potential SCRs needed to reduce NOx. While most of the ammonia reacts with the NOx to form elemental nitrogen (N_2) and water in the cleaned exhaust gas, there is a small amount of unreacted ammonia (ammonia slip) that also passes through. SCAQMD staff conducted a series of regional simulations to determine the impacts of reducing NOx by the proposed RTC shave while increasing the potential for creating ammonia slip due to increased use of ammonia needed for the operation of SCR controls. In the analysis, NOx emissions were reduced at RECLAIM facilities by a total of 14 tpd while increasing ammonia slip emissions from the same facilities by 1.63 tpd. The simulations were run for the 2021 draft baseline emissions inventory to estimate the impact when full implementation of the RECLAIM shave was expected to be achieved. The effect of decreasing 14 tpd of NOx would result in a decrease of annual PM2.5 of approximately 0.7 $\mu g/m^3$. However, since ammonia is necessary to achieve the 14 tpd of NOx emission reductions, the use of ammonia would cause a concurrent increase in annual PM2.5 of approximately 0.6 $\mu g/m^3$. Thus, increasing the amount of ammonia slip would result in net average 0.1 μg/m^3 decrease in annual PM2.5. Further, simulations showed that no change in ozone would be expected compared to what would occur with no increase in ammonia slip. The overall decrease in annual PM2.5 would occur provided that all 14 tpd of NOx emissions will be reduced, which in turn would reduce PM2.5 emissions overall, even if some PM2.5 emissions are generated from ammonia slip. In summary, the impacts to regional PM2.5 and ozone due to increased ammonia slip in the simulations would not create a significant impact.

This comment also asserts that the analysis should have used 20 ppm ammonia slip from SCRs rather than the 5 ppm required by SCAQMD permits because existing SCRs may not have that permit condition. However, existing SCRs, except for one, are not part of the proposed project and therefore, are not part of the environmental impacts of the proposed project. One existing SCR is expected to use increased catalyst as a compliance mechanism, but all other projected SCRs are new. For these reasons, the health risk analysis for ammonia in the PEA does not need to be revised.

2-42 The Draft PEA considered potential hazards impacts that were reasonably foreseeable at the time of its preparation for both accidental and non-accidental releases, Relative to accidental releases, an ammonia analysis was conducted in Chapter 4, Subchapter 4.3 of the PEA which addresses both an ammonia transportation spill scenario and two ammonia tank rupture scenarios (non-refinery and refinery). The analysis concluded that only ammonia transportation activities could potentially cause significant adverse hazards and hazardous materials impacts.

Relative to non-accidental releases (e.g., operational emissions or concentrations), the analysis in the PEA relies on SCAQMD Rule 1401 – New Source Review of Toxic Air Contaminants, which by design, prevents significant adverse environmental impacts. In order for a facility to install control equipment that requires ammonia use and storage for its operation, the facility operator will need to submit a permit application which will undergo an analysis in accordance with Rule 1401 to determine the increases, if any, in the maximum individual cancer risk (MICR), cancer burden, and chronic and acute hazard indices. The SCAQMD's CEQA significance thresholds allow any project that will comply with Rule 1401 to be considered to have a less than significant impact.

Further, ammonia slip is limited to 5 ppm concentration by permit condition for each new or modified permit unit. Based on the June 2015 Staff Report for SCAQMD Rule 1401.1 – Requirements for New and Relocated Facilities Near Schools, and SCAQMD Rule 1402 – Control of Toxic Air Contaminants from Existing Sources, the concentration at a receptor located 25 meters from a stack would be much less than one percent of the concentration at the release from the exit of the stack. Thus, the peak concentration of ammonia at a receptor located 25 meters from a stack is calculated by assuming a dispersion of one percent. So even if multiple SCRs are installed at one facility, each SCR would be limited to a concentration of 5 ppm ammonia slip which would pass the Rule 1401 requirements. When calculating risk, concentrations (mass per volume) are not additive. Multiple adjacent stacks generating 5 ppm ammonia concentrations from ammonia slip would still only result in a total maximum ammonia concentration of 5 ppm, which based on the analysis in the PEA, is not expected to cause an offsite risk.

Finally, each affected refinery is subject to the Air Toxics "Hot Spots" Information and Assessment Act in accordance with the California legislature's AB2588 program. Under AB2588, facilities are required to submit an air toxics inventory through the SCAQMD's Annual Emissions Report (AER) Program and potentially high risk facilities must prepare a health risk assessment (HRA). If the risk reported in the HRA exceeds specific thresholds, then the facility is required to provide public notice to the affected community. Facilities with health risks above the action risk levels in Rule 1402 must reduce their risks to the community.

Of course, if site-specific characteristics and circumstances are involved with future projects to install NOx control equipment that utilize ammonia that are outside the scope of this analysis, a further facility-specific ammonia hazards analysis may be warranted. This information will be considered as part of the future project level CEQA review to determine if new or worsened impacts will occur when compared to what was analyzed in the PEA.

2-43 This comment notes that SCAQMD staff identified a potential control measure for the 2016 AQMP to reduce ammonia slip from NOx controls. Even if this measure is ultimately included in the 2016 AQMP, the proposed RECLAIM amendments are not inconsistent with such a measure. The socioeconomic analysis of the staff proposal does not anticipate actual installation of controls until 2018 or later[8], which would provide sufficient time to adopt and incorporate any new ammonia control measure into the permits issued for NOx controls under RECLAIM. Moreover, even if there were increased ammonia slip that creates increased PM2.5, that would not mean the project as a whole has an adverse impact on the environment, but only that the expected PM2.5 benefits might be lessened. For a discussion of ammonia slip impacts, see Response 2-41.

2-44 CEQA Guidelines §15155 – City or County Consultation with Water Agencies, defines a "water-demand" project in several ways. While the criteria for defining water demand are not significance thresholds per se, the criteria in this section provides some insight as to how water purveyors or city or county lead agencies evaluate water-demand impacts. Note that the SCAQMD does not qualify as a water purveyor or a city or county lead agencies under this part.

Nonetheless, the analysis in CEQA documents needs to make a significance determination relative to water demand. Most of the criteria in CEQA Guidelines §15155 do not have a bright line or direct way to correlate the criteria in terms of gallons per day (gal/day) in order for SCAQMD staff to determine what a water demand project would

[8] SCAQMD, Revised Draft Socioeconomic Report for Proposed Amendments to Regulation XX - Regional Clean Air Incentive Market (RECLAIM), October 6, 2015, Table 8, p. 15. http://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/regxx/reclaim_revisedsociodraft.pdf?sfvrsn=2

be. As such, in 2008, SCAQMD staff examined CEQA Guidelines §15155 (a)(1)(C) which defines a water-demand project as: "A commercial office building employing more than 1,000 persons or having more than 250,000 square feet of floor space" and estimated what this means in terms of water demand per person relative to the square footage (sf) of the floor area of the plant[9], commercial water usage rates[10] and average employment levels[11] (i.e. the number of employees per square foot) can be applied as follows:

Commercial Water Usage in California in Year 2000:

$$\frac{\text{1,850,000 ACRE FEET WATER}}{\text{YEAR}} \times \frac{\text{325,851 GALLONS}}{\text{1 ACRE FOOT WATER}} \;/\; \text{4,920,114 X 10}^{3}\text{ FT}^{2}\text{ OF COMMERCIAL FLOOR STOCK} = \text{123 GALLONS WATER PER YEAR PER FT}^{2}\text{ OF COMMERCIAL FLOOR STOCK}$$

$$\frac{\text{123 GAL WATER}}{\text{(YEAR) (FT}^{2}\text{ OF BUILDING)}} \times \frac{\text{1,000 FT}^{2}\text{ OF BUILDING}}{\text{1.8 EMPLOYEES}} \times \frac{\text{1 YEAR}}{\text{260 DAYS}} \times \text{1,000 EMPLOYEES} = \text{262,820 GAL/DAY}$$

This water demand estimate was then applied to industrial sources because CEQA Guidelines §15155 (a)(1)(E) uses the same 1,000 employee level to defines a water-demand project as: "An industrial, manufacturing, or processing plant or industrial park planned to house more than 1,000 persons, occupying more than 40 acre of land, or having more than 650,000 square feet of floor area." Because the potable water demand calculation based on 1,000 employees is more in line with industrial applications, the potable water demand significance threshold currently in effect is 262,820 gal/day.

The PEA conducts a program level analysis that relies on this potable water significance threshold. The PEA estimates the projected increases in water demand for hydrotesting and operational activities for each affected facility. See Chapter 4, Subchapter 4.5, Tables 4.5-6 through 4.5-8 for hydrotesting water demand and Tables 4.5-9 and 4.5-10 for operational water demand.

Since the release of the Draft PEA for public review and comment, the operators of one refinery have indicated plans to shut down one FCCU in 2017. Thus, the installation of WGS technology along with the corresponding increased water demand and wastewater generation projections that were originally contemplated for one of the two FCCUs (e.g.,

Refineries 4 and 9) identified in Tables 4.5-9 and 4.5-10 are no longer expected to occur. Thus, the potential increase in water demand needed for the operation of WGS technology is expected to be less than what was previously analyzed and will affect six of the seven refineries. To protect the identity of the refinery in this document, Subchapter 4.5 of this PEA has been revised to reflect that the potential increase in operational water demand will range from 553,499 gal/day to 558,978 gal/day, instead of 602,814 gal/day as shown in Table 4.5-9. While this range still exceeds the potable water demand significance threshold of 262,820 gal/day, there are several circumstances that lead SCAQMD staff to believe that most of this water demand may be supplied with recycled water instead.

Because of the drought and the uncertainty of future water supplies, it was not clear at the time of the release of the Draft PEA whether water suppliers would be able to accommodate the additional operational water demand if the proposed project goes forward, especially if potable water would be relied upon to supply the water demand. Subsequently, SCAQMD staff has been able to verify that projected water deliveries of potable water and recycled water to industrial sources will be able to supply the potential water demand needs of the proposed project. As part of making a determination if water supplies will be sufficient for the proposed project, the availability of recycled water is an important factor. For example, as explained in Subchapter 4.5, Refineries 1, 5 and 6 currently access recycled water from the Harbor Refineries Recycled Water Pipeline (HRRWP) which is maintained by the Los Angeles Department of Water and Power (LADWP), in conjunction with the West Basin Municipal Water District (WBMWD). The LADWP/WBMWD currently provides 35 million gallons per day (MMgal/day) of recycled water to its customers, which include Refineries 1, 5, and 6. The WBMWD is also in the process of expanding its Hyperion Pump Station to accommodate a throughput of 70 MMgal/day of source water which would result in about 55 to 60 MMgal/day of saleable recycled water if, and when needed to accommodate any increased need by their customers[12]. When operators of these three refineries utilize recycled water in lieu of potable water to satisfy the water demand for the NOx control equipment that may be installed in response to the proposed project, then the LADWP/WBMWD would be able to supply the additional water (e.g., 398,767 gal/day or approximately 71 percent of the total projected water demand) to these three refineries. A mitigation measure is proposed that would effectively require these operators to use recycled water.

At the time of writing the Draft PEA, SCAQMD staff was not able to confirm whether three refineries (e.g., Refineries 4, 8 and 9) have connected to the HRRWP to access its supply of recycled water. To date, none of these refineries have connected to the HRRWP. However, Refinery 4 is in the process of finalizing an agreement with WBMWD to acquire 2,240 acre-feet/year (AF/yr)[13] of recycled water (equivalent to two MMgal/day) to replace its current potable water use with recycled water by 2018. In addition, Refineries 4, 8, and 9 are also currently in talks with LADWP to negotiate options for replacing as much as 11,100 AF/yr (equivalent to approximately 9.9

[12] Personal communications with Uzi Daniels and Joe Walters, West Basin Municipal Water District, August 3, 2015 and November 4, 2015.

[13] 1 acre-foot = 325,851 gallons

MMgal/day) of current potable water use with recycled water instead via the HRRWP[14]. Thus, if Refineries 4, 8 and 9 need additional recycled water in response to this proposed project, the LADWP/WBMWD has the capacity to provide additional recycled water as necessary[12]. If recycled water is not available at these refineries, then potable water is also available.

Further, Refinery 2 is not located near the HRRWP nor any other recycled water pipeline so it is unlikely that Refinery 2 would be able to obtain recycled water should facility operators choose to install a WGS and instead, would need to satisfy the water demand with potable water. According to the Long Beach Water Department's (LBWD's) 2010 UWMP that was prepared in accordance with the California Water Code §10608.20, the potable water delivery projections to their industrial and commercial customers show a long-term projected increase in potable water supply with a slight tapering occurring in years 2030 and 2035 to reflect offsetting by increased deliveries of recycled water to other customers currently being supplied by LBWD with potable water (see Final PEA, Chapter 4, Subchapter 4.5 – Hydrology and Water Quality, Table 4.5-18, p. 4.5-20. Based on LBWD's short- and long-term projections for potable and recycled water supplies, SCAQMD staff believes that the potential increased water demand of 40,896 gallons per day for Refinery 2 can be accommodated.

In addition, it is important to keep in mind that operators of Refinery 2 have two different types of control equipment options available for consideration. As summarized in Tables 1-2 and 1-3 for the petroleum coke calciner source category, the BARCT NOx levels of 10 ppmv corrected for 3% oxygen can be achieved with either a WGS which uses water, or a DGS, which does not. While the analysis in this subchapter considers the technology with the worst-case impacts to water demand and water quality, for Refinery 2, installing WGS technology is not their only option. Should operators choose to install a DGS, instead of a WGS, then no water would be needed.

Thus, while the amount of water demand that would be needed to operate NOx control equipment would be 398,767 gallons per day at Refineries 1, 5 and 6 and the amount of water demand at Refineries 2, 4, 8, and 9 would be in the range of 113,836 gallons per day to 160,211 gallons per day, which collectively is greater than the significance threshold of 262,820 gallons per day of potable water but less than the significance threshold of five million gallons per day of total water (e.g., potable, recycled, and groundwater), in consideration that Refineries 1, 5 and 6 have a high potential to use recycled water because of their current access and in light of the negotiations for recycled water at Refineries 4, 8, and 9, potable water only may be needed for a future project occurring at Refinery 2, or not at all if operators of Refinery 2 choose to install a DGS instead of a WGS. In any case, the previous analysis shows that water purveyor would be able to supply potable water to Refinery 2 and to Refineries 1, 4, 5, 6, 8 and 9, if needed. Thus, using an abundance of caution, because the peak daily water demand for the

[14] City of Los Angeles, Inter-Departmental Correspondence to City Council From Los Angeles Department of Water and Power and Los Angeles Department of Public Works Bureau of Sanitation, Council File No. 15-0018 Harbor Refineries Pipeline Project/Advanced Water Purification Facility/Water Supply Efforts, April 10, 2015. https://cityclerk.lacity.org/lacityclerkconnect/index.cfm?fa=ccfi.viewrecord&cfnumber=15-0018

proposed project exceeds the potable water threshold of 262,820 gallons per day and because recycled water is not currently available at Refineries 4, 8 and 9, and no contractual commitments to increase recycled water demand above the existing recycled water baseline for the three refineries that already have access to recycled water (e.g., Refineries 1, 5 and 6) have been finalized, the analysis conservatively assumes that significant adverse impacts associated with water demand are expected from the proposed project during operation.

In general, in order for a facility to install control equipment, the facility operator will need to submit a permit application to the SCAQMD which will undergo a CEQA pre-screening analysis to determine if the project complies with the analysis in the PEA and whether or the project can rely on the PEA or if an additional CEQA document would be required. If water is required for conducting hydrotesting and for operating air pollution control equipment that utilizes water, then the project would be subject to mitigation measures (e.g., HWQ-1 and HWQ-2 for hydrotesting and HWQ-3 and HWQ-4 for operation of air pollution control equipment that utilizes water) which will be incorporated into the permits for enforceability purposes.

For any facility that will need to conduct hydrotesting, mitigation measures HWQ-1 and HWQ-2 require facility operators to utilize both current supplies and future supplies of recycled water in accordance with the California Water Code, and if available, pursuant to the HRRWP or other recycled water pipeline, if available, to conduct hydrotesting. Alternately, facility operators may substitute the use of purchased recycled water with non-potable water such as treated process water (e.g., cooling tower blowdown water, etc.) that is temporarily re-routed or diverted from elsewhere within the facility. See Final PEA, Chapter 4, Subchapter 4.5 – Hydrology and Water Quality, pp. 4.5-10 – 4.5-11.

Similarly, for any facility that installs air pollution control equipment that utilizes water such as WGS as part of the proposed project, mitigation measures HWQ-3 and HWQ-4 require facility operators to utilize both current supplies and future supplies of recycled water in accordance with the California Water Code, and if available, pursuant to the HRRWP or other recycled water pipeline, if available, for operation of that air pollution control equipment. See Final PEA, Chapter 4, Subchapter 4.5 – Hydrology and Water Quality, p. 4.5-23.

These mitigation measures will, if implemented, be effective in reducing the overall demand on potable water, to a less than significant level. It is important to note that if the amount of water needed for each individual project exceeds from the quantities disclosed in the PEA, then a revised water supply assessment may be necessary.

Finally, Subchapter 4.5 of the PEA has been revised to identify the various suppliers of purchased potable and recycled water for the affected facilities and the water suppliers projected supply estimates based on each water supplier's UWMPs. In conclusion, the water demand analysis and conclusions in the PEA has been based on the best available information.

2-45 As explained in Response 2-13, the analysis in the Draft PEA relies on data and methodologies from previous CEQA documents such as the Final EA for NOx RECLAIM that was certified in January 2005 and the Final PEA for SOx RECLAIM that was certified in November 2010, for example. The NOP/ISs prepared for these projects address the potential noise impacts for refineries and other affected non-refinery facilities in a similar manner as the currently proposed project and noise impacts were concluded to be less than significant at the NOP/IS stage. The noise analysis in the NOP/IS for the proposed project was based on best available information for a program level analysis and no concerns were raised relative to noise during the NOP/IS comment period. For this reason, the PEA did not further analyze noise impacts beyond what was contained in the NOP/IS. If and when each actual construction project is proposed as a result of complying with the proposed project, each individual facility operator will have to comply with the local noise element and ordinances applicable to their facility location during both construction and operation after build-out. Thus, less than significant noise impacts would be expected.

2-46 Chapter 4, Subchapter 4.6 of the PEA contains an analysis of the potential solid and hazardous waste impacts that may occur as a result of implementing the proposed project. The significance criteria for determining whether solid and hazardous waste impacts would be significant are based on whether the generation and disposal of hazardous and non-hazardous waste would exceed the capacity of designated landfills. The analysis in the PEA examined the potential volume of operational waste that would either be recycled or disposed of, and concluded that the amount, if disposed of, would not exceed those capacity levels; indeed it is a very small (7.61 tpd) amount relative to the capacities of the 31 Class III landfills and two transformation facilities (107,933 tons per day and day and 3,240 tons per day, respectively). In addition, as explained in Chapter 4, Subchapter 4.6, due to the heavy metal content and its relatively high cost, catalyst recycling, in lieu of disposal, can be a lucrative and likely preferred choice of facility operators. If recycling is utilized, the estimated impacts to solid waste would be less than what was analyzed in the PEA.

It is important to keep in mind that landfills undergo their own separate CEQA analysis as part of their permitting process, whether to continue to operate, extend closure dates, or expand operations, and this analysis already considers the impacts on the nearby communities. Thus, the suggestion to evaluate the impact of communities that are located near hazardous waste landfills, is not necessary nor required to be included in the PEA.

Regarding the use of increased ammonia to operate SCR technology, see Responses 2-41 and 2-42.

2-47 As explained in Responses 2-21 and 6-5, the past reduction in the number of facilities that participate in the NOx RECLAIM program over the years from 392 to 275 is not a product of the proposed project that would require an analysis in this PEA. The comment also asserts that the PEA did not adequately analyze the growth-inducing impacts of the project, and that the PEA did not explain the source of the growth factors used, and that the PEA should consider a scenario which allows for more growth of RECLAIM facilities, and modify the growth-inducing impacts accordingly. The growth factors used in the analysis were provided by the Southern California Association of Governments and are the same as used in the 2012 AQMP, except for electricity generating facilities which used a growth factor from the 2014 California Gas Report (see Appendix W of the Draft Staff Report, pp. 217-218). Even if the economy grows more than projected so that the RECLAIM facilities also grow more than projected, this would not be a result of the proposed RECLAIM amendments but of independent factors in the economy. CEQA only requires consideration of the growth-inducing aspects of the project. The only potential growth inducing impact identified was an increased need for construction workers during the installation of controls. This impact was fully analyzed in the PEA (see Chapter 4, Subchapter 4.8, pp. 4.8-10 to 4.8-13).

2-48 The SCAQMD's mission statement is based on the concept that all who live or work in this area have a right to breathe clean air. The SCAQMD is committed to undertaking all necessary steps to protect public health from air pollution, with sensitivity to the impacts of its actions on the community and businesses. This is accomplished through a comprehensive program of planning, regulation, compliance assistance, enforcement, monitoring, technology advancement, and public education.

Further, when it comes to conducting a CEQA analysis for proposed projects, including amending rules and regulations as is the case with this project, CEQA Guidelines §15021 establishes a duty for all public agencies to avoid or minimize environmental damage where feasible and this duty is implemented through the findings requirements in CEQA Guidelines §15091. The findings, as well as the Statement of Overriding Considerations and mitigation monitoring plan, are included as an attachment to the Resolution of the Governing Board package.

The SCAQMD staff believes that the PEA has fully identified and analyzed the potentially significant adverse impacts of the proposed project and that the commenter has not presented any new evidence that would warrant the addition of new information to the PEA that would require recirculation of the PEA for an additional public review and comment period.

2-49 The NOP contained the following general overview of the nature, description and beneficiaries of the proposed project which clearly states in the underlined text below that the SCAQMD intended to shave available RTCs:

> *"SCAQMD staff is proposing amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM), Rule 2002 – Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx), to reduce the allowable NOx emission limits based on current Best Available Retrofit Control Technology (BARCT) to achieve additional NOx emission reductions for the following industrial equipment and processes: 1) fluid catalytic cracking units (FCCUs); 2) refinery boilers and heaters; 3) refinery gas turbines; 4) sulfur recovery units – tail gas treatment units (SRU/TGUs); 5) non-refinery/non-power plant gas turbines; 6) non-refinery sodium silicate furnaces; 7)*

non-refinery/non-power plant internal combustion engines (ICEs); 8) container glass melting furnaces; 9) coke calcining; 10) Portland cement kilns; and, 11) metal heat treating furnaces. Additional amendments are proposed to establish procedures and criteria for reducing NOx RECLAIM Trading Credits (RTCs) and NOx RTC adjustment factors for year 2016 and later. For clarity and consistency throughout the regulation, other minor changes are proposed to: 1) Rule 2011 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping Oxides of Sulfur (SOx) Emissions; and, 2) Rule 2012 Appendix A – Protocol for Monitoring, Reporting, and Recordkeeping Oxides of Nitrogen (NOx) Emissions. The Initial Study identifies the following environmental topics as areas that may be adversely affected by the proposed project: aesthetics; air quality and greenhouse gas emissions; energy; hydrology and water quality; hazards and hazardous materials; solid and hazardous waste; and, transportation and traffic. Impacts to these environmental areas will be further analyzed in the Draft Program Environmental Assessment (PEA)." [emphasis added]

Similar statements expressing this same intention were also made in the IS on pages 1-2 and 1-7, for example. It is important to keep in mind that the project description in the PEA reflects updates to the project that occurred during the rule development process and as such, the version that was in the Draft PEA was not identical to the description in the NOP. The project description in the Draft PEA represented an updated version of the project at the time and superseded the project description in the NOP. Similarly, the project description in the Final PEA has been further revised since the release of the Draft PEA, and now contains the final version of the project.

If the commenter has interpreted "modify the RTC shaving methodology" to mean that a necessary part of the project is to change from an across-the-board shave to a shave more targeted to the sources that have new BARCT controls available, this was not the intent of the statement. While staff believes that a targeted shave is more equitable, and was used in the 2010 SOx RECLAIM amendments, the PEA presents alternatives for the Governing Board's consideration that include an across-the-board shave.

2-50 This comment asserts that a 14 tpd shave is not necessary and may violate Health and Safety Code §40406 which requires consideration of economic factors in setting BARCT levels. Staff disagrees. For a discussion of why the 14 tpd shave is necessary, see Responses 2-35 and 2-37. Moreover, the Preliminary Draft Staff Report, Draft Staff Report, and Revised Draft Staff Report clearly explain that the staff considered economic factors in establishing the new BARCT levels for the individual categories of sources, to arrive at a level of remaining emissions that would occur if facilities at 2011 activity levels were to implement 2015 BARCT. Staff then further considered economic factors by adding a growth factor, a compliance margin, and an allowance for BARCT uncertainty to the target remaining emission levels. Finally, the socioeconomic impact analysis considered all the costs of compliance with the proposed amendments, and all of the CEQA alternatives.

This comment also asserts that the proposed amendments violate Health and Safety Code §39616 (c)(1) because they do not produce equivalent or more emission reductions at equivalent or less cost than command-and-control, since they use a higher cost-effectiveness threshold than the threshold stated in the AQMP, they go beyond BARCT, and the findings of Norton Engineering would further reduce the amount of emission reductions. The socioeconomic analyses conducted for the RECLAIM program proposed here satisfies the findings set forth in Health and Safety Code §39616, although it is not legally required to do so. For a discussion of the cost-effectiveness threshold, see Response 2-31. All of these comments are addressed in Appendix Z to the Revised Draft Staff Report. For a discussion of BARCT and equivalency to command-and-control, see Appendix Z, Response 1-5. For an explanation of how Norton Engineering results were addressed in the staff proposal, see Appendix Z, Response 1-6.

This comment also asserts that the staff proposal results in disproportionate impacts, because RECLAIM sources have reduced their emissions by a greater percentage than command-and-control sources since 1994. This does not mean that there are disproportionate impacts. As long as all sources are subject to BARCT, the maximum achievable reductions for that category of source - then all sources are being treated equally, regardless of whether the percent reductions are the same. There are many reasons why some source categories cannot attain the same percent reductions as other categories. For a discussion of the alleged disproportionate impact, see Appendix Z, Response 1-9. Also, the SCAQMD has adopted command-and-control rules with similar percent reductions and cost-effectiveness as are involved in this proposed amendment. For example, Rule 1146 (applies to large boilers and heaters) projected a 65 percent reduction in emissions with a cost-effectiveness ranging from $10,000 to $32,000 per ton. Rule 1146.1 (applies to small boilers and heaters) projected a 71 percent reduction in emissions with a cost-effectiveness of $14,000 to $33,500 per ton. Finally, Rule 1110.2 (applies to engines) projected a 74 percent reduction in emissions with a cost-effectiveness ranging from less than $100 up to $28,000 per ton.

This comment states that the BARCT levels selected for the source categories have not been demonstrated to be broadly achievable. However, Norton Engineering and SCAQMD staff ultimately agreed on the BARCT levels for all categories except refinery boilers and heaters, for which SCAQMD staff made an adjustment in the remaining emissions target. This comment also states that the BARCT levels go well beyond the rules adopted under SCAQMD Regulation XI – Source Specific Standards. However, the proper comparison is what level of BARCT would have been required by the SCAQMD for these same source categories under command-and-control rules, not what has been required for other Regulation XI source categories. The comment also states that the BARCT levels go beyond what is required in other air districts, but provides no supporting data, examples, or citations as evidence. Finally, the comment fails to explain how any of these issues would affect the environmental impacts of the project, which already assume that all the identified BARCT controls would be installed.

2-51 While it is correct that the BARCT analysis focuses on these equipment categories, the paragraph goes on to say: "*Additional amendments are proposed to establish procedures* *and criteria for reducing NOx RECLAIM RTCs and NOx RTC adjustment factors for year 2016 and later. Other minor changes are proposed for clarity and consistency throughout the proposed amended regulation."* Thus, the proposed project is not solely limited to the BARCT analysis. See also Responses 2-2 and 2-8.

Moreover, facility operators may choose to use existing RTCs or purchase additional RTCs in lieu of implementing any of the various control technologies analyzed in the PEA, if they find that doing so would be more cost-effective. While cost-effectiveness may provide a reasonably foreseeable projection of potential future compliance activities which were analyzed in the PEA, staff does not have a way of predicting which approach facilities will actually choose, nor does the comment suggest what facilities might do instead. For these reasons, the analysis in the PEA contemplates a combination of potential future activities, without knowing all of the actual details of individual projects that would be undertaken in the future by facility operators. See also Response 2-16.

2-52 See Response 2-28.

2-53 This comment states that the proposed amendments would result in a level of "unused" RTCs that has only been seen during the power crisis of 2000-2001. This comment is not accurate. Even after full implementation in 2023, the proposed amendments would result in a level of unused RTCs that is over 20 percent greater than expected emissions, i.e. 12.51 tpd RTCs compared to 10.21 tpd expected emissions (2.3 divided by 10.21 = 22 percent). WSPA, as part of the Industry Coalition, stated at the Special Stationary Source Committee held on October 16, 2015, that historically, the amount of unused RTCs, not including during the power crisis, had varied from 15 percent to 30 percent. Thus, because the proposed amendments would result in a 22 percent margin which is within the historical range, this topic does not qualify as a new area of controversy that needs to be added to Table 1-1 in the PEA.

2-54 This comment is a repeat of the sentiments expressed in the August 27, 2015 letter, Comment 1-20. See Revised Draft Staff Report, Appendix Z, Response 1-20, p. 284.

This comment asserts that there continues to be a significant number of unresolved issues related to the analysis by Norton Engineering. For a discussion of how staff accounted for the Norton Engineering analysis in the staff proposal, see Appendix Z to the Revised Draft Staff Report, Response 1-6. This comment also says that staff's adjustment for the one area in which its analysis continues to differ from that of Norton Engineering is improper. The difference between Norton Engineering's approach and staff's approach resulted in a difference of 0.33 tpd emissions. Staff accounted for that difference and more by subtracting 0.79 tpd from the amount of the RTC shave (i.e., increasing the allowable remaining emissions to 12.51 tpd). This comment asserts that instead, the adjustment should have been made from the BARCT level. Under staff's methodology, which establishes a remaining emissions goal, reducing the amount of the shave has the same effect as reducing the BARCT goal - in both cases the allowable remaining emissions are increased. Whether the adjustment is subtracted from the shave amount or the BARCT goal only makes a difference if the Industry methodology is used. See also

Response 2-10. For a discussion of why the Industry proposal does not meet BARCT requirements, see Response 2-35.

2-56 This comment asserts that the PEA does not support the assertion that 14 tpd must be shaved to obtain 8.77 tpd actual emission reductions, and that under the 2005 shave, a 23 percent reduction in RTCs resulted in a 24 percent reduction in emissions. See Response 2-37.

2-57 This comment claims that the staff has not explained how its proposal complies with Health and Safety Code §40406 because it does not consider economic impacts from reductions that go beyond BARCT, and does not show how the proposal results in equivalent or greater emission reductions at equivalent or less cost than would occur under command and control. These issues are addressed in the Draft Final Socioeconomic Impact Report, in particular see the section that compares the proposed project to command-and-control (Section 10). For a discussion of the assertion that the proposal goes beyond BARCT, see Responses 2-35 and 2-37 that explain why the industry proposal does not satisfy BARCT, and how the SCAQMD's proposal does not go beyond BARCT.

2-58 This comment asserts that staff's proposal for an NSR adjustment account for power plants does not apply to new facilities and that it needs to demonstrate how the proposal would comply with EPA requirements. As to the latter, this does not raise an issue of environmental impacts. SCAQMD staff has discussed this approach with EPA staff, and they did not express concerns or indicate that the provision would not be approvable into the State Implementation Plan (SIP). As for not addressing the needs of new power plants constructed after rule adoption, these emissions are included in the growth factor for the electric power industry. The comment asserts that the negative growth factor used for this industry (i.e., projected decrease in total gas-fired power generation) is not consistent with the California Air Resources Board AB 1318 Assessment Report, which shows a need for significant power plant peaking capacity in the future. However, the two projections are not necessarily inconsistent. As the power industry continues to rely more on renewable sources of power such as solar and wind, peaking capacity is needed for the times when renewables are not available, but total quarterly emissions may still go down due to the increased use of renewable sources that do not emit NOx. RECLAIM compliance is measured on a quarterly basis. However, to address concerns about potential not yet foreseeable increased demand for fossil-fueled power generation, staff proposes a Governing Board resolution that will direct staff to monitor this issue and report to the Governing Board or Stationary Source Committee, and will propose any necessary adjustments to the program as appropriate in the future. Therefore, staff believes that no significant environmental impacts have been omitted from the PEA relative to this issue. See also Response 2-39 for a description of the revised staff proposal that addresses many of the concerns that EGF stakeholders have raised.

2-59 This comment reiterates issues previously raised. See Response 2-54.

2-60 This comment asserts that the PEA did not adequately consider the impacts on facilities who must buy RTCs at a higher price, or the impacts of new facilities not being able to buy RTCs and thus locating outside the South Coast Air Basin. In the Draft Final Socioeconomic Report, staff analyzed potential economic impacts of increased prices for RTCs, at several price points, on the smaller facilities that are not subject to the shave, but did not identify any resulting environmental impacts. In addition to considering all the costs of compliance with the proposed amendments, the socioeconomic impact analysis also considered all the costs of compliance with the CEQA alternatives. The Revised Draft Staff Report also explains that SCAQMD staff further considered economic factors by adding a growth factor, a compliance margin, and an allowance for BARCT uncertainty to the target remaining emission levels. Even after full implementation of the shave, there will still be about 20 percent more RTCs in the market than expected emissions, which is within the range of the margin of unused RTCs in past years, excluding the period of the power crisis of 2000-2001. Based on the foregoing, it would be speculative to assume that any facilities would be "unable to obtain RTCs at any price," as asserted in the comment or that any potential new facility would be forced to locate outside of the South Coast Air Basin. See also Responses 2-2 and 2-8. This comment also asserts that since RECLAIM is a market-based system, it cannot be assumed that all the environmental impacts will necessarily occur at the source categories for which SCAQMD has identified new BARCT and which were assumed in the PEA. For a discussion of this issue, see Response 2-51.

2-61 This comment asks for the basis of the statement that 44 facilities are expected to comply with the proposed shave through the purchase of RTCs which will have no environmental impact. By taking the total number of facilities that would be subject to the proposed shave (65) and subtracting the 20 facilities that are expected to install controls, as well as investors, which together are treated as one "facility," a total of 44 facilities would result. However, since the release of the Draft PEA, the number of facilities that would be subject to the proposed shave has been adjusted to 56. Again, by subtracting the 20 facilities that are expected to install controls, as well as investors, which together are treated as one "facility," a total of 35 facilities would result. It is important to note that the sale and/or purchase of RTCs by investors (treated as one facility) will also have no environmental impact. This number is a conservative estimate, because as set forth in Section 9 of the Draft Final Socioeconomic Report, this group of facilities may already have excess RTCs which they can use toward covering their emissions. Simply surrendering excess unused RTCs would not in itself cause adverse environmental impacts. For those facilities that do have to buy RTCs, they will either buy them from those that have excess RTCs, which has no environmental impact, or they will buy them from facilities that install controls, thus freeing up RTCs. The environmental impacts resulting from installing and operating controls have already been analyzed in the PEA. This comment repeats the issue regarding RECLAIM being a market based program. See Response 2-51.

2-62 Table 1-3 shows 8.77 tpd of potential NOx emission reductions due to BARCT for Alternative 3, not 8.0 tpd. This comment is unclear as it seems to say both that the RTC reductions from the Industry Approach, Alternative 3, would equal the staff analysis for

BARCT reductions of 8.77 tpd, and at the same time that this number should be revised downward. It is unclear whether the comment requests the number to be 8.77 or some smaller number. If staff revises Alternative 3 by applying the Industry Proposal that was presented at the Special Stationary Source Committee on September 23, 2015, Alternative 3 would result in 6.6 tpd reductions in RTCs instead.

2-63 This comment reiterates issues previously raised. See Response 2-50.

2-64 This response states that Alternative 3 would achieve 8.77 tpd NOx reductions so the operational NOx reductions are quantifiable, contrary to the statement in Table 1-4. It is more accurate to state that Alternative 3 would result in 8.77 tpd of RTC reductions (unless the Industry Approach is revised to be 6.6 tpd as discussed in Response 2-62). However, this does not translate to actual NOx emission reductions. As explained in Response 2-35, actual NOx emission reductions could be as little as about 0.5 tpd beyond 2005 BARCT levels. There is no evidence to support the argument that facilities will install a significant amount of controls rather than giving up surplus unused RTCs under the Industry Approach, when RTC prices have been $5,500 or lower per discrete ton over the past decade, while the average cost-effectiveness for controls is about $13,615 per ton. Thus, Table 1-4 in the PEA does not need to be revised as suggested.

2-65 This response disputes the statement in Table 1-4 of the PEA that the amount of ammonia use under Alternative 3 is not quantifiable and requests acknowledgement that ammonia use will be lower than under the proposed project. Table 1-4 acknowledges that there will be less use of ammonia under Alternative 3 than there will be under the proposed project because it is expected that fewer controls will be installed and fewer emission reductions obtained. However, the lower usage is not quantifiable because it depends on the number and type of control equipment installed by facilities under Alternative 3 which cannot be accurately predicted. As explained in Response 2-36, Alternative 3 could result in as little as about 0.50 tpd of NOx emission reductions beyond 2005 BARCT levels, or it could result in somewhat greater emission reductions, but the actual amount is not predictable.

This comment also states that construction impacts are quantifiable, contrary to the statement in Table 1-4, because as listed in Table 1-3, Alternative 3 would require emission controls sufficient to obtain 8.77 tpd of reductions. However, Table 1-3 only lists the maximum obtainable RTC reductions from Alternative 3, and then assumes that all of those reductions would occur from the types of equipment identified in that table. As explained in Responses 2-35 and 2-36, this is not a realistic assumption, as it is highly likely that facilities would surrender some amount of unused RTCs in lieu of installing controls, but the exact amount is not foreseeable. So at the time when Table 1-4 was prepared, SCAQMD staff accurately reflected the expectation that construction impacts would be less than under the proposed project, but by an unquantifiable amount. Table 1-4 also acknowledges that Alternative 3 would have fewer construction impacts than the proposed project. If, as claimed by the comment, Alternative 3 actually resulted in obtaining the same actual emission reductions and installing the same controls as the proposed project, it would have the same environmental impacts. See also Responses 2-

41 and 2-43 for the discussion on the impacts relative to the use of ammonia. See also Responses 2-2, 2-33, 2-37, 2-62 and 2-64 for the various discussions on the impacts relative to Alternative 3.

2-66 This comment reiterates issues previously raised. See Responses 2-36 and 2-64.

2-67 This comment reiterates issues previously raised. See Responses 2-8, 2-30, 2-33, 2-34, 2-50, and 2-57.

2-68 The project description and project objectives are not the same thing; see CEQA Guidelines §15124. Further, project objectives are not required to be included in the NOP/IS. See also Response 2-28.

2-69 This comment claims that the Draft PEA should include a market analysis to support the statement that the market has enough unused RTCs to support a reduction of 4 tpd in 2016. Based on data in the Revised Draft Staff Report, emissions in 2011 (using 2012 for EGFs) were 20.72 tpd, while available RTCs were 26.51 tpd. Removing 4 tpd in 2016 would leave a margin of 1.79 tpd or just under 9 percent. While this percent is less than the 10 percent compliance margin allowed for the remaining emissions target under the staff proposal, it is not expected to adversely impact the market since many facilities already have the excess RTCs necessary to contribute their part of the 2016 shave. This comment also states that if the 4 tpd were just a reduction in unused RTCs then that would not equate to an emissions reduction of 4 tpd. Staff agrees. However, for purposes of accounting to EPA in our emissions inventory in the State Implementation Plan (SIP), SCAQMD staff is required to use the RECLAIM RTC amount for future NOx emissions, so reducing total RTCs in 2016 does help with demonstrating emission reductions for the SCAQMD SIP.

2-70 This comment reiterates issues previously raised. See Response 2-12.

2-71 This comment says the PEA should be revised after staff fully describes the proposed amendments and after EPA approves them. Staff believes this comment refers to the provision for a Regional NSR Holding Account. The Draft PEA will be revised to describe the current version of the proposal for a Regional NSR Holding account. However, obtaining EPA approval of the proposed amendments is not a necessary part of analyzing the environmental impacts of the proposed amendments, and final EPA approval cannot be obtained until after the proposed amendments are adopted by the Governing Board and submitted to EPA for inclusion into the SIP.

2-72 This comment reiterates issues previously raised. See Response 2-61.

2-73 This comment claims that page 3.2-34 should be updated to reflect the court invalidation of portions of EPA's GHG Tailoring Rule. Chapter 4.0, Subchapter 4.2, page 4.2-36 already contains a statement that acknowledges this court action. This acknowledgment will be added to page 3.2-34 of the PEA.

2-74 The PEA is based on reasonable assumptions supported by facts provided by the consultants and the reference materials listed in Chapter 6 of the PEA for similar types of projects. Based on staff experience with how refineries look and the likely appearances of cranes and construction equipment, staff does not believe that such temporary construction equipment would significantly adversely affect the aesthetic experience of neighbors looking at a refinery.

It is important to keep in mind that in order for a facility to install control equipment, the facility operator will need to submit a permit application which will undergo a CEQA analysis to determine if the project complies with the analysis in the PEA and whether the project can rely on the PEA or if an additional CEQA document would be required. In the former case, if a facility operator proposes a project that may create impacts to aesthetics or to any other environmental topic that are different than what was analyzed in the PEA, then an additional CEQA analysis would be required to examine the project level impacts. See also Response 2-16 for an explanation as to why the PEA conducts a program level analysis and not a project level analysis.

2-75 The different number of SCRs needed for the refinery boilers and heaters source category in the Preliminary Draft Staff Report (PDSR) (e.g., 76) compared to the Draft PEA (e.g., 74) has been attributed to counting separate individual SCRs for several heaters that share stacks (i.e., heaters D90 and D89 at Refinery 4, and heaters D913 and D914 at Refinery 6). The final count of refinery boilers and heaters has been verified and revised to reflect that 73 SCRs have been assumed for controlling NOx emissions from this source category, which is less than what was disclosed and analyzed in both the PDSR and the Draft PEA. The Staff Report and Final PEA have been updated to disclose this change. This revised number of SCRs does not undermine the analyses in either the PEA or the Staff Report because a reduced number of SCRs than what was previously analyzed means less environmental impacts. Thus, the analysis in the Draft PEA is conservative because it overestimates the potential adverse impacts by three additional SCRs.

The revised number of SCRs also does not adversely affect the socioeconomic analysis because the SCAQMD's consultant, NEC, estimated very high costs for the refinery boiler/heater SCRs based on an assumption that four layers of SCR catalysts should be used to achieve 2 ppmv NOx. NEC's assumption is not consistent with information in the facility permits for the individual refineries and information provided by SCR manufacturers. Thus, SCAQMD staff did not rely on the results of NEC's analysis which assumed only 48 SCRs. Note that the total shave has been reduced by 0.8 tpd (e.g. from 14.8 to 14 tpd) to cover any uncertainties in the analysis.

2-76 Aqueous ammonia is an EPA-regulated toxic substance that is regulated as under §112(r) as a hazardous air pollutant and is subject to analysis for the prevention of accidental releases, which includes the requirement to comply with 40 CFR Part 68 –Chemical Accident Prevention Provisions. Caustic, if made of sodium hydroxide, is an acutely hazardous substance. The analysis in the PEA is conservative in that it considers all types of construction activities that may occur, including those for building storage tanks to store chemicals to support various types of air pollution control equipment. Some chemicals may be subject to Spill Prevention Control and Countermeasure regulations, while others may be subject to a Risk Management Plan. Each facility's required Risk Management Plan may include mitigation (such as containment systems). Stormwater Pollution Prevention Plans (SWPPP) may also require containment for hazardous substances. The best management practice for storing ammonia and sodium hydroxide is to provide secondary containment that can hold up to 110 percent of the storage tank in the event of a spill or tank rupture. It is expected that the affected facilities will follow these standards.

2-77 This comment asserts that the statement that it was assumed that an operator would not install control equipment if the technology exceeded $50,000 per ton conflicts with project objectives. Staff does not identify an inconsistency. This is the assumption that was used to reject candidate BARCT control equipment and to eliminate the application of controls for some specific pieces of equipment. For a discussion of the meaning and use of the $50,000 number, and the fact it is not inconsistent with command-and-control measures, see Response 2-31. Further, the actual BARCT measures included in the staff proposal average about $13,615 per ton, and no single measure even approaches the $50,000 per ton level. See also Responses 2-27 and 6-5.

2-78 As explained in Chapter 4, Subchapter 4.4 of the PEA (see page 4.4-9), the SCAQMD recognizes that of the facilities that may be affected by the proposed project, some are currently permitted to use anhydrous ammonia for existing equipment but any existing anhydrous ammonia tanks are part of the existing setting. However, because current SCAQMD policy no longer allows the use of anhydrous ammonia, any new construction or modification of existing control equipment that needs ammonia to operate would be required to use 19 percent by volume aqueous ammonia. Thus, no offsite consequence analysis for the use of anhydrous ammonia is necessary.

2-79 The PEA already contains a conservative analysis which assumes that lead time will be needed for pre-construction/advance planning activities such as engineering analysis of the affected equipment, engineering design of the potential control equipment, contracting with a vendor, securing financing, ordering and purchasing the equipment, obtaining all types of permits and clearances, and scheduling contractors and workers. The time needed to accomplish all of these tasks, including time needed for the permitting process, would not cause or increase any existing environmental impacts.

2-80 This comment reiterates issues previously raised. See Response 2-12.

2-81 As summarized in Table 1-3 of Chapter 1 of the PEA, the NOx emission reduction potential for each source category is identified and totals 8.77 tons per day of NOx emission reductions from conducting a BARCT analysis for the proposed project. Further, an additional 5.23 tons per day of NOx RTCs need to be shaved to fully implement the required BARCT emission reductions. Staff believes that this additional RTC shave is necessary to avoid the result that facilities would simply surrender excess unused RTCs rather than making any substantial amount of real emission reductions. For a discussion of this issue, see Response 2-35.

As explained in Chapter 4, Subchapter 4.0 of the Draft PEA, the installation and operation of new or modified existing NOx emission control equipment at 20 facilities was identified as the only portion of the entire proposal that is expected to result in physical effects that may affect the environment. For this reason, the analysis in the PEA focuses on the physical effects that may occur as a result of constructing new or modifying existing NOx control equipment and operating the equipment once constructed which correlates to achieving the 8.77 tons per day of NOx emission reductions and the additional 5.23 tons per day of shaved NOx RTCs necessary to implement the BARCT reductions. See also Responses 2-2, 2-8 and 2-31.

2-82 This comment reiterates issues previously raised. See Response 2-69.

2-83 This comment claims that the statement in the PEA on page 4.2-18, that the proposed project will reduce 14 tons of NOx RTCs per day, but the actual reduction in NOx emissions may be less than the reduction in RTCs, is inconsistent with the statement on page 1-1, paragraph 4, that the project would result in "14 tons per day of NOx emission reductions." Staff does not identify an inconsistency. The introductory statement on page 1-1 of the PEA explains in general terms that the BARCT analysis could achieve NOx reductions up to 14 tpd and Table 1-3 goes into more detail by showing how the 14 tpd is distributed by a combination of actual emission reductions and reductions in NOx RTCs. Thus, the discussion on page 4.2-18 is consistent with how the 14 tpd is described in Chapter 1 of the PEA. Further, as explained in Response 2-69, the amendments will result in 14 tpd of NOx reductions creditable to the SIP. See also Response 2-50.

2-84 This comment reiterates issues previously raised. See Response 2-81.

2-85 This comment reiterates issues previously raised. See Responses 2-41 and 2-43.

2-86 This comment reiterates issues previously raised. See Responses 2-41 and 2-43.

2-87 This comment contests the statement in the Draft PEA that the control measures in the 2012 AQMP are expected to bring the region into attainment for all national ambient air quality standards by 2023 is incorrect because a significant part of the control strategy is within the Section 182 (e)(5) "black box" measures that have not been defined. This is an issue of semantics, as the Section 182 (e)(5) measures are still control measures. However, SCAQMD staff recognizes that due to the need for very large NOx emission reductions, at least 50 percent beyond the requirements of existing rules and fleet turnover in 2023, all feasible NOx reductions are needed. Indeed, one of the objectives of the proposed amendments is to help attain the national ambient air quality standards.

2-88 This comment reiterates issues previously raised. See Responses 2-34 and 2-65.

2-89 This comment requests the inclusion of an Industry Approach for calculating BARCT to be analyzed in the PEA as a CEQA alternative. This comment claims that the Industry Approach can achieve the project's objectives while reducing impacts.

As explained in Response 2-2, the Draft PEA specifically considered the Industry Approach (Alternative 3) and identified that this alternative would result in fewer impacts during construction and operation than the proposed project. Any alternative with a shave smaller than 14 tpd but larger than the Industry Approach would have environmental impacts in between those identified for the proposed project and the Industry Approach, as it would be expected to result in a lessened need and use of new control equipment. However, as explained in Response 2-33, the proposed NOx RTC shave under Alternative 3 was shown to be substantially less than the proposed project (e.g., 8.77 tpd compared to 14.0 tpd) and the PEA concluded that the entire 8.77 tpd NOx RTC shave could be addressed with unused RTCs without having any facilities modifying their equipment to achieve actual NOx reductions from installing air pollution control equipment. For this reason, Alternative 3 was concluded to not satisfy project objective #2 "to modify the RTC "shaving" methodology to implement the emission reductions per the BARCT assessment." The Industry Approach (Alternative 3) would not result in achieving the maximum level of reductions achievable and so does not meet the legal requirements under Health and Safety Code §40406, and thus, does not meet all of the project objectives. CEQA does not require consideration of alternatives that do not meet most of the basic project objectives. See CEQA Guidelines §15126.6.

2-90 This comment claims that the Industry Approach would avoid or reduce costs of the proposed project and that the CEQA document, including the alternatives analysis, should contain an analysis of these cost avoidances and reductions.

While economic or social information may be included in an EIR, it is not a requirement. The costs of implementing the proposed project or any of the alternatives is not an environmental impact. Further, economic or social effects of a project shall not be treated as significant effects on the environment. Instead, the focus of the analysis shall be on the physical changes. [CEQA Guidelines § 15131 (a)]. For this reason, the analysis in the PEA does not address the costs associated with achieving the proposed NOx emission reductions or with implementing the alternatives. Instead, as explained in Response 2-19, a socioeconomic analysis has been conducted and the analysis and findings are presented in a separate document, the Socioeconomic Report for Proposed Amendments to Regulation XX - Regional Clean Air Incentive Market (RECLAIM), initially published on September 9, 2015 and revised on October 6, 2015 and November 4, 2015.

2-91 This comment suggests that the CEQA document include a cost-effectiveness analysis of using a 10-year useful life of equipment.

This comment repeats sentiments previously expressed in Comments 2-19, 2-32 and 2-90. In particular, regarding the reasoning behind what equipment useful life period was assumed for the proposed project, see Response 2-32. Regarding why a cost-effectiveness analysis is not included in the PEA, see Responses 2-19 and 2-90.

Re: Comment Letter on Draft Program Environmental Assessment for Proposed Amended Regulation XX; Cities of Burbank and Pasadena

Dear Ms. Radlein:

On behalf of the City of Burbank, Department of Water and Power ("BWP"), and the City of Pasadena, Water and Power Department ("PWP) (collectively "the Cities"), we are submitting the following comments on the Draft Environmental Assessment ("Draft PEA") for the proposed amendments to Regulation XX, Regional Clean Air Incentives Market ("RECLAIM") ("NOx shave proposal"), for which a Notice of Completion was published on August 13, 2015. 3-1 The Draft PEA purports to contain an analysis of the potential adverse environmental impacts that could be generated from the proposed project. Unfortunately, the Draft PEA does not contain any analysis of the potential adverse environmental impacts of the potential shortage of RECLAIM Trading Credits ("RTCs") for future power plant needs, which is of great concern to the Cities. 3-2

While the NOx shave proposal appears to include provisions that would mitigate some of its worst impacts on the Cities' well-controlled power plants, it still does not provide the needed certainty that adequate RTCs will be available at a reasonable price to cover these plants' anticipated emissions and other needs related to resource adequacy and utility-specific operating contingencies. 3-3 We have suggested some improvements to the proposal that would provide the needed certainty and address other issues (see the Cities' comment letter on the proposed rule

Barbara Radlein
October 6, 2015
Page 2

dated August 21, 2015). In the absence of these improvements, the NOx shave proposal may have significant adverse air quality impacts that should be addressed in the Final PEA. 3-3 Con't

Both Cities operate their own power plants containing peaking units, and BWP also operates the Magnolia Power Plant ("MPP"), a baseload unit, on behalf of the Southern California Public Power Authority ("SCPPA"). Participants in MPP include Burbank, Pasadena, and four other municipalities. The Cities operate these power plants to serve their municipal customers. RTCs are required not only to cover anticipated annual emissions, but also to meet resource adequacy needs and prepare for utility-specific operating contingencies, such as grid reliability, increased cycling to support integration of renewables, and potential electrification of the transportation system. Unlike other industrial facilities operating under the RECLAIM program, the Cities' power plants are obligated to operate to serve load. If they are unable to serve load, there may be blackouts with serious adverse economic and other consequences. 3-4

The staff proposal would require a 47% reduction in the NOx RTC allocations for these power plants. The proposed reductions are so severe that insufficient RTCs would remain to cover Pasadena's and MPP's anticipated emissions, not to mention RTCs needed for resource adequacy and utility-specific operating contingencies. Pasadena and MPP may need to purchase additional RTCs to cover the shortfall. If these additional RTCs are prohibitively expensive or unavailable, then the Cities may be forced to curtail the output from these facilities in order to remain in compliance with the RECLAIM program. 3-5

One possible consequence of a curtailment of output from the Cities' facilities is that other facilities may generate replacement power. These facilities may be located either inside or outside of the South Coast Air Basin. Wherever they are located, these other facilities are unlikely to have emission rates as low as the emission rates from the Cities' own facilities. The increased emissions from these other facilities, and their potential adverse impacts, should be assessed in the Final PEA. 3-6

For example, replacement power may be generated by facilities that are located in the South Coast Air Basin that are not included in the RECLAIM program or that are included in the program but are not subject to the NOx shave proposal, such as certain co-generation facilities. The emissions would be generated in locations different from the locations of the Cities' facilities, and there are likely to be more emissions than would be generated by the Cities' own well-controlled units. These emissions and their potential adverse impacts, including their impacts on local receptors, should be assessed. These adverse impacts may trigger environmental justice concerns. 3-7

Replacement power may also be generated by facilities that are not located in the South Coast Air Basin. It is possible, for example, that replacement power may be generated by coal-fired units in other states. The potential adverse impacts of these emissions should be assessed. 3-8

Barbara Radlein
October 6, 2015
Page 3

When we made a similar comment on the Notice of Preparation of the Draft PEA, the District staff responded by stating that the Cities could purchase whatever RTCs are needed to operate and pass the cost through to our ratepayers. This response is not adequate if the cost of RTCs is exorbitant or if RTCs are not available. 3-8 Con't

District staff also responded by stating that the NOx shave proposal now includes a provision addressing the need for RTCs to cover the so-called "NSR holding requirement" (See our January 30, 2015, comment letter and District staff responses (see Draft PEA, Appendices, pages G-55 and 56). The Draft PEA also refers to a provision providing additional RTCs in the event of a State of Emergency as declared by the Governor (see Draft PEA at 1-16). In our comment letter on the rule proposal, we point out that these various provisions do not adequately protect the Cities against having to obtain additional RTCs when their prices are exorbitant or they are not available. Only our suggested safeguards would provide that needed protection. Absent those safeguards, an analysis of potential adverse impacts is required. 3-9

We appreciate your consideration of our comments. Please let us know if you have any questions.

Sincerely,

Charles F. Timms, Jr.

cc: Philip Fine, Deputy Executive Officer (by email)
Jill Whynot, Assistant Deputy Executive Officer (by email)

RESPONSES TO COMMENT LETTER #3
(Charles F. Timms, Jr. on behalf of
the City of Burbank Department of Water and Power – October 6, 2015)

3-1 The introduction of the parties represented by the letter does not require a response.

3-2 This issue was previously raised by this commenter in a comment letter relative to the NOP/IS (see Appendix G of the PEA, Comment Letter #5, Response 5-3).

As previously explained, SCAQMD staff acknowledged the unique situation that electricity generators have with regard to operating at BARCT or BACT and the requirement for RTC holdings for New Source Review (NSR) purposes. The project was subsequently revised to contain a proposal which establishes an adjustment account to satisfy the NSR holding requirements which would be funded by the shaved RTCs from new electricity generating facilities (EGFs). Most EGF emissions are much less than their potential to emit, so this provision will help reduce the amount of RTCs that EGFs will need to hold. Moreover, a new rule proposal includes an option for an EGF to opt-out of the RECLAIM NOx program if certain criteria are met. This option provides each EGF with the ability to remain in RECLAIM or exit and operate under a command-and-control environment, whichever best meets their needs. Even if an EGF remains in RECLAIM, SCAQMD staff's analysis shows that there is an adequate surplus of RTCs after BARCT controls are installed so that the purchase of additional RTCs to meet allocation targets will not be an issue. Even so, the rule proposal contains price triggers for RTCs that will prevent prices of RTCs from becoming unreasonable. As a result, the staff analysis shows that there will not be an additional environmental impact. Nevertheless, the RTC price analysis has been considered in the socioeconomic analysis, and the Socioeconomic Report contains such an analysis. The commenter has not provided any evidence or examples of how having to purchase additional RTCs is linked to causing potential adverse environmental impacts. SCAQMD staff disagrees with the assertion that a potential shortage of RTCs for EGFs will cause potential adverse environmental impacts that need to be analyzed in the PEA, since RTCs may be purchased. In any event, PAR 2001 contains provisions that would allow EGFs to opt out of RECLAIM.

3-3 The commenter states that the staff proposal does not provide the certainty that adequate RTCs will be available at a reasonable price to cover the power plants' anticipated emissions, resource adequacy, and other contingencies. The commenter also refers to suggested rule language in its August 21, 2015 comment letter for the proposed rule. Lastly, the commenter states that the adverse impacts should be analyzed if these suggestions are not incorporated.

The staff proposal has been refined over recent months to address many of the concerns that stakeholders have raised. While the staff proposal will not offer RTCs for sale in the event of a power emergency as the commenter proposes, the staff proposal contains several safeguards that would provide EGFs with additional credits in the event of an emergency. The safeguards include access to non-tradable/non-usable RTCs with a faster

3-month trigger, and a new 12-month trigger with a threshold level of $22,500 per ton. In the event of a State of Emergency declared by the Governor, EGFs would have access to non-tradable/non-usable credits. If these credits are exhausted, EGFs would also have access to the credits in the Regional NSR Holding Account. Furthermore, EGFs now have the option to exit the RECLAIM program if they meet certain requirements. Under this option, an EGF would no longer be concerned with the possibility of an RTC shortage, even though staff believes that there will not be a shortage.

No shortage of RTC credits is anticipated since the percent difference of the emissions from the allocation cap would be comparable to that which exists today. As explained in Response 3-2, the commenter has not provided any evidence or examples of how having to purchase additional RTCs is linked to causing potential adverse environmental impacts. SCAQMD staff disagrees with the assertion that there will be a potential shortage of RTCS that will cause potential adverse environmental impacts that need to be analyzed in the PEA.

3-4 The comment asserts that RTCs are required to cover anticipated emissions, resource adequacy, and other contingencies and that the facilities operated by the Cities are obligated to serve load. Without adequate RTCs to cover emissions, the comment claims that blackouts with adverse consequences may occur.

Staff acknowledges the necessity of RTC availability for EGFs like the ones that the commenter represents. However, as stated earlier, staff has determined that there will not be a shortage if BARCT controls are implemented. Also, as explained in Response 3-3, it is unlikely that the proposed project would result in subjecting electricity customers to blackouts since there are safeguards for maintaining an availability of RTCs for EGF utilization. The option for EGFs to exit RECLAIM and the Governing Board Resolution language that will require that staff monitor trends in electricity generation that could result from increased emissions due to cycling to accommodate more renewable energy generation or electrification of the transportation sector will help reduce any potential problems in the future.

3-5 The comment reiterates the sentiments expressed in Comments 3-3 and 3-4 that RTCs are required to cover anticipated emissions, resource adequacy, and other contingencies and that the facilities operated by the Cities may need to curtail their output if the RTCs in the market are either too expensive or unavailable.

The staff proposal would not allow RTC prices to soar to prohibitively expensive prices. As explained Response 3-3, the current proposal now contains a quicker response RTC price trigger in addition to the 12-month trigger that would make more RTCs available to stabilize the market. In addition, the current proposal contains a provision that would allow an EGF to opt-out of the RECLAIM program (see the proposed amendments to Rule 2001) so that an EGF would no longer have to keep, sell, or purchase credits.

3-6 The comment states that a result of curtailment would be that other facilities located either inside or outside the basin would produce replacement power at a higher emission rate and that these impacts should be assessed in the Final PEA.

It is not the intent of the staff proposal to encourage the curtailment of power for customers. As explained in Response 3-3, the proposed RTC shave would not cause a curtailment of power production because the proposed project contains safeguards that would preclude this type of situation. See also Responses 3-4 and 3-5.

3-7 The comment reiterates that replacement power resulting from curtailment may come from other, less-controlled plants that may have localized potential adverse impacts.

The RECLAIM program is designed with a programmatic cap where facilities can buy and sell emission credits and every facility in the NOx RECLAIM program has the ability to purchase credits at the level it desires within the confines of the market. As explained in Responses 3-3 through 3-6, the proposed shave is not expected to result in power curtailment because of the safeguards contains in the project proposal. Thus, no localized impacts or environmental justice impacts from other EGFs would be expected to occur.

3-8 The comment states that replacement power may also come from power generation outside of the Basin. A similar comment was made during the NOP/IS comment period and staff responded by stating that EGFs could purchase the RTCs that are needed and pass the costs to the ratepayers (see Appendix G of the PEA, Comment Letter #5, Response 5-2). The commenter claims that the staff response is inadequate in a situation where the cost of RTCs is too high and RTCs are not available.

As stated in Response 3-5, the safeguards contained in the staff proposal would prevent a situation where there would be a lack of RTCs because the price triggers would prevent the prices from rising unreasonably. See Responses 3-3 through 3-6 for why staff believes that the proposed shave would not result in the curtailment of power and would not cause facilities located outside the Basin to generate replacement power.

3-9 The comment states that despite staff's previous responses to their comment letter submitted relative to the NOP/IS (see Appendix G of the Draft PEA, Comment Letter #5, Responses to Comment Letter #5) regarding the Regional NSR Holding Account and its ability to supply credits in the event of a State of Emergency as declared by the Governor, the provisions do not adequately protect the Cities against having to obtain RTCs that are too high in price or unavailable. The commenter claims that only the safeguards presented by the Cities would provide the needed protection and that, otherwise, the potential adverse impacts would be required to be analyzed.

Staff disagrees with the claim that only the commenter's safeguards would provide availability of credits at a reasonable price. As stated in Response 3-3, staff has revised the proposal since the release of the Draft PEA to further accommodate the concerns of EGFs by providing several market safeguards, including the option for EGFs to opt-out of the program. See also Responses 3-4 through 3-8.

Subject: Los Angeles Department of Water and Power (LADWP) Comments on the Draft Program Environmental Assessment Report for Proposed Amendments to NOx RECLAIM Regulation XX (Draft EA)

Dear Ms. Radlein:

The LADWP appreciates the opportunity to provide the following comments on the Draft EA. In so doing, LADWP remains committed to working with the South Coast Air Quality Management District (SCAQMD) to develop additional workable and cost-effective policies to reduce NOx emissions from all source categories in order to meet the federal ozone standards in the South Coast Air Basin. 4-1

Appendix G of the Draft EA contains SCAQMD's responses to LADWP's comment letter of January 30, 2015. In its comment letter, LADWP stated that the Notice of Preparation (NOP) did not address the potential impacts on energy supply as a result of a significant shave in RECLAIM trading credits (RTCs) allocations in the power plant sector. In response, SCAQMD states that Proposed Amended Rule 2002 has been revised such that the proposal includes an Adjustment Account specifically for power generating facilities for access to additional RTCs if needed by power plants. Although SCAQMD sets up the framework and mechanism for accessing additional RTCs from the adjustment account, it is unclear whether there would be sufficient RTCs in the Adjustment Account for the Power Producing Facilities given that the proposed 14 ton per day shave would dramatically reduce the number of RTCs in the RECLAIM program. 4-2

SCAQMD proposes in its amendments (Rule 2002(f)(4) and (5)) to have an Adjustment Account comprised of RTCs set aside for power producing facilities' access under 4-3

Ms. Barbara Radlein
Page 2
October 6, 2015

certain conditions. The draft preliminary staff report states that the Adjustment Account RTCs "would be derived from the proposed programmatic 14 tons per day in NOX reductions." In previous NOx RECLAIM working group meetings, SCAQMD stated that Adjustment Account RTCs derived from the 14 tons per day NOx reductions would not be submitted to the State Implementation Plan (SIP). However, throughout the Draft EA, it is stated that the proposed shave is 14 tons per day without any qualification or limitation on their use for meeting NOx SIP reduction requirements under the Clean Air Act. As a result, it is unclear whether there would be sufficient RTCs in the Adjustment Account for the power producing facilities to address the following purposes: 4-3 Con't

- New Source Review offset needs
- Ability of power producing facilities such as LADWP to meet native load (obligation to serve its customers)
- Ability of power producing facilities to meet reliability standards implemented through the Energy Policy Act of 2005
- Ability of power producing facilities to support increased electrification of transportation and other sources

SCAQMD also states in the Draft EA that "further analysis of the actual BARCT NOx emission control opportunities for the various equipment/process categories demonstrated that the proposed project could achieve 14 tons per day of NOx emission reductions by 2023."[1] We believe that the SCAQMD analysis so far provided does not demonstrate that the power producing facilities have the ability to achieve their share of the NOx RTC reductions while simultaneously meeting their obligations to meet native load. For example, SCAQMD does not address that fact that all of LADWP's generating units in the Los Angeles basin are already retrofitted with BARCT or the most stringent Best Available Control Technology to minimize NOx emissions to the maximum extent technically feasible. This means that a deep shave of 47 percent from current RTC allocations could result in LADWP having to procure RTCs if they are even available or face the inability to meet native load and/or meet reliability standards. Thus, LADWP urges SCAQMD to provide additional information as to how the Adjustment Account would be funded, confirm through analysis that sufficient RTCs would be available for power producing facilities, and provide well-reasoned responses to stakeholder rule recommendations related to access to the RTCs (*e.g.*, that a Reliability Coordinator be able to declare an energy emergency). 4-4

In addition, LADWP remains concerned that the impacts of electrification of transportation and other sources have so far not been addressed in the rulemaking. 4-5

[1] Draft EA, page 1-1

Ms. Barbara Radlein
Page 3
October 6, 2015

Although SCAQMD staff has indicated that such impacts would be addressed at some point in the future, it is unclear what regulatory mechanisms would be available to supply RTCs back to the RECLAIM program once they are submitted to EPA and thereby effectively surrendered for SIP purposes. For these reasons, and as explained in detail in our comments on the SCAQMD proposal, LADWP urges the development of a SIP crediting mechanism that can account for and provide credit the net decrease in NOx as a result of electrification measures. 4-5 Con't

In summary, SCAQMD has not explained whether there would be sufficient RTCs available in the Adjustment Account or in the overall RECLAIM market for power producing facilities affected under the RECLAIM program. Without a clear understanding of this crucial issue, SCAQMD's analysis of the energy impacts on power producing facilities associated with the NOx RECLAIM amendments is incomplete. This matter needs to be addressed fully before SCAQMD can finalize its proposed amendments to RECLAIM Regulation XX. 4-6

LADWP appreciates the opportunity to provide comment on the Draft EA. If you have any questions or would like additional information, please contact Ms. Jodean Giese of my staff at (213) 367-0409.

Sincerely,

Jennifer Madden for

Mark J. Sedlacek
Director of Environmental Affairs

RESPONSES TO COMMENT LETTER #4
(Los Angeles Department of Water and Power – October 6, 2015)

4-1 The SCAQMD appreciates the commenter's willingness to work together to help the region achieve the federal ozone standards.

4-2 The comment refers to a letter submitted relative to the NOP/IS and SCAQMD staff's response explaining that the establishment of the Regional NSR Holding Account would address the impacts that the shave would have on energy supply (see Appendix G of the PEA, Comment Letter #4, Response 4-10). The commenter is unclear if there would be sufficient RTCs in the Regional Account for electricity generating facilities (EGFs), given the 14 ton per day shave.

Since the release of the Draft PEA, SCAQMD staff has made several adjustments to the rule proposal that adds additional safeguards regarding the availability of credits for EGFs. The safeguards include access to non-tradable/non-usable RTCs with a faster 3-month trigger. The 12-month trigger for access remains, but the threshold dollars per ton level is now $22,500. In the event of a State of Emergency declared by the Governor, EGFs would have access to non-tradable/non-usable credits. If these credits are exhausted, EGFs would also have access to the credits in the Regional NSR Holding Account. Furthermore, EGFs now have the option to exit the RECLAIM program if they meet certain requirements such as meeting BARCT or BACT with their equipment and surrendering its credits. With this option, an EGF would no longer be concerned with the possibility of an RTC shortage, even though staff feels that there will not be such a shortage if BARCT controls are implemented for those applicable facilities that were analyzed.

4-3 The commenter requests clarity on how the credits in the Regional NSR Holding Account would address the SIP commitment as it pertains to the 14 ton per day RTC reduction. The commenter also requests clarity as to whether there will be sufficient RTCs in the Regional NSR Holding Account for EGFs for NSR needs, meeting native load, meeting reliability standards, and increased electrification of the transportation sector.

The RTCs in the Regional NSR Holding Account would not be submitted into the SIP. The RTCs in this account would be comprised of the shaved credits from EGFs that are subject to NSR holding requirements. By including these additional refinements to the proposed amendments, SCAQMD staff believes the latest staff proposal addresses the NSR needs for all EGFs subject to these requirements. As explained in Response 4-2, the staff proposal now contains a mechanism that can make credits available for EGFs to meet reliability requirements if there is an extenuating need. The staff proposal also includes resolution language that would require monitoring of the electrification of the transportation sector and adjustments to be made, if necessary. In addition, the proposed opt-out provisions in PAR 2001 is another option available to EGFs that would address all the concerns that the commenter has listed.

4-4 The comment expresses concern that the staff proposal in the Draft PEA does not demonstrate that EGFs can be shaved while still being able to meet the obligation to provide native load. Additionally, the shave would result in the purchase of additional credits, even though EGFs are already at BARCT or BACT. The commenter would like clarity on how the Regional NSR Holding Account would be funded, assurances that credits will be available for EGFs, and provide a response to stakeholder recommendations that a Reliability Coordinator be able to declare a State of Emergency.

As explained in Responses 4-2 and 4-3, the staff proposal would provide a sufficient amount of credits for all the market participants if BARCT is installed for those facilities analyzed and the proposed opt-out language is a new alternative for EGFs operating at BARCT or BACT to have an off ramp from the RECLAIM program. However, the proposed language in PAR 2001 still would require the Governor to declare a State of Emergency in order to access the non-tradable credits.

4-5 The commenter expresses concern that the PEA does not address the electrification of the transportation sector and how credits could be added back to the market if this scenario is realized. The commenter urges the development of a SIP-crediting mechanism that can account for the decrease in basin-wide NOx emissions as a result of electrification measures.

The potential electrification of transportation and other sectors in the future is being considered as part of ongoing air quality planning activities related to the 2016 AQMP. Since the scope of future electrification is uncertain, the associated potential impacts on energy supply due to electrification is also too uncertain to be considered. However, the proposed project includes a Governing Board resolution to regularly meet with representatives from the power-producing sector to monitor any future electrification.

The 2016 AQMP is currently under development and on a completely separate schedule from the proposed project. As the 2016 AQMP development process moves forward, a separate CEQA analysis of the effects of what is proposed for the 2016 AQMP will be conducted and presented as part of a Program EIR which will provide multiple opportunities for review and comment by the public, stakeholders, and other interested parties.

Further, an electricity demand analysis was recently conducted in the Final Environmental Assessment for Rule 2202 Emission Reduction Quantification Protocol for Electric Vehicle Charging Station Projects[15] to determine if sufficient electricity would be available to handle the future projected electricity demand for electric vehicles (EV). The Final EA concluded that there would be less than significant impacts to electricity demand primarily from direct input and reports provided by utility providers, Southern California Edison (SCE) and the Los Angeles Department of Water and Power (LADWP), as follows:

[15] SCAQMD, Final Environmental Assessment for Rule 2202 Emission Reduction Quantification Protocol for Electric Vehicle Charging Station Projects, SCAQMD No. 150123JI, certified May 1, 2015, pp. 2-20 to 2-25. http://www.aqmd.gov/docs/default-source/ceqa/documents/aqmd-projects/2015/rule2202fea.pdf?sfvrsn=2

> *"According to the representatives, both SCE and LADWP have forecasted potential load impacts from increased EV charging in the future. SCE and LADWP currently do not have the need to build any new electric generation facilities or alter the transmission system due to projected EV charging demands."*

Thus, the commenter's expressed concern about the impacts of electrification of this aspect of transportation in this comment is inconsistent with the statements made as part of the rule development process for the Rule 2202 Protocol.

Finally, as explained in both the Revised Draft Staff Report (see Comment Letter 18, Response 18-8) and in Responses 4-3 and 4-5, the commenter's resolution language has been noted and resolution language has been prepared that directs staff to monitor the power-producing sector for trends in power consumption and associated NOx emissions as electricity demand potentially increases. The crediting of basin-wide NOx emissions as a result of electrification would be handled via a SIP amendment in the future.

4-6 The comment summarizes the previous comments by stating that staff has not explained whether there would be sufficient RTCs available in the Regional NSR Holding Account or in the overall market for EGFs and requests that this issue be addressed.

As explained in Responses 4-2 through 4-5, staff believes that the revised proposal is designed to ensure that there will be sufficient RTCs available in the market and to also provide an option for EGFs to exit the RECLAIM program.

Subject: Phillips 66 Comments on Draft PEA for NOx RECLAIM Amendments
PHILLIPS 66 COMPANY - LOS ANGELES REFINERY

Dear Ms. Radlein:

Phillips 66 Company supports and adopts the comments on the South Coast Air Quality Management District's (SCAQMD or District) proposed regulation to reduce emissions of oxides of (NOx) from the Regional Clean Air Incentives Market (RECLAIM) Program that were submitted by the Western States Petroleum Association today. Attached to this letter is a copy of those comments. 5-1

Sincerely,

Marshall Waller
Director, Environmental Services, Los Angeles Refinery

Re: Draft Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market

Dear Ms. Radlein:

We respectfully submit, on behalf of the Western States Petroleum Association ("WSPA") and its members, these comments on the draft Program Environmental Assessment ("PEA") for Proposed Amended Regulation XX – Regional Clean Air Incentives Market ("RECLAIM"). WSPA is a non-profit trade association that represents oil and gas exploration, production, refining and marketing companies, some of whom own and operate facilities in the RECLAIM program.

The draft PEA suffers from fundamental problems that undermine the entire environmental analysis. The draft PEA purports to consider a project to implement the Air Quality Management Plan ("AQMP") and to evaluate best available retrofit control technology ("BARCT"), but narrowly focuses on construction activities associated with the replacement NOx emissions control equipment for selected facilities to achieve 14 tons per day ("TPD") in NOx reductions. Further, the construction activities that are evaluated in the draft PEA have not been confirmed by the District's independent expert, resulting in a proposed project that is likely infeasible. The District's improper focus on 14 TPD in NOx reductions is particularly apparent in the alternatives analyses where the majority of the alternatives require 14 TPD or more of NOx reductions – a skewed selection of alternatives which fails to meet the "reasonable range of alternatives" requirement. Aside from these fundamental problems, the draft PEA lacks adequate analysis in several individual resource areas.

Ms. Barbara Radlein
October 6, 2015
Page 2

Attachment 1 to this letter provides more detailed comments on this draft PEA from WSPA's technical consultant, and are hereby incorporated by reference. ("Attachment 1").

WSPA has previously submitted numerous comments on the proposed regulation itself, as well as the notice of preparation and initial study ("NOP/IS") for the draft PEA, but these comments have received insufficient attention from the District in its environmental analyses.[1] The District responds to the NOP/IS Letter by claiming that technical analyses have been considered, when an in-depth evaluation of the industry's technical concerns has not been performed.

WSPA has serious concerns with both the proposed rule amendments and the draft PEA, and believe that the requirements under the California Environmental Quality Act ("CEQA") have not been satisfied. Furthermore, both the proposed amendments and the draft PEA must be revised and recirculated to address the comments raised by WSPA and the numerous other commenters in order to correct errors, disclose all significant impacts, and allow the consideration of feasible mitigation measures or project alternatives to reduce or avoid these impacts.

I. Fundamental Problems With The Draft PEA Undermine The Environmental Analysis

Under CEQA, an EIR is an informational document designed to provide public agencies and the public with detailed information about the impacts that a proposed project is likely to have on the environment, analyze the ways in which the significant effects of a project might be minimized, and identify alternatives to the project.[2] The District's draft PEA, as a substitute EIR under its certified regulatory program, is also subject to the substantive provisions of CEQA.[3]

Fundamental flaws in the draft PEA's project description and objectives, the scope of review, and the selection and analysis of alternatives, pervade the document, ultimately resulting in a misleading document in specific resource areas as well. Many of the errors in the draft PEA are related to problems with the methodology, assumptions,

Ms. Barbara Radlein
October 6, 2015
Page 3

which WSPA described in detail in its August 21 Letter and which are reiterated here as they also relate to inadequacies under CEQA. WSPA believes that the draft PEA must be revised and recirculated for further public review and comment, all in compliance with CEQA.

A. The Project Description is Flawed, Misleading and Hinders Analysis

"An accurate, stable and finite project description is the *sine qua non* of an informative and legally sufficient EIR."[4] An accurate project description is an essential requirement because an EIR must be "prepared with a sufficient degree of analysis to provide decisionmakers with information which enables them to make a decision which intelligently takes account of environmental consequences."[5] If the project description contains inaccurate or misleading information, the entire analysis may be tainted. "A curtailed, enigmatic or unstable project description draws a red herring across the path of public input."[6]

1. The project description includes amendments to Regulation XX, but the draft PEA evaluates only environmental effects of BARCT construction activities

The proposed project is described as "amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM) to achieve additional NOx emission reductions to address best available retrofit control technology (BARCT) requirements and to modify the RECLAIM trading credit (RTC) 'shaving' methodology."[7] However, the draft PEA examines only the construction activities that purportedly achieve a reduction of 14 TPD of NOx emissions, and fails to evaluate in any manner the potential environmental effects of effectively eliminating the NOx RTC market.

The RECLAIM program is a cap and trade program, and it is misleading for the District to characterize the proposed severe changes to this program as merely a series of construction projects to achieve BARCT requirements. Depending on how they are implemented, changes to the marketplace can have wide-ranging impacts that are not limited to BARCT construction, but also to the operation of the RECLAIM facilities subject to the District's proposed severe shave. The District's focus on NOx emissions reduction – and the PEA's correspondingly limited analysis – has resulted in foreseeable consequences that are neither considered in the District's rulemaking nor analyzed in its environmental assessment in the form of the draft PEA.

[7] Draft PEA, p. 1-1.

Ms. Barbara Radlein
October 6, 2015
Page 4

While the District certainly has the authority to prepare a CEQA document solely for BARCT requirements, and if that is the District's intention with the draft PEA, then the draft PEA needs to clearly state that intention in the project description. "[I]ncessant shifts among different project descriptions" undermines the CEQA process "as a vehicle for public participation."[8] However, the project description purports to include an RTC "shave," and the CEQA document needs to evaluate it. For this reason alone, the draft PEA must be revised and recirculated for further public review and comment.

2. The draft PEA does not substantiate the fundamental assumptions that form the basis of the BARCT construction activities

As explained above, the draft PEA improperly focuses solely on BARCT construction activities for its analysis, but the viability of those construction activities being adequately represented and analyzed in the draft PEA cannot be substantiated, creating further uncertainty for the project description. "An EIR may not define a purpose for a project and then remove from consideration those matters necessary to the assessment of whether the purpose can be achieved."[9] Given that the District has narrowly defined the purpose of the project as implementing BARCT, it still must be able to substantiate that those BARCT construction activities can actually be performed.

The District erroneously assumes all its proposed BARCT requirements are not only technologically feasible but can be achieved unilaterally despite evidence suggesting the proposed BARCT levels may not be cost effective or feasible for all RECLAIM facilities subject to the District's proposed severe shave. As WSPA has explained previously, most recently in its August 21 Letter, this is not the case. In November 2014, Norton Engineering Consultants ("NEC"), the third party expert hired by the District to "ground truth" the District's technical analysis in this rulemaking, presented findings in its BARCT Feasibility and Analysis Review.[10] However, when the preliminary draft staff report for the proposed amendments was released on July 21, 2015, it was apparent that many of NEC's findings were ignored, misunderstood, or misstated by the District. As described in WSPA's August 21 Letter, failure to correct some of the assumptions and errors in the staff report for this rulemaking skews the analysis for nearly 40 operating units (i.e., RECLAIM NOx sources).

[8] *Inyo,* 71 Cal.App.3d at 197.

[10] Norton Engineering Consultants (NEC), SCAQMD NOx RECLAIM – BARCT Feasibility and Analysis Review, Non-Confidential Final Report No. 14-045-4, 26 November 2014, http://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/regxx/noxreclaimbarct-nonconf-refinery_112614.pdf?sfvrsn=2 (last accessed September 13, 2015).

Ms. Barbara Radlein
October 6, 2015
Page 5

Moreover, there is no support for the District's assumption that certain NOx sources subject to this rulemaking can achieve 2 ppm NOx levels using new or upgrade selective catalytic reduction systems ("SCR"). This 2 ppm NOx level assumption is an integral component of the District's calculus justifying the currently proposed severe shave. While CEQA provides that disagreements among experts does not make an EIR inadequate, that is not the case here with the draft PEA.[11] As a threshold matter, the District cannot claim to be an expert in specific applications unique to the refining and petrochemical industry; indeed that is apparently the reason for its hiring of an outside third party expert to verify (i.e., "ground truth") the District's technical assumptions. Importantly, the District has been presented with a highly technical analysis from its own third party expert on the ability – or inability – of certain types of NOx sources to achieve 2 ppm NOx levels using SCR, and effectively dismissed this information in favor of unsubstantiated assertions that certain equipment can, indeed, meet such NOx levels and reductions.[12]

The District also assumes that the installation of the BARCT can and will be implemented in the specified timeframe, which is fairly aggressive. This aggressive time frame is unrealistic and again, has not been substantiated. A number of internal and external factors influence when a company can and will undertake a construction project. WSPA members report that completion of all needed projects to implement the proposed NOx reductions would likely require at least eight (8) years. (Attachment 1, p. 13).[13] It is also a possibility that, depending on the economic climate and incentives, a project would not be implemented at all. In the current economic climate for the oil and gas industry, a more realistic schedule is required for an adequate CEQA review.

The draft PEA also purports to conduct a site-specific analysis for certain resource areas, but makes unsubstantiated conclusions to eliminate further environmental analysis. For example, the PEA determines noise impacts will not occur from the project because any increase in noise levels will be within the thresholds of the industrial facilities. The PEA makes similar extrapolations from a site specific review of the aesthetics, taking a specific example of a facility where a wet gas scrubber ("WGS") had been installed, resulting in a characteristic steam plume. The PEA essentially states that because these refineries are in industrial areas, additional WGS plumes would not have an aesthetic impact.[14] The PEA's assumptions and extrapolations make an informed analysis difficult.

---

[11] See, e.g., *Karlson v. City of Camarillo*, 100 Cal.App.3d 789, 805 (1980).

[12] See letter from NEC to the District dated August 10, 2015, and included as Attachment 2 to WSPA's August 21 Letter, attached to this letter as Attachment 2.

[13] WSPA also recommended that the shave implementation schedule be "back-loaded" to accommodate a longer, more realistic project implementation period with at least 2 of the proposed 4 TPD (currently being proposed for 2016) being moved to 2019 or later. WSPA's August 21 Letter, p. 3, attached to this letter as Attachment 2.

[14] Draft PEA, p. 4.1-4.

Ms. Barbara Radlein
October 6, 2015
Page 6

The draft PEA should identify realistic assumptions based on facts to properly evaluate potential environmental effects of construction activities, and a one-size fits all approach that dismisses the potential for environmental effects based on the industrial locations of the facilities is not sufficient.

In short, the PEA makes unsubstantiated industry-wide generalizations in determining that technology is feasible, implementation timeframes are reasonable, the site specific impacts will be negligible, and the individual businesses will perform as expected. These generalizations cannot support the PEA's assumptions, particularly in light of the District's own third party expert's efforts to correct the errors in its technical analysis. If an EIR is "so fundamentally and basically inadequate and conclusory in nature" that public comment on the draft is essentially meaningless, or if significant new information is added to an EIR, it must be recirculated for further public review.[15] The PEA should be revised to substantiate its assumptions and reevaluate its conclusions accordingly, and should then be recirculated for further public review and comment.

B. The PEA Purports To Be A Program-Level Document, But Construction Activities Generally Require Project-Level Review

The draft PEA is described as a "program CEQA document" ostensibly because it consists of proposed amendments to Regulation XX.[16] As noted above, however, the draft PEA appears to evaluate BARCT construction activities, and specific construction projects generally require a project-level analysis. This distinction is important because a program-level review can be more abbreviated and the District apparently seeks to utilize that approach, but it has now embarked on a partial project-level review of BARCT construction activities. As noted above, noise is dismissed in the PEA and not evaluated at all, even though noise is an environmental topic commonly reviewed in a project level EIR for a construction project. If the District seeks to transform a rule-making into a construction project, it needs to do so in compliance with CEQA.

Furthermore, the draft PEA, which is a "substitute CEQA document" pursuant to the District's certified regulatory program, states that the "program" CEQA document may be used by other agencies for "future related actions." Section 15253 of the CEQA Guidelines addresses use of a substitute CEQA document by responsible agencies, and the District should clarify how the provisions of that Section have been satisfied.

The draft PEA's insufficient project level analysis for BARCT construction activities reinforces WSPA's main critique of the District's proposed amendments to Regulation XX—the technical analysis to support the proposed amendments is

[15] *Laurel Heights Improvement Ass'n v Regents of Univ. of Cal.*, 6 Cal.4th 1112 (1993); 14 Cal. Code Regs. §15088.5(a).

[16] Draft PEA, p. 1-3.

Ms. Barbara Radlein
October 6, 2015
Page 7

inadequate.[17] If these construction activities had been properly evaluated in the CEQA document at a project level, the infeasibility of the proposed BARCT would have become apparent.

C. The PEA Overlooks Impacts From the "Whole Of The Project"

An EIR must consider the whole of an action.[18] "Project" means the whole of an action, which has a potential for resulting in either a direct physical change in the environment, or a reasonably foreseeable indirect physical change in the environment, and that is an activity directly undertaken by any public agency.[19] An "indirect physical change" may be one resulting from any economic and social effects of a project, and that change too must be evaluated.[20] The CEQA Guidelines provide: "Where a physical change is caused by economic or social effects of a project, the physical change may be regarded as a significant effect in the same manner as any other physical change resulting from the project."[21] While not all projects evaluated under CEQA have sufficient economic and social effects to warrant further analysis regarding consequential physical effects, this project is unique in that it consists of amendments to a market system – economic consequences are integral to RECLAIM operations.

1. The Draft PEA fails to consider the physical effects resulting from reasonably foreseeable economic and social effects

The draft PEA summarily asserts: "No indirect or indirect physical changes resulting from economic or social effects have been identified as a result of implementing the proposed project."[22] No citation is provided for this conclusion, and no analysis was performed to support this conclusion. As a result and the clear fact that the draft PEA proposes such a severe RTC "shave" that it could potentially eliminate the NOx RTC market, an analysis must be performed to evaluate the potential physical changes that might result from the reasonably foreseeable economic and social effects of the project.

---

[17] *See also* WSPA's August 21 Letter.

[18] Because the District has adopted a Certified Regulatory Program under California Public Resources Code §21080.5, an environmental assessment ("EA") may be prepared instead of an EIR or negative declaration. An EA is the equivalent of an EIR under the Certified Regulatory Program.

[19] Cal. Code Regs. § 15378(a)(1).

[20] CEQA Guidelines Section 15131. See, e.g., *Bakersfield Citizens for Local Control v. City of Bakersfield*, 124 Cal.App.4th 1184 (2004) (holding that CEQA requires consideration of social or economic impacts if they may lead to adverse changes in the physical environment such as "urban decay").

[21] 14 Cal. Code Regs. §15064(e).

[22] Draft PEA, p. 1-16.

Ms. Barbara Radlein
October 6, 2015
Page 8

More specifically, the draft PEA fails to consider the physical impacts of an analysis in which the economic consequences of the rule result in reasonably foreseeable changes in the regulated sectors. The District is well aware of the statistic it cites in its staff report and PEA: since the start of the RECLAIM program, the number of facilities in the program has shrunk by approximately 30 percent.[23] Where there were once 392 RECLAIM facilities in the South Coast Air Basin, there are now only 276. While the District cites this statistic, it makes no effort to analyze or consider the significance of it, or to examine the physical changes in the environment that resulted in the PEA.

This reduction in RECLAIM facilities means that some productivity within the Basin has been lost, and the draft PEA should evaluate the potential for future loss of productivity from sources within the RECLAIM system, particularly those RECLAIM facilities subject to the District's proposed severe shave. This analysis in the PEA should evaluate the Basin's energy needs and assess whether there would be adequate sources of reliable power if the proposed project were to result in lowered productivity within RECLAIM facilities and the businesses that support and supply these facilities. It should also consider whether lowered production of the affected products could result in adverse environmental impacts within or outside of the Basin. It should consider the environmental impacts of leakage, which is a well-known, and thus, foreseeable consequence of sub-regional cap and trade schemes. CEQA provides that "[a]ny emissions or discharges that would have a significant effect on the environment in this state" are subject to CEQA.[24] Accordingly, the District is obligated to analyze whether potential changes in operations resulting from the imposition of this aggressive RTC shave would result in potential environmental impacts, including increased emissions due to needing to source products from outside the South Coast Air Basin where the RECLAIM program applies.

The District's incomplete and selective approach neglects to consider potential environmental impacts beyond the narrow scope of construction associated with installation of the anticipated BARCT required by the proposed project. In the District's own words, RECLAIM is a market-based program which was "designed to use the power

[23] Draft PEA, p. 2-2.

[24] Cal. Pub. Resources Code § 21080. In certain instances, the mandate of CEQA to ensure a high level of environmental protection extended to considering out of state activities as part of the project due to resulting in-state impacts. (See 58 Ops. Cal. Atty. Gen. 614 (1975), opining that where California cities were joining forces with Utah cities to construct a coal plant in Utah that would provide power to California, and related transmission lines would have to be built from Utah into California, any project-related EIRs had to examine the environmental consequences of the project as a whole. Additionally, because the project area spanned multiple states, local California agencies were required to look at the impacts of the project as a whole.)

Page 9

of the marketplace" to reduce air emissions from stationary sources.[25] A proposed shave effectively manipulates that marketplace. It stands to reason that an aggressive, deep manipulation – like the one proposed by the District – will impact RECLAIM facilities differently than one that is less drastic. The District is proposing a massive change in the marketplace designed to change behavior and cause reactions, yet the District assumes that the only reaction will be small scale construction projects involving installation of NOx control equipment to meet shave requirements. The District is proposing a massive change that will cause RECLAIM facilities and the businesses that support and supply these facilities to *react* in ways that are reasonably foreseeable by the District. These reactions, in turn, will have environmental impacts, which should have been analyzed in the PEA.

The RECLAIM program was introduced as an alternative to traditional command and control requirements, and was intended to provide business within the South Coast Air Basin with greater flexibility and financial incentive to reduce air pollution. As set forth in WSPA's August 21 Letter, the District has accomplished the substantial NOx emissions reductions achieved to date by reducing RTCs across the board. With the present project, not only is the District proposing deep cuts to the remaining RTCs, but it is imposing these cuts in a targeted, uneven manner. This is a significant manipulation of the marketplace, with foreseeable consequences that the PEA has neglected to analyze. The likely impacts resulting from the District's chosen methodology occur in various resource areas, as described further in this letter. However, by not recognizing the market-driven business considerations, the PEA has neglected to analyze and disclose the "whole of the project," in violation of CEQA.

CEQA prohibits segmenting a project into separate actions in order to: avoid environmental review of the "whole of the action"[26]; defer environmental analysis; ignore the foreseeable environmental impacts of the end result of a project; or, avoid considering potential cumulative impacts. Thus, a lead agency may not limit environmental disclosure by ignoring other activities that will ultimately result from approval of a particular project. The District's limited focus on technical equipment related to control of NOx emission reductions to achieve the severe RTC shave, to the exclusion of other foreseeable impacts is evidence of the District's failure to consider the entire project and its potential environmental impacts.

2. The draft socioeconomic report is deficient, and a revised report should be prepared and recirculated concurrently with a revised draft PEA

The draft Socioeconomic Report for the RECLAIM amendments provides little assistance in evaluating this issue as it considers only a limited number of potential economic and social issues, based solely on BARCT construction activities, and does not delve into the potential for physical effects resulting from the severe RTC "shave." WSPA will be submitting comments on the draft Socioeconomic Report, and once those comments have been considered and addressed, the draft PEA should be revised and recirculated for public review and comment to reflect the District's analysis of the potential environmental effects of any physical changes resulting from these economic and social effects.

Furthermore, the Draft Socioeconomic Report was only circulated on September 7, 2015 – weeks after the completion of the PEA. Failure to consider socioeconomic impacts in conjunction with the environmental review hampers the environmental review of the whole of the project. A proper socioeconomic analysis should have been completed in advance of, or at minimum in conjunction with, the draft PEA, and the draft PEA should have analyzed the resulting physical changes based on the socioeconomic effects of the RECLAIM amendments.

For example, the socioeconomic analysis with respect to the BARCT cost effectiveness could well have environmental impacts which were not adequately analyzed in the PEA. Health and Safety Code §39616 requires RECLAIM to achieve emissions reductions "at equivalent or less cost" than otherwise applicable command and control regulations. The project proposes cost effectiveness of $50,000/ton threshold, above which the District assumes, for purposes of CEQA analysis, that a facility would decline to install the given air pollution control technology. However, as discussed in greater detail below, this $50,000 is more than twice the AQMD's cost effectiveness threshold for command-and-control programs. The socioeconomic impacts of adopting new BARCT threshold, and setting such a high cost effectiveness figure, could result in operational changes which have physical impacts on the environment. In order to comply with CEQA, the PEA must analyze the foreseeable impacts of this component of the project.

D. The Project Objectives Are Disconnected From The Project Evaluated In The Draft PEA

An EIR is required to have a "statement of objectives sought by the proposed project."[27] The statement of objectives should include the underlying purpose of the project, and it should be clearly written to guide the selection of alternatives to be

[27] 14 Cal. Code Regs. §15124(b).

Ms. Barbara Radlein
October 6, 2015
Page 11

evaluated in the EIR.[28] Here, however, the objectives do not appear to inform the alternatives; instead, they appear to be independent of the proposed project. In fact, the Alternatives section of the draft PEA contains little analysis of whether the project objectives can be satisfied because they have become irrelevant, thereby infecting the Alternative analysis in its entirety (as discussed below).

The draft PEA appears instead to apply an unstated objective – reduce NOx RTCs by 14 TPD or more – which actually creates inconsistencies with the District's own plans and with the Health & Safety Code provisions with which it purports to comply. The District's 2012 Air Quality Management Plan ("AQMP") included NOx reduction control measure CMB-01. This control measure provided that additional reductions of NOx RTCs in the range of 3 to 5 tons per day ("TPD") would occur. The PEA states that one of the project objectives is to "[a]chieve the proposed NOx emission reduction commitments" of CMB-01. Yet the current project's proposal to reduce NOx RTCs by 14 TPD goes far beyond the control measure's initial recommendation of 3 to 5 TPD target.

WSPA and the Industry RECLAIM Coalition commented on this issue in their NOP/IS Letter. The District's response is that the current project "is the result of a much more rigorous and in-depth analysis as compared to the analysis that supported control measure CMB-01."[29] However, it is apparent that the analysis conducted by the District focused primarily on assessing the maximum number of remaining NOx emissions that could be reduced, to the exclusion of other analyses. As described above, the proposed project has the potential to trigger unintended consequences that were not considered in the draft PEA. The new, aggressive reduction in NOx RTCs, combined with the ambitious timeframe and questionable assumptions about facility performance suggest that the District did not undertake the same holistic view of the RECLAIM program and market as it did when it adopted the 2012 AQMP. Again, it appears that in its zeal to reduce NOx emissions by as much as possible, the District has ignored the potential repercussions of such a severe reduction.

Another unstated, but unsubstantiated, objective is the establishment of a $50,000/ton cost effectiveness threshold that justifies its severe shave. However, this is inconsistent with the stated District's objective: to "[c]omply with the requirements in Health and Safety Code …§39616 by conducting a BARCT assessment of the NOx RECLAIM program and reducing the amount of available NOx RTCs to reflect emission reductions equivalent to implementing available BARCT."[30] Compliance with that provision of the Health and Safety Code requires that the market-based emissions program should result in (1) emissions reductions equivalent to or greater than reductions that would have resulted under command and control, **and** (2) "***at equivalent or less cost***

[28] 14 Cal. Code Regs. §15124(b).

[29] Draft PEA, p. 1-15.

[30] Draft PEA, p. 2-4.

Ms. Barbara Radlein

Page 12

compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the District's plan for attainment."[31] The currently proposed emissions reductions may well provide greater reductions of NOx than would occur under traditional command and control regulation. However, this comes at a cost which far exceeds what implementation of BARCT would cost under command and control.

More specifically, the project proposes a $50,000/ton cost effectiveness threshold, above which the District assumes, for purposes of a CEQA analysis, a facility would decline to install a given NOx air pollution control technology to meet the severe shave requirements.[32] However, this $50,000 is more than twice the District's cost effectiveness threshold for command-and-control programs. As WSPA explains in its August 21 Letter, the 2012 AQMP used a cost threshold for NOx control measures of $22,500 per ton.[33] As another point of reference, the District's current Best Available Control Technology ("BACT") guidance document presents a discounted cash flow ("DCF") cost effectiveness threshold of only $19,100 per ton.[34]

The District, in its preliminary draft staff report for the NOx shave rulemaking, has also made misleading cost analysis assumptions which have the effect of making the overall costs for the severe shave look lower than actual. For example, in its staff report, the District proposed a 25-year Useful Life when calculating equipment cost effectiveness. This is misleading because the District rulemaking – which is often technology forcing – occurs on a more frequent basis. For example, the District last amended the NOx RECLAIM rules only 10 years ago. As WSPA explains in its August 21 Letter, assuming a 25-year project life dilutes the capital cost over a longer period of time than what the company is likely to actually realize.

As discussed below, Alternative 3 (the Industry Approach) meets project objectives, with fewer impacts. Thus, the project, as currently proposed, does not meet CEQA's requirements, and the PEA must be revised and recirculated for public review and comment.

E. The Alternatives Analysis Is Flawed

1. The analysis of alternatives is inadequate to allow for informed comparison

The alternatives analysis is critical to the integrity of an EIR.[35] Under CEQA, an EIR must describe a reasonable range of alternatives to the proposed project, or to its location, that would feasibly attain most of the project's basic objectives while reducing or avoiding any of its significant effects, and must evaluate the comparative merits of those alternatives.[36] The alternatives analysis has been described as "the core of an EIR."[37]

An EIR's analysis of alternatives and mitigation measures must focus on those alternatives with the potential to avoid or lessen a project's significant environmental effects.[38] The alternatives discussed in an EIR should be ones that offer substantial environmental advantages over the proposed project.[39]

Here, the PEA evaluates 5 alternatives, and except for the Alternative 4 (No Project) and Alternative 3 (Industry Approach), all other alternatives propose 14 TPD or more of NOx emission reductions. Given that the proposed project has remaining significant environmental effects with the proposed project at 14 TPD, the failure to include any additional alternatives other than Alternative 3 (Industry Approach) at a lesser reduction of NOx emissions does not satisfy CEQA's requirement for a "reasonable range of alternatives." Furthermore, CEQA generally prohibits a selection of "straw man" alternatives which are intended to be knocked down in favor of the proposed project.[40] The majority of the alternatives require 14 TPD or more of NOx reductions, including an alternative for 15.87 TPD, suggesting that the District's selection of alternatives was guided not by the ability to reduce environmental effects, but by an effort to support the proposed project.

Page 14

2. Alternative 3 is the environmentally superior alternative

The PEA's alternatives analysis is flawed because it appears to reject alternatives based solely on the total TPD of emissions reduced, rather than a more comprehensive analysis that evaluates the remaining significant effects associated with the proposed project. The CEQA Guidelines provide that "the discussion of alternatives shall focus on alternatives to the project or its location which are capable of avoiding or substantially lessening any significant effects of the project, even if these alternatives would impede to some degree the attainment of the project objectives,…"[41] Alternative 3 achieves the project objectives and is the environmentally superior alternative. As such, the District should adopt Alternative 3 rather than the proposed project.

Here, the District has chosen, as the proposed project, to employ a methodology that has significantly greater potential environmental impacts than Alternative 3. Specifically, the District proposes that NOx RTC holdings for major refineries be "shaved" by 67 percent; NOx RTC holdings for non-major refineries and other facilities among the top 90 percent of RTC holders be shaved by 47 percent. This aggressive "shaving" method would remove nearly all of the unused NOx RTCs from the RECLAIM market, ostensibly to reduce NOx emissions from RECLAIM facilities. However, the PEA suffers from a narrow view of the RECLAIM universe: by focusing almost exclusively on potential benefits from NOx emissions, the District fails to analyze the environmental impacts that such a drastic NOx RTC reduction is likely to have.

On the other hand, the Industry Approach (Alternative 3) to NOx reduction would take a more measured and holistic approach, resulting in fewer environmental impacts while still achieving a reduction in NOx emissions. More specifically, the Industry Approach proposes to reduce the unused RTCs in an amount equivalent to those reductions that could be directly attributable to an appropriate and valid BARCT.[42] The Industry Approach would result in an across the board reduction of 33 percent of the unused NOx RTCs – a significant reduction of RTCs and advancement of BARCT – without many of the environmental impacts resulting from the District's methodology.

The draft PEA downplays that Scenario 3 (Industry Alternative) will require less operational use of ammonia, by claiming that it is "not quantifiable."[43] However, no evidence is provided to support that conclusion. In the alternatives air quality analysis, the District asserts that if Alternative 3 were implemented, it would be too difficult to

[41] 14 Cal. Code Regs. § 1526.6(a).

[42] The Industry Approach is described in section 5.3.2.4 of the draft PEA, as well as in the January 30, 2015 letter to the District regarding the NOP/IS, submitted by WSPA and the other members of the Industry RECLAIM Coalition.

[43] Draft PEA, Table 1-4.

Ms. Barbara Radlein

Page 15

predict the number of facilities that would install NOx control equipment.[44] First, the District should have acknowledged the unpredictability of facilities implementing the proposed project, which is more aggressive and could trigger correspondingly more drastic business reactions. Instead, the District assumes there that all facilities will fall in line to install NOx control equipment as it predicts. Second, the likely NOx control equipment installation projects can be quantified.

Furthermore, the alternatives analysis in the PEA fails to explain why the proposed project will only reduce NOx emissions 8.72 TPD when history suggests a 1:1 relationship between RTC reductions and program emissions.[45] If the project objective is to meet BARCT at 8.7 TPD, Alternative 3 meets that objective with fewer environmental impacts, and thus, should be the environmentally preferred alternative.

The lead agency has the flexibility to approve an alternative to the proposed project if that alternative better addresses the agency's environmental concerns.[46] An EIR's failure to analyze an adequate range of alternatives deprives the lead agency of the ability to provide this sort of meaningful review and selection. Recirculation of a new draft PEA will be required by CEQA because the current PEA has not considered alternatives that have not been previously adequately analyzed but must be analyzed as part of a reasonable range of alternatives.

II. Specific Resource Areas Lack Adequate Analysis

A. Energy Reliability Impacts Were Not Considered

The District's proposal will dramatically increase the costs for the facilities it has selected to be regulated and the businesses that support and supply these facilities. The PEA acknowledges that if the BARCT is implemented at these selected facilities, there will be an increase in the amount of energy used both during construction, and more significantly, during operation of the facilities. But the PEA only considered whether there would be sufficient energy when all the facilities installed and implemented the BARCT. Given that 100 facilities have ceased to exist in the District's RECLAIM market since its inception, the District needs to consider not only whether there will be sufficient energy to power the BARCT NOx control equipment, but whether important energy reliability needs of the region and State can be met or whether they will be impacted by the District's proposal.

Page 16

There is a complete absence of any analysis of electricity or fuel supply impacts. The potential for outages, interruptions and severe price spikes should be considered and analyzed. Also, the future growth in energy demand should be assessed and the impact of this proposed project on the ability to maintain adequate energy supply. This analysis should consider proposed population growth and growth in use of power-consuming electronics (e.g., hospital diagnostic and treatment tools such as high proton lasers are replacing lower-energy using tools) and growth in electrification and energy use more generally.

B. Air Quality Impacts Were Not Fully Addressed

1. Direct impacts of new and expanded ammonia sources are not addressed

The PEA notes that the proposed project will increase operational use of ammonia, a toxic air contaminant, by 39.5 TPD.[47] The increase is due to the large number of new and expanded ammonia emissions sources associated primarily with the larger number of SCRs that would be required to be installed to meet the severe NOx shave requirements. However, the PEA does not address the impacts from a program which results in increased ammonia emissions. Additionally, as the District's other documents acknowledge,[48] ammonia is a precursor to PM2.5. Accordingly, the PEA should have analyzed the regional impacts from increased secondary formation of PM2.5.

Furthermore, the draft PEA's analysis of ammonia slip depends on physical conditions which are explicitly omitted from the project description (e.g., use of Ammonia Slip Catalysts or ASC) despite recommendations by Norton to use ASC.[49] Without the ASC, the ammonia slip could be as great as 20 ppmv, but the draft PEA underestimates the ammonia slip to be 5 ppmv, ostensibly based on permit conditions for new SCRs. However, existing SCRs are not necessarily subject to those permit conditions, and thus, ammonia slip of up to 20 ppmv should be considered in the health risk assessment for ammonia emissions.[50]

October 6, 2015
Page 17

2. Cumulative impacts from air emissions are not adequately considered

An EIR must discuss the cumulative impacts of a project when its incremental effects are "cumulatively considerable."[51] Moreover, in the specific context of a programmatic EIR, one of the key purposes of the EIR is to "ensure consideration of cumulative impacts that might be slighted in a case-by-case analysis."[52] Programmatic EIRs play an instrumental role in allowing the lead agency to consider broad policy alternatives and program-wide mitigation measures at an early time when the agency has greater flexibility to deal with basic problems in program implementation, or cumulative impacts.[53] Accordingly, the CEQA Guidelines require lead agencies to explain how implementing the particular requirements in the plan, regulation or program under review "ensure[s] that the project's incremental contribution to the cumulative effect is not cumulatively considerable."[54]

Cumulative impacts are defined as "two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts."[55] "Cumulatively considerable" impacts are present when "the incremental effects of an individual project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects" and activities.[56] A lead agency's threshold findings of significance with regard to cumulative impacts must "be supported by substantial evidence"; and, where found, cumulatively considerable impacts must be adequately mitigated.[57]

As discussed above, there are indirect air impacts from increased ammonia emissions for SCRs. The District also fails to provide substantial evidence that cumulative impacts from increased ammonia emissions for SCRs (which could number in the dozens at a single refinery) will not result in cumulative health risk impact. The PEA makes the conclusory statements that "[e]ven if multiple SCRs are installed at one refinery facility, the locations of all the stacks would not be situated in the same place within the affected facility's property. As such, even with multiple SCR installations, the acute and chronic hazard indices would not be expected exceed the significance

[57] 14 Cal. Code Regs. § 15064.7 (b).

threshold."[58] However, no evidence is provided to support this assumption, and the draft PEA should base its analysis on a conservative assumption regarding the locations of SCRs, and not dismiss the potential environmental effect by relying on unsupported and result-driven assumptions.

Furthermore, the PEA's conclusions with respect to potential cumulative health impacts are contradicted by recent District statements that recognize a potential need to control SCR ammonia slip. In a presentation on August 26, 2015, the District proposes possible "short-term" implementation for such a control.[59] Although CEQA does not require compliance with rule or programs that have not yet been adopted, the PEA should address, in its air quality analysis, the underlying concerns driving the proposed 2016 AQMP control measure. However, the project appears to value NOx RTC reductions above all other concerns, and accordingly the lopsided analysis does not acknowledge the related potential ammonia issues.

C. Water Supply Impacts Are Not Adequately Mitigated

The EIR "must assume that all phases of the project will eventually be built and will need water, and must analyze, to the extent reasonably possible, the impacts of providing water to the entire proposed project." (*Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova*, 40 Cal.4th 412, 431 (2007).) Also, "the future water supplies identified and analyzed must bear a likelihood of actually proving available; speculative sources and unrealistic allocations ('paper water') are insufficient bases for decision-making under CEQA." (*Id*. at 432.)

The draft PEA acknowledges "significant adverse water demand impacts from hydrotesting" requiring the imposition of mitigation measures.[60] The mitigation measures consist of a requirement to use recycled water "if available" and if not, a declaration from the water purveyor indicating why the recycled water cannot be supplied to the project.[61] The draft PEA summarily states that "the potential increase in potable water use cannot be fully supplied either with all potable water or with a combination of recycled water and potable water, since some potable water may still be required." The draft PEA also states: "[T]here is no absolute guarantee at the time of this writing that future supplies of potable or recycled water will be available to all of the affected facilities."

[61] Draft PEA, pp. 4.5-9 – 4.5-10.

Ms. Barbara Radlein
October 6, 2015
Page 19

CEQA requires a more in-depth evaluation of the availability and reliability of both potable and recycled water for the project.[62] It is insufficient to conclude that a significant impact for water supply exists without providing a more detailed analysis of the amount of water available, the reliability of such water, all of which has become more important as California is facing one of the most serious droughts in history. While the draft PEA identifies the existence of emergency drought regulations, it does not analyze the effect of these regulations – or of local water restrictions – on the facilities subject to the rule.

A similarly deficient analysis was presented in the draft PEA for the water usage associated with the wet gas scrubbers.[63] In that section, the District states that it cannot confirm or verify the use of recycled water and that "it is not known at this time whether water purveyors would be able to supply potable water for those facilities." CEQA requires an actual analysis of the water availability and reliability, and the inability to verify the use of recycled water means that the use of potable water must be evaluated, including an understanding of whether it is available at all.

Furthermore, the draft PEA fails to evaluate any further mitigation measures, other than a commitment to use recycled water, if available. Such mitigation measures are speculative, and may be found to be legally inadequate if they are so undefined that it is impossible to gauge their effectiveness.[64] Feasible – and therefore defensible – mitigation could include provisions in the rule that allow for alternative technologies and additional NOx RTCs in the foreseeable event that water supply is increasingly restricted, and the cost of water increases accordingly.

D. Noise Impacts Should Have Been Analyzed

The NOP/IS for the project determined that noise was among the environmental areas which would not be significantly adversely affected by the project. The PEA, in explaining why noise is not considered, states that the facilities are generally industrial in nature, and any increase in noise levels due to construction and installation of BARCT NOx control equipment would be within acceptable limits for an industrial facility. However, this is an example of the District's programmatic review failing to take into account site-specific conditions which could have an adverse impact. Rather than make generalizations about the facilities and extrapolated that there will be no adverse noise levels, the PEA should have undertaken a more conservative analysis to assess whether noise could, in fact, adversely affect receptors in the vicinity of the facilities, including on

Page 20

nearby roadways based on the local noise ordinances or requirements. Noise impacts could occur from the use of large construction equipment to construct and install NOx control equipment and increase in construction traffic, which can include large trucks, trailers and cranes. Additionally, there could be an increase in noise impacts associated with the operation of the NOx control equipment and the ammonia delivery trucks.

E. Solid And Hazardous Waste Is Not Adequately Considered

The PEA fails to adequately analyze potential impacts of hazardous waste as a result of the project. The significant NOx RTC reductions necessitate a high degree of BARCT NOx control installation, most of which consists of SCR technology. While SCR technology has been used in a wide variety of applications and industries over the decades, it nonetheless is generates a hazardous wastestream in the form of spent catalyst which, in turn, requires potential on site storage and off-site transport and disposal.[65] Section 4.6 of the PEA acknowledges that the hazards exist and acknowledges that the generation of hazardous waste and materials will increase. The PEA should also evaluate the impact on communities near hazardous waste landfills, such as Kettlemen Hills, where the impacts may be greater without any corresponding benefit from the District's proposed action. Also, as discussed earlier, the emissions implications of the increased ammonia from the SCR have been overlooked in the District's PEA.

F. Growth-Inducing Impacts Analysis Is Flawed

An EIR must describe any growth-inducing impacts of the proposed project.[66] As part of the analysis, the EIR must discuss ways in which the project could directly or indirectly foster economic or population growth,[67] and should also describe growth-accommodating features of the project that may remove obstacles to population growth. An EIR must discuss growth-inducing effects even though those effects will result only indirectly from the project.[68] A discussion on growth-inducing effects should not necessarily make assumptions about whether the growth is beneficial, detrimental, or inconsequential to the environment.[69] The purpose of the EIR is to act as an informational document.

Here, not only does the draft PEA fail to consider the significance of the shrinking number of RECLAIM facilities (as discussed in Section I.C. of this letter), but the PEA also fails to consider the possibility that the facilities within the RECLAIM universe

could grow. In a footnote, the PEA assigns a "growth factor" to different categories of RECLAIM facilities.[70] No explanation is provided about how that growth factor was derived, nor whether it is current or likely to change. The PEA must consider a scenario which allows for more growth of those industries within the RECLAIM universe, and modify the growth-inducing impacts analysis accordingly.[71]

III. Conclusion

The District has a very admirable – but narrow – statutorily defined focus: to promulgate rules and regulations which promote air quality in its jurisdiction. Under CEQA, the District is the lead agency for purposes of its own rulemaking. The District must be able to square its obligations as a lead agency to fully analyze and disclose impacts of its discretionary approvals with the narrow focus required of the District's mission to promote air quality within a specific geographic area. The District has failed to adequately balance those obligations here, which has resulted in a PEA that presents a skewed analysis of the potential benefits and impacts of the proposed rule amendments. The District must address the numerous inadequacies of the draft PEA raised in this comment letter, and then, revise and recirculate the draft PEA for public review and comment in order to meet its mandate under CEQA.

Sincerely,

Nicki Carlsen

ATTACHMENT 1

ADDITIONAL WSPA COMMENTS ON DRAFT PROGRAM ENVIRONMENTAL ASSESSMENT (PEA) FOR NO_X RECLAIM AMENDMENTS

Page/Section	WSPA Comment
Page 1-1, 3rd paragraph	This paragraph describes the project as "amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM) to achieve additional NOx emission reductions to address best available retrofit control technology (BARCT) requirements and to modify the RECLAIM trading credit (RTC) "shaving" methodology." [emphasis added] This description is not consistent with the project description contained in the AQMD's Notice of Preparation issued 4 December 2014,[1] nor is the description consistent with Project Description contained in the Initial Study.[2] Specifically, neither the NOP Project Description nor the Initial Study Project Description includes any reference to modifying "the RECLAIM trading credit (RTC) "shaving" methodology" in the description of the project or the project objectives.
Page 1-1, 4th paragraph	The Draft PEA states that "further analysis of the actual BARCT NOx emission control opportunities for the various equipment/process categories demonstrated that the proposed project could achieve 14 tons per day of NOx emission reductions by 2023 which is much higher than estimates provided in the 2012 AQMP." While this value is certainly much higher than contemplated in the 2012 AQMP, it is also not supported by the AQMD Staff's technical analysis.[3] The Staff's analysis does not support a 14 ton per day (TPD) shave as necessary for BARCT equivalency. Rather, the Preliminary Draft Staff Report (PDSR) very clearly demonstrates that not more than 8.79 TPD of emission reductions from the RECLAIM program can be attributed to BARCT advancement; a conclusion that is later echoed in the Draft PEA.[4] Furthermore, a 14 TPD shave reduction of the RECLAIM market may violate the project objectives under the California Health & Safety Code (H&SC). Contrary to H&SC §40406, Staff have failed to take into account the economic impacts for each class or category of source. The Staff analysis only considers costs and cost effectiveness for the BARCT equivalency amount of 8.79 TPD (i.e., advancement from 2005 BARCT to 2015 BARCT). There is absolutely no consideration of the economic impacts which would be incurred by RECLAIM facilities under a 14 TPD market adjustment that goes beyond BARCT.

[3] AQMD, Preliminary Draft Staff Report (PDSR) for Proposed Amendments to NOx RECLAIM, 21 July 2015.
[4] AQMD, Draft Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), 15 August 2015. See Table 1-3.

	And contrary to H&SC §39616(c)(1), AQMD Staff has failed to demonstrate that the RECLAIM program will result in an equivalent or greater reduction in emissions **at equivalent or less cost compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the district's plan for attainment**. Staff has instead applied a cost effectiveness threshold for this RECLAIM rulemaking of $50,000 per ton of NOx reduction which is more than double the cost threshold used for command-and-control rules within the District (i.e., $22,500 per ton[5]). This higher cost threshold clearly imposes a greater cost on RECLAIM sources than would be incurred under command and control regulations. But the Staff proposal to shave 14 TPD, which goes beyond BARCT, exposes RECLAIM facilities to even greater costs than would have been incurred under a command-and-control program. According the Staff's analysis, BARCT equivalency is not more than 8.79 TPD and even that value is overstated since adjustments are needed to account for the findings of the AQMD's third-party refinery expert (Norton Engineering) would reduce the shave for BARCT equivalency to not more than 7.94 TPD.[6] And contrary to H&SC §39616(c)(7), AQMD has failed to demonstrate that the RECLAIM program as amended will not result in disproportionate impacts, measured on an aggregate basis, to those stationary sources included in the program as compared to other permitted stationary sources in the district's plan for attainment. RECLAIM program sources have already reduced NOx emissions by 69% since 1994, whereas command-and-control stationary sources have only reduced NOx emissions by about 44% during that same period.[7] The BARCT levels being proposed by AQMD Staff represent performance levels that have not been demonstrated as broadly achievable for most of the source categories in question. Furthermore, these performance levels go well beyond the command-and-control standards adopted by AQMD under Regulation XI (i.e., the District's command-and-control program), and are well beyond BARCT determinations made by other major California air agencies administering command-and-control programs (e.g., SJVAPCD, BAAQMD, etc.). The resultant impacts would be disproportionate and that is in conflict with H&SC §39616(c)(7). For these reasons, the Draft PEA must be revised to address inconsistencies between the AQMD Staff's proposal and the project objectives, as well as inconsistencies with the Health & Safety Code.
Page 1-2, 1st full paragraph	This paragraph suggests that the proposed project will be limited to specific types of equipment/source categories in the RECLAIM program. While these types of equipment/source categories are certainly in the

5 AQMD, 2012 Air Quality Management Plan (AQMP), December 2012.
6 AQMD, Preliminary Draft Staff Report, Proposed NOx RECLAIM Amendments, July 2015, p. 18.
7 "RECLAIM Sources" data is computed from data presented in AQMD's RECLAIM Audit Report (March 2015). Command-and-control stationary sources NOx emissions is computed from data presented in AQMD Air Quality Management Plans (1997, 2003, 2007, 2012) and AQMP NOx RECLAIM Working Group Meeting #5, Agenda Item #3.

	RECLAIM program, the program is a market-based program; not a command-and-control program. Furthermore, the stated objectives of Control Measure CMB-01 Phase I and Phase II which this rulemaking intends to implement are for **programmatic equivalency.** Since this is a market-based system, it cannot be assumed that all impacts from the proposed rulemaking will be exclusively borne by specific equipment/source categories even where AQMD Staff have clearly attempted to target those impacts on specific facilities as is clearly the case here. The language in the referenced section needs to be revised to reflect that (a) proposed project is seeking programmatic equivalency within the requirements and limitations of the California Health & Safety Code and (b) acknowledge that there may be impacts on other RECLAIM facilities given the market-based design of the RECLAIM program. Those impacts must be analyzed to the extent practicable.
Page 1-2, 2nd full paragraph	As discussed above (see comments on Page 1-1, 4th paragraph), the Draft PEA must be revised to address inconsistencies between the AQMD Staff's proposal and the project objectives.
Page 1-13, Table 1-1, Areas of Controversy Line 1, Amount of proposed NOx shave and availability of RTCs	Draft PEA claims "The staff analysis shows that after the proposed shave is imposed, there will be sufficient NOx RTCs available to maintain trading within the NOx RECLAIM program given foreseeable opportunities for emissions reductions." This statement is without technical foundation; neither the PEA nor the PDSR includes such a market analysis. On the contrary, the Staff's proposal would reduce the quantity of RECLAIM Trading Credit (RTCs) to levels without historical precedent and that action, according to Staff's own analysis, would result in a level of "unused" RTCs (i.e., RTCs not used to cover facility emissions) for which the only historical precedent was observed during the RECLAIM market collapse during the California power crisis of 2000-2001.[8] WSPA and the Industry RECLAIM Coalition have repeatedly expressed concerns about shaving the RECLAIM program to this level when such action is clearly beyond what is needed for BARCT equivalency and in conflict with California Health & Safety Code requirements. Table 1-1 must be revised to accurately reflect the actual technical record; not assert conclusions without technical foundation.
Page 1-14, Table 1-1, Areas of Controversy Line 2, Equity of proposed NOx shave	The Draft PEA states that for 210 facilities holding 10% of the available NOx RTCs that "no NOx RTC shave is proposed because no new BARCT (not cost effective and/or infeasible) was identified…for the types of equipment and source categories." This statement is factually incorrect and should be corrected. In actuality, AQMD Staff elected not to review BARCT for these facilities under this RECLAIM rulemaking. And contrary to the statement, AQMD and other California air districts have previously made BARCT determinations that do apply to the types of equipment and operations at those smaller emitting facilities (e.g., boilers, heaters, etc.) were they not under RECLAIM.[9]

[8] AQMD Annual RECLAIM Audit Report, March 2015.
[9] See SCAQMD Regulation XI for examples.

Page 1-14, Table 1-1, Areas of Controversy Line 3, Results of the BARCT analysis	The Draft PEA states "While staff believes the engineering assumptions in the staff BARCT analysis are appropriate, the difference in BARCT reductions attributable to the alternate engineering assumptions suggested by the consultant is relatively small. To account for this difference and to provide a compliance margin, staff is proposing a shave of 14 tpd, reduced from the initial BARCT result of 14.85 tpd." We disagree. There continues to be a significant number of unresolved issues which result in uncertainty in the Staff's BARCT analysis as presented in the PDSR. This includes, but is not limited to the Staff's decision to selectively ignore the findings of the agreed upon third-party expert for the Refinery Sector, Norton Engineering Consultants. These issues are fundamental to the engineering design basis of the Staff's proposed BARCT determinations for most refinery sector source categories. These discrepancies were exhaustively described in Norton Engineering's expert analysis of the AQMD Staff's analysis,[10] as well as reiterated in NEC's letters dated 10 August 2015[11] and 4 September 2015.[12] Norton's comments are incorporated herein by reference. Furthermore, Staff's "after-the-fact" 0.85 TPD adjustment to the overall shave (i.e., reduces proposed shave from 14.85 to 14.0 TPD) is an improper application of the adjustments necessitated by Norton Engineering's expert findings. Such an adjustment, which is necessary, must be applied to the quantity of BARCT equivalency emission reductions attributed to refinery sector source categories. By failing to properly adjust this value, the AQMD Staff have distorted their own methodology to increase the burden of this shave on one sector (i.e., refineries). This is disproportionate and without technical foundation.

[11] James Norton, NEC, letter to Dr. Phillip Fine, SCAQMD, Comments on Preliminary Draft Staff Report Proposed Amendments to Regulation XX Regional Clean Air Incentives Market (RECLAIM) NOx RECLAIM – SCRs for FCCUs Document No. 14-045-7, 10 August 2015.

[12] James Norton, NEC, letter to Dr. Phillip Fine, SCAQMD, Comments on Preliminary Draft Staff Report Proposed Amendments to Regulation XX Regional Clean Air Incentives Market (RECLAIM) NOx RECLAIM – SCRs for Fired Heaters & Boilers Document No. 14-045-8, 4 September 2015.

Page 1-14, Table 1-1, Areas of Controversy Line 4, Equivalency with command-and-control	The Draft PEA asserts that the proposed shave amount of 14 tpd is consistent with previous RECLAIM rule amendments, the California Health & Safety Code, and the purpose of the program. As noted above (see above comments on Page 1-1, 4th paragraph), the AQMD Staff have not demonstrated that the Staff proposal is consistent with certain provisions of the California Health & Safety Code. Table 1-1, Line 4 must be revised to describe how the Staff proposal will comply with the project objective requiring compliance with all applicable H&SC requirements. The Draft PEA goes on to state "…This approach will result in approximately 8.79 tons per day of BARCT reductions of actual NOx emissions attributable to installing and operating additional controls. Otherwise, actual emissions reductions of only about two tpd over the next seven years would be achieved." WSPA agrees that under the AQMD Staff's analysis, BARCT equivalency as currently presented is not more than 8.79 TPD. And with adjustments needed to fully account for the findings of the AQMD's third-party refinery expert, Norton Engineering, the shave needed for BARCT equivalency is not more than 7.94 TPD.[13] Staff has provided no information to support the assertion that 14 TPD must be shaved to achieve the 8.79 TPD (or 7.94 TPD) required for BARCT equivalency. And RECLAIM program history does not support that conclusion. Under the 2005 Shave, a 23% reduction in RTCs resulted in a 24% reduction in NOx RECLAIM emissions; a nearly 1:1 relationship.[14] The Staff proposal must be revised to reflect the project objective of BARCT equivalency. That has not been demonstrated as any more than 8.79 TPD.
Page 1-15, Table 1-1, Areas of Controversy Line 5, 2012 AQMP Commitment in the State Implementation Plan (SIP)	The Draft PEA states: "This staff proposal recommends a reasonably available 14 tpd of NOx RTC reductions, based on BARCT, as required by state law." In fact, the PDSR presents BARCT equivalency as not more than 8.79 TPD, and the AQMD Staff have not explained how its proposal will comply with H&SC §40406, since there is no consideration of the economic impacts which would be incurred under a 14 TPD market adjustment that goes beyond BARCT. Furthermore, AQMD Staff's proposal is contrary to H&SC §39616(c)(1), which requires the market to perform at equivalent or less cost compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the District's plan for attainment. The Draft PEA must be revised to fully demonstrated compliance with the project objectives and relevant H&SC requirements.

[13] AQMD Preliminary Draft Staff Report, Proposed NOx RECLAIM Amendments, July 2015, p. 18.
[14] SCAQMD Annual RECLAIM Audit Report, March 2015. Under the 2005 shave, RTCs were reduced from 34.2 to 26.5 TPD between 2005 and 2011 and emissions declined from 26.4 to 20 TPD over the same period.

Page 1-16, Table 1-1, Areas of Controversy Line 6, Availability of RTCs for future power plant needs	The Draft PEA states" The staff proposal would establish a separate adjustment account to hold RTCs for power plants to meet their NSR holding obligations. Many newer peaking plants are required to hold RTCs at the potential to emit level each year even though their actual emissions are far below this level. The adjustment account would relieve power producing facilities from the obligation of holding RTCs in order to meet the NSR holding requirements of Rule 2005." The AQMD Staff proposal for a separate "adjustment account" has not been fully defined, and the Staff proposal and Draft PEA fail to address how such a mechanism would comply with U.S. EPA requirements for New Source Review. The PDSR and Draft PEA must be revised to demonstrate how such a proposed adjustment account would function, and demonstrate that it is approvable by U.S. EPA. Furthermore, Staff's proposal would apparently not apply to new peaking power plants. The California Air Resources Board prepared assessment of electrical grid reliability needs in the South Coast air basin which suggested a significant amount of peaking power plant capacity would be needed to ensure reliability in the future.[15] This report was prepared in conjunction with the California's power sector regulators (i.e., California Public Utilities Commission, California Independent System Operator, and California Energy Commission). Contrary to the CARB report, AQMD Staff's analysis depends on a negative growth rate for power sector emissions and RTC demand. This is a significant difference. The Draft PEA should be revised to clarify that the Staff proposal would provide no relief to any new peaking power plants. The Draft PEA should also be revised to demonstrate how the Staff proposal will accommodate new power sector facilities which may be needed to ensure electric reliability and integration of renewable electricity.
Page 1-17, 3rd paragraph	The Draft PEA states "For the remaining 210 facilities that hold 10 percent of the 26.5 tpd of the NOx RTCs, no NOx RTC shave is proposed because no new BARCT (not cost effective and/or infeasible) was identified for the types of equipment and source categories at these facilities." This statement is factually incorrect and should be revised. As noted above, AQMD Staff elected not to review BARCT for these smaller facilities for this RECLAIM rulemaking (i.e., no analysis was performed).

[15] CARB, Assembly Bill 1318: Assessment of Electrical Grid Reliability Needs and Offset Requirements in the South Coast Air Basin, Draft Final Report, October 2013.

Page 1-20, 1st paragraph, 3rd sentence Air Quality and Greenhouse Gases	The Draft PEA states "For the 275 facilities that are in the NOx RECLAIM program, the 14 tpd of NOx RTC reductions will affect 65 facilities plus the investors, who collectively hold 90 percent of the NOx RTC holdings." This paragraph suggests that the proposed project will be limited to specific facilities in the RECLAIM program. While the application of the shave may be limited to these facilities, the impacts of the proposed shave will be broader. RECLAIM is a market-based program; not a command-and-control program. Since this is a market-based system, it cannot be assumed that all impacts from the proposed rulemaking will be exclusively borne by specific equipment/source categories even where AQMD Staff have clearly attempted to target those impacts on specific facilities as is clearly the case here. For example, smaller facilities without Infinite Year Basis (IYB) RTC holdings may incur higher RTC prices to meet their future compliance obligations. Alternatively, such facilities may find themselves unable to purchase RTCs at any price similar to the RTC supply crisis observed during the 2000/2001 power crisis which nearly collapsed the RECLAIM program. Also, Staff has not considered potential impacts to new or expanding facilities which are required to participate in RECLAIM. Or the potential consequences to the regional economy if those facilities are unable to obtain RTC supply. Or the potential environmental impacts of those operations if they are forced to locate outside of the South Coast air basin where they would presumably be subjected to lessor regulation. These are all issues and impacts which have been identified and should be disclosed as potential impacts from the project. The Draft PEA must be revised to clarify that market impacts may be broader than intended or even recognized by Staff, and those impacts must be quantified to the extent possible.
Page 1-20, 2nd paragraph	The Draft PEA states "…only 44 facilities are expected to comply with the proposed NOx RTC shave through the purchase of RTCs which will have no environmental impact." The Draft PEA should be revised to present supporting analysis demonstrating how this conclusion was reached. RECLAIM is a market-based program; not a command-and-control program. Since this is a market-based system, it cannot be assumed that all impacts from the proposed rulemaking will be exclusively borne by specific equipment/source categories even where AQMD Staff have clearly attempted to target those impacts on specific facilities as is clearly the case here.
Table 1-3, Summary of Proposed Project & Alternatives Alternative 3	This table reports the NOx Reduction Potential (tons/day) for Alternative 3 at 8.00 TPD. As proposed by the Industry, RECLAIM Coalition, Alternative 3 would result in BARCT equivalent reductions. Using the AQMD Staff's latest BARCT analysis, which needs to be revised downward as discussed earlier herein, the Proposed NOx RTC "Shave" for this alternative should be 8.79 TPD. The Draft PEA should be revised.

Table 1-3, Summary of Proposed Project & Alternatives Proposed Project Page 1-26	This table clearly shows that the AQMD Staff proposal, which would shave 14 TPD, would include removing 5.21 TPD of RTCs from the RECLAIM market that cannot be attributed to BARCT. The table even labels these 5.21 TPD as "NOx RTCs Needed to Fulfill Shave Post-BARCT." [Emphasis Added] This proposal is beyond BARCT. Furthermore, a 14 TPD shave reduction of the RECLAIM market could violate the project objectives under the California Health & Safety Code (H&SC). Contrary to H&SC §40406, Staff have failed to take into account the economic impacts for each class or category of source. The Staff analysis only considers costs and cost effectiveness for the BARCT equivalency amount of 8.79 TPD (i.e., advancement from 2005 BARCT to 2015 BARCT). There is absolutely no consideration of the economic impacts which would be incurred under a 14 TPD market adjustment that goes Beyond BARCT. Contrary to H&SC §39616(c)(1), AQMD Staff has failed to demonstrate that the RECLAIM program will result in an equivalent or greater reduction in emissions **at equivalent or less cost compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the District's plan for attainment**. Staff has instead applied a cost effectiveness threshold for this RECLAIM rulemaking of $50,000 per ton of NOx reduction which is more than double the cost threshold used for command-and-control rules within the District (i.e., $22,500 per ton[16]). This clearly imposing a greater cost on RECLAIM sources than would be incurred under command and control regulations. Furthermore, Staff has proposed a market shave of 14 TPD which goes beyond BARCT. Under AQMD Staff's analysis, BARCT equivalency is currently presented as not more than 8.79 TPD. Even that value is overstated since adjustments needed to fully account for the findings of the AQMD's third-party refinery expert, Norton Engineering, would reduce the shave for BARCT equivalency to not more than 7.94 TPD.[17] Thus, RECLAIM facilities would have greater costs under the Staff proposal than would have been incurred under a command-and-control program. And contrary to H&SC §39616(c)(7), AQMD has failed to demonstrate that the RECLAIM program as amended will not result in disproportionate impacts, measured on an aggregate basis, to those stationary sources included in the program as compared to other permitted stationary sources in the District's plan for attainment. RECLAIM program sources have already reduced NOx emissions by 69% since 1994, whereas command-and-control stationary sources have only reduced NOx emissions by about 44% during that same period.[18] The BARCT levels being proposed by

[16] AQMD, 2012 Air Quality Management Plan (AQMP), December 2012.
[17] AQMD Preliminary Draft Staff Report, Proposed NOx RECLAIM Amendments, July 2015, p. 18.
[18] "RECLAIM Sources" data is computed from data presented in AQMD's RECLAIM Audit Report (March 2015). Command-and-control stationary sources NOx emissions is computed from data presented in AQMD Air Quality

	AQMD Staff generally represent performance levels that have not been demonstrated as broadly achievable for the source categories in question. Furthermore, these performance levels go well beyond the command-and-control standards adopted by AQMD under Regulation XI (i.e., the District's command-and-control program), and are well beyond BARCT determinations made by other major California air agencies administering command-and-control programs (e.g., SJVAPCD, BAAQMD, etc.). For these reasons, the Draft PEA must be revised to address inconsistencies between the AQMD Staff's proposal and the project objectives.
Table 1-4, Comparison of Adverse Environmental Impacts of the Alternatives Row 3: Air Quality & GHGs	This table reports for Alternative 3 "Less operational NOx reductions than proposed project but not quantifiable." As correctly reported in Table 1-3, Alternative 3 would actually reduce emissions by 8.79 TPD so it clearly is quantifiable. Table 1-4 must be revised to correctly report the emission reduction potential for Alternative 3.
Table 1-4, Comparison of Adverse Environmental Impacts of the Alternatives Row 3: Air Quality & GHGs Page 1-29	For the proposed project, the table reports "Increases operational use of NH3 (a TAC) by 39.5 tpd." But for Alternative 3, the table reports that ammonia (NH3) use is not quantifiable. However, no evidence is provided to support that conclusion. In the alternatives air quality analysis, the District asserts that if Alternative 3 were implemented, it would be too difficult to predict the number of facilities that would install NOx control equipment. First, the District should have acknowledged the unpredictability of facilities implementing the proposed project, which is more aggressive and could trigger correspondingly more drastic business reactions. Instead, the District assumes there that all facilities will fall in line to install equipment as it predicts (i.e., command and control). Second, the likely NOx control installation projects can be quantified at a program level since it is a function of the same stoichiometric relationship used in the Staff's analysis for the proposed project. The Draft PEA should be revised to provide an estimate of the operational ammonia use for Alternative 3. Since this value will be lower than the proposed project, Alternative 3 would have lower ammonia emissions by comparison and would therefore be environmentally preferable on this issue. Is Staff's estimate for increased operational use of ammonia based on 8.79 TPD of NOx emission reductions (i.e., BARCT equivalency)? Since the Staff's 14 TPD proposal would require significantly greater emission reductions (i.e., beyond BARCT), the Draft PEA should be revised to explain the basis for this ammonia use figure to ensure that project's potential environmental impacts are fully disclosed. The ammonia figure also drives traffic and construction impacts which may be greater than disclosed in the Draft PEA. For similar reasons, the Staff's statement that Alternative 3 emissions for construction are "not quantifiable" is not accurate. As reported in Table 1-3, Alternative 3 would require emission controls sufficient to reduce NOx emissions by 8.79 TPD (again, using the Staff's BARCT analysis). The

Management Plans (1997, 2003, 2007, 2012) and AQMP NOx RECLAIM Working Group Meeting #5, Agenda Item #3.

	Draft PEA must be revised to include a quantified estimate of the construction emissions needed to deliver those emissions control using a methodology similar to the Staff's analysis of the proposed project.
Table 1-4, Comparison of Adverse Environmental Impacts of the Alternatives Row 3: Air Quality & GHGs Page 1-30	The Alternative 3, the Draft PEA reports impacts are "Less than significant; achieves net NOx emission reductions during operation (less reductions than the proposed project <u>but not quantifiable</u>)." [emphasis added] This is not correct. As reported in Table 1-3, Alternative 3 would require emission controls sufficient to reduce NOx emissions by 8.79 TPD (again, using the Staff's BARCT analysis) so clearly the impacts from Alternative 3 are quantifiable. The Draft PEA must be revised to include a quantified estimate of the NOx emission reductions during operation for Alternative 3.
Page 2-2, Section 2.2 Project Objectives	The Draft PEA states: "The objectives of the proposed project are to: 1) Comply with the requirements in Health and Safety Code (HSC) §§40440 and 39616 by conducting a BARCT assessment of the NOx RECLAIM program and reducing the amount of available NOx RTCs to reflect emission reductions equivalent to implementing available BARCT; 2) Modify the RTC "shaving" methodology to implement the emission reductions per the BARCT assessment; 3) Ensure that RECLAIM facilities, in aggregate, achieve the same emission reductions that would have occurred under a command-and-control approach; 4) Achieve the proposed NOx emission reduction commitments in the 2012 AQMP Control Measure #CMB-01: Further NOx Reductions from RECLAIM; and, 5) Achieve NOx emission reductions to assist in attaining the NAAQS." This highlights several problems with the Draft PEA and the Staff proposal. WSPA agrees that AQMD has a legal obligation to comply with the requirements in Health and Safety Code (HSC) §§40440 and 39616. However, Staff has oversimplified what those obligations are by suggesting this is entirely about conducting a BARCT assessment. The AQMD Staff's proposed 14 TPD shave reduction from the RECLAIM market could violate the project objectives under the California Health & Safety Code (H&SC). With respect to H&SC §40406, Staff have failed to take into account the economic impacts for each class or category of source. The Staff analysis only considers costs and cost effectiveness for the BARCT equivalency amount of 8.79 TPD (i.e., advancement from 2005 BARCT to 2015 BARCT). There is no consideration of the economic impacts which would be incurred under a larger 14 TPD market adjustment that goes beyond BARCT. With respect to H&SC §39616(c)(1), AQMD Staff has failed to demonstrate that the RECLAIM program will result in an equivalent or greater reduction in emissions **at equivalent or less cost compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the**

	District's plan for attainment. Staff has instead applied a cost effectiveness threshold for this RECLAIM rulemaking of $50,000 per ton of NOx reduction which is more than double the cost threshold used for command-and-control rules within the District (i.e., $22,500 per ton[19]). This clearly imposes a greater cost on RECLAIM sources than would be incurred under command and control regulations. Furthermore, Staff has proposed a market shave of 14 TPD which goes beyond BARCT. Under AQMD Staff's analysis, BARCT equivalency is currently presented as not more than 8.79 TPD. Even that value is overstated since adjustments needed to fully account for the findings of the AQMD's third-party refinery expert, Norton Engineering, would reduce the shave for BARCT equivalency to not more than 7.94 TPD.[20] Thus, RECLAIM facilities would have greater costs under the Staff proposal than would have been incurred under a command-and-control program. And contrary to H&SC §39616(c)(7), AQMD has failed to demonstrate that the RECLAIM program as amended will not result in disproportionate impacts, measured on an aggregate basis, to those stationary sources included in the program as compared to other permitted stationary sources in the District's plan for attainment. RECLAIM program sources have already reduced NOx emissions by 69% since 1994, whereas command-and-control stationary sources have only reduced NOx emissions by about 44% during that same period.[21] The BARCT levels being proposed by AQMD Staff generally represent performance levels that have not been demonstrated as broadly achievable for the source categories in question. Furthermore, these performance levels go well beyond the command-and-control standards adopted by AQMD under Regulation XI (i.e., the District's command-and-control program), and are well beyond BARCT determinations made by other major California air agencies administering command-and-control programs (e.g., SJVAPCD, BAAQMD, etc.).

[19] AQMD, 2012 Air Quality Management Plan (AQMP), December 2012.
[20] AQMD Preliminary Draft Staff Report, Proposed NOx RECLAIM Amendments, July 2015, p. 18.
[21] "RECLAIM Sources" data is computed from data presented in AQMD's RECLAIM Audit Report (March 2015). Command-and-control stationary sources NOx emissions is computed from data presented in AQMD Air Quality Management Plans (1997, 2003, 2007, 2012) and AQMP NOx RECLAIM Working Group Meeting #5, Agenda Item #3.

Page 2-2, Section 2.2 Project Objectives (continued)	Next, the Draft PEA suggests an objective to "modify the RTC "shaving" methodology to implement the emission reductions per the BARCT assessment." That is not consistent with the project description contained in the Notice of Preparation issued 4 December 2014,[22] nor is it consistent with project description contained in the Initial Study.[23] Specifically, neither the NOP Project Description nor the Initial Study Project Description included any reference to modifying "the RECLAIM trading credit (RTC) "shaving" methodology" in the description of the project or the project objectives. And this is also inconsistent with the objectives approved by the Governing Board under Control Measure CMB-01. For these reasons, all references to "modifying "the RECLAIM trading credit (RTC) "shaving" methodology" should be removed from the Draft PEA.
Page 2-2, Section 2.2 Project Objectives (continued)	This section also suggests an objective "Achieve NOx emission reductions to assist in attaining the NAAQS." This is also not consistent with the Project Description contained in the Notice of Preparation issued 4 December 2014,[24] or the description contained in the Initial Study Project Description.[25]

[22] AQMD, Notice of Preparation of a Draft Program Environmental Assessment, Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), 4 December 2014. See "Description of Nature, Purpose, and Beneficiaries of Project."

[23] AQMD, Initial Study for Draft Program Environmental Assessment, Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), December 2014. See page 1-7, Project Description.

[24] AQMD, Notice of Preparation of a Draft Program Environmental Assessment, Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), 4 December 2014. See "Description of Nature, Purpose, and Beneficiaries of Project."

[25] AQMD, Initial Study for Draft Program Environmental Assessment, Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), December 2014. See page 1-7, Project Description.

Page 2-6, 4th paragraph	The Draft PEA states "the proposed project is estimated to reduce four tons per day of NOx emissions starting in 2016 because the amount of unused RTCs in the NOx RECLAIM program over the past five years (e.g., from 2009 to 2013) ranged from five tpd to eight tpd, demonstrating that there is enough cushion to support reduction of four tpd in 2016." While the quantities of "unused" RTCs are a matter of historical record, Staff has provided no evidence to support that supposition that the RECLAIM market has "enough cushion to support reduction of four tpd in 2016." And if this was just a reduction of unused RTCs, that would not equate to an emissions reduction in 4 TPD. The Draft PEA needs to be revised to include a market analysis to support that supposition or this statement should be deleted.
Page 2-6, 4th paragraph (continued)	The Draft PEA goes on to state "it could take from two to four years for the affected facilities to plan, obtain permits, and install air pollution control equipment or modify existing equipment in response to the proposed project." According to information from WSPA members, this estimate is too short.[26] While some individual projects might be complete able in 2-4 years, the proposed project would require dozens and dozens of emission control projects to be completed. For the refinery sector, such projects would need to be planned, engineered, and sequenced for construction in consideration of unit turnaround schedules. WSPA members report that completion of all needed projects for the proposed project would likely require not less than eight (8) years. The Draft PEA should be revised to reflect this timetable and the Proposed Amended Rules and PDSR should be similarly adjusted.
Page 2-9, PAR 2005 Requirements for New or Relocated RECLAIM Facilities – Subdivision (b)	The AQMD Staff have yet to provide a complete description of the amendments to this rule. AQMD Staff have also not obtained U.S. EPA approval that such amendments would even be approvable into the State Implementation Plan (SIP). The Draft PEA and PAR 2005 should be revised to reflect these important details after AQMD Staff have obtained the U.S. EPA approval needed for such amendments to be legal.
Page 2-10, top of page	The Draft PEA states "Further, only 44 facilities are expected to comply with the proposed NOx RTC shave through the purchase of RTCs which will have no environmental impact." The Draft PEA should be revised to present supporting analysis demonstrating how this conclusion was reached.
Page 3.2-34, 2nd paragraph, GHG Tailoring Rule	This section should be revised to note that the courts vacated significant portions of the GHG Tailoring Rule. The applicability criteria as described in the Draft PEA are not consistent with current regulations.
Page 4.1-3, Section 4.1.3.1	The Draft PEA states "Because each affected facility is located in heavy industrial areas, the construction equipment is not expected to be substantially discernable from what exists on-site for routine operations and maintenance activities. Further, the construction activities are not expected to adversely impact views and aesthetics resources since most of the heavy equipment and activities are expected to occur within the confines of each existing facility and are expected to introduce only minor visual changes to areas outside each facility, if at all, depending on the location of the construction activities within the facility."

[26] WSPA/ERM confidential survey of WSPA members concerning refinery heaters/boilers, March 2015.

	This statement oversimplifies the range of physical settings existent for RECLAIM facilities. In actuality, some refinery or non-refinery RECLAIM facilities are located areas where additional vertical obstructions from cranes or new emission control structures could be "discernable" and may adversely impact views and aesthetics resources for adjacent communities. The Draft PEA should be revised to clarify the range of settings which would be impacted by the proposed project and acknowledge the range of potential impacts associated with the proposed project.
Page 4.2-2, Table 4.2-1 Estimated Number of NOx Control Devices Per Sector and Equipment/Source Category	As shown in this table, the Draft PEA states that Staff has assumed 74 SCRs would be installed on Refinery Process Heaters and Boilers under the proposed project. Staff does not explain the basis for this value, which conflicts with the Preliminary Draft Staff Report (PDSR). The PDSR suggests that the proposed project would result in 76 SCRs (25 upgraded, 51 new) for refinery heaters and boilers,[27] in which case the Draft PEA would be understating the potential project impacts. It should also be noted that AQMD's third-party refinery sector expert, Norton Engineering, found that only 48 refinery heaters and boilers could be cost effectively retrofit with new or upgraded SCRs.[28] Staff have done nothing to reconcile this discrepancy which is material. The Draft PEA must be revised to clarify the technical basis for the assumed emission controls outcome and associated potential impacts to the environment. The Draft PEA should also explain how emission controls which are not cost effective, according to AQMD's own third-party expert, will be implemented.
Page 4.2-4, Section 4.2.3.1, first paragraph	The Draft PEA states "Further, operators at each affected facility who construct NOx control equipment that utilize chemicals as part of the NOx control equipment operations, such as a new ammonia or caustic storage tank, may also need to build a containment berm large enough to hold 110 percent of the tank capacity in the event of an accidental release, pursuant to U.S. EPA's spill prevention control and countermeasure regulations." While other regulations and good engineering practices would require containment features for these tanks, the Spill Prevention Control and Countermeasure (SPCC) regulations actually don't apply to ammonia or caustic storage vessels. The Draft PEA should be clarified accordingly.
Page 4.2-7, last paragraph	The Draft PEA states "if a particular technology was identified as having a cost that exceeds $50,000 per ton, this CEQA analysis assumed that the facility operator would not install this type of air pollution control technology in response to the project." This statement is inconsistent with the project objectives which require compliance with the California Health & Safety Code. The $50,000 threshold fails in this regard. Under H&SC§39616(c)(1), the RECLAIM program is required to result in "an equivalent or greater reduction in emissions **at equivalent or less cost compared with current command and control regulations** and future air quality measures that would otherwise have been adopted as part of the District's plan for attainment." AQMD Staff has failed to demonstrate that the proposed amended RECLAIM program will be **at equivalent or less**

[27] AQMD Preliminary Draft Staff Report, Proposed NOx RECLAIM Amendments, July 2015, Table B.10.
[28] AQMD Preliminary Draft Staff Report, Proposed NOx RECLAIM Amendments, July 2015, Table B.9.

	cost compared with current command and control regulations. On the contrary, Staff's proposed $50,000 cost effectiveness threshold for this RECLAIM rulemaking is more than double the cost threshold used by AQMD for command-and-control rules (i.e., $22,500 per ton[29]). This clearly imposes a greater cost on RECLAIM sources than would be incurred under command and control regulations. The Draft PEA and Proposed Amended Rules must be revised is be consistent with the project objectives and all applicable H&SC requirements.
Page 4.2-8, Section 4.2.3.1, first paragraph	The Draft PEA states "In order to operate SCR and UltraCat technology, ammonia is necessary and, as such, tanks to store ammonia would also need to be installed. The size of each ammonia tank needed to operate the SCR units and one UltraCat filtration unit have been estimated to range between 2,000 and 11,000 gallons in capacity." While this statement may be appropriate for characterizing new tanks which are likely to handle aqueous ammonia, it ignores the fact that some existing ammonia tanks are used to store anhydrous ammonia. The PEA should be revised to address this description. Staff should consider whether this condition requires revision of the offsite consequence analysis presented in the Draft PEA.
Page 4.2-8, Section 4.2.3.1, 5th paragraph	The Draft PEA states "From a construction point of view, the installation of a NOx control technology at a refinery is a complex process. For example, if a facility operator chooses to install NOx control equipment, time will be needed for pre-construction/advance planning activities such as engineering analysis of the affected equipment, engineering design of the potential control equipment, contracting with a vendor, securing financing, ordering and purchasing the equipment, obtaining permits and clearances, and scheduling contractors and workers. The amount of lead time can vary from six months (e.g., for a SCR for refinery/boiler heater or gas turbine) to up to 18 months for a scrubber (either a WGS or DGS)." AQMD permitting for new emission controls can easily take as much as 18 months for Title V facilities. This could easily increase the amount of lead time a company requires to 2-3 years. Some of the pre-construction activities cannot be conducted until the Permit to Construct has been issued.
Page 4.2-11, top of page	The Draft PEA states "…the analysis also includes an analysis of the overlapping impacts spread out over a five- and seven-year period." According to information from WSPA members, this estimate is too short. While some individual projects might be complete able in 2-4 years, the proposed project would require dozens and dozens of emission control projects to be completed. For the refinery sector, such projects would need to be planned, engineered, and sequenced for construction in consideration of unit turnaround schedules. WSPA members report that completion of all needed projects for the proposed project would likely require not less than eight (8) years.[30] The Draft PEA should be revised to reflect this timetable and the Proposed Amended Rules and PDSR should be similarly adjusted.

[29] AQMD, 2012 Air Quality Management Plan (AQMP), December 2012.
[30] WSPA/ERM confidential survey of WSPA members concerning refinery heaters/boilers, March 2015.

Page 4.2-13, 1st paragraph Combined Construction Emissions From Non-Refinery and Refinery Facilities	The Draft PEA does not disclose the assumed basis for construction impact estimates. Are these impacts based on construction of emission controls to deliver 8.79 TPD (i.e., BARCT equivalency), or has Staff assumed construction sufficient to deliver the proposed 14 TPD of emission reductions (i.e., beyond BARCT equivalency)? The amount of construction activity for modification of existing SCRs will be different than the activity needed for entirely new SCR installations. The Draft PEA must be revised to fully disclose the technical basis of this analysis so the public can understand whether the impacts presented are complete.
Page 4.2-13, last paragraph Combined Construction Emissions From Non-Refinery and Refinery Facilities	The Draft PEA notes "…it is likely that only minimal, if any, construction activities would occur at any refinery facilities during 2016." This is exactly why the Staff proposal to remove four (4) TPD of RTCs in 2016 is too much, too fast. Staff has provided no evidence to support that supposition that the RECLAIM market has "enough cushion to support reduction of four tpd in 2016."
Page 4.2-18, 1st paragraph	The Draft PEA states "Implementation of the proposed project is expected to result in direct air quality benefits from the reduction of 14 tons per day of NOx RTCs by 2022. Because of the RECLAIM market system, the actual reduction in NOx emissions each year may be less than the reduction in RTC holdings imposed by the project." This statement conflicts with Page 1-1, 4th paragraph. Please see our comment to that prior statement.
Page 4.2-20, Refinery Facilities	This section presents impacts from operation of the proposed project for refinery facilities in the South Coast air basin. The Draft PEA does not disclose the assumed basis for these impact estimates. Are these impacts based on operation of emission controls to deliver 8.79 TPD (i.e., BARCT equivalency), or has Staff assumed operations sufficient to deliver the proposed 14 TPD of emission reductions (i.e., beyond BARCT equivalency)? The Draft PEA should be revised to explain the basis of the technical analysis so the public can understand whether the impacts presented are complete.
Page 4.2-22, 1st paragraph	The Draft PEA states "Ammonia slip is limited to five parts per million (ppm) by permit condition." This is an oversimplification since some existing SCRs are permitted with higher ammonia slip limits. These existing units may not be required to open their permits, in which case they could continue to operate with higher than 5 ppmv ammonia slip performance. Furthermore, the Draft PEA analysis of ammonia slip for new SCR installations depends on physical conditions which the Staff analysis explicitly omitted from the project description (e.g., use of Ammonia Slip Catalysts or ASC) despite recommendations by the AQMD's third-party expert, Norton Engineering, to use ASC.[31] Without the ASC, ammonia slip from individual devices could be as great as 20 ppmv, but the draft PEA underestimates the ammonia slip by assuming it will universally be 5 ppmv. However, existing SCRs are not necessarily subject to those permit

[31] Draft Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), 15 August 2015. See Table 2-3.

	conditions, and thus, ammonia slip of up to 20 ppmv should be considered in the health risk assessment for ammonia emissions.[32] The Draft PEA should be revised to more accurately reflect the range of ammonia slip conditions which could exist. Importantly, the screening Health Risk Assessment results presented in the Draft PEA would need to be revised to reflect that broad range of ammonia slip performance.
Section 4.2.4, Cumulative Air Quality Impacts	The Draft PEA does not discuss the potential secondary impacts on air quality associated with increased emissions of ammonia from the numerous SCRs mandated by this rulemaking. Ammonia is a precursor to PM2.5 formation for which the South Coast AQMD is in nonattainment, so the PEA should consider whether additional ammonia emissions would represent a cumulatively considerable impact.
Page 4.2-26, 1st full paragraph	The Draft PEA states "…based on regional modeling analyses performed for the 2012 AQMP, implementing control measures contained in the 2012 AQMP, in addition to the air quality benefits of the existing rules, is anticipated to bring the District into attainment with all national and most state ambient air quality standards by the year 2023." This statement is at best incorrect. A significant portion of the control strategy presented in the 2012 AQMP was still 182(e) "black box" measures which have not been defined.
Chapter 5, Alternatives	In this section, the Draft PEA presents 5 alternatives to the proposed project, but except for Alternative 4 (No Project) and Alternative 3 (Industry Approach), all other alternatives propose 14 TPD or more of NOx emission reductions. Given that the proposed project has remaining significant environmental effects with the proposed project at 14 TPD, the failure to include any additional alternatives other than Alternative 3 (Industry Approach) at a lesser reduction of NOx emissions does not satisfy CEQA's requirement for a "reasonable range of alternatives." In addition, the Draft PEA repeatedly claims that the impacts from the alternatives are "not quantifiable" for unspecified reasons. But these figures are not unknowable. In most cases, Staff could have easily made bounding or other technical assumptions to complete the quantification to allow the public to understand how the impacts from the alternatives compare to the Staff's proposed project. The Draft PEA must be revised to include this additional technical detail.

[32] Draft Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), 15 August 2015. See Tables 4.2-18 and 4.2-21.

RESPONSES TO COMMENT LETTER #5
(Phillips 66 Company – October 6, 2015)

5-1 This comment supports the sentiments expressed in Comment Letter #2. While Comment Letter #2 was submitted with four additional documents that are included in this appendix, Comment Letter #5 only provided a copy of the first two documents submitted as part of Comment Letter #2 (e.g., the main letter dated October 6, 2015 and Attachment 1 of Comment Letter #2) as reference. See Responses to Comment Letter #2.

Comment Letter #6

VIA ELECTRONIC MAIL

Ms. Barbara Radlein
Program Supervisor, CEQA Special Projects
South Coast Air Quality Management District
21865 Copley Drive
Diamond Bar, CA 91765

SUBJECT: NOx RECLAIM INDUSTRY COALITION COMMENTS ON DRAFT PROGRAM ENVIRONMENTAL ASSESSMENT FOR PROPOSED AMENDMENTS TO REGULATION XX

Dear Ms. Radlein:

The NOx RECLAIM Industry Coalition ("the Coalition") consisting of the industry trade associations listed below submits these comments on the Draft Program Environmental Assessment ("DPEA") for Proposed Amendments to Regulation XX.

California Asphalt Pavement Association (CalAPA)
California Construction & Industrial Materials Association (CalCIMA)
California Council for Environmental and Economic Balance (CCEEB) 6-1
California Manufacturers and Technology Association (CMTA)
California Metals Coalition (CMC)
California Small Business Alliance (CSBA)
Regulatory Flexibility Group (RFG)

Southern California Air Quality Alliance (SCAQA)
Western States Petroleum Association (WSPA)
Los Angeles Business Federation (BizFed) 6-1 Con't

I. PROJECT DEFINITION NOT CONSISTENT WITH THE PROJECT ANALYZED

The Project is defined as the amendment of Regulation XX to implement a reduction in NOx RECLAIM Trading Credits ("RTCs") of 14 tons per day. However, the project analyzed is only the installation of BARCT at various facilities. These are not the same things. The construction activities related to the potential installation of BARCT at various facilities is only a subset of the proposed Project, and represents only 8 tons per day of the proposed 14 tons per day reduction. The cost of removing the additional 6 tons per day to get to 14 tons per day must be included in this analysis. 6-2

The project as actually proposed and defined would virtually eliminate the NOx RTC market. The RECLAIM program is a cap-and-trade program that relies on the availability of RTCs to provide structural buyers a source of credits, provide for NSR holdings required by RECLAIM NSR rules, and provide for construction of new facilities and expansion of existing facilities. The removal of 14 tons per day of NOx RTCs will adversely impact all of these uses but there is no analysis even attempted in the DPEA of such impacts. Since the DPEA only analyzes a subset of the entire project, it fails to comply with CEQA's requirement to evaluate impacts from the "whole of the action" being proposed. CEQA Guidelines §15378(a). It appears that removal of 14 tons per day of NOx RTCs and the potential destruction of the NOx RTC market is "assumed" to have no effect.

II. REMOVAL OF 14 TONS PER DAY OF NOX RTCS WOULD HAVE SIGNIFICANT IMPACTS

There are potential impacts on energy supply and reliability in the event insufficient RTCs are available to provide for increased energy demand (which will be exacerbated by District plans, as expressed in ongoing air quality planning activities related to the 2016 AQMP, to electrify large segments of the Southern California industrial, service, and residential sectors). There is no analysis whatsoever of the potential impacts on structural buyers or any other RECLAIM participants (including many NOx RECLAIM Industry Coalition members), other than those who the District expects to have to install emission control equipment. 6-3

III. USE OF A PROGRAM ENVIRONMENTAL ASSESSMENT IS INAPPROPRIATE WHEN PROJECT LEVEL IMPACTS ARE BEING ASSESSED 6-4

The PEA states that it is a program level document. However, it only evaluates BARCT related construction activities which are really "project level" activities. The DPEA should include a project level review of impacts, which it does not do.

2

IV. THE PROPOSED PROJECT IS INCONSISTENT WITH THE STATED OBJECTIVE OF COMPLYING WITH HEALTH AND SAFETY CODE SECTION 39616

The stated objective of the Project is to comply with the requirements in Health and Safety Code §39616 by conducting a BARCT assessment of the NOx RECLAIM program and reducing the amount of available NOx RTCs to reflect emission reductions equivalent to implementing BARCT. However, compliance with that section also requires that RECLAIM emission reductions be equivalent or greater than reductions that would have resulted under command and control at equivalent or less cost compared with command and control. The Project fails to meet the cost equivalency of that requirement. The District uses a cost-effectiveness figure of $50,000 per ton for RECLAIM BARCT and $22,500 per ton for command and control BARCT. This is inconsistent with state law and thus with the stated objective of cost equivalency and results in a reduction of RTCs that will necessitate emission reductions beyond what can be achieved by application of BARCT (relative to a command and control rulemaking). Furthermore, only a portion of the shave has received any cost estimate at all. SCAQMD has only provided cost estimates for 8.8 tons per day (related to installing technology) of a 14 tons per day shave. Obviously shaving beyond the portion of the shave attributable to technology will exceed costs for equivalent command and control regulations. 6-5

There is also no analysis of potential business closures as a result of such a severe shave that would reduce the availability and increase the cost of RTCs. While the District has noted that the number of facilities in RECLAIM has dropped from 392 facilities to 276, there has been no effort to evaluate the significance of this change and whether the proposed 14 ton per day shave would be consistent with the requirements of §39616(c)(4). That section requires that the RECLAIM program "not result in a greater loss of jobs or more significant shifts from higher to lower skilled jobs, on an overall districtwide basis, than that which would exist under command and control air quality measures that would otherwise have been adopted as part of the district's plan for attainment."

V. THE DPEA FAILS TO ANALYZE A REASONABLE RANGE OF ALTERNATIVES THAT COULD MEET THE OBJECTIVE OF THE PROJECT WITH LESSER IMPACTS

The PEA fails to analyze whether alternatives to the 14 ton per day proposed shave could also meet the objective of obtaining emissions reductions from the RECLAIM universe equivalent to the BARCT reductions identified by staff. For example, staff could have reviewed past shaves to determine the ratio between the amount shaved and the amount of actual emission reductions that occurred from the RECLAIM universe. This would at least provide an empirically derived alternative to the District's 14 ton per day NOx shave, which is beyond any previously imposed shave and would seem to be (empirically) much greater than necessary to achieve 8.7 tons per day of actual emission reductions (actually 8 tons per day after the 0.7+ tons per day are given back on BARCT as a result of the Norton Engineering kerfuffle). If the BARCT reduction could be achieved with less than 14 tons per day of RTC reductions, it would significantly reduce, and possibly avoid, many if not all of the impacts of the 14 ton per day proposed reduction. 6-6

3

VI. CONCLUSION

In summary, the PEA needs to be redone to address all of the potential project impacts, not just the construction related impacts, and additional alternatives can and should be identified that could achieve the project's objective while avoiding the significant impacts and inconsistency with Health and Safety Code Section 39616 associated with a 14 ton per day shave. 6-7

Respectfully,

Curtis L. Coleman
Executive Director, Southern California Air Quality Alliance
On behalf of the NOx RECLAIM Industry Coalition

cc: Dr. Phil Fine, SCAQMD

4

RESPONSES TO COMMENT LETTER #6
(Curtis L. Coleman on behalf of
the NOx RECLAIM Industry Coalition – October 6, 2015)

6-1 This comment introduces the parties represented by the letter. No response is necessary.

6-2 The project consists of the proposed amendments to Regulation XX, which includes a proposal to reduce NOx RTC holdings by 14 tpd by 2023. Based on the analysis, SCAQMD staff's opinion is that the 14 ton per day reduction is necessary to implement the actual BARCT reduction because of the substantial number of unused RTCs in the market. As explained in Chapter 4, Subchapter 4.0 of the Draft PEA, the installation and operation of new or modified existing NOx emission control equipment at 20 facilities was identified as the only portion of the entire proposal that is expected to result in physical effects that may affect the environment, since they were the only ones identified that would install pollution control equipment as a result of the proposed shave. According to CEQA Guidelines §15126.2, "An EIR shall identify and focus on the significant environmental effects of the proposed project. In assessing the impact of a proposed project on the environment, the lead agency should normally limit its examination to changes in the existing physical conditions in the affected area as they exist at the time the notice of preparation is published..." For this reason, the analysis in the PEA focuses on the physical effects that may occur as a result of constructing new or modifying existing NOx control equipment and operating the equipment once constructed.

Because of the substantial excess of RTCs in the market, SCAQMD staff disagrees with the assertion about "the potential destruction of the NOx RTC market." SCAQMD staff's proposal includes allowing for growth between now and 2023, allowing a compliance margin of 10 percent, and providing an additional amount of RTCs to account for BARCT uncertainties. Therefore, no significant adverse impacts on construction of new facilities and expansion of existing facilities is expected. In any event, SCAQMD staff is proposing to increase the RTC price trigger to reevaluate the RECLAIM program from $15,000 per ton to $22,500 per ton. SCAQMD staff expects that there will still be enough RTCs to support a functioning market. After the shave, there will still be nearly as large a margin as there was before the shave, in terms of percentage of actual emissions. Moreover, while economic or social information may be included in an EIR, it is not a requirement. The costs of removing the unused RTCs (5.23 tpd, not the 6 tpd asserted by the commenter) is not an environmental impact. Further, economic or social effects of a project shall not be treated as significant effects on the environment. Instead, the focus of the analysis shall be on the physical changes. [CEQA Guidelines § 15131 (a)]. For this reason, the analysis in the PEA does not address the costs associated with achieving the proposed NOx emission reductions. Instead, as explained in Response 2-19, a socioeconomic analysis has been conducted and the analysis and findings are presented in a separate document, the Socioeconomic Report for Proposed Amendments to Regulation XX - Regional Clean Air Incentive Market (RECLAIM), initially published on September 9, 2015 and revised on October 6, 2015 and November 4, 2015[16].

The socioeconomic analysis addresses the socioeconomic impacts relating to the availability of RTCs to provide structural buyers (e.g., facilities where no controls were identified in the 2015 BARCT analysis) a source of credits and to provide for NSR holding requirements under SCAQMD Regulation XIII - New Source Review. In particular, the socioeconomic analysis describes the potential incremental costs of RTCs needing to be purchased by structural buyers (although that cost will be a profit to those who have RTCs to sell) as well as quantifying the potential "loss in value" due to removal of excess unused RTCs. In terms of compliance costs, the socioeconomic analysis addresses the potential cost impacts that may result from the construction and operation of new or modified NOx emissions control equipment that may be installed as a result of the proposed project.

6-3 SCAQMD staff has consulted with the power-producing sector, which uniformly agrees that any potential shortage of RTCs may only occur during rare events where electrical demand far exceeds normal operations. The potential increase in energy demand has been addressed in the staff proposal, which provides several safeguards that would provide electricity generating facilities (EGFs) with an adequate amount of credits. The safeguards include access to non-tradable/non-usable RTCs with a faster 3-month trigger. The 12-month trigger remains, but the threshold dollars per ton level is now $22,500. In the event of a State of Emergency declared by the Governor, EGFs would have access to non-tradable/non-usable credits. If these credits are exhausted, EGFs would also have access to the credits in the Regional NSR Holding Account. Furthermore, EGFs now have the option to exit the RECLAIM program if they meet certain requirements. With this option, an EGF would no longer be concerned with the possibility of an RTC shortage, even though staff feels that there will not be such a shortage if BARCT controls are implemented for those applicable facilities that were analyzed. Resolution language will be prepared that directs staff to monitor the power-producing sector for trends in power consumption as electricity demand potentially increases. With these safeguards in place, no adverse impact on electrical reliability is anticipated.

In addition, Chapter 4, Subchapter 4.3 of the PEA, contains an energy impact analysis which identifies the net effect on energy resources relating to the construction and operation of new or modified NOx air pollution control equipment that may occur as a

SCAQMD, Draft Socioeconomic Report for Proposed Amendments to Regulation XX - Regional Clean Air Incentive Market (RECLAIM), September 9, 2015. http://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/regxx/reclaim_sociodraft_090915.pdf?sfvrsn=4

result of implementing the proposed project. The energy analysis does not contain an analysis of the effects of structural buyers or other RECLAIM participants that have been demonstrated to not have a cost-effective option for controlling NOx emissions further because neither of these groups have been demonstrated to have an increased demand for energy as a result of implementing the proposed project. If this comment is intended to refer to electricity generating facilities, the above-cited provisions of the amendments are designed to address the needs of this sector.

The electrification of "large segments of the Southern California industrial, service, and residential sectors" as part of ongoing air quality planning activities related to the 2016 AQMP is not part of the proposed project. As noted above, SCAQMD staff has proposed provisions in the amendments to address the electric utility sector's foreseeable needs. At this point, it would be speculative to predict increased needs as a result of increased electrification. Nevertheless, staff will include a Governing Board resolution to address this long-term issue if it ever arises.

The 2016 AQMP is currently under development and on a separate schedule from the proposed project. As the 2016 AQMP development process moves forward, a separate CEQA analysis of the effects of what is proposed for the 2016 AQMP will be conducted and presented as part of a Program EIR which will provide multiple opportunities for review and comment by the public, stakeholders, and other interested parties.

See Response 6-2 regarding analysis of potential impacts on structural buyers and other RECLAIM participants.

6-4 As part of the rule development process for amending Regulation XX for SOx RECLAIM in October 2010, SCAQMD staff originally intended to prepare an Environmental Assessment (EA) for the project. However, during the public review and comment period of the NOP/IS for the project, the SCAQMD received a comment suggesting that a program level CEQA analysis be conducted instead. Going forward at that time, SCAQMD staff agreed with the suggestion, and subsequently prepared a Program Environmental Assessment (PEA). The decision to prepare a Draft PEA was based on the SOx RECLAIM project: 1) being connected to the issuance of rules, regulations, plans, or other general criteria to govern the conduct of a continuing program [CEQA Guidelines §15168 (a)(3)]; and, 2) containing a series of actions that can be characterized as one large project and the series of actions are related as individual activities that would be carried out under the same authorizing regulatory authority and having similar environmental effects which can be mitigated in similar ways [CEQA Guidelines §15168 (a)(4)[17]]. The analysis in the Final PEA for SOx RECLAIM, evaluated the physical effects of installing and operating new or modified air pollution control equipment to reduce SOx emissions for the various affected facilities.

[17] SCAQMD, Final Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), October 2010; SCAQMD No. 06182009BAR, State Clearinghouse No: 2009061088, page 1-3. http://www.aqmd.gov/docs/default-source/ceqa/documents/aqmd-projects/2010/final-program-environmental-assessment-for-proposed-amended-regulation-xx.pdf?sfvrsn=4.

The SOx RECLAIM PEA allowed the consideration of broad policy alternatives and program-wide mitigation measures at a time when an agency has greater flexibility to deal with basic problems of cumulative impacts. [CEQA Guidelines §15168 (b)(4)]. Further, the SOx RECLAIM PEA played an important role in establishing a structure within which CEQA review of future related actions could effectively be conducted.

Similarly, for the current proposed amendments to Regulation XX for NOx RECLAIM, SCAQMD staff prepared a Draft PEA which also evaluated the physical effects of installing and operating new or modified air pollution control equipment, but to reduce NOx instead of SOx emissions for the various affected facilities. Seeing no fundamental difference between the SOx and NOx RECLAIM projects relative to the possibility for future project-level analysis, a program level analysis was determined to be appropriate and was conducted for the proposed NOx RECLAIM project. The fact that the PEA evaluates the "BARCT related construction activities" that are projected to occur does not mean that a project-level, instead of a programmatic analysis, was conducted. Moreover, in accordance with CEQA Guidelines §15168 (c)(5), a program analysis should deal with program impacts as specifically and comprehensively as possible and the PEA did so.

The PEA estimates, using engineering assumptions and the best data available, what the potential impacts may be. However, in recognition that the potential future actions conducted by individual facility operators may actually contemplate activities that could create resulting environmental impacts that may be different or new from what was analyzed in the PEA, individual facility operators will be afforded the opportunity to rely upon the PEA if it covers impacts of their project, as part of conducting a future CEQA analysis of any actual projects proposed subsequent to the proposed adoption of the amendments to the NOx RECLAIM program.

This comment also states that the PEA should include a project-level review of impacts, while at the same time stating that the PEA only evaluated project-level impacts. SCAQMD staff assumes the commenter meant to say that the PEA should have included a program-level review of impacts. The PEA did so by including a comprehensive analysis of expected environmental impacts of the proposed amendments, as well as the impacts of the alternatives considered in the PEA, specifically including the impacts of the Industry Approach (Alternative 3). SCAQMD staff does not expect physical impacts to occur beyond those identified in the PEA. The comment does not provide substantial evidence of additional physical impacts on the environment. See also Response 2-16 for an explanation as to why the PEA conducts a program level analysis and not a project level analysis.

6-5 The comment states that the proposed project does not comply with Health and Safety Code §39616, which requires a finding that the RECLAIM program result in equivalent or greater emission reductions at equivalent or less cost compared with command-and-control, because the analysis used a $50,000 per ton cutoff for RECLAIM BARCT while the SCAQMD uses a $22,500 per ton cost-effectiveness for command-and-control BARCT.

As of the third quarter 2015, the SCAQMD's BACT cost-effectiveness is $27,107 per ton for minor sources, whereas most of the RECLAIM sources that will be expected to install BARCT controls, including all of the refineries, are major sources. Health and Safety Code §39616 calls for a comparison with what would have been achieved by the RECLAIM sources themselves under command-and-control, not what is achieved by some other sources. Moreover, the $50,000 figure does NOT mean that the cost-effectiveness of the proposed amendments is $50,000 per ton. Instead, the $50,000 figure was used to eliminate candidate BARCT technologies from consideration. None of the technologies actually identified as BARCT exceeds the mid to upper $30,000s per ton, and then only for the refineries. In fact, the average cost-effectiveness for the proposed amendments (total costs divided by total tons) is only $13,615 per ton. Thus, the proposed project satisfies the findings set forth in Health and Safety Code §39616, although it is not legally required to do so. Finally, the SCAQMD Governing Board has adopted rules for smaller sources which have cost-effectiveness values ranging up to the upper $20,000s and lower $30,000s per ton, such as Rule 1146.1, Rule 1147, and Rule 1110.2. SCAQMD staff has already explained in the socioeconomic analysis why the costs to buyers of purchasing RTCs are cancelled out on a programmatic basis by the gains to the sellers of RTCs, and why the "value" of shaved, unneeded RTCs cannot be compared to command-and-control because there are no RTCs, and thus no such "value" to begin with, under command-and-control.

According to CEQA Guidelines §15125, an EIR must include a description of the physical environmental conditions in the vicinity of the project, as they exist at the time the Notice of Preparation (NOP) is published and this environmental setting normally constitutes the baseline physical conditions by which a lead agency determines whether an impact is significant. At the time the NOP was published, SCAQMD staff identified 275 facilities that are currently in the NOx RECLAIM universe of sources and these 275 facilities are considered to be part of the existing environmental setting or baseline. For this reason, the reduction in the number of facilities that participate in the NOx RECLAIM program over the years from 392 to 275 and any corresponding loss of jobs or shift from higher to lower skilled jobs is not a part of the proposed project that would require an analysis in this PEA.

Macroeconomic factors could have played a far more pivotal role in the changes to the composition of the RECLAIM universe. For example, RECLAIM was adopted in 1993 shortly after the 1990-91 recession which severely affected Southern California's aerospace industry triggering protracted ripple effects throughout the entire regional economy. This event, combined with the national trend of a declining manufacturing sector, likely has contributed to business shutdowns and relocations. The 2001 and the more recent 2007-2009 economic recessions also impacted business operations to various degrees. Other factors such as business consolidations and mergers could also have affected the RECLAIM universe.

Moreover, there is no evidence that RECLAIM was in any way the cause of a significant number of facilities shutting down. Each year, the SCAQMD staff prepares a program audit and report to the SCAQMD Governing Board pursuant to Rule 2015 (b) which includes the facilities that have shut down and the reasons given for their shutdown. SCAQMD staff has reviewed all annual program audits and concluded that although about 178 facilities have shut down (while about 50 new facilities have entered the market), only three facilities identified RECLAIM as a reason for their shutdown and only 10 identified environmental regulations other than RECLAIM as a reason for their shutdown. Since the majority of facilities that shutdown was not due to RECLAIM, any resulting environmental impacts form the shutdowns are also not caused by RECLAIM. Based on this past history, and the fact that the market will continue to have a comparable level of excess unused RTCs even after the shave is implemented as it has had historically, no significant number of facility shutdowns and thus no resulting significant environmental impacts can be predicted. See also Response 2-21.

6-6 Two opportunities (e.g., during the 57-day public review and comment period of the NOP/IS and at the CEQA scoping meeting) were provided to commenters to suggest ways of crafting the various alternatives to be analyzed in the PEA. The SCAQMD staff received several suggestions for alternatives, with a consensus to analyze an "industry" alternative which was included in the PEA as Alternative 3. In addition, four other alternatives, one of which was the no project alternative (e.g., Alternative 4), were analyzed in the PEA. When considering and discussing alternatives to the proposed project, an EIR need not consider every conceivable alternative to a project but instead consider a reasonable range of potentially feasible alternatives that will foster informed decision making and public participation. [CEQA Guidelines 15126.6 (a)]. For this reason, the PEA analyzes five alternatives to the project. Aside from Alternative 4, the no project alternative, the remaining alternatives each contains varying approaches to the NOx RTC shave with varying degrees of potential NOx emission reductions applicable to various sources. As such, SCAQMD staff believes that the PEA contains a reasonable range of potentially feasible alternatives, thus, no additional alternatives are necessary or required.

The suggestion by the commenter to review past shaves and to ratio the amount between the amount shave and the actual emission reductions has been conducted as part of rule development. The data review conducted during rule development as part of the BARCT equivalency demonstration concluded that past NOx RTC shaves were ineffective at reducing emissions. Because this data review comprised an important impetus to demonstrate the need for the proposed project (e.g., the need for the NOx RTC shave), the suggested ratio analysis does not qualify as an alternative to the project. With respect to Norton Engineering, it is noteworthy that Norton Engineering agreed with SCAQMD staff regarding the appropriate BARCT levels for all categories except boilers/heaters, which amounted to about 0.35 tpd difference in the total shave. SCAQMD staff increased this BARCT uncertainty factor to over 0.8 tpd to account for any other potential uncertainty.

This comment states that the PEA fails to analyze whether alternatives to the proposed 14 ton per day shave could meet the objective of obtaining equivalent emissions reductions to the BARCT reductions identified by SCAQMD staff. A CEQA document is only required to consider a range of reasonable alternatives to the project which would feasibly obtain most of the basic objectives of the project but would avoid or lessen any of the significant effects of the project. [CEQA Guidelines §15126.6 (a)]. The PEA meets this test. The comment suggests that the PEA should look at other ways of achieving emission reductions equivalent to the BARCT reductions identified by SCAQMD staff. Assuming that this comment means alternative ways of achieving actual emission reductions to result in remaining emissions equivalent to those in the staff proposal, this would still require reducing actual emissions by the same amount as the staff proposal. Since actual emissions are reduced by installing and operating additional control equipment, the environmental effects of such an alternative would be the same.as those analyzed in the PEA.

The commenter suggests that SCAQMD staff could have looked at past shaves to determine the ratio between the amount shaved and the amount of actual emission reductions that occurred from the RECLAIM universe (presumably to derive an alternative shave amount). The problem with this approach is that there is no fixed ratio between actual emissions reductions and RTCs shaved. Comment Letter #1 suggests that between 2005 and 2011, a comparison of 0.83 tpd emission reductions to 1 tpd RTC reductions would result in a ratio of 0.83, but that included two years (2005 - 2006) when there were actual emission reductions, but no RTC shave. If the analysis looked at the actual shave years (2007 through 2011), the ratio would be a comparison between 4.09 tpd reductions to 7.66 tpd RTCs reduced, or 0.53 instead of 0.83. Moreover, if there were a larger amount of available unneeded RTCs, such as the 73 percent projected to occur with the Industry Approach (or even more if the Industry Approach used the 6.6 tpd target) it is likely that facilities would not significantly reduce actual emissions but would simply surrender unneeded RTCs. Thus, no fixed ratio can be determined to allow the suggested alternative approach.

6-7 As explained in more detail in Response 6-2, the PEA analyzes both the construction and operational impacts of the project elements that may result in physical changes to the environment. The commenter has not identified any new aspects of the proposed project that would cause potential significant impacts that should be included and analyzed in the PEA. Thus, SCAQMD staff disagrees that the PEA needs to be "redone."

With regard to the analyzing additional alternatives in the PEA, see Response 6-6.

Re: Program Environmental Assessment
Proposed Amended Regulation XX (RECLAIM)

Dear Ms. Radlein,

The following comments are provided by the Natural Resources Defense Council, Sierra Club, Earthjustice, and Communities for a Better Environment regarding the South Coast Air Quality Management District Program Environmental Assessment (PEA) for Proposed Regulation XX (RECLAIM). 7-1

The RECLAIM project has not proven its value as a cheaper or more efficient way to reduce NOx emissions in the South Coast Air Basin compared to a command and control model. If it is to be retained, it needs to be substantially strengthened and accelerated. 7-2

With respect to the PEA, there are three major flaws, all of which flow from the PEA's overly-narrow reading of its own project objectives: failure to include ending the RECLAIM program as an alternative, failure to choose the environmentally superior alternative among the alternatives presented, and failure to assess RECLAIM in connection with the NOx reduction needs to be covered in the 2016 AQMP and beyond. We will discuss the project objectives and the ensuing flaws in turn. 7-3

Project Objectives

The PEA lists these project objectives: 7-4

1) Comply with the requirements in Health and Safety Code (HSC) §§40440 and 39616 by conducting a BARCT assessment of the NOx RECLAIM program and reducing the amount of available NOx RTCs to reflect emission reductions equivalent to implementing available BARCT;

2) Modify the RTC "shaving" methodology to implement the emission reductions per the BARCT assessment;

NATURAL RESOURCES DEFENSE COUNCIL
1314 2ND STREET | SANTA MONICA, CA | 90401 | T 310.434.2300 | F 310.434.2399 | NRDC.ORG

3) Ensure that RECLAIM facilities, in aggregate, achieve the same emission reductions that would have occurred under a command-and-control approach;

4) Achieve the proposed NOx emission reduction commitments in the 2012 AQMP Control Measure #CMB-01: Further NOx Reductions from RECLAIM; and, 7-4 Con't

5) Achieve NOx emission reductions to assist in attaining the NAAQS. PEA 2-4.

However, the discussion in the PEA, particularly with respect to alternatives, seems to ignore objectives 3 and 5 by tinkering with the existing RECLAIM rules rather than asking whether the rules serve the purposes of RECLAIM and its governing statute. If the scope of the PEA truly matched up with the project objectives, the errors that we discuss below would not have occurred.

Ending RECLAIM

The goal of RECLAIM is to reduce NOx emissions as efficiently and quickly as possible; this is recognized in project objective no. 3. Although emissions have dropped, it is not at all clear that this has been because of or in spite of RECLAIM. The over-allocation of RECLAIM credits has depressed their price and diminished the economic drivers to reduce actual emissions. When staff completed its most recent BARCT analysis, it became clear that there are too many cheap credits in the market and that a deep "shave" is required. The PEA should take this finding to its logical conclusion and examine whether RECLAIM can, in fact, provide the same emissions reductions as would be achieved under a command and control system. 7-5

Failure to Choose the Environmentally Superior Alternative

The PEA states that Alternative 2, most stringent shave, is the environmentally superior alternative in that it will lead to the greatest NOx reductions. PEA at 5-43. But the PEA rejects Alternative 2 on the basis that it does not "satisfy Objective No. 2 "to modify the RTC "shaving" methodology to implement the emission reductions per the BARCT assessment."" PEA at 5-44. In addition, the PEA states: "the proposed project is considered to provide the best balance between emission reductions and the adverse environmental impacts due to construction and operation activities while meeting the objectives of the project." *Id.* 7-6

This only makes sense if a very strained view of the objectives of RECLAIM is adopted and objectives and project objectives 3 and 5 are ignored. The construction and operational impacts from maximizing the "shave" are tiny in comparison to the benefits to be obtained. It seems more likely that the rejection of Alternative 2 is the result of a political calculation of how strongly the regulated community will complain.

NATURAL RESOURCES DEFENSE COUNCIL
1314 2ND STREET | SANTA MONICA, CA | 90401 | T 310.434.2300 | F 310.434.2399 | NRDC.ORG

NOx Reductions and the Ozone NAAQS

South Coast has not met the 1979 1-hour ozone standard, the 1997 8-hour ozone standard, nor the 2008 8-hour ozone standard, and will continue to be hard pressed as it seeks to meet the just-announced 70 ppb standard. The PEA needs to evaluate RECLAIM against the statutory background of the Clean Air Act and the NAAQS ozone limits, as recognized in project objective no. 5, but has not done so in a meaningful way. 7-7

Thank you for your consideration of this letter.

RESPONSES TO COMMENT LETTER #7
(Natural Resources Defense Council et al. – October 6, 2015)

7-1 This comment introduces the parties represented by the letter. No response is necessary.

7-2 This comment asserts that RECLAIM has not proven its value as a cheaper or more efficient way to reduce NOx than command-and-control and needs to be substantially strengthened. Staff analysis indicates that RECLAIM has saved facilities substantial sums of money; however, the 2005 shave has not resulted in facilities actually achieving 2005 BARCT levels of emissions. For that reason, SCAQMD staff proposes to substantially strengthen the program by shaving enough RTCs to result in actually achieving 2015 BARCT levels of emissions.

7-3 With regard to the comment about not analyzing an end to the RECLAIM program as a project alternative in the PEA, two opportunities (e.g., during the 57-day public review and comment period of the NOP/IS and at the CEQA scoping meeting) were provided to commenters to suggest ways of crafting the various alternatives to be analyzed in the PEA. The SCAQMD received several suggestions for alternatives to be analyzed, but none of the suggestions requested an alternative that contemplates ending the entire RECLAIM program. For this reason, an alternative contemplating the end of the RECLAIM program was not included in the Draft PEA.

Further, it is important to keep in mind that ending the RECLAIM program would require rescission of all of the rules that comprise Regulation XX, at least to the extent that they would apply to NOx. Proposing to rescind Regulation XX as an alternative would go way beyond the scope of the current project, which is limited to the NOx RECLAIM program and its affected sources. Further, doing so would be an entirely different project that would require its own rule language, stakeholder meetings, public workshops, CEQA analysis, socioeconomic analysis, et cetera. Finally, the concept of ending the RECLAIM program would not qualify as a reasonable alternative to the project because it would not be able to feasibly attain most of the basic objectives of the project while avoiding or substantially lessening any of the significant effects of the project as is required by CEQA Guidelines §15126.6 because one of the basic objectives of the project was to modify RECLAIM by reducing available NOx RTCs to reflect emission reductions equivalent to implementing BARCT. However, to the extent an alternative of ending the RECLAIM program was analyzed, it would have to require implementation of BARCT for the RECLAIM sources, as required by Health and Safety Code §§40440 and 40919. As a result, the environmental impacts of such an alternative would likely be similar to those of the proposed project since they would require similar emission reductions, and thus, would not eliminate or reduce any of the significant adverse environmental impacts of the project.

With regard to the comment about failing to choose the environmentally superior alternative in the PEA, see Response 7-6. With regard to the comment about the project objectives, see Response 7-4.

Finally, with regard to the comment about failing to assess RECLAIM in connection with the NOx reduction needs to be covered in the 2016 AQMP, as explained in Response 6-3, the 2016 AQMP is currently under development and on a completely separate schedule from the proposed project. Staff is fully aware of the needs to get additional NOx reductions from all sources in order to meet the future air quality standards for both ozone and particulates. The proposed RECLAIM amendments attempt to reduce NOx commensurate with BARCT levels for facilities in the NOx RECLAIM program, which will contribute towards air quality goals. As the 2016 AQMP development process moves forward, a separate CEQA analysis of the effects of what is proposed for the 2016 AQMP will be conducted and presented as part of a Program EIR which will provide multiple opportunities for review and comment by the public, stakeholders, and other interested parties.

7-4 Because this comment is vague and omits the basis for the unsubstantiated opinion that the alternatives analysis ignores project objectives #3 and #5, the scope of the project does not match with project objectives, and these factors caused errors in the PEA, SCAQMD staff is unable to provide a detailed response. All the alternatives except Alternative 3 (the Industry Approach) and the Alternative 4 (the No Project alternative) result in a shave that is equivalent to BARCT-level reductions in the aggregate. Therefore, they implement project objective #3, which is to ensure aggregate emission reductions equivalent to what would have occurred under command-and-control. The comment does not identify any additional reductions, beyond BARCT, that could be added to the proposed reductions to assist in attaining the NAAQS, which is project objective #5 per the comment.

7-5 The emission reductions that have occurred since the last BARCT adjustment for RECLAIM facilities in 2005, in aggregate, can be attributed to several factors. From 2007 to 2012, NOx emissions were reduced due to impacts from the economic recession which caused reduced production and facility shutdowns as well as from the installation of some control equipment. The purpose of these currently proposed rule amendments are to further reduce RECLAIM emissions based on BARCT.

As explained in Response 6-6, the data review conducted during rule development as part of the BARCT equivalency demonstration concluded that past NOx RTC shaves were ineffective at reducing emissions to a level that would have occurred under a command-and-control approach. As such, this data review comprised one factor of demonstrating the need for the proposed project (e.g., the need for the NOx RTC shave). For that reason, SCAQMD staff believes that the proposed shave must reduce a significant amount of excess unused RTCs, and the staff proposal does so. The PEA analyzes the environmental effects of implementing the proposed project, and in particular, the environmental effects of providing the same emission reductions as would be achieved under a command-and-control system. The purpose of CEQA is to analyze the adverse environmental effects of a proposed project, identify significant adverse impacts, and adopt feasible mitigation or alternatives to mitigate or avoid those impacts, (Public Resources Code §21002.1) and the PEA has done so. The PEA analyzed a reasonable range of alternatives. Therefore, whether another project (command-and-control rules) would be preferable is not within the required scope of this CEQA analysis. See also Response 7-3.

7-6 The analysis of Alternative 2 concluded that because it may achieve the greatest emission reductions, Alternative 2 qualified as the environmentally superior alternative. However, the goal of project objective #3 is to ensure that the affected RECLAIM facilities would be subject to the same reductions that would otherwise occur under command-and-control and the goal of project objective #5 is to achieve NOx emission reductions to assist in attaining the NAAQS. Contrary to the comment, all of the project objectives were carefully considered in the overall evaluation of Alternative 2, as well as the other alternatives.

Specifically, for facilities with types of equipment and source categories for which no new BARCT (not cost-effective and/or infeasible) was identified and cannot reduce emissions further would not be subject to the RTC shave under the proposed project, but would be shaved under Alternative 2. The proposed project satisfies all of the project objectives but Alternative 2 does not satisfy project objective #3 because staff estimated that it would force many of the 219 facilities to buy more RTCs in order to achieve compliance (see Draft Final Socioeconomic Report, Section 9) while under a command-and-control regime and under the proposed project, these same facilities would not have to make any additional changes to achieve more NOx emission reductions. Because of this disparity that would apply to a disproportionately large number of RECLAIM facilities, the alternatives analysis concluded that the proposed project is preferred over Alternative 2 as well as the other alternatives.

7-7 The comment states that the PEA has not evaluated RECLAIM against the statutory background of the Clean Air Act and the NAAQS ozone limits, but project objective #5 was carefully considered in drafting the SCAQMD staff's proposal. The commenter has not identified any additional emission reductions beyond BARCT-level reductions that are feasible for the RECLAIM universe.

The purpose of project objective #5 is to ensure that the proposed project achieves NOx reductions to <u>assist</u> with achieving attainment the National Ambient Air Quality Standards (NAAQS). However, project objective #5 is not to be achieved in conflict with project objective #3, which is to ensure BARCT emission reductions are commensurate with command-and-control. SCAQMD staff has conducted a BARCT analysis and believes that a 14 ton per day reduction will result in the necessary, actual BARCT reductions required by the analysis. If the proposed project is adopted by the SCAQMD Governing Board, the NOx emission reductions will be accounted for in the overall attainment demonstration as part of the ongoing development of the 2016 AQMP, which is a comprehensive and integrated Plan primarily focused on addressing the ozone and PM2.5 standards. As with every AQMP, a comprehensive analysis of emissions, meteorology, atmospheric chemistry, regional growth projections, and the impact of existing control measures and the corresponding rules or rule amendments, is updated with the latest data and methods. The result is a targeted level of emissions in the Basin that would allow attainment of the NAAQS. The 2016 AQMP will incorporate the latest scientific and technical information and planning assumptions, including the latest applicable growth assumptions, Regional Transportation Plan/Sustainable Communities Strategy, and updated emission inventory methodologies for various source categories.

Comment Letter #8

COMMUNITIES FOR A BETTER ENVIRONMENT

October 6, 2015
Barbara Radlein

Re: Comments on SCAQMD Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM)

Dear Ms. Radlein,

Thanks for your work on this important issue. We submit the following comments regarding the Draft Program Environmental Assessment (PEA) for the Proposed Amended RECLAIM regulations,[1] in addition to the comments submitted today by Natural Resource Defense Council and Sierra Club. Additional reductions beyond those proposed in the PEA are readily achievable, cost-effective, and necessary, given the severe impacts on health of these air pollution sources in the South Coast. Incorporating these additional reductions into Regulation XX would "reduce the allowable NOx emission limits based on current Best Available Retrofit Control Technology (BARCT) to achieve additional NOx emission reductions," and must be included in any rule purporting to reflect BARCT for refinery boilers and heaters. The PEA must be recirculated, and must include a preferred alternative that, at a minimum, reflects these reductions. 8-1

Additional reductions are readily achievable from Refinery Boilers and Heaters

The proposed Draft PEA NOx reductions for Refinery Boilers and Heaters in the South Coast is 0.96 tons per day (tpd), using the addition of SCR (Selective Catalytic Reduction).[2] There is substantial evidence that much higher reductions could be achieved. In 2010, CBE evaluated data provided by the California Air Resources Board (CARB) on Refinery Boilers and Heaters.[3] CARB listed many additional control options for improving the efficiency of Boilers and Heaters 8-2

[1]Draft Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), August 2015, SCAQMD No. 12052014BAR, State Clearinghouse No: 2014121018, Author Barbara Radlein, **hereafter the DRAFT PEA**, available at: https://mail.google.com/mail/u/0/#advanced-search/subset=inbox&has=RECLAIM&within=1d&sizeoperator=s_sl&sizeunit=s_smb/14ffcf615d913d4d?projector=1
[2]*Id.* at p. 1-26.
[3] The CARB Boiler and Heater data was downloaded from http://www.arb.ca.gov/regact/2010/capandtrade10/capandtrade10.htm at the bottom of the page, "Supplemental Material," Compliance Pathways Analysis – Boilers, and Compliance Pathways Analysis—Heaters.

statewide. CARB focused on greenhouse gas emissions reductions, but because these control options save fuel, they also substantially reduce emissions of co-pollutants, including NOx.

The measures identified are an indication that there is a much higher potential to reduce NOx from Refinery Boilers and Heaters, beyond SCR controls. The CARB data identified many measures to improve the efficiency of the fleet of refinery boilers and heaters, ranging from simply stopping leaks and improving insulation, to completely replacing old boilers. These measures were found not only to be cost-effective, but to actually *save* money for oil refineries. The RECLAIM PEA, by contrast, did not provide such a wholesale evaluation of clean-up measures for Boilers and Heaters.

CBE took the CARB data (which provided fuel use, GHG emissions, and cost of various measures), and calculated tables showing NOx co-pollutant reductions that would be associated with these GHG reductions and fuel use reductions.[4] CBE reported these in the December 14, 2010 comments to CARB (pages 27-30, in the NOx tables), which are attached. We are also attaching the original CARB spreadsheets, which have CBE's calculations added. 8-2 Con't

These resulted in 15.08 tpd in NOx reductions from Refinery Boilers (16.44 for all Boilers sources) and 7.1 tpd for Refinery Heaters (7.35 tpd for all sources), for a total of 22.18 tpd statewide for refineries (and 23.79 for all sources). Oil refineries within the South Coast make up about 54% of the state's refining capacity,[5] and 54% of 22 tpd from the statewide oil refinery Boiler and Heater NOx reduction opportunities would result in about 12 tpd in NOx reductions, far above the .96 tons per day proposed. These do not include the other sources listed by CARB (non-refinery Industrial Boilers and Heaters). This data provides substantial evidence that much higher reductions could be achieved from this one source.

The PEA should therefore be revised to provide a more refined and updated analysis specific to the South Coast data. SCAQMD should re-circulate this revised PEA, providing a detailed alternative evaluation of NOx reductions achievable through the measures identified by CARB, including:

1. Replacing low and medium efficiency Boilers
2. Optimizing Boilers by reducing excess air
3. Retrofitting Feedwater Economizers
4. Retrofitting with Air Preheaters
5. Blowdown Reduction With Controls and with Feedwater Cleanup 8-3
6. Blowdown Heat Recovery
7. Optimizing Steam Quality
8. Optimizing Condensate Recovery
9. Minimizing Vented Steam
10. Insulation Maintenance
11. Steam Trap Maintenance
12. Steam Leak Maintenance

[4] For this calculation, CBE applied standard AP-42 Boiler and Heater NOx emissions factors.
[5] CA.gov Energy Almanac, listing capacity of each California refineries, November 2014, http://energyalmanac.ca.gov/petroleum/refineries.html http://energyalmanac.ca.gov/petroleum/refineries.html

2

13. Replacing Low and Medium Efficiency Heaters
14. Optimizing Heaters
15. Recovering Flue Gas Heat
16. Replacing Refractory Brick
17. Insulation Maintenance

8-3 Con't

These reduction measures in total would also achieve about 4 million tonnes CO_2 equivalent/year, and save about $46 million dollars, as determined by the CARB data. CBE has noted that despite the savings that oil refineries could achieve from cleaning up old boilers and heaters, they frequently put off doing so until they can use the reductions as offsets for other refinery expansions planned, leaving boilers and heaters to go on unnecessarily polluting for decades. We urge the AQMD to provide the public with a detailed analysis of the additional reductions that could be achieved through *requiring* such measures.

Sincerely,

Shana Lazerow, Staff Attorney

Julia May, CBE Senior Scientist

Re: CBE Comments on Draft Cap and Trade Regulation: Draft Cap & Trade Regulation Misses California GHG and Pollution Reduction Opportunities, Job Opportunities, and Contains Egregious Errors

Dear Chairman Nichols and Mr. Goldstene,

In our October and December 2008 comments on ARB's Scoping Plan, Communities for a Better Environment raised numerous substantial concerns and described the significant pitfalls of cap and trade schemes. We specifically described why cap and trade programs do not work to significantly reduce greenhouse gas emissions and how they harm low-income communities and communities of color. ARB did not respond to these concerns. Indeed the proposed regulation would animate some of CBE's greatest fears.

Overwhelmingly, cap and trade programs suffer from credit overallocation, monitoring and equivalency problems, loss of innovation, unverifiability of offsets, unverifiable accounting practices, and lack of additionality. Cap and trade schemes also exacerbate environmental injustice by increasing hotspots, creating price volatility, and leading to oppression through high risk and fraudulent offset projects that too often also result in displacement. The proposed regulation does nothing to avoid the known pitfalls inherent to cap and trade.[1] Instead, the regulations bend over backwards to accommodate polluters' desire for zero cost compliance, ease and flexibility at the expense of true significant reductions, health protection (avoiding increases in other pollution), and environmental justice. It also used a flawed calculation of emissions as the foundation for

[1] For more information on these issues, please see further exploration and elaboration in comments written by the Center on Race, Poverty & the Environment and cosigned by CBE.

1440 Broadway #701 · Oakland, CA 94612 · PH: (510) 302-0430 // Fax (510) 302-0437

all of its estimates. Throughout its pages, the proposed regulation violates the letter and spirit of AB32.

AB32 specifically requires that ARB "ensure that activities undertaken to comply with the regulations do not disproportionately impact low-income communities."[2] The regulations may not "interfere with efforts to achieve and maintain federal and state ambient air quality standards to reduce toxic air contaminants,"[3] must minimize leakage,[4] "consider overall societal benefits, including reductions in other air pollutants, diversification of energy sources, and other benefits to the economy, the environment and public health",[5] and "consider the significance of the contribution of each source or category of sources to statewide emissions of greenhouse gases[6]. But if ARB adopts a cap and trade program, AB32 additionally requires ARB to affirmatively "design" the program "to prevent any increase in emissions of toxic air contaminants or criteria pollutants,"[7] consider direct, indirect and cumulative emission impacts from the program, and direct private and public funds to disadvantaged communities.[8] The proposed regulations overwhelmingly ignore these requirements, and ARB's failure to analyze reasonable alternatives makes adoption of the draft regulations even more irrational.

The comments below find:

- **Industrial GHG emission sources are massive** (largely oil industry emissions), but still underestimated in CARB documents
- **Despite the volume and toxicity of industrial co-pollutants (especially oil industry), there are zero tonnes of direct controls required for this source** – all are allowed to be completed through buying pollution credits from outside any particular industry, and carried out outside California or the U.S.
- **Furthermore, industrial sources are not required even to buy credits under the proposal** – they are 100% free.
- **Large California NOx, CO, and other co-pollutant reductions can be achieved if an alternative is adopted requiring direct control measures**[9]

[7] H&S Code § 38570(b)(2).
[8] H&S Code § 38565.
[9] Termed by CARB as measures "complementary" to Cap and Trade, and agreed by CARB and other agencies to be key for overall success of the program.

using methods known by CARB (e.g. for boilers and heaters). These co-pollutants otherwise cause large cumulative impacts in communities of color. Similarly CARB should evaluate other co-pollutants including pm2.5 and toxics which feasible direct controls would achieve. AB32 requires addressing the co-pollutants issues, but the proposed Cap and Trade regulation and Scoping Plan do not.

- **Such project alternatives just described would create California jobs, California health improvements**, and the best model for regions outside California to replicate. They were not considered. Cost effectiveness calculation of such controls should include the benefits of reducing GHGs, reducing smog and toxics, and reducing health impacts.
- **The current project not only misses these opportunities, but allows harms to California,** for instance, by allowing increasing industrial pollution in heavily industrialized California communities, and by causing evictions of indigenous people through fake forest offset projects.
- **Outright exemption from regulation is provided for large portions of oil refinery sources,** which must also be removed (see below).
- Available measures for industrial sources that should be added, include:
    - Implementing **industrial boiler and heater replacement** listed by CARB in the published spreadsheets
    - **Removing methane exemptions** present in California smog regulations, which will reduce both GHGs and regional smog co-pollutants.
    - Requiring implementation of specific refinery by refinery measures identified in the **industrial energy efficiency audits**
    - **Limits on the use of dirty crude oil,** which is similar to what the electric power industry must meet.
    - **A thorough evaluation of Reasonably Available Control Measures** at oil refineries and industrial sources, minimizing both GHGs and co-pollutants
    - Additional measures discussed in this document

- **CARB originally considered direct control of oil refinery reduction measures and found them feasible,** but later lumped oil refineries and industrial sources in with all other Cap and Trade sources, despite findings that direct controls were

feasible. If CARB made these fixes for industrial sources and as well for other sources causing health impacts in California (such as agricultural and electrical sources), the severe impacts caused by Cap and Trade, and the ineffectiveness of it, would be greatly lessened.

- **CARB must include a strategy to implement the requirement to direct monetary benefits to disadvantaged communities.**

Overview of Cap & Trade harms:

1904 Franklin #600 · Oakland, CA 94612 · PH: (510) 302-0430 // Fax (510) 302-0437
In Southern California: 5610 Pacific Blvd., Suite 203 · Huntington Park, CA 90255 · PH: (323) 826-9771

I. Cap & Trade Industrial GHG reductions are tiny & can be beefed up; if instead achieved in-state, they would generate local jobs, health benefits, and be verifiable

A. Industrial emissions, especially oil industry, are big but underestimated

The success of cap and trade programs is dependent on identifying the correct number of reductions needed, requiring those reductions, and setting a low enough cap, but CARB systemically miscalculates industrial emissions, making it difficult or impossible to verify reductions in comparison to the targets and initial allocations.

Moreover, AB32 requires ARB to adopt regulations to achieve the maximum technologically feasible GHG reductions from sources and categories of sources.[10] Here, GHG industrial sources are very large, but reductions in the proposed Cap and Trade plan, especially for oil refineries, are miniscule, despite many available options for reductions. Total emissions from the capped portion of this sector were found by CARB at 75.69 million metric tonnes CO2 equivalent (or MM tonnes CO2e) in 2008. An excerpt from CARB's document *2020_ghg_emissions_forecast_2010-10-28* (attached), last updated 10/28/2010 shows the large contribution of different industrial subsectors to California (shown projected without Scoping Plan reductions):**[11]**

Category	2008	2009	2010	2011	2012

[11] *California GHG Emissions - Forecast (2008-2020)*, 10/28/2010, 2020_ghg_emissions_forecast_2010-10-28, http://www.arb.ca.gov/cc/inventory/data/tables/2020_ghg_emissions_forecast_2010-10-28.pdf

74.03	***74.10***	***74.12***	***74.17***	***74.20***	***74.20***	***74.21***	***74.21***
8.64	8.64	8.63	8.63	8.63	8.63	8.63	8.63
10.08	10.27	10.46	10.65	10.83	11.01	11.19	11.38
2.18	2.18	2.17	2.17	2.17	2.17	2.17	2.17
33.85	33.82	33.80	33.77	33.75	33.72	33.69	33.66
0.23	0.23	0.23	0.24	0.24	0.24	0.25	0.25
19.06	18.97	18.83	18.70	18.57	18.43	18.28	18.13

The table shows industrial emissions at about 74 MM tonnes CO2e from 2008 to 2020. Oil refineries, the largest industrial subsector, is shown at about 34 MM tonnes CO2e over this period. The whole industrial sector in fact is even larger when uncapped industrial sources are included. Another CARB chart (*Gross emissions and sinks* excerpted below) provides the total for all industrial sources at about 100 MM tonnes CO2e.

Oil industry sources are even bigger than they appear, because the listings split them into separate categories, with some categories not clearly labeled. Oil refineries should be added to Hydrogen Plants (which produce hydrogen at oil refineries for oil refinery use, by burning fossil fuels), and added to a large portion of the Cogeneration total, since large numbers of cogeneration comes from oil refinery sources.

It appears that another hidden oil industry source is also contained under the label “General Stationary Combustion.” This can be determined by reviewing the CARB table below. “Oil & Gas Extraction” at 17.04 MM apparently makes up most of the 18.91 MM tones of “General Stationary Combustion.” Because the oil industry is not only a major contributor to GHGs and toxics, the breadth of the oil industry sources should be made clear in the inventories.

California Greenhouse Gas Inventory for 2000-2008 — Summary by Economic Sector[12]

CBE Comment
December 15, 2010
Page 8 of 30

Gross emissions & sinks	2008
Industrial	**100.03**
CHP: Industrial	10.47
Landfills	6.71
Manufacturing	22.47
Mining	0.19
Not Specified Industrial	2.24
Oil & Gas Extraction	17.04
Petroleum Marketing	0.00
Petroleum Refining	35.60
Pipelines	2.62
Wastewater Treatment	2.70

This puts the oil industry sources in the CARB documents at:

Oil refineries 34 MM tonnes
\+ Hydrogen plants about 2MM tonnes
\+ Oil and gas extraction at 17 MM tonnes
\+ Cogeneration -- some large portion of 11 MM tonnes

= about 55 to 60 MM tonnes from the oil industry,
currently required to achieve zero direct emission reductions

Even this large sum of emissions is an underestimation.

Hydrogen Plant emissions are underestimated:

For example, hydrogen plants at oil refineries are growing at a fast rate, in order to allow refineries to process heavier, more contaminated crude oil. Just one hydrogen plant can emit over a million tonnes per year of CO2e (such as at the ConocoPhillips Rodeo facility[13]), so it is almost certain that the total of 2.22 MM tonnes listed for hydrogen plants now is actually much higher and getting even bigger than listed in the CARB chart.

CBE has previously provided a partial list of additional hydrogen plant projects in comments to CARB, and we incorporate those by reference. CBE also previously requested that CARB perform a more detailed assessment of planned hydrogen plants expansions at refineries, and we included the following chart in both written comments

[13] Excerpt of ConocoPhillips Rodeo Refinery Clean Fuels Expansion Project, Final Environmental Impact Report, Volume 1 – Response to Comments, cover and table of GHG emissions, Attachment CBE 1 - ConocoPhillips Rodeo H2 Plant GHGs

1904 Franklin #600 · Oakland, CA 94612 · PH: (510) 302-0430 // Fax (510) 302-0437
In Southern California: 5610 Pacific Blvd., Suite 203 · Huntington Park, CA 90255 · PH: (323) 826-9771

submitted,[14] and in testimony at a CARB hearing. This chart shows that just due to new hydrogen plants added, or in the process of being built, in the last decade, about 6 million tonnes per year of CO2 emissions were added.. This is a continuing trend that needs to be reigned in; it is caused by huge GHG increases that appear not to be accounted for by CARB, as well as by big local pollution increases during these oil refinery expansions that are occurring for the purpose of switching to heavier, more contaminated, cheaper crude feedstocks at oil refineries.

Examples of CA Refinery Hydrogen Plant Expansions (not comprehensive) (million standard cubic feet)	**Approximate CO2 Emissions** (metric tonnes /yr)
2007 ConocoPhillips Rodeo --120 MMscf	at least 1,250,000
2007 Chevron Richmond -- 100 MMscf	at least 900,000
2007 Valero Benicia – unknown MMscf	≈ 860,000
2003 Chevron El Segundo -- 90MMscf	≈ 940,000
1999 Air Products Wilmington for area refineries -- 96 MMscf	≈ 1,000,000
1996 Air Products for Ultramar, Wilmington --83 MMscf	≈ 860,000
493 MMscf (million standard cubic feet)	**Almost 6 million metric tons per year**

Furthermore, GHGs from oil refineries overall are getting worse due to switches to dirtier crude oil, running counter to other industries (such as electric power plants), which are switching to lighter feedstocks. The recent peer-reviewed study published by CBE Senior Scientist Greg Karras in the journal Environmental Science and Technology[15] found that very large increases in GHG emissions are occurring due to the switching to dirtier crude oil at oil refineries, underlining the importance of accurate inventories and

[14] Attachment C -- Comments on CARB AB32 Scoping Plan, Oil Refineries, by CBE (part of a 3-part comment by EJ groups, previously submitted to CARB, May 2008, attached, Attachment CBE 2 – Previous CBE Comments May 2008

[15] *Combustion Emissions from Refining Lower Quality Oil: What Is the Global Warming Potential?*, *Environ. Sci. Technol.*, 2010, *44* (24), pp 9584–9589, DOI: 10.1021/es1019965, November 30, 2010, Copyright © 2010 American Chemical Society http://pubs.acs.org/doi/abs/10.1021/es1019965, Attachment CBE 3 – GKarras Environ Sci Technol paper High GHGs Dirty Crude

forecasts, and controls and limits addressing this switch. While CBE has testified on this issue to CARB for a number of years, and CARB is well aware of this general trend, the new study provides a detailed evaluation of data nationally, which shows in detail how sharp this increase is. The paper found: *"Fuel combustion increments observed predict that a switch to heavy oil and tar sands could double or triple refinery emissions and add 1.6−3.7 gigatons of carbon dioxide to the atmosphere annually from fuel combustion to process the oil."* We urge CARB to review the attached publication, and to address this issue.

Pressure for growth in polluting oil refinery cogeneration of electricity

In addition,oil refineries have pushed for subsidized cogeneration, a truly bad idea, which would replace clean energy electricity, with oil refinery-generated electricity. While industrial energy efficiency is essential, and while existing refinery processes should be required to capture waste heat, adding unneeded, expanding oil refinery electricity is directly counter to the RPS (Renewable Portfolio Standard), which is aiming at converting fossil fueled electricity into clean electricity. **CARB must not allow oil refinery-generated electricity to subvert this process and take us backwards.**

Large portions of refineries have been removed from regulation by redefining them as non-refineries

Even the seemingly straightforward category of "oil refineries" is being parsed into bits, with oil refineries that process intermediate materials being exempted, and even removed from the definition of oil refineries in the regulation, despite the fact that they are inherently part of an oil refining company's overall production process. It is unclear whether the re-defined refinery portions are included in the capped emission estimation of 34 MM tonnes or not, but it is clear they are exempted from the caps. This approach undermines the requirement to adopt regulations that achieve technologically feasible GHG reductions from sources and categories of sources because it allows large unregulated oil refining emissions.[16] The proposed Cap and Trade oil regulation definition states:

> *"Petroleum refinery" or "refinery" means any facility engaged in producing gasoline, gasoline blending stocks, naphtha, kerosene, distillate fuel oils, residual fuel oils, lubricants, or asphalt (bitumen) through distillation of petroleum or through re-distillation, cracking, or reforming of unfinished petroleum*

[16] H&S Code § 38560.

1904 Franklin #600 · Oakland, CA 94612 · PH: (510) 302-0430 // Fax (510) 302-0437
In Southern California: 5610 Pacific Blvd., Suite 203 · Huntington Park, CA 90255 · PH: (323) 826-9771

> *derivatives. **Facilities that distill only pipeline transmix (off-spec material created when different specification products mix during pipeline transportation) are not petroleum refineries, regardless of the products produced.***[17]

Recommendation: **The last sentence in the regulation definition should be struck,** as this definitional difference has no relation in determining whether such facilities emit large amounts of GHGs, criteria pollutants, or toxics. CARB should use standard industrial classification codes for oil refineries used by EPA and remove baseless exemptions, to prevent large unregulated oil refining emissions.

CARB provided no evaluation of the environmental impacts caused by exempting these sources. This definition is another means by which the oil industry has received special unnecessary exemptions from regulation under the Scoping Plan and its implementation. Many individual oil refining companies own geographically separated facilities that nevertheless are operated together as an integrated refining operation whether or not one portion treats intermediate materials. Regional smog regulators routinely treat these facilities as one facility, and would never consider exempting them from regulatory standards, such as Clean Air Act requirements, based on whether they process "transmix" materials, rather than based on their actual air emissions and impact on the environment. For greenhouse gas purposes, there is similarly no justification for treating some refinery facilities as exempt without at least providing an emission threshold above which they are subject to regulation. Other entities must abide by simple emission thresholds (>25,000 metric tonnes), so this exemption also represents an unfair business practice, with oil refineries getting a sweetheart deal.

B. Oil industry reductions are small or non-existent

The industrial sector has zero tonnes of specific reduction requirements, as provided by CARB in the chart below, including for the largest sources, the oil industry. This most polluting industrial sector has been successful in winning the complete abandonment in control requirements, a fact which is nothing less than shameful for our State. AB32 requires ARB to consider the significance of the contribution of each source or category of sources(in adopting a regulation).[18] There is no way this can be argued as

[17] Regulation Definitions, page A-28 , http://www.arb.ca.gov/regact/2010/capandtrade10/capv1appa.pdf
[18] H&S Code §38562(b)(9).

meeting AB32's requirement to maximize reductions, and to reduce co-pollutants.[19] CBE urges CARB to correct this egregious error.

Last Updated: 10/28/2010

According to CARB's regulation notice document, the entire Cap and Trade regulation will get 18 to 27 MMTCO2e reduction by 2020, but none of these reductions are required to be achieved by oil refineries.[21] The regulation and staff report documents make it clear that no entity is required to reduce emissions at their site.

[19] H&S Code §§ 38560, 38562(b)(6), 38570(b)(2).

[20] CARB, reproduced above and available at: http://www.arb.ca.gov/cc/inventory/data/tables/reductions_from_scoping_plan_measures_2010-10-28.pdf

[21] "Staff estimates that implementation of the proposed regulation would reduce GHG emissions by 18 to 27 MMTCO2e in 2020." *Notice of Public Hearing to Consider the Adoption of a Proposed California Cap on Greenhouse Gas Emissions and Market-based Compliance Mechanisms Regulation, including Compliance Offset Protocols,* http://www.arb.ca.gov/regact/2010/capandtrade10/capnotice.pdf

A highly preferable alternative proposal would have been a thorough evaluation of Reasonably Available Control Measures necessary to meet CARB's requirements under AB32 for maximum reductions, to reduce smog in non-attainment zones, and toxics in overburdened heavily industrial areas. The following sections identify specific sources that should have been considered. For example, additional reductions could be achieved from:

- Requiring In-State reductions from industrial **boilers and heaters**, which CARB has already identified
- Removing **industrial exemptions for methane** from smog regulations,
- Requiring implementation of specific refinery by refinery measures identified in the **industrial energy efficiency audits**
- Limiting emissions and conversion to processing **Heavier Crude** at oil refineries (which is not cancelled out by adding polluting ethanol to gasoline)
- Requiring oil refineries to **switch fossil fuel electricity** use to clean alternative energy sources (since oil refineries use significant electricity)

More detail is provided below. CARB also found during the Scoping Plan process that many of these refinery control measures are feasible, but never required that these be carried out.

C. Boiler and Heater NOx and CO Co-pollutant emissions are large and if directly controlled would yield large local health benefits

AB32 requires ARB to design the program to *prevent* any increase in emissions of toxic air contaminants or criteria pollutants.[22] It also requires it to consider the overall societal benefits of reducing other air pollutants and benefits to the environment and public health.[23] Yet the draft regulation demonstrates that reductions could have been achieved to substantially reduce co-pollutant emissions but was rejected.

CARB provided two spreadsheets calculating available measures for reducing CO2 emissions from industrial boilers and heaters, which are major pollution sources.[24] Measures include replacing old boilers of low or medium

[22] H&S Code § 38570(b)(2).

[23] H&S Code § 38562(b)(6).

[24] Compliance Pathways Analysis – Boilers, available at http://www.arb.ca.gov/cc/capandtrade/capandtrade/compathboiler.xls and Compliance Pathways Analysis -

1904 Franklin #600 · Oakland, CA 94612 · PH: (510) 302-0430 // Fax (510) 302-0437
In Southern California: 5610 Pacific Blvd., Suite 203 · Huntington Park, CA 90255 · PH: (323) 826-9771

efficiency, optimizing combustion, improving insulation maintenance, etc. (listed below and in the attached spreadsheets). CARB identified how much energy would be saved for each of these measures in MMBTU (million British Thermal Units). CARB provided these reduction opportunity calculations not because these are being directly mandated, but to show possible ways that industrial sources *could* reduce, but are nevertheless allowed to buy their way out of under Cap and Trade. There was no showing that these reductions would not have been cost-effective. Regardless, the CARB list underscores the availability of measures for direct control. If these controls were implemented locally instead of traded, they would not only result in the CO2 emissions reductions identified by CARB, but would also result in very substantial co-pollutant reductions. **CARB should have considered such an alternative project to address co-pollutant impacts.**

It is a simple matter to calculate the co-pollutants associated with the energy savings identified in the boiler and heater speadsheets. For example, standard AP42 emission factors for NOx and CO are available, based on natural gas combustion.[25] This will generally underestimate emissions because more polluting fuels are often used by these boilers and heaters, but applying the natural gas factors provides a conservative estimation, and still comes out to large emissions. The result, in tons per day, is provided below. The detailed tables are attached as an appendix. Thethe full spreadsheets are separately attached.

Process Heaters, available at http://www.arb.ca.gov/cc/capandtrade/capandtrade/compathprocessheat.xls , also attached with CBE calculation sheet added to original CARB spreadsheet, Attachment CBE 4 – CBE calcs added to CARB Boiler data, and Attachment CBE 5 – CBE calcs added to CARB Heater data

[25] AP42 Chapter 1.4 provides the emission factors in units of lbs/scf (standard cubic feet of natural gas). Calculating as if all the units used natural gas, which is about 1020 btu/scf, we can convert the emissions factors to lbs NOx and CO per MMBTU. Since CARB provides the MMBTU, our spreadsheet provides the results in lbs NOx and CO. CARB's data was for 2008annual emissions. Converting lbs/year to tons per day (a standard form used to evaluate the significance of criteria pollutants or smog precursors) yields the data provided in the chart below. CBE's spreadsheet, which includes the CARB spreadsheets plus CBE's NOx and CO calculations, is attached., Attachment CBE 6 – AP42 Chapter 1.4

1904 Franklin #600 · Oakland, CA 94612 · PH: (510) 302-0430 // Fax (510) 302-0437
In Southern California: 5610 Pacific Blvd., Suite 203 · Huntington Park, CA 90255 · PH: (323) 826-9771

The results are:

Boiler NOx reductions of 16.44 tpd + **Heater NOx** reductions of 7.35 tpd
= **about 24 tons per day NOx**

Boiler CO reductions of 5.7 tpd + **Heater CO** reductions of 2.47 tpd
= **about 8 tons per day CO**

For comparison, the following South Coast Air Quality Management District's ("SCAQMD") 2007 Clean Air Plan chart[26] shows total NOx for all the region's oil refineries averaged at about 13 tpd and total refinery CO emissions averaged at about 20 tpd:

Total Criteria Emissions South Coast Oil Refinery Emissions Data

(tons per day)	1999-2000	2000-2001	2001-2002	2002-2003	2003-2004	Average of 2001-2002 & 2002-2003 time periods
ROG	8.0	7.7	7.3	8.2	7.9	7.7
NOx	20.1	15.5	13.4	12.8	12.3	13.1
SOx	21.3	19.9	17.2	15.8	14.0	16.5
CO	18.4	14.6	18.2	22.0	21.8	20.1
PM	4.0	4.0	4.0	3.6	3.7	3.8

This demonstrates that NOx and CO reductions achievable statewide from directly controlling industrial boilers and heaters is large, using the methods identified by CARB. Reductions are on a par with the entire NOx and CO refinery emissions in the Los Angeles region. This region is the biggest refining area in the state. The Cap and Trade program on the other hand, allows refineries to buy their way out of achieving these reductions through credits obtained from other states or countries. Since most of these refinery sources are located in heavily industrial area, in communities of color, these sources create cumulative impacts in these areas, and allowing refineries to do buy pollution credits instead of directly controlling these sources, is inconsistent with environmental justice.

D. Methane is exempted from smog regulations, statewide

[26] *Refinery Trends – Criteria Pollutants*, 8/18/05, http://www.aqmd.gov/prdas/refinery/pdf/emission_trend.pdf, attached, Attachment CBE 7 – SCAQMD Refinery Criteria Pollutants

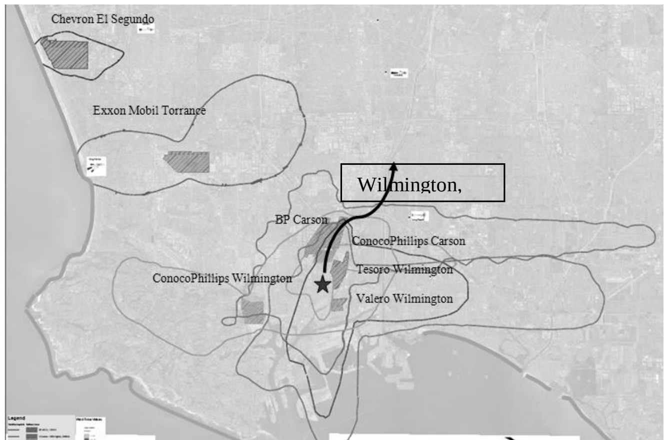
Comments submitted to CARB by CBE in May of 2008 on the Scoping Plan identified, based on CARB data, methane emissions that are exempt from regulation. For example, three categories of Stationary Sources listed (Fuel Combustion, Petroleum Production and Marketing, and Industrial Processes) emitted about 466 tons per day (about 170,000 tons methane per year) of exempt compounds, which is likely to be mostly methane. This is about 4 million tons CO2e per year. There is no reason to continue exempting these emissions, either for smog, or for GHG impacts. Please see the attached comments, page 10.[27] It is now known that methane is a considerable contributor to smog, as also discussed in this earlier comment. AB32 requires the maximum technologically feasible GHG reductions of carbon dioxide, methane, nitrous oxide, hydroflourocarbons, perflurocarbons, and sulfur hexafluoride; carbon is only one GHG.[28] Furthermore, CARB should remove entirely the methane exemptions for all sources in the state, including transportation sources. CBE proposed this, and CARB found it to be a feasible reduction measure, but never implemented it. Now CARB should evaluate adding this measure as a complementary reduction, as an alternative to the current Cap and Trade proposal, in order to achieve the maximum technologically feasible reductions.

E, Needed Co-Pollutant reductions do not address Environmental Justice issues

Any area with one refinery in it is impacted by a major pollution source. One example of extreme Environmental Injustice impacts due to the oil industry, with the very highest concentration of oil refineries in the state, is the Wilmington/Carson area in Southern California which contains about a third the state's refining capacity. This area includes about half of Los Angeles' refining capacity (five refineries and about 650,000 bpd). In the Los Angeles region overall, refineries dominate the top 15 VOC (Volatile Organic Compound) emitters, out of many hundreds of Stationary Sources listed by SCAQMD in the 2007 Air Quality Management Plan. The Wilmington Area includes about half the refinery VOCs emissions[i] (about 1,600 out of 3,200 tons per year) in the LA region. A plume map provided by SCAQMD graphically displays that Wilmington receives the air pollution from five overlapping refining plumes (isopleths) generated over this area (two ConocoPhillips refineries, Valero, BP, and Tesoro):

[27] Ibid, Attachment C -- Comments on CARB AB32 Scoping Plan, Oil Refineries, by CBE (part of a 3-part comment by EJ groups, this portion provided by CBE, attached), May 2008
[28] H&S Code §§ 38505(g), 38560.

1904 Franklin #600 · Oakland, CA 94612 · PH: (510) 302-0430 // Fax (510) 302-0437
In Southern California: 5610 Pacific Blvd., Suite 203 · Huntington Park, CA 90255 · PH: (323) 826-9771



Wilmington has the following demographics, [29] which demonstrate that people of color and low income people are bearing the brunt of the heavy industry concentration in this area.

	Wilmington	**LA**
Hispanic or Latino of any race	85%	45%
Median household income	$30,260	$42,190
Individuals below the poverty level	27%	18%

As if this extreme concentration of oil refineries was not enough to warrant local cleanup efforts, this area also includes oil drilling operations (Wilmington is the third largest oil field in the U.S.), extreme heavy diesel truck traffic (as a major goods movement corridor), the biggest Ports in the Country (Ports of LA and Long Beach which are the biggest single pollution sources in the area), and hundreds of other industrial sources. Clearly, refining areas are in need of direct, local pollution controls, not the potential for further concentration and expansions that the Cap and Trade proposal makes likely, through allowing refineries to buy their way out of local pollution control.

[29] U.S. Census Bureau, Zip Code Tabulation Area 90744, Census 2000 Demographic Profile HIghlights

II. The Cap and Trade regulation can cause Co-Pollutant hotspots, especially due to foregoing reductions of more toxic emitters for more benign ones

Pollution hotspots are areas where pollution concentrates locally rather than dispersing. (Greg Karras, *Flaring hot spots: Assessment of episodic local air pollution associated with oil refinery flaring using sulfur as a tracer* CBE Report (July 2005). Hotspots can have dire health and other quality of life consequences. For instance, modeling has shown that RECLAIM actually increased NO_x concentrations in Wilmington, a low income community of color in Los Angeles, beyond what would have resulted without RECLAIM. (*See* Raul P. Lejano et al, *Testing the assumptions behind emissions trading in non-market goods: the RECLAIM program in Southern California*, ENV'T SCIENCE & POLICY 8 (2005) pp. 371, 374)

Hotspots are an issue in the carbon trading context because carbon dioxide is almost always released with other pollutants, or "co-pollutants. These co-pollutants can include particulate matter including heavy metals, VOCs such as benzene, sulfur compounds, and hundreds of other toxic compounds. If a facility located in an overburdened community "buys" carbon from other facilities so that it can increase its GHG emissions, it is also increasing its emissions of toxic compounds. Said another way, by taking pollution that occurs across a large area and concentrating that pollution in an environmental justice community, the toxic load in that community increases.

In addition, by mixing many different sources together into one big Cap and Trade program, the differences in co-pollutants emitted by different facilities and equipment is lost, and left unaddressed. Consequently an oil refinery CO2 source that happens to have high benzene or high mercury, or high PM2.5 co-pollutants emissions, is treated the same as a food industry source CO2 that burns natural gas, but has low co-pollutant emissions. This allows an oil refinery source to avoid regulation, or even expand, by buying it's way out through clean up of a facility with less toxic co-pollutants. If the oil refinery uses forest credit offsets, it definitely means that a more toxic source (an oil refinery) is offset by a less toxic source.

The proposed regulation does nothing to avoid hotspots or co-pollutant emissions. Yet AB32 requires that,

> "*Prior to the inclusion of any market-based compliance mechanism in the regulations* . . . the state board shall . . . **(**1) Consider the potential for direct, indirect, and cumulative emission impacts from these mechanisms, including localized impacts in communities that are already adversely impacted by air pollution; (2) *Design* any market-based compliance

> mechanism to prevent any increase in the emissions of toxic air contaminants or criteria air pollutants."[30]

This failure must be corrected. In fact, ARB failed to take the first step necessary to do the analysis to determine cumulative impacts.

Framework for the Co-Pollutant Emissions Scenarios is flawed

CARB did not properly assess the co-pollutant risk. Co-Pollutant Emissions Assessment is limiting in that it only identifies four "impacted communities" for the purposes of demonstrating the hypothetical bounding exercise and has a problematic boundaries for the communities. ARB should reduce the scale of this assessment to magnify the local communities that are experiencing high exposures to pollution. It is unclear why CARB chose to exclude the West Oakland community and the Port of Oakland and yet, include predominately white, upper class and upper middle class cities such as Piedmont, Orinda and Regional Parks areas in East Contra Costa County. If the intent was to give a regional assessment, CARB should have included the East Bay communities where local PM 2.5 daily concentrations are exceeding federal standards. Low-income communities of color such as in East Oakland are overburdened by exposure to fine particulates and other pollutants and are vulnerable to cumulative impacts[31].

ARB should adopt and utilize the Environmental Justice Screening Method (EJSM) to identify and monitor communities highly impacted by the cumulative emissions. [32] The report states that this is not available on a statewide level, but the academic researcher team stated otherwise to the Environmental Justice Advisory Committee (EJAC) at their June 9, 2010 meeting. The EJAC strongly recommended that CARB utilize the tool to screen for impacted communities throughout the state to meet the requirements and the intent of AB 32[33]. The EJSM may also be used to screen for other categories of impacted communities, whether they are highly impacted or not in order to ensure pollution reductions in communities highly impacted and that no new hot spots are being created, especially in a "medium" impacted community.

ARB includes three scenarios for Community Case Studies (Appendix P-50). We find Scenario 1 – where all covered facilities reduce within the community and use offsets within the community – highly unlikely in the regulation's proposed form in Richmond and Wilmington, due to expected trends in increasing refinery capacities and the unlimited geographic boundaries of the offset program. There are no requirements or

---

[33] The final EJAC comment letter on the 'Proposed Screening for Low-Income Communities Highly Impacted by Air Pollution for AB 32 Assessments' dated August 25, 2010 is available for download at: http://www.arb.ca.gov/cc/ejac/ejac.htm

1904 Franklin #600 · Oakland, CA 94612 · PH: (510) 302-0430 // Fax (510) 302-0437
In Southern California: 5610 Pacific Blvd., Suite 203 · Huntington Park, CA 90255 · PH: (323) 826-9771

incentives to do this; in fact the whole regulation is stated to be designed for trading across state and international lines. However, this scenario could be more likely if the regulation is amended to geographically restrict trading and offsets. Scenario 2 – where all covered facilities increase their emissions – seems very likely, especially for sources like refineries, which are attempting to expand and will have to purchase offsets or additional allowances. Scenario 3 – where a new combined heat and power unit at an existing refinery is built in the community – there is a major deficiency in the analysis because it does not account for the possibility that refineries will utilize this increased efficiency in one area of the refinery to allow increased capacity to refine heavier, dirtier crude, resulting in a net increased emissions and exacerbating localized impacts. For example, CARB and the Air Quality Management Districts are well aware that this is the standard approach used in air permitting, and routinely carried out during expansions. Furthermore, due to the flexibility of the proposed regulation, we find the equally apportioned 4% greenhouse gas reduction at every cap-and-trade industrial and electricity generation facility in the community region extremely unrealistic.

Restricted trading zones within already impacted communities

The cap and trade regulation as currently proposed allows significant flexibility and benefits to polluters, but it impermissibly creates environmental justice problems. For example, because the regulation allows off-site reductions, we lose the potential for localized benefits and ARB creates a hard-to-track system that defeats the purpose of public vigilance and accountability. In highly impacted communities, there should be restrictions to trading to ensure meeting the requirements to not exacerbate hot spots of pollutions. Refineries will purchase additional credits or offsets if the cost of reducing greenhouse gases on-site exceeds the costs for other sectors because they can buy credits for a much lower cost. Oil refineries are expanding to accommodate a switch to process heavy crude oil in and around the Richmond and Wilmington communities.[34] Refinery emissions from fuel combustion are predicted to increase two to three times and add 1.6 to 3.7 billion tons greenhouse gas emissions annually from a switch to heavy crude oil or tar sands.[35] If trading is restricted to within these communities, reducing local emissions of criteria and air toxics will benefit the health of these same communities that are already overburdened by pollution. Furthermore, including direct emission reduction measures will ensure real, placed-based reductions, reduce cumulative impacts, and ensure meeting the maximum feasible reductions requirement of AB 32.

II. Many inappropriate exemptions are provided in the proposed regulation

---

[34] See CBE's and the EJAC's comments on the Proposed AB 32 Scoping Plan.

[35] Ibid, Karras, G.

Despite the large emissions and low reductions for industrial pollution sources, the regulation goes even further to protect these sources from regulation by providing outright exemptions. For example:

> § 95852.2. Emissions without a Compliance Obligation.
>
> **Emissions from the following source categories** as identified in sections 95100 through 95199 of the Mandatory Reporting Regulation count toward applicable reporting thresholds but **do not count toward a covered entity's compliance obligation set forth in this regulation.** These source categories include:
>
> (f) Fugitive and process emissions from:
>
> **(4) At petroleum refineries: asphalt blowing operations, equipment leaks, storage tanks, and loading operations; or**
>
> (5) At the facility types listed in section 95101(e) of the Mandatory Reporting **Regulation, Petroleum and Natural Gas Systems: leak detection and leaker emission factors, and stationary fugitive and "stationary vented" sources on offshore oil platforms.**

Neither a justification for this exemption, nor an evaluation of impacts was provided, nor could we imagine any possible justification. These exemptions are entirely inconsistent with requirements for maximizing reductions and should be struck.

Another exemption is provided for the use of ethanol:

> **§ 95852.2. Emissions without a Compliance Obligation.**
>
> Emissions from the following source categories as identified in sections 95100 through 95199 of the Mandatory Reporting Regulation count toward applicable reporting thresholds but do not count toward a covered entity's compliance obligation set forth in this regulation. These source categories include:
>
> (c) Fuel ethanol:
>
> (1) Cellulosic biofuel produced from lignocellulosic or hemicellulosic material that has a proof of at least 150 without regard to denaturants;
>
> (2) Corn starch; or
>
> (3) Sugar cane.

Again, no justification can be provided for this exemption, since ethanol introduction has many environmental impacts in California, the rest of the U.S., and

1904 Franklin #600 · Oakland, CA 94612 · PH: (510) 302-0430 // Fax (510) 302-0437
In Southern California: 5610 Pacific Blvd., Suite 203 · Huntington Park, CA 90255 · PH: (323) 826-9771

internationally, since it greatly increases smog, water pollution, and causes displacement of better land uses. These impacts were documented in CBE's comments on the Scoping Plan, and we refer CARB to those comments, as well as comments made by SCAQMD regarding the problem of the inclusion of ethanol causing increased smog in the region. It is a bad idea to exacerbate this further by giving ethanol a free ride.

III. CARB's accounting systems, particularly the International Forest protection programs (REDD) are vulnerable to fraud, and causes indigenous people's evictions

Three major criticisms of cap and trade schemes are that either the offsets themselves or the trading practices used to account for them are often not verifiable and are fraudulent, and that they can lead to oppression for indigenous communities.[36] The scoping plan proposes to expand a California cap and trade system to other countries where others might benefit from offsets. Put differently, AB32 would allow more pollution in California, including co-pollutants that would concentrate in low-income communities of color, with the hope that other countries will allow clean development. This vision fails to consider that these trades are not verifiable, they are often not surplus, they exacerbate the equivalency problem, and they increase the likelihood of oppression. AB32 specifically requires that the regulations do not disproportionately impact low-income communities,[37] that ARB consider the overall societal benefits of any regulation,[38] and that regulations minimize leakage[39]. These requirements have not been met.

The Indigenous Environmental Network (IEN) has documented severe impacts due to carbon credit trading involving forests, including fake forest protection projects that also cause harm to indigenous people. For example, a company which is responsible for large deforestation projects can clear cut old growth in Southeast Asia, then grow monocropped junk non-native junk trees on the same land, and be paid by fossil fuel polluters to do so. The land must be purchased by the forestry company in order to get paid for the credits. For these reasons, indigenous people are being been evicted from lands after large companies purchase these lands. This is a lose-lose situation for the

[36] For example, the regulations define (#143) "permanent" offsets as offsets that are permanent *or* have a system in place to replace them when they expire. This multilayered system of verification, particularly in an international context, will be extremely hard to monitor.

[37] H&S Code § 38562(b)(2).

[38] H&S Code § 38562(b)(6).

[39] H&S Code § 38562(b)(8).

environment – no reductions in fossil fuel are carried out because the polluter buys credits from the forestry operator. No forests are protected, and human rights are violated. California's Cap and Trade program, which is seeking to expand internationally it's linkage to other trading programs, is vulnerable to such bad offsets. IEN has published a popular education piece that graphically explains these problems. The publication includes detailed citations documenting examples of such occurrences. We urge CARB to evaluate this information, attached.[40]

IV. The Proposed Regulation Fails to Fulfill the Mandate for Community Investment

Nowhere in the regulations or even in the staff report did ARB describe a strategy to implement the requirement to direct monetary benefits to disadvantaged communities. Yet AB32 requires that,

> The state board shall ensure that the greenhouse gas emission reduction rules, regulations, programs, mechanisms, and incentives under its jurisdiction, where applicable and to the extent feasible, direct public and private investment toward the most disadvantaged communities in California and provide an opportunity for small businesses, schools, affordable housing associations, and other community institutions to participate in and benefit from statewide efforts to reduce greenhouse gas emissions.[41]

In its discussion of the incomplete Health Impact Assessment, ARB notes that it will explore potential uses of revenue generated by the program to improve public health in California.[42] It also notes that distribution of revenues is an issue that deserves further discussion.[43] While the draft regulation does *recommend* a Community Benefit Fund, as noted in , none of these recommendations commits ARB to any concrete action that would actually move private and public money into disadvantaged communities. Moreover, the section lacks a clear vision on the mechanism for giving a value to the

carbon credits, determining the allocation to the CBF and the best way to direct investments to the communities most impacted by air pollution.

Community Benefits Fund

Communities for a Better Environment was a co-sponsor of AB 1405, De León, California Global Warming Solutions Act of 2006: California Climate Change Community Benefits Fund, which was vetoed by Governor Schwarzenegger recently. This bill would have ensured that the most impacted and disadvantaged communities would get their fair share of revenues and mitigations from the implementation of AB 32. In this piece of legislation, there were three essential components – the creation of the fund, a percentage of revenues generated to fund direct health and environmental mitigations, and a clear definition of the communities to benefit from the fund[44]. Though it did not pass, the inception and development of the bill provides a framework that the staff at CARB could use with amendments.

The amount going to these communities should be significant enough to fund sizeable projects that will have significant environmental benefits to local communities, especially communities living "fenceline" to pollution. Low-income communities tend to pay a higher proportion of their income on water, energy, and food than higher income people and this is expected to increase with the effects of climate change[45]. We recommend allocating no less than 30%.of the total revenues generated from the annual purchase of allowances and offsets that will be allocated to CBF. The revenues should directly benefit local communities most impacted by climate change in California to mitigate the costs of reducing carbon, which disproportionately falls on low-income communities[46]. These communities need funds for planning, adaptation, mitigation, local solutions to reducing greenhouse gases and protecting their health now.

CARB should evaluate communities based on exposure to pollution as well as socioeconomic vulnerability that exacerbate the impacts of pollution. The academic research team of Rachel Morello-Frosch, Manuel Pastor, and Jim Sadd has been working on the EJSM as a product from contract work with the Air Resources Board and we believe this is the closest to the optimal statewide screening methodology for determining communities at the census tract level most impacted by pollution or cumulative impacts.[47] These indicators include: criteria and toxic air pollutant levels, proximity to

[44] AB 1405 information is available at: http://www.leginfo.ca.gov/cgi-bin/postquery?bill_number=ab_1405&sess=PREV&house=B&author=de_leon

[47] Environmental Justice Screening Methodology. Rachel Morello-Frosch, Jim Sadd, Manuel Pastor. June 9, 2010 Environmental Justice Advisory Committee Meeting. Presentation available for download at: http://www.arb.ca.gov/cc/ejac/meetings/060910/presentation.pdf

hazards, sensitive land use, poverty level, educational attainment, percent home ownership, housing value, sensitive populations (less than 5 years and older than 60 years old), birth outcomes, linguistic isolation, and voter turnout. AB 1405 included unemployment level, while the EJSM does not. We recommend that ARB use the EJSM in the development of the CBF to adequately screen for eligible communities, but also include the communities that may not be included in the screening due to non-incorporated status. The EJSM should also be updated on a frequent and regular basis to accommodate new and developing research and statewide databases.

CARB must develop specific criteria for how the CBF should be used in order to meet AB 32 requirements to ensure low-income communities are not disproportionately impacted and that there are other benefits beyond greenhouse gas reductions[48]. To address the need for stimulating the clean green tech industries, creating job training opportunities for low-income communities, job creation for low-income communities and to address possible disasters such as Hurricane Katrina, CBE recommends including, but not limiting the CBF funding these types of projects:

- projects that reduce both GHGs and co-pollutants in highly impacted communities, including stationary and mobile source pollution;
- non-fossil fuel electricity generating projects in and by local communities;
- green jobs training for low-income residents;
- disaster planning and preparedness, such as flooding, wildfires and other extreme weather events;
- creating community and specific plans to mitigate land use conflicts;
- reducing heat-island effects with strategies such as tree shade planting and "cool pavements";
- improving access to mass transit for low-income riders;
- improving training of industry workers and reducing exposure to pollutants;
- supporting local sustainable agriculture;
- water conservation programs including water catchment projects for homes, roadways and buildings, and greywater use;
- improving water quality in low-income communities;
- and improving or creating park space in low-income communities.

Health Analysis Is Needed

CARB needs to complete and include a health analysis before taking action on the proposed regulation. This assessment would include the existing localized health burdens, the impacts of free allowances, trading, out-of-state offsets, economic impacts

[48] AB 32 requires consideration of "overall societal benefits, including reductions in other air pollutants, diversification of energy sources, and other benefits to the economy, environment, and public health." Health & Safety Code §38562(b)

and directing investments into the most impacted communities. This analysis is crucial to evaluating the proposed regulation.

Thank you for your consideration of our comments.

Sincerely,

Bill Gallegos, Executive Director, EJAC Representative
Adrienne Bloch, Senior Attorney

							(Annual)

To calculate NOx & CO CoPollutants, using AP42 Emission Factors:
AP42 - 1.4 Natural Gas Combustion Emission Factors:

	AP42 Factors:			Converting AP42 to lb/MMBTU assuming natural gas, at 1020 MMbtu/MMscf:		
Large Wall-Fired Boilers (>100)	Nox, (lb/ million scf)	CO, (lb/ million scf)	CO2 lbs/million scf	Nox, (lb/ MMBTU)	CO, (lb/ MMBTU	TCO2 /MMBTU
Uncontrolled (Pre-NSPS)c	280	84	120,000	0.275	0.082	0.053
Uncontrolled (Post-NSPS)c	190	84	120,000	0.186	0.082	0.053
Controlled - Low NOx burners	140	84	120,000	0.137	0.082	0.053
Controlled - Flue gas recirculation	100	84	120,000	0.098	0.082	0.053

Natural gas - (lbs/MM scf) /(1020 MM btu/MM scf) = lbs/MMBTU

For comparison SCAQMD refinery inventory:

Total Criteria Emissions South Coast Oil Refinery Emissions Data

(tons per day)	1999-2000	2000-2001	2001-2002	2002-2003	2003-2004	Average of 2001-2002 & 2002-2003 time periods
ROG	8.0	7.7	7.3	8.2	7.9	7.7
NOx	20.1	15.5	13.4	12.8	12.3	13.1
SOx	21.3	19.9	17.2	15.8	14.0	16.5
CO	18.4	14.6	18.2	22.0	21.8	20.1
PM	4.0	4.0	4.0	3.6	3.7	3.8

Estimations assume Category 1 similar to Pre-NSPS Emission Factors
and Category 2 similar to Category 2 Post-NSPS Emission Factors

To calculate NOx & CO CoPollutants, using AP42 Emission Factors:
AP42 - 1.4 Natural Gas Combustion Emission Factors:

	AP42 Factors:			Converting AP42 to lb/MMBTU assuming natural gas, at 1020 MMbtu/MMscf:		
Large Wall-Fired Boilers (>100)	Nox, (lb/ million scf)	CO, (lb/ million scf)	CO2 lbs/million scf	Nox, (lb/ MMBTU)	CO, (lb/ MMBTU	TCO2 /MMBTU
Uncontrolled (Pre-NSPS)c	280	84	120,000	0.275	0.082	0.053
Uncontrolled (Post-NSPS)c	190	84	120,000	0.186	0.082	0.053
Controlled - Low NOx burners	140	84	120,000	0.137	0.082	0.053
Controlled - Flue gas recirculation	100	84	120,000	0.098	0.082	0.053

Natural gas - (lbs/MM scf) /(1020 MM btu/MM scf) = lbs/MMBTU

For comparison SCAQMD refinery inventory:

Total Criteria Emissions South Coast Oil Refinery Emissions Data

(tons per day)	1999-2000	2000-2001	2001-2002	2002-2003	2003-2004	Average of 2001-2002 & 2002-2003 time periods
ROG	8.0	7.7	7.3	8.2	7.9	7.7
NOx	20.1	15.5	13.4	12.8	12.3	13.1
SOx	21.3	19.9	17.2	15.8	14.0	16.5

RESPONSES TO COMMENT LETTER #8
(Communities for a Better Environment – October 6, 2015)

8-1 The claim that additional cost-effective NOx emission reductions beyond what was analyzed in the PEA proposed project are available, achievable and necessary and that they should be included as an alternative in a recirculated PEA is addressed partially below and in more detail in Responses 8-2 and 8-3.

Two opportunities (e.g., during the 57-day public review and comment period of the NOP/IS and at the CEQA scoping meeting) were provided to commenters to suggest ways of crafting the various alternatives to be analyzed in the PEA. The SCAQMD received several suggestions for alternatives and none included the alternative suggested in this comment. This is why the Draft PEA does not contain an analysis of this suggested alternative.

Based on input from the public, stakeholders and other interested parties, SCAQMD staff crafted five alternatives that were included in the PEA and one of the five is the no project alternative (e.g., Alternative 4) as required by CEQA Guidelines §15126.6 (e). When considering and discussing alternatives to the proposed project, an EIR need not consider every conceivable alternative to a project but instead consider a reasonable range of potentially feasible alternatives that will foster informed decision making and public participation. [CEQA Guidelines 15126.6 (a)]. SCAQMD staff believes that the PEA contains a reasonable range of potentially feasible alternatives. Thus, as further explained in Responses 8-2 and 8-3, no additional alternatives are necessary or required and the Draft PEA does not need to be recirculated.

8-2 This comment suggests that there are other control measures (e.g., replacing low and medium efficiency boilers or heaters, optimizing boilers by reducing excess air, retrofitting feed water economizers, retrofitting air preheaters, etc.) that could be implemented to reduce the fuel usage in boilers and heaters, and as a consequence reduce greenhouse gases, and other co-pollutants such as NOx and CO. This comment is addressed in Response 8-3.

This comment also claims that there is a NOx emission reduction potential of 12 tpd from an average inventory of 13.1 tpd for the 2001-2002 and 2002-2003 time frame which could result in a remaining inventory of 1.1 tpd NOx (13.1 – 12 = 1.1 tpd). Finally, this comment suggests that the SCAQMD's current proposal of 0.96 tpd reductions for boilers and heaters was too low and much higher reductions could be achieved from the refinery boilers and heaters source category.

It appears that the commenter has misunderstood the emission inventory and emission reduction data that was presented in the Table 5.1 of the Staff Report. For clarification, the 13.1 tpd emission inventory and emission reduction data mentioned in the comment is specific to the refinery boilers and heaters source category. The data from Table 5.1 has been summarized in the following table.

	A	B	C	D = A – C
Equipment Source Category	**2011 NOx Emissions (tpd)**	**2023 NOx Emission Reductions Beyond 2000/2005 BARCT (tpd)**	**2023 NOx Emissions at 2015 BARCT (tpd)**	**NOx Emission Reductions from 2011 Baseline (tpd)**
Boilers/Heaters >110 mmbtu/hr	4.88	0.44	0.38	4.50
Boilers/Heaters >40-110 mmbtu/hr	2.00	0.50	0.47	1.53
Boilers/Heaters 20-40 mmbtu/hr	0.45	0.00	0.10	0.35
Boilers/Heaters <20 mmbtu/hr	0.06	0.00	0.02	0.04
TOTAL	**7.39**	**0.94**	**0.97**	**6.42**

Note: Data in Columns A, B and C are from Table 5.1 of Draft Staff Report, October 2015.

As shown in Column A, the total inventory of NOx emissions from the refinery boilers and heaters source category was approximately 7.4 tpd in 2011. The inventory for the refinery boilers and heaters source category was reduced by 5.7 tpd NOx (13.1 – 5.7 = 7.4 tpd) since the 2002-2003 time frame. The 0.94 tpd in Column B represents the *incremental* emission reductions that occurred from the 2000/2005 BARCT levels analysis to the 2015 BARCT levels analysis, and does not reflect the entire amount of emission reductions from the baseline. In actuality, the entire amount of emission reductions from the 2011 baseline is 6.42 tpd as shown in Column D. By counting from the 2002-2003 baseline, the full amount of NOx emission reductions would be 12.1 tpd (5.7 + 6.4 = 12.1 tpd), which is a value that is consistent with the commenter's estimate. Finally, as shown in Column C, the remaining NOx emissions inventory would be 0.97 tpd, which is lower than the remaining emissions inventory of 1.1 tpd that was proposed by the commenter. Because the commenter's recommendation would actually result in less NOx emission reductions when compared to the proposed project, SCAQMD staff believes that the current staff proposal for reducing NOx emissions from the refinery boilers and heaters source category represents the maximum level that is technically feasible and cost-effective for add-on controls.

8-3 This comment provides suggestions for achieving additional NOx reductions that entail modifying equipment to make fuel efficiency and other improvements and that the PEA should be revised to reflect these suggestions.

In the upcoming 2016 AQMP, staff will propose two preliminary control measure concepts (e.g., CMB-01 and ECC-02) to specifically explore any potential air pollution benefits that may occur as a result of improving maintenance and energy efficiency, and from applying other optimizing approaches in order to reduce greenhouse gases and provide co-benefits of NOx reductions. CMB-01 is a proposed control measure concept that will examine potential NOx and greenhouse gas emission reduction opportunities that may be achieved from commercial and multi-residential space and water heating. Similarly, proposed control measure concept ECC-02 will examine potential NOx and greenhouse gas emission reduction opportunities that may be achieved from implementing energy efficiency measures for existing residential and commercial buildings.

Because these concepts are preliminary in nature, staff believes that additional time, data, and input from the stakeholders and the public are needed in order to conduct this type of analysis. Further, the incorporation of the commenter's suggestions into the PEA for this project would be premature because the 2016 AQMP is currently under development and on a completely separate schedule from the proposed project. As the 2016 AQMP development process moves forward, a separate CEQA analysis of the effects of what is proposed for the 2016 AQMP will be conducted and presented as part of a Program EIR which will provide multiple opportunities for review and comment by the public, stakeholders, and other interested parties. Thus, SCAQMD staff disagrees that the PEA for this project needs to be revised to analyze the suggestions provided in this comment.

1. EXECUTIVE SUMMARY

A socioeconomic analysis has been conducted to assess the impacts of the proposed amendments to Regulation XX – RECLAIM. The same level of analysis has also been performed on the California Environmental Quality Act (CEQA) alternatives. A summary of the analysis and findings are presented below.

Key Elements of the Proposed Amendments	The proposed amendments would reduce (or "shave") 14 tons per day (tpd) of NOx RECLAIM Trading Credits (RTCs) by the year 2023, of which 4 tpd would occur in 2016, and the remaining 10 tpd would be distributed evenly over the period of 2018–2022 at the rate of 2 tpd per year. These reductions will help the region attain federal ozone and PM2.5 standards. The amount and distribution of the proposed shave was determined based on the Best Available Retrofit Control Technology (BARCT) analysis. A new level of BARCT is proposed for Fluid Catalytic Cracking Units (FCCUs), boilers/heaters >40 mmBtu/hr, gas turbines, coke calciners, and sulfur recovery and tail gas incinerators used in the refinery sector. For the non-refinery sector a new BARCT level is proposed for container glass melting furnaces, sodium silicate furnaces, metal melting furnaces >150 mmBtu/hr, gas turbines and Internal Combustion Engines (ICEs) not located on the outer continental shelf (OCS). The proposed NOx shave of 14 tpd would be distributed as a 66 percent shave for 9 refineries and investors, a 49 percent shave for 21 electricity generating facilities, a 49 percent shave for 26 non-major facilities, and no shave for the 219 remaining facilities. By 2023, it would result in 12.51 tpd of remaining RTCs (26.51 tpd – 14 tpd = 12.51 tpd). This amount is expected to sufficiently account for the needs of all RECLAIM facilities, including growth and a compliance margin.
Affected Facilities and Industries	The proposed amendments would affect the current RTC holdings for 56 out of 275 RECLAIM facilities. The 56 affected facilities would include 9 major refineries, 21 electricity generating facilities, and 26 other top emitting non-refinery facilities. The nine affected refineries belong to the sector of petroleum product manufacturing (NAICS 324), the 21 electricity generating facilities belong to the sector of utilities (NAICS 221), the remaining 26 facilities belong to the sectors of manufacturing (NAICS 31-33), mining, oil and gas exploration (NAICS 211), utilities (NAICS 221), amusement and recreation industries (NAICS 713), and a military facility. Facilities in the 219 group represent a range of industries, but are largely comprised of manufacturing (NAICS 31-33), mining, oil and gas

	exploration (NAICS 211), and utilities (NAICS 221) industries.
Assumptions for the Analysis	The proposed amendments are assumed to induce full BARCT installation by 2023 at the 9 refineries and 11 non-refinery facilities where the 2015 BARCT analysis identified cost-effective controls for their major NOx emission sources. This assumption is made to arrive at the most conservative (i.e., maximum) compliance cost estimates. In reality, the RECLAIM program affords facilities with compliance flexibility so that the actual costs may be lower if a facility identifies any other more cost-effective alternatives to remain in compliance, such as RTC purchases and operational changes. The 9 refineries currently have the following equipment/source categories that have BARCT determinations for the proposed rule amendments: FCCUs, Sulfur Recovery Units/Tail Gas Incinerators (SRU/TGUs), coke calciners, refinery boilers and heaters, and refinery gas turbines. In response to the proposed rule amendments, operators of these refineries are assumed to install Selective Catalytic Reduction (SCR) technology, UltraCat Dry Gas Scrubbers (DGS), and Low Temperature Oxidation (LoTOx^{TM}) with Wet Gas Scrubbers (WGS). The 11 non-refinery facilities currently have the following equipment/source categories that have BARCT determinations for the proposed rule amendments: container glass melting furnaces, glass melting furnace facilities, sodium silicate furnaces, metal heat treating furnaces rated >150 mmBtu/hour, stationary ICEs and non-electricity generating plant stationary gas turbines. In response to the proposed rule amendments, operators of these facilities are assumed to install SCR technology or UltraCat DGS. For the purpose of conducting a worst-case analysis, 34 SCR units and 1 UltraCat DGS are assumed to be installed at the 11 non-refinery affected facilities. It is possible that another UltraCat DGS may also be installed in lieu of 1 of the 34 SCR units. In total, the proposed rule amendments are assumed to result in the installation of the following new NOx air pollution control equipment: 116 SCRs, 8 LoTOx^{TM} with WGSs, 1 LoTOx^{TM} without WGS, and 3 UltraCat DGSs. The annualization factor used for capital costs is based on a discount rate of 1 or 4 percent and a 25-year equipment life for all control equipment including SCRs, UltraCat DGS, and LoTOx^{TM} technology.

Cost Impacts	Total compliance cost associated with control equipment installation by 9 refineries and 11 non-refinery facilities would range from $728 million to $1.1 billion in present worth values (expressed in 2014 dollars). Using the high-end cost estimates, the annualized compliance cost is estimated to be approximately $70 million when evaluated at a 4 percent discount rate, or $60 million when evaluated at a 1 percent discount rate from year 2022 onwards when all controls are assumed to have been installed. More than 73 percent of the annualized compliance cost is expected to occur in the refinery sector, and more than 43 percent of the sector's annualized compliance cost would be associated with FCCU installation. Among the non-refinery sectors, gas turbines would account for more than 60 percent of the sector's annualized compliance cost. It should be noted that these cost estimates do not consider the possibility that these 20 facilities could potentially sell surplus NOx RTCs, if any, resulting from control installation. This would then offset some of the control installation costs. The proposed shave could potentially affect facilities with no identified cost-effective controls in two ways. First, 36 of these facilities would be subject to the proposed shave, and some of them would need to buy additional NOx RTCs to reconcile actual emissions. Second, all facilities could potentially pay a higher price for NOx RTCs that they purchase each year for compliance. Additionally, higher NOx RTC prices could be potentially induced by the opt-out of any electricity generating facilities that regularly sell their surplus discrete credits or by removing from the market NOx RTCs resulting from the shut-down of RECLAIM facilities. Furthermore, under the proposed amendments, the 12-month rolling average price trigger would be raised to $22,500 per ton (discrete credits), thus potentially allowing NOx RTC prices to increase further before non-tradable/non-usable NOx RTCs are converted to tradable/usable NOx RTCs; however, the proposed addition of a 3-month rolling average price trigger of $35,000 per ton (discrete credits) would institute another safeguard. Total incremental compliance cost (expressed in 2014 dollars) associated with RTC purchases over the course of 25 years is estimated to range from $19 million—if discrete NOx RTC prices remain the same—to $500 million—if the average annual discrete NOx RTC prices increase to $22,499/ton for a total of 25 years and none of the affected facilities pursue any other more cost-effective compliance options.
Job Impacts	Assuming that the proposed amendments would induce full BARCT installation by 2023 and the 9 refineries and 11 non-refinery facilities would incur the high-end estimated costs, it is projected that about 20 jobs on the net would be created on an annual average between 2018 and 2035, and about 140 net jobs would be foregone when the

	analysis horizon is extended to 2043. (Note that jobs foregone may include either losses of existing jobs or projected additional jobs not created.) The difference is because the majority of jobs, mostly in the construction sector, would be created at the beginning of the analysis period (2018-2022) when control installation is assumed to take place. Despite having a large share of the total compliance cost, the refinery industry is projected to have fewer jobs forgone relative to other industries with similar magnitude of cost impact due to the fact that the industry is the most capital-intensive. As such, less labor would be required to produce the same amount of products or services. Note that the projected job impact would be more positive (i.e., fewer jobs foregone) if facilities sell any surplus NOx RTCs that result from installing control equipment, to offset control installation costs. Regarding the incremental compliance cost that could be potentially incurred by the rest of NOx RECLAIM facilities, the associated job impacts have been estimated under various scenarios of discrete NOx RTC prices. If prices remain the same, little job impact is expected due to the proposed amendments. If the average annual discrete NOx RTC prices increase to $22,499/ton and none of the affected facilities pursue any other more cost-effective compliance options, then about 40 jobs on the net would be foregone annually between 2023 and 2035. However, this latter price scenario is unlikely to occur, particularly if the 9 refineries and 11 non-refinery facilities install identified cost-effective controls, which would then either decrease the market demand or increase the market supply of NOx RTCs by these facilities.
Impact of CEQA Alternatives	Five alternatives to the proposed amendments were developed for the CEQA analysis associated with this proposal: Alternative 1 (Across the Board), Alternative 2 (Most Stringent), Alternative 3 (Industry Approach), Alternative 4 (No Project), and Alternative 5 (Weighted by BARCT Reduction Contribution for all Facilities and Investors). After further analysis, staff determined Alternatives 3 and 4 do not comply with state law. Regarding cost-effective control installation, the proposed rule amendments have the highest cost but the second to highest positive job impact, due to increased labor demand for the full, instead of partial, installation of control equipment. Alternative 4 would maintain the status quo and serves as a benchmark against which other alternatives were evaluated; however, it does not comply with state law. Of the four remaining alternatives, Alternative 3, which also does not comply with state law, has the lowest annualized cost ($9.40 million) because it is expected to induce the lowest number of control equipment to be installed; for the same reason, however, it

	would not create as many jobs and would result in an average of 30 jobs foregone on an annual average. Alternatives 1 and 2 would cost less than the proposed amendments, yet would experience more negative job impacts (approximately 80 jobs forgone on an annual average basis). This is due to less control equipment installation spending in the refinery sector relative to the 11 non-refinery facilities and would result in negative net job impacts. For the incremental costs associated with NOx RTC purchases that could potentially be incurred by some of the facilities without identified cost-effective controls, Alternative 2 has the highest estimated costs (up to $31 million in total), as it would result in the largest amount of NOx RTC shave. In terms of job impacts, all CEQA alternatives except Alternative 4 (No Project) would result in a more negative job impact—up to about 60 jobs foregone on an average annual basis if the average annual discrete NOx RTC prices increase to $22,499/ton and none of the affected facilities pursue any other more cost-effective compliance options—than the proposed amendments. This is mainly because, unlike the proposed amendments, Alternatives 1, 2, 3 and 5 would not exempt from the shave the 219 facilities that tend to be smaller and use more labor-intensive production technologies than, for example, those used by the refineries.
Health Benefits	The South Coast Air Basin is one of only two "extreme" non-attainment areas in the nation that have not reached the federal 8-hour ozone standard. The amount of pollutants produced by modern urban life and industrial activities, combined with Southern California's year- round sunny weather, all contribute to the high concentrations of ground-level ozone in the area. Ozone exposure can cause immediate, adverse effects on the respiratory system. Long-term impacts of frequent exposure to ozone may lead to permanent lung damage and increase the risk of premature death. In addition, the South Coast Air Basin remains a non-attainment area for the federal 24-hour and annual PM2.5 standards. Exposure to high levels of PM2.5 have been shown to cause and aggravate cardiopulmonary illnesses. NOx is a precursor of PM2.5. These outcomes result in increased absences from school and work, hospitalization, and other medical expenses. Exposure to PM2.5 is associated with premature deaths. According to recent estimates by the California Air Resources Board, elevated ambient PM2.5 levels result in approximately 4,100 premature deaths annually in the South Coast Air Basin.

Costs of Command and Control Compared to RECLAIM	RECLAIM allows facilities to use the least costly option to remain in compliance. Unlike command-and-control rules where every source has to be controlled to the same emission standard, RECLAIM facilities can pursue operational changes or purchase RTCs from investors or other facilities with surplus credits in lieu of upgrading existing control equipment, installing new control equipment or making other changes. Therefore, by design, total costs to install controls under the RECLAIM program since its adoption will always be equal to or less than total costs under command and control. The stream of cost-savings for any RECLAIM facility would only be reduced when, at a point in time, it becomes more economical for the facility to install the control equipment that would have been required under command-and-control. However, the future cost-savings may not be completely eliminated by control installation as long as the facility is able to sell surplus RTCs to offset some of the control installation costs. For example, following the 2005 NOx RECLAIM amendments, none of the 51 SCRs identified in the BARCT analysis for refineries have been installed because of RECLAIM, and 4 SCRs were installed only due to orders for abatement. As a result, refineries have saved approximately $205 million since 2007 by delaying installation of 47 SCRs. The cost-savings would continue to accumulate as long as refineries are able to further delay the installation of SCRs and still remain in compliance under RECLAIM. This continuous stream of cost-savings would only be reduced or even ceased if the currently proposed shave could eventually induce at least some of the 47 SCRs to be installed.

2. INTRODUCTION

RECLAIM allows facilities to use the most cost-effective approach to meet their obligation to surrender RTCs to match their quarterly and annual emissions, while helping the region attain clean air goals. This is possible, because unlike command-and-control regulations where every source is controlled to the same emission standard, a RECLAIM facility with more emissions than its actual RTC holdings has the option to install pollution control equipment, change operations, or purchase additional RTCs to offset its total emissions. Facilities are expected to choose whichever option is more economical for their business.

The proposed rule amendments consist of applying a shave to investors and to the facilities holding the top 90 percent of NOx RTCs, as weighted by a Best Available Retrofit Control Technology (BARCT) reduction contribution to achieve an overall reduction of 14 tons of NOx per day by 2023 according to the following implementation schedule as summarized below:

Table 1: Implementation Schedule for NOx RTC Reductions

Implementation Year	Amount of NOx RTC Reductions (tons/day)
2016	4
2018	2
2019	2
2020	2
2021	2
2022	2
TOTAL	**14**

The proposed shave of 14 tpd of NOx RTCs for the top 56 emitters is expected to assist in achieving clean air goals and meeting the requirements of state law by inducing the 20 facilities (9 refineries and 11 non-refineries[1]) to reduce actual emissions.

At the beginning of the RECLAIM program in 1994, a total of 392 NOx facilities were allocated RTC holdings at no cost. As a net outcome of facility shutdowns and new facilities joining the universe, there were 275 facilities in the NOx program in 2013, with a total of 26.51 tpd RTC holdings. Over the past decade, facilities have met their emission-reduction obligations under RECLAIM by purchasing unused “excess” RTCs and, only to a lesser extent, by reducing actual NOx emissions. Some of these unused “excess” credits can be attributed to facility shutdowns and the subsequent selling of credits. Regardless of why there are excess credits, their existence exerts downward pressure on the RTC market price and may have dis-incentivized RECLAIM facilities to install many of the already identified cost-effective control measures. For example, in the 2005 NOx RECLAIM amendments, the BARCT analysis included the potential installation of 51 SCR units at refineries. However, not one has been installed due to the RECLAIM program (4 SCR units were installed only due to orders for abatement).

[1] Two of the 11 non-refineries would not have their NOx RTC holdings shaved because they are not among the top 90 percent holders of NOx RTCs.

According to staff analysis of the RECLAIM transaction records, many of the unused RTCs were sold, as Infinite-Year-Blocks (IYBs), to operating RECLAIM facilities by some of the now-closed facilities prior to facility closure. These excess RTCs have been artificially depressing RTC prices and have induced RECLAIM facilities to delay the installation of cost-effective controls. A case in point is the 2005 NOx RECLAIM amendments. Despite 7.7 tpd of NOx RTC shave from the 2005 amendments being implemented over the period of 2007-2011, only 4 tpd of actual NOx emission reductions had occurred by the end of the 2012 Compliance Year. Some of the 4 tpd of actual reductions came from operational changes at refineries, which chose to run gas turbines instead of higher-emitting boilers at various points in time. However, just less than two thirds of the 4 tpd actual reductions were due to facility shut-downs (Table 2) and not measures taken to reduce actual emissions by facilities in the program. This outcome is not optimal for achieving clean air goals in the Basin.

Table 2: RECLAIM Facility Shutdowns from 2006 to 2012

Facility	**2006 Audited NOx emissions (lbs)**	**2012 Audited NOx emissions (lbs)**	**Difference (tpd)**
A	1,582,879	9,372	2.16
B	136,876	655	0.19
C	125,778	0	0.17
D	80,669	0	0.11
Total			**2.62**

Excess RTC holdings have ranged between 5.45-8.41 tpd over the past five years. Removing at least a portion of these excess credits from the market would relieve the downward pressure on the RTC market price and would be more likely to make control equipment installation a more cost-effective option than purchasing RTCs, particularly for the 20 facilities with newly identified control equipment.

In accordance with the requirements of the California Health and Safety Code (H&SC), SCAQMD staff conducted a BARCT assessment of the NOx RECLAIM program to: 1) assess advancements in control technology; 2) to ensure that RECLAIM facilities achieve the same emissions reductions as the implementation of BARCT; 3) to ensure that emission reductions from the NOx RECLAIM program contribute towards achieving the federal National Ambient Air Quality Standards (NAAQS); and, 4) to assure that the participating facilities will continue to achieve emission reductions as expeditiously as possible to carry out the commitments in the 2012 Air Quality Management Plan (AQMP).

Based on the BARCT analysis[2], a new level of BARCT is proposed for Fluid Catalytic Cracking

[2] Except for electricity generating facilities, the proposed RTC shave reduction will be based on compliance year 2011 activity levels for all other affected facilities. The 2012 activity levels will be used for RTC reductions from electricity generating facilities because this activity level better represents this sector's energy consumption.

Units (FCCUs), boilers/heaters >40 mmBtu/hr, gas turbines, coke calciners, and sulfur recovery and tail gas incinerators used in the refinery sector. For the non-refinery sector (except electricity generating plants), a new BARCT level is proposed for container glass melting furnaces, sodium silicate furnaces, metal melting furnaces >150 mmBtu/hr, gas turbines and ICEs not located on the outer continental shelf (OCS).

To realize the emission reduction potential of 2015 BARCT and help the Basin achieve the PM2.5 standards by 2019 and 2024 and the ozone standards by 2024 and 2032, staff proposes reductions (or a "shave") of NOx RECLAIM Trading Credits (RTCs) by a total of 14 tpd to be implemented over a seven-year period from 2016 to 2022. This number includes shaving unused RTCs as well as assuming programmatic BARCT equivalency. See the Staff Report for the rationale for this approach. Currently, there are 275 RECLAIM facilities holding 26.51 tpd of NOx RTCs in total, among which the refinery sector holds 51 percent of the RTCs, electricity generating plants 21 percent, investors 4 percent and other RECLAIM facilities 24 percent. The proposed shave of 14 tpd would result in 12.51 tpd of remaining RTCs (26.51 tpd – 14 tpd = 12.51 tpd). This amount is expected to sufficiently account for:

- The projected 2023 emissions by RECLAIM facilities at the proposed 2015 BARCT levels[3], which would be 10.23 tpd (2.76 tpd for the refinery sector plus 7.47 tpd for the non-refinery sector).
- A 10 percent compliance margin that has been added to the projected 2023 emissions
- An adjustment to account for other uncertainties (e.g. uncertainties in BARCT analysis, and base year activity level adjustments)

Under the proposed amendments, the 14 tpd of NOx RTC reductions would be distributed as a 66 percent shave for 9 refineries and investors, a 49 percent shave for 21 electricity generating facilities, a 49 percent shave for 26 non-major facilities, and no shave for the 219 remaining facilities. As a result, the shave would directly affect a total of 56 facilities plus investors that together hold 90 percent of the 26.51 tpd of the NOx RTCs. Other facilities that would not be shaved may also be indirectly impacted by potential changes in RTC price due to the proposed NOx RTC reductions.

3. METHODOLOGY FOR SOCIOECONOMIC ASSESSMENT

For the purpose of the socioeconomic analysis of the proposed amendments and CEQA alternatives for the NOx RECLAIM program, staff has assumed three compliance cost categories: (1) costs of control equipment implementation for 9 refineries and 11 non- refineries that would be shaved,[4] assuming all control equipment identified in the 2015 BARCT analysis would be

[3] To account for projected industry growth, the growth factor assumptions are: 1) 1.0 for the refinery sector; 2) 0.89 for electricity generating facilities; and 3) 1.1 -1.3 for the non-refinery sector. These growth factors are based on those in the Draft Final Staff Report, which are based on growth factors for point sources in 2012 AQMP made by SCAG. The only exception is for EGFs, whose growth factors were based on the 2014 Gas Fuel Report.

[4] Note that the current socioeconomic analysis uses the high-end cost estimate specified in the Revised Draft Staff Report. Cost estimates based on Norton Engineering Consultants (NEC)'s analysis for the refinery FCCUs lie between

installed by 2023 in lieu of other compliance options such as RTC purchases or operational changes, (2) incremental costs for a fraction of the remaining 36[5] shaved facilities to purchase RTCs to remain in compliance, due to both additional credits potentially needed and any potential increase in RTC price, and (3) incremental costs of purchasing RTCs at potentially higher prices for a fraction of the 219 non-shaved facilities that historically purchase credits from the market to reconcile actual emissions with RTCs. The costs associated with control equipment implementation are described in the cost section and then used as inputs to simulate and assess the regional macroeconomic impact of the proposed amendments and CEQA alternatives. The costs and job impacts resulting from the shave for a fraction of the 36 facilities and the 219 non-shaved facilities are discussed further in the Market Analysis section.

4. REGULATORY HISTORY

In 1993, SCAQMD adopted an emissions trading program (RECLAIM) for stationary sources as a market incentive system to cost-effectively achieve emission reductions. RECLAIM establishes facility mass emission limits for NOx and SOx and allows sources the flexibility to achieve regional prescribed emission reduction targets through process changes, installation of control equipment, and emissions trading. H&SC §39616 (c)(1) and (c)(4) required that findings be made that a market-based incentive program would result in "equivalent or less cost" and "not result in greater loss of jobs or more significant shifts from higher to lower skilled jobs than" the counterpart command-and-control regulation, at the time of adoption and 5 years later. Staff does not expect a shift from high- pay to low-pay jobs as a result of the proposed rule amendments.

A socioeconomic analysis of RECLAIM was conducted at the time of its adoption. The cost of RECLAIM was estimated to be $80.8 million annually, on average, compared with the $138.7 million cost of the corresponding command-and-control system (which included rules and control measures in the 1991 AQMP that were subsumed by RECLAIM). RECLAIM was predicted to result in an average of 866 jobs forgone annually, compared with 2,013 jobs forgone under the command-and-control system. Based on the five occupational categories from the lowest-paid to the highest-paid, RECLAIM was projected to result in increased employment opportunities for nearly every category relative to the command-and-control system.

Until the year 2000, prices of NOx RTCs were relatively stable between $1,500 and $3,000 an annual ton per day. In 2000, prices of NOx RTCs rose very quickly to over $45,000 a ton due to the increased demand for RTCs from electricity generating plants in response to the deregulated electricity generation market and limited installation of air pollution controls. In order to address the issues in the RECLAIM market, the Board removed large electricity generating plants from the market in May 2001. These electricity generating plants were required to file compliance plans for the installation of BARCT and restrictions were placed on the use and trade of their NOx RTCs. Other amendments to RECLAIM in 2001 included filing of compliance plans and forecast reports by large (at least 50 tons of NOx emissions) and medium (between 25 and 50 tons of NOx emissions) non-electricity generating facilities and the access to RECLAIM Air Quality Investment Program (AQIP), Mitigation Fee Program, and state Emission Credit Bank by

---

the low- and high-end of the range provided in the staff report.

[5] Inland Empire Energy Center and General Electric are considered as one facility, as the latter serves as a holding account for the former.

designated facilities. At the time, the Board also adopted several mobile and area source emission reduction credit rules whose credits could be used by RECLAIM facilities to comply with their allocations.

The annualized cost for installing controls on electricity generating facilities was projected to be $9 million. The annualized cost for the level 1 controls (known technologies at the time) on non-electricity generating facilities was estimated to be $26 million.[6] It was projected that 640 jobs would be forgone annually from the proposed controls, filing of compliance plans and forecast reports, the access to a reserve of NOx emission reductions, and the creation of mobile and area source credit rules.

In 2005, Regulation XX – RECLAIM was amended to achieve additional NOx reductions pursuant to the 2003 AQMP Control Measure #2003CMB-10. The proposed amendments also addressed requirements for demonstrating BARCT equivalency in accordance with H&SC §40440. In addition, trading restrictions for electricity generating producing facilities were removed.

4.1 Legislative Mandates

The socioeconomic assessments at the SCAQMD have evolved over time to reflect the benefits and costs of regulations. The legal mandates directly related to the assessment of the proposed rule include the SCAQMD Governing Board resolutions and various sections of the H&SC.

4.2 SCAQMD Governing Board Resolutions

On March 17, 1989 the SCAQMD Governing Board adopted a resolution that calls for an economic analysis of regulatory impacts that includes the following elements:

- Affected industries
- Range of control costs
- Cost effectiveness
- Public health benefits

On October 14, 1994, the Board passed a resolution which directed staff to address whether the rules or amendments brought to the Board for adoption are in the order of cost effectiveness as defined in the AQMP. The intent was to bring forth those rules that are most cost-effective first.

4.3 Health & Safety Code Requirements

The state legislature adopted legislation that reinforces and expands the Governing Board resolutions for socioeconomic assessments. H&SC §40440.8(a) and (b), which became effective on January 1, 1991, require that a socioeconomic analysis be prepared for any proposed rule or rule amendment that "will significantly affect air quality or emissions limitations." Specifically, the scope of the analysis should include:

[6] Specifically, Level 1 technologies included selective catalytic reduction (SCR) and low-NOx burner (LNB) controls on non-electricity generating turbines (SCR), internal combustion engines (SCR), boilers (LNB), heaters (ultra LNB), dryers (ultra LNB or LNB), ovens (LNB), furnaces (LNB or oxy-fuel), and afterburners (LNB).

- Type of affected industries
- Impact on employment and the economy of the district
- Emission reduction potential
- Necessity of adopting, amending or repealing the rule in order to attain state and federal ambient air quality standards
- Availability and cost effectiveness of alternatives to the rule

Additionally, the SCAQMD is required to actively consider the socioeconomic impacts of regulations and make a good faith effort to minimize adverse socioeconomic impacts. H&SC §40728.5, which became effective on January 1, 1992, requires the SCAQMD to:

- Examine the type of industries affected, including small businesses; and
- Consider socioeconomic impacts in rule adoption

Finally, H&SC §40920.6, which became effective on January 1, 1996, requires that incremental cost effectiveness be performed for a proposed rule or amendment that imposes BARCT or "all feasible measures" requirements relating to ozone, carbon monoxide (CO), oxides of sulfur (SOx), oxides of nitrogen (NOx), and their precursors.

Furthermore, H&SC §39616 (c)(1) and (c)(4) requires that at adoption, a market-based incentive program result in equivalent or less cost and not result in greater job losses or more significant shifts from high- to low-skilled jobs as compared with command-and- control measures. This finding was made in 1993 when RECLAIM was adopted and in 2000 when the findings were ratified.

Finally, H&SC §40440.5 requires that social, economic, and public health analyses of proposed rules be available to the public by at least 30 days prior to the hearing.

5. SHORT-TERM/LONG-TERM ECONOMIC OUTLOOK

According to the Wells Fargo Economic Forecast released on June 3, 2015, "California's economy should continue to outperform the national average over the next couple of years, led by continued gains in the state's technology sector and stronger growth in residential and commercial construction." Despite a whole host of challenges ranging from the drought to labor strikes at its major ports, California's economy has maintained strong momentum through the first part of 2015.

According to the 2015-2016 Economic Forecast and Industry Outlook from Los Angeles Economic Development Corporation (LAEDC), Southern California will continue employment gains and experience a decline in local unemployment rates. Southern California's leading industries are:

- Healthcare and Social Assistance
- Construction
- Professional, Scientific and Technical Services

- Administrative Support
- Waste Services

The lagging industries are other services, nondurable goods manufacturing, and financial activities.[7]

The economy of the four counties falling under the SCAQMD's jurisdiction is comprised of a large non-manufacturing sector and a much smaller manufacturing sector. The service sector and the retail and wholesale trade sector combined constituted over 52 percent of the region's employment in 2014 Regional Economic Models (REMI, 2014). Most of the affected RECLAIM facilities belong to manufacturing and utilities sectors. For these sectors, the California State University, Fullerton (CSUF) projected steady and positive employment growth in 2015 and 2016 for the counties of Orange, Riverside, and San Bernardino. Table 3 presents the projected annual percentage employment growth by sector for 2015 and 2016.

Table 3: Annual Percentage Employment Growth by Sector

Sector	Los Angeles			Orange			Riverside & San Bernardino			Southern California		
	2014	2015f	2016f	2014	2015f	2016f	2014	2015f	2016f	2014	2015f	2016f

Riverside & San Bernardino	12.0%	10.2%	8.8%	8.4%	8.3%

Source: CSUF 2015 Economic Forecast.

For the long-term economic outlook, all sectors of the local economy, except manufacturing, will experience a positive job growth.[8] The long-term growth is robust in construction, mining, transportation, and utilities sectors. The manufacturing sector is projected to incur a modest negative job growth from 2012-2022. Please see Appendix A for 10-year industry employment projections for the 4-county area.

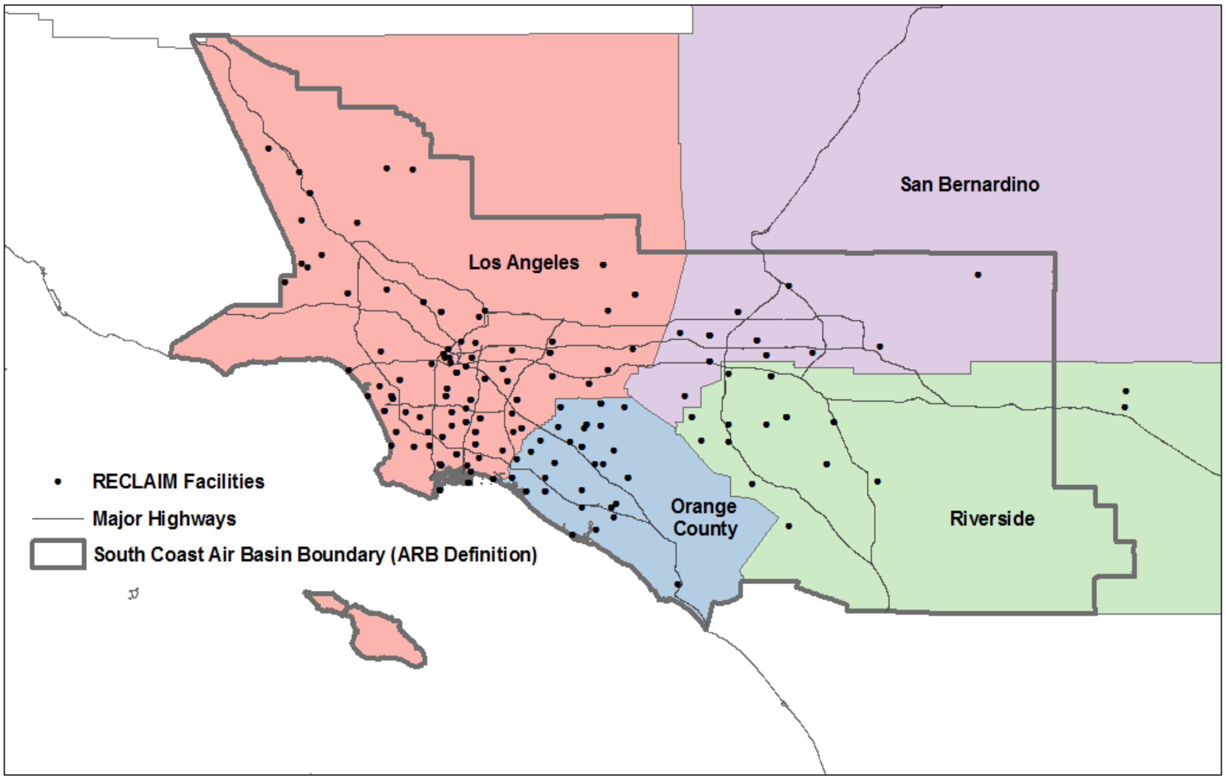
6. AFFECTED FACILITIES

The RECLAIM universe of facilities evolves due to shutdowns and the entry of new facilities. The RECLAIM program started with 392 NOx facilities in 1994 when RECLAIM went into effect. By the end of compliance year 2013, there were about 275 facilities in the NOx RECLAIM universe. Most of the RECLAIM facilities are relatively large emitting businesses (greater than 4 tons of NOx) with respect to their cohort in the same industry. These facilities are spread across all industries in the four-county economy. Of the 275 facilities, 66 percent were in Los Angeles County, 18 percent in Orange County, and 8 percent in both Riverside and San Bernardino Counties. Figure 1 shows the location of these facilities within the SCAQMD jurisdiction.[9]

[8] http://www.labormarketinfo.edd.ca.gov/data/employment-projections.html.

[9] While two facilities located in Desert Hot Springs fall outside the South Coast Air Basin Boundary as defined by the California Air Resources Board, Desert Hot Springs falls within the SCAQMD's jurisdiction for Riverside County. For more information see: http://www.aqmd.gov/home/about/jurisdiction.

Figure 1: Location of RECLAIM Facilities as of 2013



For the 275 facilities that are in the NOx RECLAIM program, the 14 tpd of NOx RTC reductions will only directly affect 56 facilities plus the investors that currently hold 90 percent of the NOx RTC credits. Out of the 56 facilities, 76 percent are in Los Angeles County, 4 percent in Orange County, 9 percent in Riverside County, and 11 percent in San Bernardino County.

They include 9 major refineries, 21 electricity generating facilities, and 26 other top-emitting non-refinery facilities. The 9 affected refineries belong to the sector of petroleum product manufacturing (NAICS 324), the 21 electricity generating facilities belong to the sector of utilities (NAICS 221), the remaining 26 facilities belong to the sectors of manufacturing (NAICS 31-33), mining, oil and gas exploration (NAICS 211), utilities (NAICS 221), amusement and recreation industries (NAICS 713), and a military facility.

For the remaining 219 facilities, no NOx RTC shave is proposed. Facilities in this group represent a range of industries, but are largely comprised of manufacturing (NAICS 31-33), mining, oil and gas exploration (NAICS 211), and utilities (NAICS 221) industries. Cost impacts on these facilities individually are expected to be small (if not zero). Any cost impacts that could potentially occur would be the result of any NOx RTC price increases due to the proposed amendments, and they are expected to be proportional to the amount of NOx RTCs currently needing to be purchased by these facilities.

6.1 Small Business

The SCAQMD defines a "small business" in Rule 102 for purposes of fees as one which employs 10 or fewer persons and which earns less than $500,000 in gross annual receipts. The SCAQMD also defines “small business” for the purpose of qualifying for access to services from the SCAQMD’s Small Business Assistance Office (SBAO) as a business with an annual receipt of $5 million or less, or with 100 or fewer employees. In addition to the SCAQMD's definition of a small business, the federal Small Business Administration (SBA) and the federal 1990 Clean Air Act Amendments (1990 CAAA) also provide definitions of a small business.

The 1990 CAAA classifies a business as a "small business stationary source" if it: (1) employs 100 or fewer employees, (2) does not emit more than 10 tons per year of either VOC or NOx, and (3) is a small business as defined by SBA. The SBA definitions of small businesses vary by six-digit NAICS codes. In general terms, a small business must have no more than 500 employees for most manufacturing and mining industries, and no more than $7 million in average annual receipts for most nonmanufacturing industries. For instance, the sector of petroleum refineries (NAICS 324110) has 1,500 employees as the threshold below which a business is considered small. The sector of utilities (NAICS 221111) has 500 to 1,000 employees as a threshold and non-metallic mineral products (NAICS 327213) which includes glass plants, has fewer than 750 employees as a threshold below which a business is considered small.

The 2015 Dun and Bradstreet data includes employment or gross revenue information for about half of the 275 facilities in the RECLAIM universe. According to the SCAQMD (Rule 102) definition of a small business, 11 facilities would be classified as small businesses. Under the 1990 CAAA definition, 26 facilities are considered small businesses. Based on SBA’s definition of a small business, 85 facilities would be small businesses.[10] For the 56 facilities affected by the shave and for which Dun and Bradstreet data is available, none are considered small businesses under either the SCAQMD or 1990 CAAA definitions. Twenty-two are considered small businesses under the SBA definition.[11]

7. COST OF BARCT INSTALLATION

This section estimates the total cost of BARCT installation. However, it should be noted that a RECLAIM facility is expected to retrofit an emission source only when it meets both of the following conditions: first, it does not hold sufficient RTCs to offset facility-wide emissions at the end of the compliance period; second, the cost of control installation per ton of emission reduction is lower than the expected average RTC price over the life of the control equipment. Even if a facility finds it more cost-effective to install pollution control equipment, it still would not incur the full cost of control installation if control installation results in surplus RTCs that the facility eventually sells to offset the control installation cost. Therefore, the compliance cost estimated in this section should be considered as the most conservative (i.e., maximum) estimate of the overall

[10] See the SBA website (http://www.sba.gov/community/blogs/community-blogs/small-business- matters/what-small-business-what-you-need-know-and-wh).The latest SBA definition of small businesses by industry can be found at http://www.sba.gov/content/table-small-business-size-standards.

[11] In order to reconcile discrepancies in Dunn & Bradstreet employment figures, estimates were acquired from SCAQMD Engineering & Compliance (RECLAIM Audit) permit data where applicable.

compliance cost for the proposed shave that will be needed to achieve the BARCT-equivalent level of NOx emission reductions.

Based on the BARCT analysis detailed in the Revised Draft Staff Report, the total compliance cost for BARCT installation would be potentially incurred by the 9 refineries and 11 non-refineries that have sources/equipment that can be upgraded to the 2015 BARCT level (for more detailed information on methodology and assumptions used, please see the Staff Report).Table 5 presents the estimated number of upgradable control devices at the 20 facilities per equipment/source category.

Under the proposed amendments, the 9 refineries would have the flexibility of changing operations, holding sufficient RTCs, or installing Selective Catalytic Reduction (SCR) technology, UltraCat Dry Gas Scrubbers (DGS), and Low Temperature Oxidation (LoTOxTM) with Wet Gas Scrubbers (WGS) to reduce NOx emissions coming from FCCUs, Sulfur Recovery Units/Tail Gas Incinerators (SRU/TGUs), coke calciner, refinery boilers and heaters, and refinery gas turbines.

The 11 non-refinery facilities currently have the following equipment/source categories: container glass melting furnaces, glass melting furnace facilities, sodium silicate furnaces, metal heat treating furnaces (rated greater than 150 mmBtu/hour), stationary ICEs and non- electricity generating facility stationary gas turbines. Under the proposed amendments, operators of these facilities would have the flexibility of changing operations, holding sufficient RTCs, or installing SCR technology or UltraCat DGS to reduce NOx emissions. For the purpose of conducting a worst-case analysis, 34 SCR units and 1 UltraCat DGS are assumed to be installed at the 11 non-refinery affected facilities. It is possible that another UltraCat DGS may also be installed in lieu of 1 of the 34 SCR units.

In total, the proposed project is assumed to result in the installation of the following new NOx air pollution control equipment: 116 SCRs, 8 LoTOxTM with WGSs, 1 LoTOxTM without WGS, and 3 UltraCat DGSs.

Table 5: Estimated Number of NOx Control Devices per Sector and Equipment/Source Category

Sector	Equipment/Source Category	Number of Affected Facilities	Estimated Number of Control Devices
Refinery	Fluid Catalytic Cracking Units (FCCUs)	5	3 SCRs 2 LoTOx™ with WGSs 1 LoTOx™ without WGS
Refinery	Refinery Process Heaters and Boilers	8	73 SCRs
Refinery	Refinery Gas Turbines	5	7 SCRs + Add Catalysts to 4 SCRs
Refinery	Sulfur Recovery Unit / Tail Gas Units (SRU/TGUs)	4	5 LoTOx™ with WGSs and 1 SCR**
Refinery	Petroleum Coke Calciner	1	1 UltraCat DGS or LoTOx™ ***
Non-Refinery	Container Glass Melting Furnaces	1	2 SCR or 1 UltraCat DGS
Non-Refinery	Sodium Silicate Furnaces	1	1 SCR or 1 UltraCat DGS

Sector	Equipment/Source Category	Number of Affected Facilities	Estimated Number of Control Devices
Non-Refinery	Metal Heat Treating Furnaces	1	1 SCR
Non-Refinery	Internal Combustion Engines (Non-Refinery/Non-Electricity Generating)	3	16 SCRs
Non-Refinery	Turbines (Non-Refinery/ Non-Electricity Generating)	7	13 SCRs and 1 SCR replacement
		TOTAL	**116 SCRs** **8 LoTOx™ with WGSs** **1 LoTOx™ without WGS** **3 UltraCat DGSs**

Under the assumption that all BARCT control devices listed above would be installed, an assumed implementation schedule was developed based on the required construction time (Table 6) and cost-effectiveness of control equipment (Table 7), which would ensure the achievement of projected emission reductions in 2018 and 2022. To the extent possible, it was assumed that the most cost-effective NOx control equipment would be installed or modified first, taking into account unit turnaround schedule information available to staff at this time. Table 8 summarizes the assumed implementation schedule.

Table 6: Construction Time by Source Category and Control Equipment

Non-Refinery		
Source Category	**Control Equipment**	**Required Time**
Sodium Silicate Furnace	SCR	2 years
ICE Engines	SCR	2 years
Container Glass Furnace	SCR/UltraCat DGS	2 years
Gas Turbines	SCR	2 years
Metal Heat Treating Furnace >150mmBtu/hr	SCR	2 years
Refinery		
Source Category	**Control Equipment**	**Required Time**
Refinery FCCU	SCR/ LoTOx™	3 Years
Coke Calciner	LoTOx™ /UltraCat DGS	3 Years
Boilers/Heaters	SCR	3 Years
Gas Turbines	SCR	2-3 years
SRU/TGs	SCR/ LoTOx™	3 Years

The cost estimates in this analysis are based on the combined estimates provided by SCAQMD consultants and staff for each affected facility. In addition, when applicable, the assumptions applied in the previous CEQA documents were used which analyzed similar equipment in both the 2005 amendments to NOx RECLAIM and the 2010 amendments to SOx RECLAIM.[12] Further, if a particular technology was identified as having a cost that exceeds $50,000 per ton for a particular facility, staff did not include that equipment as having feasible BARCT controls or emission reduction potential in the analysis. This is consistent with past practice for proposed RECLAIM amendments.

Table 7: Distribution of Control Equipment by Equipment Category and by Cost-Effectiveness

Equipment Category	Average DCF $/ton	Average LCF $/ton
Refinery Gas Turbine	$2,046	$3,250
Metal Heat Treating Furnace >150mmBtu/hr	$3,400	$5,500
Sodium Silicate Furnace	$4,750	$7,600
Glass Melting Furnace	$5,950	$9,450
Non-Refinery ICE Engine	$6,000	$9,600
Refinery FCCU	$8,200	$14,300
Non-Refinery Gas Turbine	$20,300	$32,500
Coke Calciner	$23,500	$38,000
Refinery Boiler/Heater	$28,000	$45,000
SRU/TG	$34,000	$56,000
Average	**$13,615**	**$22,120**

* DCF stands for Discounted Cash Flow and LCF stands for Levelized Cash Flow.
** Each of the cost-effective values in this table corresponds to the midpoint of the cost-effectiveness ranges reported in the Revised Draft Staff Report.

[12] Staff has met with three refineries who provided varying levels of detail regarding their projected costs that would occur for these facilities to comply with the proposed amendments. There is not sufficient information for staff to verify the WSPA cost estimates. Some of the difference related to staff using an incremental cost-effectiveness calculation, which assumes that 2005 BARCT levels are in place, which may or may not be the case for individual facilities, but is needed for a programmatic evaluation. The individual facilities include total costs, and often include full costs for additional equipment such as substations that may support the new control equipment, as well as other operations at the facility.

[13] In 1987, SCAQMD staff began to calculate cost-effectiveness of control measures and rules using the Discounted Cash Flow method with a discount rate of 4 percent. Although not formally documented, the discount rate is based on the 1987 real interest rate on 10-year Treasury Notes and Bonds, which was 3.8 percent. The maturity of 10 years was chosen because a typical control equipment life is 10 years; however, a longer equipment life would not have corresponded to a much higher rate-- the 1987 real interest rate on 30-year Treasury Notes and Bonds was 4.4 percent. Since 1987, the 4 percent discount rate has been used by SCAQMD staff for all cost-effectiveness calculations, including BACT analysis, for the purpose of consistency. The compliance cost reported in this assessment was thus annualized using a real interest rate of 4 percent. As a sensitivity test, a real interest rate of 1 percent was also used, which is closer to the prevailing real interest rate (see https://www.whitehouse.gov/omb/circulars_a094/a94_appx-c/).

As shown in Table 9, more expensive controls would not be installed until the 2019- 2022 timeframe. Based on this schedule and facility-specific estimates, the average annualized cost of the proposed amendments is estimated to be approximately $70 million (at 4 percent discount rate) or $60 million (at 1 percent discount rate) from year 2022 onwards when all controls are assumed to have been installed. More than 73 percent of the annualized compliance cost is expected to occur in the refinery sector, and more than 43 percent of the sector's annualized compliance cost would be associated with FCCU installation. Among the non-refinery sectors, gas turbines would account for more than 60 percent of the sector's annualized compliance cost.

Table 10 presents the annual compliance cost of full BARCT implementation by industry. Refineries (NAICS 324) would incur the majority of the compliance costs. Among the non- refinery sectors, glass melting furnaces, sodium silicate furnaces and metal heat treating furnaces belong to nonmetallic mineral product manufacturing (NAICS 327), chemical manufacturing (NAICS 325), and primary metal manufacturing (NAICS 311) sectors. Gas turbines were used in airport operations (NAICS 488), oil and gas extraction (NAICS 211), and paper manufacturing (NAICS 322) sectors. Internal Combustion Engines (ICE) engines were used in the utilities sector (NAICS 221).

7.1 BARCT Cost Estimates for the Refinery Sector

There are 9 refinery facilities subject to the NOx RECLAIM rules whose operators may choose to install NOx air pollution control equipment in response to the proposed RTC shave. These facilities include the 6 refineries owned by 5 companies operating FCCUs, refinery boilers and heaters, refinery gas turbines, and SRU/TGUs.

As discussed previously, the 9 refineries may choose among changing operations, obtaining sufficient RTC holdings, and installing NOx control devices, presumably based on which option would be more economical. The analysis herein assumes that the 9 refineries would install BARCT controls under the proposed amendments, a scenario representing the maximum potential cost.

As a conservative approach to cost estimation, the most stringent controls with the high- end cost (worst case scenarios) are assumed for the proposed amendments as well as for the CEQA alternatives. In total, 84 SCR units, 6 LoTOxTM with WGSs, 1 LoTOxTM without WGS, and 1 UltraCat DGS are assumed to be installed at the 9 refinery sector facilities. In order to operate SCR and UltraCat DGS, ammonia is necessary and, as such, tanks to store ammonia would also need to be installed. The size of each ammonia tank needed to operate the SCR units and 1 UltraCat DGS have been estimated to range between 2,000 and 11,000 gallons in capacity. For a full description of the control technologies, please see the CEQA NOx Control Technologies section.

7.1.1 Refinery FCCUs

The purpose of an FCCU at a refinery is to convert or "crack" heavy oils (hydrocarbons), with the assistance of a catalyst, into gasoline and lighter petroleum products. Each FCCU consists of three main components: a reaction chamber, a catalyst regenerator and a fractionator. There are 5 refineries that operate 6 FCCUs in the SCAQMD. The FCCUs are classified as major sources of emissions in RECLAIM, and as such, the NOx emissions from FCCUs are required to be monitored with a continuous emission monitoring system (CEMS), and reported on a daily basis electronically to the SCAQMD.

To further reduce NOx emissions from a FCCU (beyond what is currently being achieved through the use of NOx reducing additives), the potential available control technologies are either: 1) SCR; or, 2) LoTOxTM with WGS.

Two out of the 5 affected refineries are assumed to install SCRs and the remaining 3 are assumed to install LoTOxTM with WGS. The total compliance cost of the proposed amendments for refinery FCCUs includes one-time cost and recurring cost. The one-time cost includes the capital cost of SCRs and LoTOxTM with WGS and their installations (demolition, concrete, structural, piping, electrical, contractors, contingencies).

The capital cost and installation of the 2 SCRs are estimated at $30 and $48.3 million, respectively. Based on vendor–supplied costs and the assumptions made in staff's engineering analyses, the capital cost and installation of the 3 LoTOxTM with WGSs are estimated at $33.47, $54.89, and $60.62 million, respectively. Assuming a 25-year life[14] for equipment and installation, and a real interest rate of 4 percent, the total one-time annualized cost of compliance for the refinery FCCUs would sum up to $14.53 million.

The annual operating costs for the 2 SCR units include utilities (electricity), ammonia, catalyst

[14] Although the Bay Area AQMD and EPA OAQPS assume an SCR lifespan of 20 years, staff assumed a 25-year equipment life for SCRs to be installed based on the profiles of SCRs used by refineries in the Basin. Nearly 30 percent of the refinery combustion equipment in the Basin has SCRs that were installed more than 25 years ago, and more than 60 percent of the refinery combustion equipment has SCRs that were installed more than 20 years ago. These units are still in operation and thus support the assumption of a 25-year useful life in the cost analysis.

replacement (every 5 years), and other periodic maintenance. The annual operating cost for each SCR unit is estimated at $0.12 and $0.19 million, respectively. The catalyst replacement costs for each SCR unit is estimated at $1.5 million and $2.4 million, respectively. Staff used data provided in the 2005 SOx RECLAIM amendments for the annual costs associated with the WGS and manufacturer's data for the annual costs associated with the LoTOxTM with WGS portion of the system. The annual operating costs for the 3 LoTOxTM with WGSs units include utilities (electricity), ammonia/caustic, waste water, and other periodic maintenance. The annual operating cost for each LoTOxTM with WGS unit is estimated at $2.4 and $3.5, and $3.9 million, respectively. The total annualized operating and maintenance costs for the 2 SCRs and 3LoTOxTM with WGS units would sum up to about $10.7 million.[15] Summing up the capital, operating, and maintenance costs, total annualized cost of compliance for the FCCU units would amount to $25 million using a 4 percent discount rate.

Table 11: Total Capital, Installation, and Annual Operating Cost of SCRs/LoTOx™ for Refineries FCCUs (Millions of 2014 dollars, present value)

Refinery	Equipment Cost	Installation Cost	Total O&M Cost	Electricity/ Water	Ammonia/ Caustic	Catalyst*
5	$7.5	$22.5	$0.12	$0.036	$0.084	$1.5
6	$12.0	$36.0	$0.192	$0.058	$0.134	$2.4

*Total cost recurring every 5 years

7.1.2 Refinery Process Heaters and Boilers

Refinery process heaters and boilers are used extensively throughout various processes in refinery operations such as distillation, hydrotreating, fluid catalytic cracking, alkylation, reforming, and delayed coking. There are 23 boilers and 189 heaters in the refineries classified as major or large NOx sources. The refinery heaters and boilers primarily burn refinery gas which is generated at the refinery. Most of these boilers and heaters use natural gas as back-up or supplemental fuel.

For the purpose of the analysis, controlling NOx emissions from refinery boilers and process heaters was assumed to be accomplished with SCR technology. It was assumed that 8 refineries would

[15] The total O&M cost in Table 11 is the sum of annual electricity/water, ammonia/caustic and annualized cost of the catalyst.

install 73 SCR units. Based on the vendor–supplied costs and the assumptions made in staff's engineering analyses, the total capital, installation, and operating costs of each SCR is presented in the table below. It should be noted that the annual operating costs were distributed among electricity, ammonia, annual catalyst replacement, and other annual maintenance.

Assuming a 25-year life for equipment and installation, and a real interest rate of 4 percent, the total one-time annualized cost of compliance of 73 SCR installations for the refinery boilers and heaters is estimated at $15.02 million. The total annual operating and maintenance costs for the 73 SCR units are estimated at $0.15 million.[16] Summing up the capital, operating, and maintenance costs, total annualized cost of compliance for the boilers and heaters would amount to $15 million using a 4 percent discount rate. Table 12 presents the detailed costs per refinery.

Table 12: Total Capital, Installation, and Annual Operating Cost of SCRs for Refineries Process Heaters and Boilers (Millions of 2014 dollars, present value)

Refinery	Equipment Cost	Installation Cost	Total O&M in $1,000	Electricity/Water	Ammonia/Caustic	Catalyst	Other Maintenance
1	$7.36	$25.80	$21.44	$6.43	$8.58	$4.29	$2.14
3	$0.44	$1.54	$1.28	$0.38	$0.51	$0.26	$0.13
4	$4.51	$15.79	$13.12	$3.94	$5.25	$2.62	$1.31

6	$11.32	$39.67	$32.97	$9.89	$13.19	$6.59	$3.30
7	$7.80	$27.34	$22.72	$6.82	$9.09	$4.54	$2.27
8	$3.85	$13.48	$11.20	$3.36	$4.48	$2.24	$1.12
9	$5.93	$20.80	$17.28	$5.18	$6.91	$3.46	$1.73
Total	**$52.08**	**$182.54**	**$151**	**$45.51**	**$60.68**	**$30.34**	**$15.17**

7.1.3 Refinery Gas Turbines

Gas turbines are used in refineries to produce both electricity and steam. Refinery gas turbines are typically combined cycle units that use 2 work cycles from the same shift operation. There are a total of 21 gas turbines/duct burners classified as major NOx sources at the refineries in the SCAQMD. Collectively, the 21 gas turbines/duct burners emitted about 1.33 tpd of NOx in 2011.

For the purpose of the analysis, controlling NOx emissions from refinery gas turbines was assumed to be accomplished with SCR technology. A total of 5 refineries are affected in this category. Refinery 1 is assumed to add catalyst to existing SCRs and the remaining 4 refineries are assumed to install SCRs: Refinery 4 (2 SCRs), Refinery 3 (3 SCRs), Refinery 6 and 7 each to install 1 SCR.

Based on vendor–supplied costs and the assumptions made in staff's engineering analyses, the total capital, installation, and operating costs of each SCR is presented in the table below. It should be

[16] The total O&M cost in Table 12 is the sum of annual electricity/water, ammonia/caustic, annual cost of the catalyst, and other maintenances.

noted that the annual operating costs were distributed among electricity, ammonia, annual catalyst replacement, and other annual maintenance. Assuming a 25-year life for equipment and installation, and a real interest rate of 4 percent, the total one-time annualized cost of compliance of the SCRs installations for the refinery gas turbines is estimated at $1 million. The total annual operating and maintenance costs of SCR units are estimated at $5.25 million.[17] Summing up the capital, operating, and maintenance costs, total annualized cost of compliance for the gas turbines would amount to $6 million using a 4 percent discount rate. Table 13 presents the detailed costs per refinery.

Table 13: Total Capital, Installation, and Annual Operating Cost of SCRs for Refineries Gas Turbines (Millions of 2014 dollars, present value)

Refinery	Equipment Cost	Installation Cost	Total O&M Cost	Electricity/ Water	Ammonia /Caustic	Catalyst	Other Maintenances
1	$0.77	$2.30	$1.03	$0.31	$0.41	$0.21	$0.10
4	$0.71	$2.14	$0.96	$0.29	$0.38	$0.19	$0.09
5	$1.51	$4.54	$2.03	$0.61	$0.81	$0.41	$0.20
6	$0.29	$0.86	$0.39	$0.12	$0.15	$0.08	$0.04
7	$0.63	$1.89	$0.85	$0.25	$0.34	$0.17	$0.09
Total	**$3.91**	**$11.73**	**$5.25**	**$1.58**	**$2.09**	**$1.06**	**$0.52**

7.1.4 Sulfur Recovery Units and Tail Gas Units (SRU/TGUs)

Refinery SRU/TGUs, including their incinerators, are classified as major sources of both NOx and SOx emissions. Because sulfur is a naturally occurring and undesirable component of crude oil, refineries employ a sulfur recovery system to maximize sulfur removal. The type of NOx control option to be utilized in response to this portion of the proposed project is assumed to be LoTOxTM technology with a WGS or SCR. Three refineries are assumed to install 1 LoToxTM with WGS each and 1refinery is assumed to install 2 LoTOxTM with WGS and 1 SCR.

Based on vendor–supplied costs and the assumptions made in staff's engineering analyses, the total capital, installation, and operating costs of LoTOxTM with WGS and SCR are presented in the table below. It should be noted that the annual operating costs were distributed among electricity, ammonia/caustic, waste water, annual catalyst replacement, and other annual maintenance.

Assuming a 25-year life for equipment and installation, and a real interest rate of 4 percent, the total one-time annualized cost of compliance of the LoTOxTM with WGS and SCR installations for the refinery SRU/TGUs is estimated at $6.2 million. The total annual operating and maintenance costs

[17] The total O&M cost in Table 13 is the sum of annual electricity/water, ammonia/caustic, annual cost of the catalyst, and other maintenances.

are estimated at $0.57 million.[18] Summing up the capital, operating, and maintenance costs, total annualized cost of compliance for the gas turbines would amount to $7 million using a 4 percent discount rate. Table 14 presents the detailed costs per refinery.

Table 14: Total Capital, Installation, and Annual Operating Cost of Sulfur Recovery Units and Tail Gas Units (SRU/TGUs) (Millions of 2014 dollars, present value)

Refinery	Equipment Cost	Installation Cost	Total O&M Cost	Electricity/ Water	Ammonia/ Caustic	Waste Water	Other Maintenance
1	$4.52	$15.82	$0.15	$0.07	$0.06	$0.01	$0.01
5	$7.91	$27.68	$0.14	$0.07	$0.05	$0.01*	$0.01
6	$4.57	$15.99	$0.13	$0.07	$0.05	$0.01	$0.01
8	$4.52	$15.82	$0.15	$0.07	$0.06	$0.01	$0.01

***** Refinery 5 cost estimates for annual cost of catalyst

7.1.5 Petroleum Coke Calciner

Petroleum coke is the heaviest portion of crude oil which cannot be recovered in the normal oil refining process. Instead, it is processed in a delayed coker unit to generate a carbonaceous solid referred to as "green coke," a commodity. To improve the quality of the product, it is sent to a calciner to make calcined petroleum coke.

There are two commercially available multi-pollutant control technologies for the low temperature removal of NOx emissions from the coke calciner: 1) LoTOxTM with scrubber; and, 2) UltraCat DGS. The type of NOx control option to be utilized for the coke calciner in response to the proposed amendments would depend on the facility's individual operations and the current control technologies and techniques in place. For the purpose of the socioeconomic analysis, 1 refinery is assumed to control NOx emissions from a coke calciner with UltraCat DGS. It should be noted that the annual operating costs were distributed among electricity, ammonia, waste water, annual catalyst replacement, and other annual maintenance.

Based on vendor–supplied costs and the assumptions made in staff's engineering analyses, the total capital and installation of LoTOxTM with UltraCat DGS is estimated at $50.84 million. Assuming a 25-year life for equipment and installation, and a real interest rate of 4 percent, the total one-time annualized cost of compliance of 1 UltraCat DGS is estimated at $3.25 million. The total annual operating and maintenance costs are estimated at $2.58 million. Summing up the capital, operating, and maintenance costs, total annualized cost of compliance for the coke calciner would amount to

[18] The total O&M cost in Table 14 is the sum of annual electricity/water, ammonia/caustic, waste water, and other maintenances.

$6 million using a 4 percent discount rate.

7.2 BARCT Cost Estimates for the Non-Refinery Sector

In addition to the 9 refineries, 11 non-refinery facilities also operate with equipment that can be further controlled to meet 2015 BARCT levels. They include 1 container glass manufacturing plant, 1 sodium silicate manufacturing plant, 1 steel plant operating 2 metal heat treating furnaces rated greater than 150 mmBtu/hr, 7 facilities operating gas turbines, and 3 facilities operating ICEs. The analysis herein assumes that the 11 non-refinery facilities would choose to install BARCT controls under the proposed amendments, the maximum potential compliance cost scenario.

As a conservative approach to cost estimation, the most stringent controls with the high- end cost (worst case scenarios) are assumed for the proposed amendments as well as for the CEQA alternatives. In total, 34 SCR units and 1 UltraCat DGS are assumed to be installed at these facilities.

7.2.1 Container Glass Melting Furnaces

A container glass melting furnace is the main equipment used for manufacturing glass products, such as bottles, glassware, pressed and blown glass, tempered glass, and safety glass. In the NOx RECLAIM program there is 1 facility among the top NOx emitting facilities that operates glass melting furnaces. This facility produces container glass from dry, solid raw materials that are melted in the furnaces and then formed into glass container bottles.

To effectively reduce NOx emissions from this category, staff assumed the affected facility would chose to install 2 Tri-Mer UltraCat Systems for treating the flue gas of glass melting furnaces. Based on vendor–supplied costs and the assumptions made in staff's engineering analyses, the total capital and installation of 2 Tri-Mer UltraCat Systems is estimated at
$5.68 million. Assuming a 25-year life for equipment and installation, and a real interest rate of 4 percent, the total one-time annualized cost of compliance of 2 UltraCat DGS is estimated at $0.36 million. The total annual operating and maintenance costs are estimated at $0.67 million. The annual operating costs were distributed among electricity, ammonia and sorbent, waste water, waste disposal, annual catalyst replacement, and other annul maintenance. The total annualized cost of compliance for the container glass melting furnace including capital, operating, and maintenance, is estimated to be $1.03 million.

7.2.2 Sodium Silicate Furnace

In the NOx RECLAIM program, there is only 1 facility that produces sodium silicate in a melting furnace. NOx emissions are also created from combusting fuel needed to heat the furnace. To effectively achieve the largest reduction of NOx emissions, it was assumed that the affected facility would choose to install 1 UltraCat DGS.

Based on vendor–supplied costs and the assumptions made in staff's engineering analyses, the total capital and installation costs of 1 UltraCat DGS is estimated at $2 million. Assuming a 25-year life for equipment and installation, and a real interest rate of 4 percent, the total one-time annualized cost of 1 UltraCat DGS is estimated at $0.13 million. The total annual operating and maintenance costs are estimated at $0.17 million. The annual operating costs were distributed among electricity, ammonia, waste water, waste disposal, annual catalyst replacement, and other annual maintenance. Summing up the capital, operating, and maintenance costs, total annualized cost of compliance for the container glass melting furnace would amount to $300,000 using a 4 percent discount rate.

7.2.3 Metal Heat Treating Furnaces

A metal melting furnace burns liquid or gaseous fuel to generate enough pre-heated air at a temperature high enough to melt solid metal into a liquid molten consistency and to maintain the metal in a liquid state until it is ready for later use. Among the top NOx emitting facilities in the NOx RECLAIM program, there is only 1 facility that processes steel in 2 metal heat furnaces with individual heat ratings above 150 mmBtu/hr. To effectively achieve a substantial NOx reduction from these metal heat treating furnaces, SCR is the technology that is best suited for the flue gas treatment of NOx. As a result, it was assumed that the operator of the affected facility would chose to install 1 SCR system.

Based on vendor–supplied costs and the assumptions made in staff's engineering analyses, the total capital and installation of 1 SCR is estimated at $2.80 million. Assuming a 25- year life for equipment and installation, and a real interest rate of 4 percent, the total one- time annualized compliance cost is estimated at $0.18 million. The total annual operating and maintenance costs are estimated at $0.44 million. The annual operating costs were distributed among electricity, ammonia, annual catalyst replacement, and other annual maintenance. Summing up the capital, operating, and maintenance costs, total annualized cost of compliance for the metal melting furnace would amount to $600,000 using a 4 percent discount rate.

7.2.4 Gas Turbines (Non-Refinery/Non-Electricity Generating Plant)

Stationary gas turbines are used primarily to drive compressors or to generate electricity. Among the top non-electricity generating facility NOx emitting facilities in the RECLAIM universe, there are 20 gas turbines that are either major or large source units. For the purpose of the analysis, controlling NOx emissions from the 4 non-refinery/non-electricity generating facility gas turbines is assumed to be accomplished with SCR technology.

Based on vendor–supplied costs and the assumptions made in staff's engineering analyses, the total capital, installation, and operating costs of 14 SCRs for the 7 affected facilities are presented in the table below. It should be noted that the annual operating costs were distributed among electricity, ammonia and annual catalyst replacement. Assuming a 25- year life for equipment and installation, and a real interest rate of 4 percent, the total one- time annualized cost of compliance of 14 SCRs is estimated at $2.02 million. The total annual operating cost of these 14 SCRs is estimated at $4.94 million.[19] Summing up the capital, operating, and maintenance costs, total annualized cost of compliance for the gas turbines would amount to $7 million using a 4 percent discount rate. Table 15 presents the detailed costs per facility.

[19] The total O&M cost in Table 15 is the sum of annual electricity, ammonia/urea, and annual cost of catalyst.

Table 15: Total Capital, Installation, and Annual Operating Cost of SCRs for Non-Electricity generating facilities Gas Turbines (Millions of 2014 dollars, present value)

Facility	Equipment Cost	Installation Cost	Total O&M Cost	Electricity	Ammonia /Urea	Catalyst
1	$2.81	$5.62	$2.12	$0.41	$1.34	$0.37
2	$2.03	$4.06	$0.27	$0.08	$0.15	$0.03
3	$0.77	$1.55	$0.44	$0.02	$0.32	$0.10
4	$0.96	$1.92	$0.17	$0.04	$0.09	$0.04
5	$0.92	$1.84	$0.56	$0.02	$0.35	$0.19
6	$1.62	$3.25	$0.79	$0.27	$0.29	$0.23
7	$1.40	$2.81	$0.6	$0.2	$0.2	$0.2
Total	**$10.51**	**$21.05**	**$4.95**	**$1.04**	**$2.74**	**$1.16**

7.2.5 Internal Combustion Engines (Non-Refinery/Non-Electricity Generating Facility)

Stationary Internal Combustion Engines (ICEs) are used primarily to drive pumps, compressors, or to generate electricity. For the purpose of the analysis, controlling NOx emissions from this category is assumed to be accomplished with SCR technology.

Based on vendor–supplied costs and the assumptions made in staff's engineering analyses, the total capital, installation, and operating costs of 16 SCRs for the 3 affected facilities are presented in the table below. It should be noted that the annual operating costs were distributed among electricity, ammonia and annual catalyst replacement. Assuming a 25- year life for equipment and installation, and a real interest rate of 4 percent, the total one- time annualized cost of compliance of 16 SCRs is estimated at $1.38 million. The total annual and operating costs of these 16 SCRs is estimated at $0.99 million.[20] Summing up the capital, operating, and maintenance costs, total annualized cost of compliance for the ICEs would amount to $2 million using a 4-percent discount rate. Table 16 presents the detailed costs per facility.

[20] The total O&M cost in Table 16 is the sum of annual electricity, ammonia/urea, annual cost of catalyst, and other maintenances.

Table 16: Total Capital, Installation, and Annual Operating Cost of SCRs for Non- Electricity generating facilities ICE Engines (Millions of 2014 dollars, present value)

Facility	Equipment Cost	Installation Cost	Total O&M Cost	Electricity	Ammonia /Urea	Catalyst	Other Maintenances
1	$0.53	$3.93	$0.18	$0.005	$0.08	$0.08	$0.02
2	$0.68	$4.78	$0.31	$0.004	$0.07	$0.22	$0.02
3	$0.80	$10.80	$0.50	$0.01	$0.21	$0.22	$0.06
Total	**$2.01**	**$19.51**	**$0.99**	**$0.02**	**$0.36**	**$0.52**	**$0.10**

8. MACROECONOMIC IMPACTS ON REGIONAL ECONOMY

The Regional Economic Model (REMI, PI+ v1.7.2) (PI+ v1.7.2) was used to assess the total socioeconomic impacts of a policy change (i.e., the proposed rule). The model links the economic activities in the counties of Los Angeles, Orange, Riverside, and San Bernardino, and for each county, it is comprised of five interrelated blocks: (1) output and demand, (2) labor and capital, (3) population and labor force, (4) wages, prices and costs, and (5) market shares.[21]

8.1 Impact of Proposed Amendments

The assessment herein is performed relative to a baseline ("business as usual") where the proposed amendments would not be implemented. The proposed amendments are assumed to induce full BARCT installation at the 9 refineries and 11 non-refinery facilities, which would create a policy scenario under which the affected facilities would incur a total annual compliance cost of approximately $70 million when evaluated at a 4 percent discount rate, or $60 million when evaluated at a 1 percent discount rate from year 2022 onwards when all controls are assumed to have been installed. It is assumed that the 20 facilities would finance the capital and installation costs of control equipment, or more specifically, these one-time costs are assumed to be amortized and incurred over the equipment life.

Direct effects of the proposed amendments are used as inputs to the REMI model in order for the model to assess secondary and induced impacts for all the industries in the four- county economy on an annual basis and across a user-defined horizon: 2018 (first year of assumed BARCT implementation) to 2035, and a sensitivity analysis was conducted that extends the horizon to

[21] Within each county, producers are made up of 66 private non-farm industries, three government sectors, and a farm sector. Trade flows are captured between sectors as well as across the four counties and the rest of U.S. Market shares of industries are dependent upon their product prices, access to production inputs, and local infrastructure. The demographic/migration component has 160 age/gender/race/ethnicity cohorts and captures population changes in births, deaths, and migration. (For details, please refer to REMI online documentation at http://www.remi.com/products/pi.)

2043. Direct effects of the proposed amendments include additional costs to the 20 facilities that would install control equipment and additional sales, by local vendors, of equipment, devices, or services that would meet the proposed requirements. Whereas all the compliance expenditures that are incurred by the affected facilities would increase their cost of doing business, the purchase of additional control equipment such as SCR, LoTOxTM, UltraCat DGS, and equipment installation would increase the spending and sales of businesses in various sectors, some of which may be located in the SCAQMD region. Table 17 lists the industry sectors modeled in REMI that would either incur cost or benefit from the compliance expenditures.

Table 17: Industries Incurring *vs.* Benefitting from Compliance Costs/Spending

Source of Compliance Costs	REMI Industries Incurring Compliance Costs (NAICS)	REMI Industries Benefitting from Compliance Spending (NAICS)
Installation of SCR, LoTOx™, UltraCat DGS	Refinery (NAICS 324), Manufacturing (NAICS 331), Utilities (NAICS 221), Chemical Manufacturing (NAICS 325), Nonmetallic Mineral Product Manufacturing (NAICS 327), Oil and Gas Extraction (NAICS 211), and Support Activities for Transportation (NAICS 488)	*One-time-Capital:* Machinery Manufacturing (NAICS 333)
Installation of SCR, LoTOx™, UltraCat DGS	Refinery (NAICS 324), Manufacturing (NAICS 331), Utilities (NAICS 221), Chemical Manufacturing (NAICS 325), Nonmetallic Mineral Product Manufacturing (NAICS 327), Oil and Gas Extraction (NAICS 211), and Support Activities for Transportation (NAICS 488)	*One-time-Capital:* Construction (236)
Operating and Maintenance Cost of SCR, LoTOx™, UltraCat DGS	Refinery (NAICS 324), Manufacturing (NAICS 331), Utilities (NAICS 221), Chemical Manufacturing (NAICS 325), Nonmetallic Mineral Product Manufacturing (NAICS 327), Oil and Gas Extraction (NAICS 211), and Support Activities for Transportation (NAICS 488)	*Recurring:* Professional, Scientific, and Technical Services (541)
Other Operating and Maintenance Costs: Electricity, Water	Refinery (NAICS 324), Manufacturing (NAICS 331), Utilities (NAICS 221), Chemical Manufacturing (NAICS 325), Nonmetallic Mineral Product Manufacturing (NAICS 327), Oil and	*Recurring:* Utilities (221)

Source of Compliance Costs	REMI Industries Incurring Compliance Costs (NAICS)	REMI Industries Benefitting from Compliance Spending (NAICS)
	Gas Extraction (NAICS 211), and Support Activities for Transportation (NAICS 488)	
Other Operating and Maintenance Costs: Ammonia, Caustic, Oxygen	Refinery (NAICS 324), Manufacturing (NAICS 331), Utilities (NAICS 221), Chemical Manufacturing (NAICS 325), Nonmetallic Mineral Product Manufacturing (NAICS 327), Oil and Gas Extraction (NAICS 211), and Support Activities for Transportation (NAICS 488)	*Recurring:* Chemical Manufacturing (NAICS 325)
Other Operating and Maintenance Costs: Solid Waste Disposal & Waste Water	Refinery (NAICS 324)	*Recurring:* Waste Management (NAICS 562)

It should be noted that the REMI model is not designed to assess impacts on individual operations. The model was used to assess the impacts of the proposed amendments on various industries that make up the local economy. Cost impacts on individual operations were assessed outside of the REMI model and used as inputs into the REMI model.

When the compliance cost annualized at a 4 percent interest rate is used, it is projected that an average of 20 net jobs could be created annually from 2018 to 2035, and about 140 net jobs foregone when the analysis horizon is extended to 2043. The difference is because the majority of jobs would be created at the beginning of the analysis period (2018-2022) when control installation is assumed to take place, as shown in Figure 2. (Note that jobs foregone may include either losses of existing jobs or projected additional jobs not created). The projected job impact becomes slightly more positive when the compliance cost annualized at a 1 percent interest rate is used. This analysis only considers the potential compliance cost of full BARCT installation at the 20 facilities, and it does not take into account the monetary benefits for facilities that potentially will have more RTCs available for sale as a result of NOx emission reductions due to BARCT installation. (Please see next section for an RTC market analysis.)

In earlier years of the implementation of these amendments, the positive job impacts from the compliance expenditures made by refineries, container glass, sodium silicate plant, and sulfur acid plants would more than offset the jobs forgone from the additional cost of doing business (Table 18). In 2021, where most of the spending is expected to occur, about 2,000 additional jobs are projected in the regional economy. The positive job impact would trickle down to the sectors of construction, miscellaneous professional services, retail, wholesale, and business services. However, as refineries, glass, sulfur acid plant, and other non-major facilities continue to incur the amortized capital expenditures, reductions in job growth would set in, resulting in jobs forgone in later years.

The oil and gas extraction sector is projected to have about 30 average annual jobs forgone, due to additional spending on SCRs required on gas turbines. Despite having a large share of the total compliance cost, the refinery industry is projected to have fewer jobs forgone (about 10) relative to other industries with a similar magnitude of cost impacts. This is due to the fact that the industry is the most capital-intensive. As such, less labor would be required to produce the same amount of products or services.

In earlier years, positive job impacts are projected in the sectors of fabricated metal products (NAICS 332) and machinery manufacturing (NAICS 331), due to purchase of various types of control equipment (including SCR, LoTOxTM, and UltraCat DGS) by the affected facilities (as presented in Table 17). Likewise, the sector of construction is projected to gain many jobs during the beginning period, due to the installation of control equipment. In addition, the sector of professional and technical services (NAICS 541) is projected to also gain jobs in earlier years from additional demand for equipment installation and maintenance. Operating and maintenance expenditures would benefit the industries of chemical products (NAICS 325) for additional sales of ammonia and public utilities (NAICS 22) for electricity.

The projected reduction in disposable income from the overall jobs forgone in the later years would dampen the demand for goods and services in the local economy, thus contributing to jobs forgone in sectors such as the rest of manufacturing, retail trade, wholesale, and accommodation and food services. As presented in Table 18, many major sectors of the regional economy would experience negative, albeit minor, job impacts in later years from the secondary and induced effects of BARCT implementation.

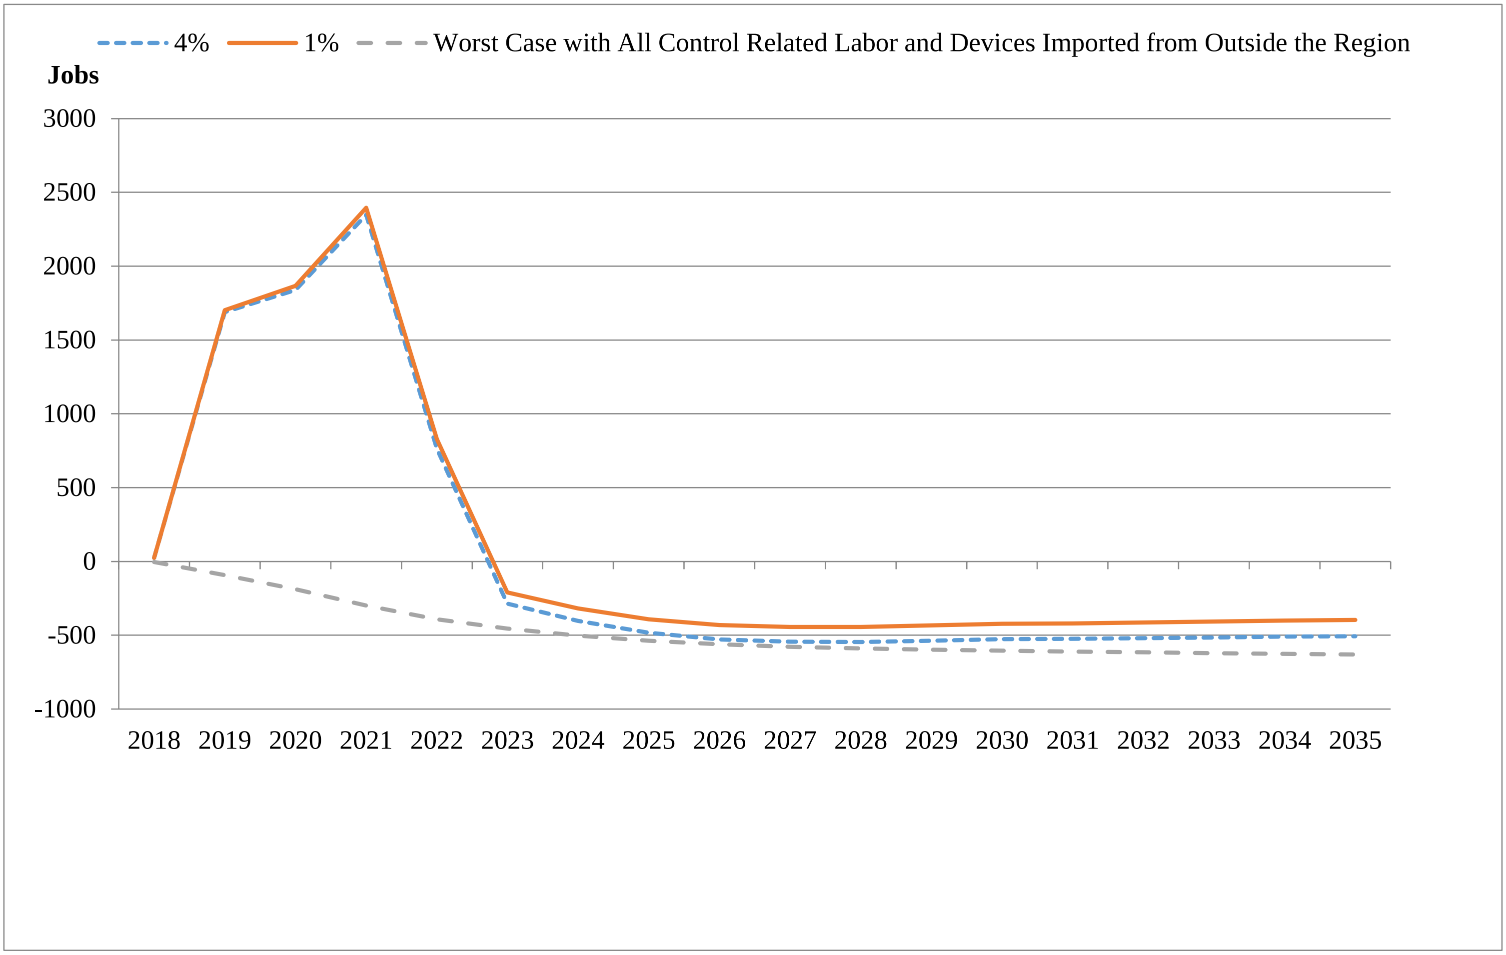
*The job impacts are projected for the regional economy, which includes jobs at all businesses, whether directly affected by full BARCT implementation or not.

Figure 2 presents a projected time series of job impacts over the 2018-2035 time period. Based on Abt Associate's 2014 recommendation to enhance socioeconomic analysis by conducting scenario analysis on major assumptions, staff has analyzed an alternative scenario (worst case) where the affected facilities would not purchase any control equipment or services from providers within the Basin. This is a highly hypothetical scenario in order to test the sensitivity of the previously discussed scenarios where the analyses rely on REMI's embedded assumptions about how the capital and O&M spending would be distributed inside and outside the region. In reality, utilities expenditures are paid to local utilities producers. Moreover, construction jobs related to control installation are likely to increase hiring from the local labor force. This worst-case scenario would result in an annual average of approximately 450 jobs forgone. The approximately 480 jobs forgone in 2035 represent less than 0.01 percent of total jobs in the region. It is not expected that the proposed rule amendments will create a shift from high-to-low skill jobs.

Figure 2: Projected Regional Job Impact, 2018-2035



8.1.1 Potential Health Benefits

The South Coast Air Basin is one of only two "extreme" non-attainment areas in the nation that have not reached the federal 8-hour ozone standard. Ground-level ozone, or smog, forms when volatile organic compounds (VOC) photochemically react with nitrogen oxides (NOx) in the presence of sunlight. Encompassing a major swath of Southern California, the South Coast Air Basin is among the most densely populated areas nationwide, with about 13 million cars, trucks, and other vehicles operating on its extensive network of highways and roads.[22] The amount of pollutants produced by modern urban life and industrial activities, combined with Southern California's year-round sunny weather, all contribute to the high concentrations of ground-level

[22] According to estimates provided by the California Department of Motor Vehicles, there were a total of 13.7 million registered vehicles in Los Angeles, Orange, Riverside, and San Bernardino counties for the period of January 1 to December 31, 2013. (https://www.dmv.ca.gov/portal/wcm/connect/add5eb07-c676-40b4-98b5-8011b059260a/est_fees_pd_by_county.pdf?MOD=AJPERES, accessed February 18, 2015.) The South Coast Air Basin covers all of Orange County and the urban portions of Los Angeles, Riverside and San Bernardino counties; therefore, the total number of vehicles would have been somewhat smaller.

ozone in the area. Ozone exposure can cause immediate, adverse effects on the respiratory system and result in various symptoms such as coughing, throat irritation, chest pain, and shortness of breath. It can also inflame the lining of the lungs, and for asthma patients, it may increase the number and severity of attacks. Long-term impacts of frequent exposure to ozone may lead to permanent lung damage and increase the risk of premature death.

In addition, the South Coast Air Basin remains a non-attainment area for the federal 24- hour and annual PM2.5 standards. NOx is also a precursor to PM2.5. Exposure to high levels of PM2.5 have been shown to cause and aggravate cardiopulmonary illnesses, including heart attacks, irregular heartbeat, aggravated asthma, decreased lung function, and increased respiratory symptoms, such as irritation of the airways, coughing or difficult breathing. These outcomes result in increased absences from school and work, hospitalization, and other medical expenses. Exposure to PM2.5 is associated with premature deaths. According to recent estimates by the California Air Resources Board, elevated ambient PM2.5 levels result in approximately 4,100 premature deaths annually in the South Coast Air Basin.

The reductions in ozone and PM2.5 associated with the proposed rule amendments have the potential to reduce the mortality and morbidity incidences associated with NOx emissions.

8.1.2 Competiveness

The additional cost for the proposed rule would increase the cost of services rendered by the affected industries in the region. The magnitude of the impact depends on the size and diversification of, and infrastructure in, a local economy as well as interactions among industries. A large, diversified, and resourceful economy would absorb the impact described above with relative ease.

Changes in production/service costs would affect prices of goods produced locally. The relative delivered price of a good is based on its production cost and the transportation cost of delivering the good to where it is consumed or used. The average price of a good at the place of use reflects prices of the good produced locally and imported elsewhere.

It is projected that the manufacturing sector, where most of the affected RECLAIM facilities belong, would experience a rise in its relative cost of services by about 0.013 percent and a rise in its delivered price by less than 0.001 percent in 2022 from the implementation of the proposed amendments.

8.1.3 Job Impact by Occupation

Occupations can be grouped into five categories according to median weekly earnings (See Table A in Appendix B for more details). Group 1 has the lowest-paid occupations while Group 5 has the highest-paid occupations. Table X shows the job impact as a percentage of the baseline jobs under the proposed amendments for each occupational wage group. Median weekly U.S. wage rates for 95 occupations are obtained from the 2013 BLS Employment and Earnings. The wage rates are ranked in ascending order, and then divided into five groups. The range of occupational wage rates as listed in the Appendix B.

A positive figure indicates that the proposed amendments create more jobs and a negative figure means the opposite. In earlier years of the implementation of these amendments, the positive job impacts from the compliance expenditures made by affected facilities would more than offset the jobs proportionally forgone from the additional cost of doing business. However, as affected facilities continue to incur the amortized capital expenditures, reductions in job growth would set in, resulting in jobs forgone in later years.

For example, in 2018 through 2022, the full installation of BARCT controls is projected to result in more jobs created with respect to the baseline for all occupational groups. As shown in Table 19, however, proportionately fewer jobs would be foregone (e.g., in 2030 and 2035) for lower skilled than higher skilled jobs. For the purpose of this analysis, staff assumed lower skilled jobs as those jobs that do not require a bachelor's degree which according to the 2014 Bureau of Labor Statistics would have weekly earnings of about $1,100 per week. Similar job impacts by occupational group would have occurred under command-and-control regulations as they would also require the full installation of BARCT controls.

Table 19:
Job Impact of the Proposed Amendments by Occupational Wage Group by Year

Group	Median Weekly Earnings*	% Impact from Baseline					No. of Occupations
		2018	2021	2022	2030	2035	
1	$236 - $480	0.0002%	0.0104%	0.0033%	-0.0032%	-0.0032%	19
2	$481 - $619	0.0003%	0.0152%	0.0046%	-0.0051%	-0.0049%	19
3	$620 - $767	0.0009%	0.0453%	0.0173%	-0.0065%	-0.0054%	19
4	$768 - $980	0.0003%	0.0119%	0.0045%	-0.0040%	-0.0040%	19
5	$990 - $1738	0.0004%	0.0193%	0.0069%	-0.0049%	-0.0047%	19

According to the 2014 California State Board of Equalization, total gasoline sales in California were 14.57 billion gallons, of which the region's share is estimated to be 46 percent. The annual compliance cost of refineries due the proposed amendments, if fully passed on to gasoline consumers, would result in a gasoline price increase of up to 0.8 cents per gallon in the four-county area.[23] Gasoline produced by refineries within SCAQMD is also consumed in a larger region including other parts of California and areas in neighboring states (e.g. Nevada and Arizona), therefore, the actual added cost is expected to be lower than the stated amount. It should be noted that due to possible outside competition in the gasoline market, refineries may not be able to pass on the full cost of the proposed amendments to consumers. However, it should be noted that due to clean air regulations, the gasoline blends sold in this region are different from those permitted in other parts of the country. Therefore, any outside competition, if any, is expected to be very limited.

8.1.4 Rule Adoption Relative to the Cost Effectiveness Schedule

On October 14, 1994, the Governing Board adopted a resolution that requires staff to address whether rules being proposed for adoption are considered in the order of cost- effectiveness. The 2012 AQMP ranked, in the order of cost-effectiveness, all of the control measures for which costs were quantified. It is generally recommended that the most cost- effective actions be taken first.

The proposed amended rules implement control measure CMB-01 (Additional Reductions for

[23] The rate of 46 percent was applied to the state's total of 14.57 billion gallons sold to get the Basin's share of 6,702 million gallons sold. Dividing the average annual cost of the proposed amendments ($52 million) by 6,702 million gallons will result in $0.008 or (0.8 cents/gallon) increase in gasoline price.

NOx RECLAIM) in the 2012 AQMP. The cost effectiveness of this measure (Phase II) was estimated to be $16,000 per ton of NOx reduced. This measure was ranked 8th among all the SCAQMD control measures for stationary sources in terms of cost-effectiveness in the 2012 AQMP.

8.1.5 Incremental Cost Effectiveness

The annualized BARCT costs for the Proposed Rule Amendments and Alternative 3—Industry Proposal—are shown in Table 21 below. Alternative 3 will result in 5.23 less emissions reductions than the Proposed Rule Amendments (8.77 tpd vs. 14 tpd). The incremental cost of achieving the additional 5.23 tpd is taken as the difference in cost between the Proposal and Alternative 3, which is calculated by converting annualized BARCT costs into PWV 2014 dollars. The incremental cost-effectiveness for achieving the additional 5.23 tpd of NOx reductions is therefore $17,000/ton.

8.2 Impact of CEQA Alternatives

Five alternatives to the proposed amendments were developed for the CEQA analysis associated with this proposal. This section provides an assessment of the possible different socioeconomic impacts resulting from these alternatives. Table 19 below summarizes the proposed shave for each affected source category. Alternative 1 (Across the Board), Alternative 2 (Most Stringent), Alternative 3 (Industry Approach), Alternative 4 (No Project), and Alternative 5 (Weighted by BARCT Reduction Contribution for all Facilities and Investors). The primary components of the proposed alternatives that have been modified are the source categories that may be affected, and the manner in which compliance with the proposed NOx BARCT emission limits would be achieved. After further analysis, staff determined Alternatives 3 and 4 do not comply with state law.

Table 20: Proposed Amendments and CEQA Alternatives

	Proposed Amendments	**Major Refineries/ Investors**	**Non-Major Faciliti**	**Electricity generating Facilities**	**Remaining Facilities**
Staff Proposal	**Shave Applied to Facilities and Investors Holding the Top 90% of RTCs (Weighted by BARCT Reduction Contribution)** *56 total facilities, plus investors*	**66%** ***(9 Facilities)***	**49%** ***(26 Facilities)***	**49%** ***(21 Facilities)***	**0%** ***(219 Facilities)***
CEQA Alternatives					
CEQA Alternative #1	**Across the Board** *Affects all facilities and investors*	**53%**	**53%**	**53%**	**53%**

CEQA Alternative #2	**Most Stringent Approach** *Across the Board without 10% Compliance Margin*	**60%**	**60%**	**60%**	**60%**
CEQA Alternative #3	**Industry Approach** *Across the Board: Difference between previous BARCT and new BARCT*	**33%**	**33%**	**33%**	**33%**
CEQA Alternative #4	**No Project**	**0%**	**0%**	**0%**	**0%**
CEQA Alternative #5	**Weighted by BARCT Reduction Contribution** *Affects all facilities and investors*	**66%**	**36%**	**36%**	**36%**

To analyze the worst case scenarios, the CEQA analysis assumes that all other components of the project alternatives are identical to the components of the proposed project (i.e., the same control equipment); therefore, the corresponding impacts would also occur under all the alternatives except the ‘no project’ alternative. However, for the purpose of conducting socioeconomic analyses and comparing costs and job impacts under different CEQA alternatives, staff assumed that a different set of source categories would be affected under each CEQA alternative.

The analysis conducted in the ensuing subsection focuses on the 9 refineries and 11 non- refinery facilities with identified 2015 BARCT.

8.2.1 Alternative 1 – Across the Board Shave of NOx RTCs

Alternative 1 consists of an across-the-board NOx RTC shave of 14 tpd that would affect all NOx RECLAIM facilities and investors. Although the total amount of the shave is identical to the proposed project, the NOx RTC holdings would be shaved by 53 percent overall.

For the purpose of the socioeconomic analysis of the CEQA alternatives, staff assumed fewer control equipment to be installed by refineries since less reduction (53 percent vs. 66 percent) is required. To meet the proposed 53 percent shave, refinery sector needs to only reduce 4.76 out of 6.00 tpd required under the proposed project. To meet the 4.76 tpd reductions and based on the cost-effectiveness schedule, only control costs for the refinery FCCUs, gas turbines, and coke calciners are considered for the cost estimates.

On the other hand, the remaining 11 non-major facilities would need to reduce more of their current holdings relative to the proposed project (53 percent vs. 49 percent, or 3.12 vs. 2.77 tpd). Since these facilities will have their holdings reduced by 53 percent rather than the 49 percent in the proposed project, these facilities are assumed to need to purchase RTCs to meet the difference. While these facilities may purchase some RTCs, this would not be an additional cost of the program since the sellers would be paid for these RTCs. For the purpose of worst-case analysis, staff assumed these facilities will purchase 0.35 (3.12 tpd - 2.77 tpd = 0.35 tpd) tpd of RTCs at a price of $22,499 per ton (i.e. the Proposed Amended Rule 2002 trigger), irrespective of the projected demand and supply of NOx RTC and how the market would behave under this alternative shave.

8.2.2 Alternative 2—Most Stringent Shave of NOx RTCs

Alternative 2 consists of the most stringent approach by applying an across-the-board NOx RTC shave of 15.87 tpd. Alternative 2 would affect all RECLAIM facilities and investors, but without including the 10 percent compliance margin or the BARCT adjustment for refinery equipment. Under Alternative 2, the NOx RTC holdings would be shaved by 60 percent overall. Under Alternative 2, the total shave of 15.87 tpd is greater than the 14 tpd shave that is contemplated by the proposed project. In addition, the distribution of the shave under Alternative 2 would reduce the NOx RTC holdings differently than the proposed amendments: 60 percent reduction would be applied to all 275 NOx RECLAIM facilities and investors.

For the purpose of the socioeconomic analysis of the CEQA alternatives, staff assumed less control equipment to be installed by refineries since less reduction (60 percent vs. 66 percent) is required. To meet the proposed 60 percent shave, the refinery sector needs to only reduce 5.34 tons out of 6.00 tons required under the proposed project. To meet the 5.34 tons reductions and based on the cost-effectiveness schedule, only control costs for the refinery FCCUs, gas turbines, coke calciners, and boilers/heaters are considered for the cost estimates.

On the other hand, the remaining 11 non-major facilities need to reduce more relative to the proposed project (60 percent vs. 49 percent or 3.39 vs. 2.77 tpd). Since these facilities will have their holdings reduced by 60 percent rather than the 49 percent in the proposed project, these facilities are assumed to need to purchase RTCs to meet the difference. For the purpose of the worst-case analysis, staff assumed these facilities to purchase 0.62 tpd of RTCs at a price of $22,499 per ton, irrespective of the projected demand and supply of NOx RTCs and how the market would behave under this alternative shave.

8.2.3 Alternative 3 – Industry Approach

Alternative 3, an approach that has been proposed by industry representatives does not comply with state law because it does not meet the definition of BARCT as the maximum degree of reductions achievable, taking into account economic and other impacts (HS&C 40406). This proposal consists of an across the board NOx RTC shave of 8.77 tpd that would affect all RECLAIM facilities and investors. The total amount of shave would be lower than the 14 tpd shave that is contemplated by the proposed project. Under Alternative 3, the NOx RTCs held by all RECLAIM facilities and investors would be shaved by 33 percent. Since there are unused RTCs in the system, it is very likely that facilities would first give up most of their unused credits and install additional controls as needed to reach the total 8.77 tons. However, the analysis assumes that facilities would install controls to reach the required 33 percent reduction to provide a conservative estimate of costs.

For the purpose of the socioeconomic analysis of the CEQA alternatives, staff assumed less control equipment to be installed by refineries since less reduction (33 percent vs. 66 percent) is required. To meet the proposed 33 percent shave the refinery sector needs to only reduce 2.97 tons out of 6.00 tons required under the proposed project. To meet the 2.97 tons reductions and based on the cost-effectiveness schedule, only control costs for the refinery gas turbines are included for the cost estimates.

As in the refinery sector, the remaining 11 non-major facilities would have fewer holding reductions relative to the proposed project (36 percent vs. 47 percent or 1.94 vs. 2.77 tons/day). To meet the 1.94 tons reductions and based on the cost-effectiveness schedule, only control costs for the sodium silicate furnace, ICE engines, container glass furnace, and metal heat furnaces are considered for the cost estimates.

8.2.4 Alternative 4—No Project

Alternative 4 is the "No Project" approach such that no NOx RTC reductions would be applied to any RECLAIM facility or investor. CEQA requires the specific alternative of No Project to be evaluated even though it also does not comply with state law for the same reason as Alternative 3. A No Project Alternative consists of what would occur if the proposed amendments were not approved. The net effect of not amending Regulation XX to reduce the available RTCs on the market would be a continuation of the 2005 amendments to the NOx RECLAIM program

Under Alternative 4, existing Regulation XX would remain as currently written. Additional NOx reductions are not anticipated because the current level of NOx allocations is projected to exceed NOx emissions. Consequently, no additional cost is expected from Alternative 4 and no other socioeconomic impacts are foreseen.

8.2.5 Alternative 5—Weighted by BARCT Reduction Contribution

Alternative 5 consists of an across the board NOx RTC reduction of 14 tpd that would affect all NOx RECLAIM facilities and investors. Although the total amount of shave is identical to the proposed project, the NOx RTC reductions under this alternative would be weighted by the BARCT reduction contribution for major refineries and all other facilities, with investors grouped with the major refineries. As such, NOx RTC holdings for major refineries and investors would be shaved by 66 percent and the NOx RTC holdings for non-major refineries and all other facilities would be shaved by 36 percent.

For the purpose of the socioeconomic analysis of the CEQA alternatives, staff assumed the same control equipment to be installed by refineries as the proposed project since the same reduction (66 percent) is required. To meet the proposed 36 percent shave, the remaining 11 non-major facilities need to reduce less relative to the proposed project (36 percent vs. 47 percent or 2.12 vs. 2.77 tpd). Based on the cost-effectiveness schedule, only control costs for the sodium silicate furnace, ICE engines, container glass furnace, and gas turbines are considered for the cost estimates.

Table 21 presents a comparison of the alternatives in terms of annual average cost and jobs forgone. This table assumes that, under Alternatives 1 and 2, facilities would buy unused RTCs at a greater rate than in the proposed project in lieu of installing more expensive controls. Therefore, costs are lower but actual emission reductions are also lower than from the proposed project.

Table 21: Average Annual Costs and Job Impacts by CEQA Alternative For 9 Refineries and 11 Non-Major Facilities

CEQA Alternatives	BARCT Cost In $ Millions (annualized using a 4 percent discount rate)	Jobs	Amount of RTC Credits Removed from Market (Tons/day)
Proposed Amendments	$61.59	+23	14
Alternative 1	$45.83	-76	14
Alternative 2	$55.00	-83	15.87
Alternative 3	$9.40	-30	8.77
Alternative 4	$0	0	0
Alternative 5	$60.23	+34	14

The proposed project has the highest cost but the second to highest positive job impact, due to increased labor demand for the full, instead of partial, installation of BARCT equipment. Alternative 4 serves as a benchmark against which other alternatives were evaluated. Of the four remaining alternatives, Alternative 3, which does not comply with state law, has the lowest cost ($9.40 million) because it is expected to induce the least number of BARCT equipment to be installed; however, it would result in an average of about 30 jobs foregone annually. This alternative excludes controls on FCCU and SRU/TGUs, boilers/heaters, and coke calciner units at refineries and hence would avoid potential costs, but also the jobs that could be potentially created due to additional expenditure on these controls. In addition, this alternative would achieve fewer emission reductions from the 20 BARCT facilities.

Alternatives 1 and 2 would cost less than the proposed amendments, yet would experience much more negative job impacts (about 80 annual jobs forgone). This is due to less BARCT installation spending in the refinery sector relative to the 11 non-refinery facilities and would result into negative net job impacts.

9. MARKET ANALYSIS

In addition to the potential compliance cost of control equipment installation and operation for these 20 facilities, the proposed amendments may potentially result in new or additional compliance costs for some of the 36 facilities where no control equipment was identified for installation. New costs would be the result of some facilities finding that their emissions exceed their RTC holdings post-shave. These facilities with negative balances would become net buyers and face the costs of purchasing additional RTCs to remain compliant. Additional costs would be incurred by facilities that were net buyers before the shave and would see their holdings further reduced under the proposed shave.

Along with the cost of additional credits that would need to be purchased, every unit of traded NOx RTCs could potentially become more expensive as a result of the proposed shave. In the short term, these net buyers are expected to purchase RTCs at a higher price, although RTC costs may go down in the long-term, if some (or all) of the 20 facilities with identified control equipment chose to install controls and offer surplus RTCs for sale. In addition to the potential compliance cost that would be incurred by the 36 shaved facilities with no identified control equipment, compliance costs could also be incurred by the net buyers who already exist within the remaining group of 219 facilities that are exempt from the RTC shave under the proposed rule. These facilities are expected to buy RTCs every year and would also face possibly higher RTC prices as the potential market supply decreases (at least in the short term). Under CEQA alternatives, these 219 facilities may incur even more costs from varying degrees of RTC shaves.

In order to estimate the magnitude of these market impacts, a price analysis has been conducted. To estimate the potential impact of price increases on the projected net buyers, a sensitivity analysis was conducted where prices grew from 100, 200, 300 percent, and up to $22,499/ton, which is just below the proposed amended price exceeding which the non- tradable/non-usable credits will be converted to tradable/usable NOx RTCs upon Governing Board concurrence. It should be noted that the compliance costs incurred by these projected net buyers would at the same time create monetary benefits to other RECLAIM facilities and/or investors who would be the sellers of these credits.

Finally, the monetary value of the shaved RTC holdings, which would be removed from the 56 facilities, has also been estimated. However, it should be noted that this estimated value is not considered a compliance cost as RTCs were originally allocated to RECLAIM facilities at zero cost and are not legally considered a facility's property. The results of this "value" analysis are set forth below on page 47.

9.1 Assumptions for Price Analysis

Two types of credits exist within the RECLAIM market: Discrete-year credits which are valid within the year of issuance and Infinite-Year Blocks (IYB) which are bundles that extend into perpetuity after the initial purchase year. Given that prices for discrete-year are the most reflective of actual market behavior, they form the basis of this analysis. Over the past 5 years, prices for discrete RTCs begin at about $3,000 to $4,000 per ton and eventually drop to around $1,000 per ton as the end of the year approaches. RTCs are much less expensive near the end of the year when the RTC expiration date approaches.

The base price of $3,779 per ton for discrete RTCs from January in compliance year 2015 was used for this analysis.[24] In order to capture a realistic range of increases up to the $22,500 per ton trigger, an increase of 100 percent, 200 percent, and 300 percent was applied to the base price of $3,779 per ton. These values were then aggregated into their yearly totals. Table 22 summarizes

[24] This price represents a 12-month rolling average which is calculated to smooth out short-term fluctuations and present long-term trends. For more information see: http://www.aqmd.gov/docs/default- source/reclaim/nox-rolling-average-reports/12-mo-rolling-avg-price-comp-yrs-2014-15-nox-rtcs---july- 2015.pdf?sfvrsn=6

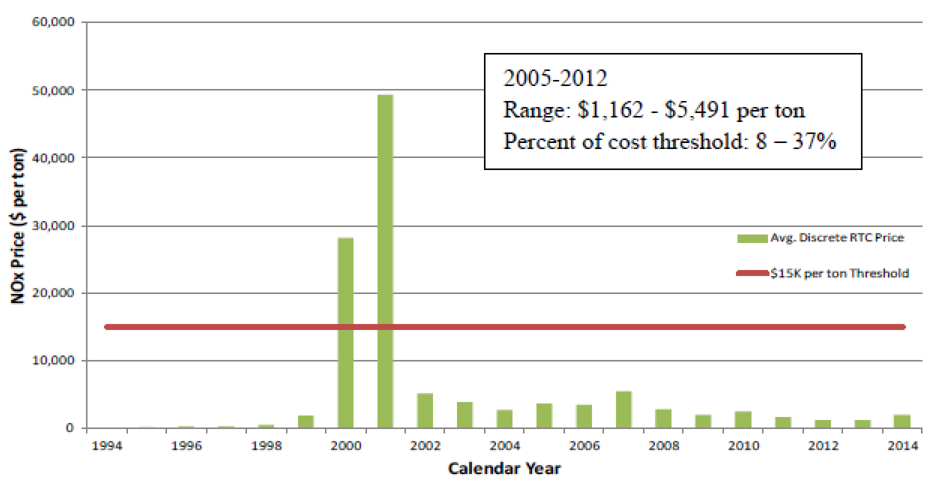
the results below.

Table 22: Estimates of RTC price increase

Type	Market price	100 percent Increase	200 percent Increase	300 percent Increase	Proposed Amended Rule 2002 Price Trigger
Discrete Ton	$3,779	$7,558	$11,337	$14,999	$22,499

These cost assumptions are conservative given historical trends in the marketplace. Since the adoption of Regulation XX, there have been a number of amendments to the RECLAIM rules, including BARCT reassessments for NOx in 2005. As a result of the January 2005 amendment, NOx RTCs were reduced by 7.7 tpd (accounting for approximately 22.5 percent of the total RTC holdings at that time) uniformly across the then 281 RECLAIM facilities. This reduction was implemented in phases: 4 tpd in 2007 and an additional 0.925 tpd in each of the following 4 years. Figure 3 shows discrete RTC prices for compliance years 1994 to 2013, reflecting the fact that the NOx reductions specified by the January 2005 amendment did not cause major RTC price spikes.

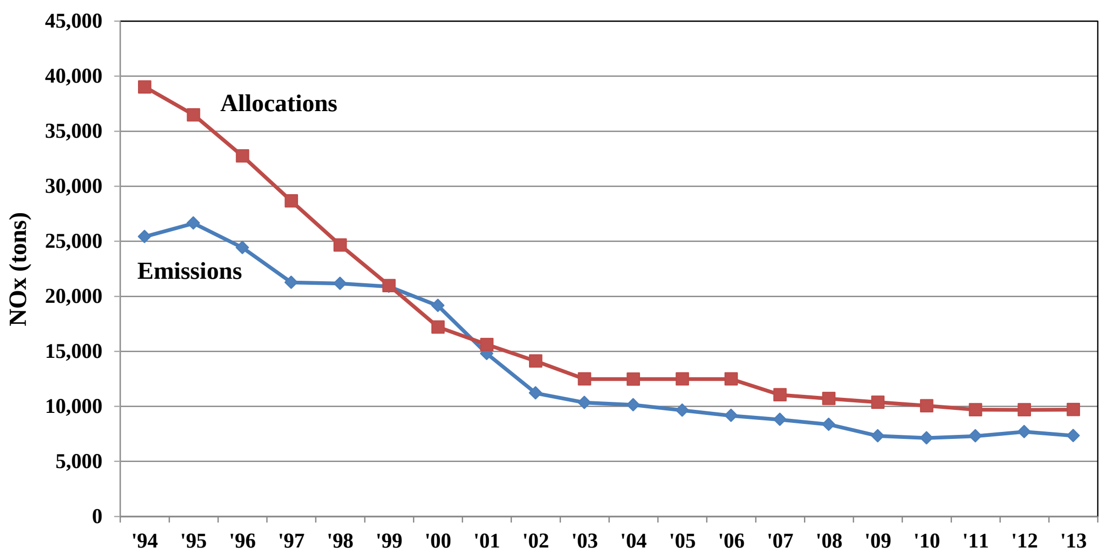
Figure 3: NOx Discrete Prices vs. Threshold



Additionally, since the RECLAIM program began in 1994, actual NOx emissions have consistently been well below total RTC holdings (except during California's energy crisis in 2001). Figure 4 shows how, despite past changes in the market's structure, there were sufficient amounts of NOx RTCs available to allow for expansion and modification by RECLAIM facilities. In drafting the proposed rule, staff added a 10 percent compliance margin to the projected 2023 emissions by RECLAIM facilities at the proposed 2015 BARCT levels and an additional 0.85 tpd to account for uncertainties in the BARCT analysis and base year activity level adjustments. Given this historical trend and staff's efforts to structure the rule effectively, the remaining NOx RTC holdings after the proposed shave is fully phased in are not expected to drop below actual total NOx emissions, even with less than the full implementation of control equipment. Large price spikes are not expected unless some facilities hoard large quantities of RTCs, thus constricting the supply such that prices are not set competitively.

In order to identify the potential buyers of NOx RTCs in 2023 and subsequent years, staff assumed that the only change in RTC allocations would be the proposed shave. Regarding future emissions, staff started with the actual 2011 NOx emissions among existing emission sources, except electricity generating facilities for which their 2012 emissions were used as in the Revised Draft Staff Report. Sector-specific growth factors were then applied to project NOx emissions at each facility in 2023. By doing so, staff assumes in the analysis that emissions at each facility would grow at the same rate; however, it is possible that emissions would grow more at facilities with surplus NOx RTC holdings and less at facilities who already need to purchase NOx RTCs annually from the market. Therefore, the projected incremental compliance cost reported in this section can be considered as a conservative estimate. In the meantime, potential increases in compliance cost due to higher RTC prices was not explicitly considered for new and modified sources, nor for the required holdings beyond actual emissions for the electricity generating facilities. Staff did not explicitly consider increases due to higher RTC prices for facilities with new and modified sources, given that staff cannot predict the number of new and modified sources and the amount of RTCs needed for them. However, they are implicitly taken into account when growth factors were applied to project future growth by industry. These projected future emissions by industry-wide growth factors may be able to capture at least a portion of the incremental compliance costs potentially incurred by these facilities.

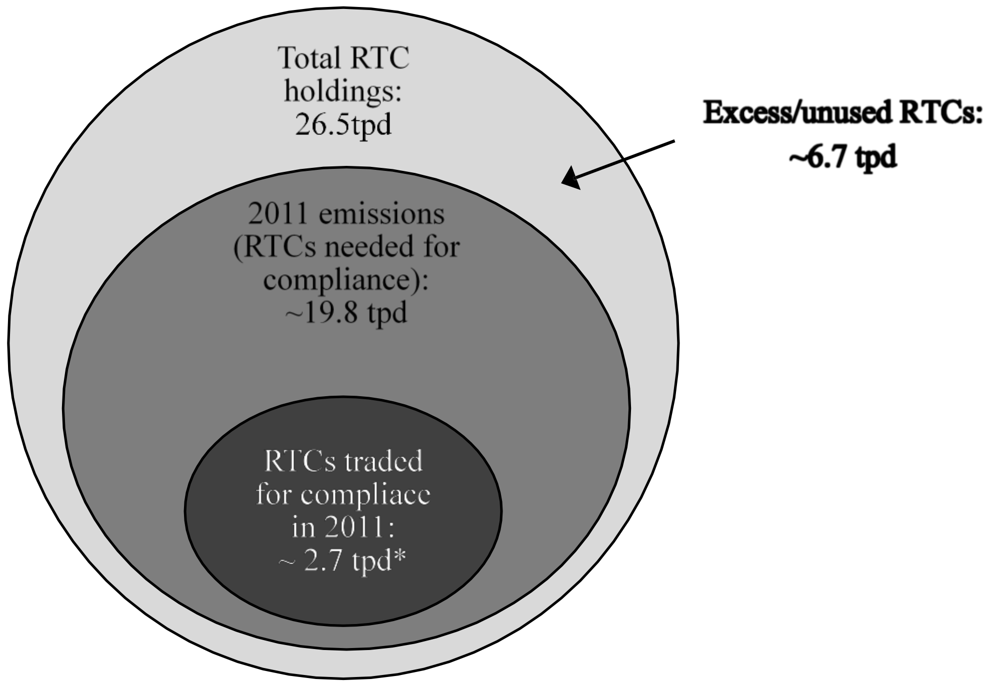
Figure 4: Audited Emissions and RTC Holdings



9.2 Understanding the Impact of the First 4 tpd Shave

Under the proposed rule amendments, 4 tpd of NOx RTCs would be removed from the NOx RECLAIM program in 2016, and this analysis assumed that no new BARCT control equipment would be installed in that year. Based on 2011 data, there existed a wide margin between the overall NOx RTC holdings and actual emissions. As illustrated in Figure 5, a total of about 6.7 tpd were unused and considered as excess NOx RTC credits. Moreover, in 2011, only 2.7 tpd of NOx RTCs were traded in the market directly for the purpose of regulatory compliance, while 6.7 tpd of excess RTCs remained unused. Therefore, even with no assumed BARCT installation in 2016 (thus, no additional credits expected to be released into the market for trading), it would be unlikely that NOx RTC prices would skyrocket after the first 4 tpd of NOx RTCs are shaved. To be conservative, however, the following analysis will examine different price scenarios to evaluate the potential cost impact in the first year of the proposed shave.

Figure 5: Distribution of RTCs in NOx RECLAIM Market, 2011



*RTCs traded for compliance was calculated for each NOx RECLAIM facility by: 1) subtracting 2011 RTC holdings from 2011 NOx emissions and 2) summing up the negative balance, which is equivalent to the amount of facility emissions that a facility did not have RTC holdings for. Among the approximately 2.7 tpd RTCs traded for compliance in 2011, close to 60 percent was purchased by the 9 refineries and 11 non-refinery facilities with identified control equipment.

9.3 Potential Compliance Cost for Net Buyers: 36 Affected Facilities

For the first shave of 4 tpd in 2016, up to 7 of the 36 shaved facilities (3 existing net buyers and 4 new net buyers) could have their emissions exceed their RTC holdings, based on 2013 emission data. These 7 facilities are expected to purchase up to 0.45 tpd of NOx RTCs annually from the market, up from 0.32 that are currently needed. If RTC price remains constant following the shave, the facilities would incur costs of about $0.18 million for the additional 0.13 tpd of NOx credits needed (0.45 tpd - 0.32 tpd = 0.13 tpd). If the price increases by 100 percent, 200 percent, 300 percent or up to $22,499/ton, then these facilities would incur a higher cost of $0.81 million/$1.43 million/$2.04 million/$3.27 million respectively, not only for the cost of additional RTCs needed due to the initial 4 tpd shave but also for the higher price of the 0.32 tpd already needed before the shave.[25]

As a result of the 14 tpd shave fully phased-in in 2022, up to 15 of the 36 facilities (6 existing net buyers plus 9 new net buyers) are expected to have their 2023 emissions exceed their projected RTC holdings, unless they make operational changes at their facility or purchase RTCs.[26] When CEQA alternatives are considered, the number of facilities that fall into this group of net buyers ranges from 6 to 17.

Under the proposed shave, these 15 facilities are expected to need to purchase up to 1.52 tpd of NOx RTCs annually from the market, up from 0.97 tpd that are currently needed. If RTC price remains constant following the shave, the facilities would incur costs of $0.76 million for the additional 0.55 tpd of NOx RTCs needed (1.52 tpd –0.97 tpd = 0.55 tpd). If the price increases by 100 percent, 200 percent, 300 percent and up to $22,499/ton trigger, then these facilities would incur a higher cost of $2.85/$4.94/$6.97/$11.13 million respectively, not only for the cost of additional RTCs needed due to the shave but also for the higher price of 0.97 tpd already needed before the shave. By comparison, these potential compliance costs could represent up to 16 percent of the overall annual compliance cost associated with control installation.[27] However, these costs are not additional to the overall cost of the proposed shave because increased costs to RTC buyers are canceled out by increased gains to RTC sellers.

Under the CEQA alternatives, these 36 facilities would be subject to different shaves and result in different projected amounts of RTCs that would needed to be purchased. Under the CEQA alternatives, the potential compliance costs for some of these 36 facilities would range between $0 and $14 million, depending on the price differential assumed. It is assumed these funds would remain in the local economy as they flow to other RECLAIM holders who are selling RTCs. Table 23 summarizes the potential compliance cost for the proposed rule amendment and the CEQA alternatives for this group of facilities under different price scenarios.

---

[25] The formula used for calculating this cost is: [pre-shave RTC purchase necessary for compliance*(post- shave RTC price – pre-shave RTC price) + (post-shave RTC purchase necessary for compliance - pre-shave RTC purchase necessary for compliance)*post-shave price]*365 days.

[26] 2023 emissions are calculated by applying a growth factor of 0.87 to the 21 electricity generating facilities' 2012 actual emissions and 1.10 growth factor to the remaining 16 facilities' 2011 actual emissions. See Revised Staff Report for emissions projections.

[27] To arrive at this percent increase, the total compliance cost of full BARCT installation was converted to 2015Q1 dollars using the Marshall & Swift Indices.

Table 23: Annual Price Increases for Net Buyers for 36 Facilities from 2023 onwards

36 Facilities	Number of Net Buyers	Amount of RTCs to be purchased (TPD)	Estimated Incremental Increases in Cost				
			Current Market Price (Thousands)	100 percent differential (Thousands)	200 percent differential (Thousands)	300 percent differential (Thousands)	$22,499 (Thousands)
Proposed Rule Amendments	15	1.52	$760	$2,850	$4,940	$6,970	$11,130
Alternative 1	17	1.63	$910	$3,160	$5,410	$7,580	$12,040
Alternative 2	17	1.82	$1170	$3,690	$6,200	$8,630	$13,620
Alternative 3	11	1.25	$380	$2,110	$3,830	$5,500	$8,920
Alternative 4	6	0.97	$0	$0	$0	$0	$0
Alternative 5	12	1.30	$460	$2,260	$4,060	$5,800	$9,370

9.4 Potential Compliance Cost for Net Buyers: 219 Facilities

Among the 219 facilities that would be exempt from the proposed shave, 102 facilities were estimated to have purchased NOx RTCs to remain in compliance according to the projected 2023 emissions and the projected RTC holdings in 2023. These 102 facilities represent 13 different industries with half belonging to the manufacturing sector (NAICS 31-33). In 2013, this group's NOx RTC holdings fell short of its actual NOx emissions by roughly 0.81 tpd, and this gap is expected to widen to 1.33 tpd in 2023 due to industry growth.[28] Therefore, some facilities have needed and will continue to need to purchase RTCs from the market to ensure they have sufficient RTCs to cover their emissions.

Under the proposed rule amendments, the 219 facilities would not be shaved. If the price of NOx RTCs remains unchanged from the current market price, no additional compliance cost would be incurred. If, however, the price increases by 100 percent, 200 percent, or 300 percent and up to $22,499/ton trigger, then these facilities would have to pay an additional $1.84/$3.67/$5.45/$9.6 million respectively in order to be compliant. By comparison, these potential compliance costs could represent up to 13 percent of the overall annual compliance cost associated with control installation.[29] However, these costs are not additional to the overall cost of the proposed shave because increased costs to RTC buyers are canceled out by increased gains to RTC sellers.

Under the CEQA alternatives, these 219 facilities would be subject to different shaves and the projected amount of RTCs needed to be purchased would increase as a result. The potential compliance cost under these alternatives would range between $0 and $17 million annually, depending on the price differential assumed. It is assumed these funds would remain in the local economy as they flow to other RECLAIM holders who are selling RTCs. Table 24 below summarizes the potential compliance cost for the proposed rule amendment and the CEQA alternatives for this group of facilities, under different price scenarios.

[28] 2023 emissions are calculated by applying a growth factor of 1.3 to each of the 210 facilities' 2011 actual emissions.
[29] See footnote 25.

Table 24: Annual Price Increases for Net Buyers in 219 Facilities Group from 2023 onwards

219 Facilities	Number of Net Buyers	Amount of RTCs to be purchased (TPD)	Estimated Incremental Increases in Cost				
			Current Market Price (Thousands)	100 percent differential (Thousands)	200 percent differential (Thousands)	300 percent differential (Thousands)	$22,499 (Thousands)
Proposed Rule Amendments	102	1.33	$0	$1,840	$3,670	$5,450	$9,100
Alternative 1	146	2.19	$1,190	$4,210	$7,240	$10,170	$16,170
Alternative 2	150	2.34	$1,390	$4,610	$7,830	$10,960	$17,350
Alternative 3	127	1.80	$650	$3,140	$5,620	$8,030	$12,960
Alternative 4	102	1.33	$0	$0	$0	$0	$0
Alternative 5	133	1.87	$740	$3,330	$5,910	$8,410	$13,530

9.5 REMI Job Impacts of RTC Purchases

Regarding the incremental compliance cost that could potentially be incurred by the NOx RECLAIM facilities that do not have cost-effective controls identified by the 2015 BARCT analysis, the associated job impacts in the regional economy have been estimated under various scenarios of discrete NOx RTC prices. In addition to the incremental costs incurred by RTC buying facilities, the transactions will at the same time create financial gains for the RTC sellers. In order to project future NOx RTC sales by industry, staff used the 2010-2014 NOx RTC transaction data to arrive at an average percent distribution of sales by industry.

If prices remain the same, little job impact is expected due to the proposed amendments. If the average annual discrete NOx RTC prices increase to $22,499/ton and none of the affected facilities pursue any other more cost-effective compliance options, then about 40 jobs on the net would be foregone annually between 2023 and 2035. However, this latter price scenario is unlikely to occur, particularly if the 9 refineries and 11 non-refinery facilities install identified cost-effective controls, which would then either decrease the market demand or increase the market supply of NOx RTCs by these facilities.

It should be noted that all CEQA alternatives except Alternative 4 (No Project) would result in a more negative job impact—up to about 60 jobs foregone on an average annual basis if the average annual discrete NOx RTC prices increase to $22,499/ton and none of the affected facilities pursue any other more cost-effective compliance options—than the proposed amendments. This is mainly because, unlike the proposed amendments, Alternatives 2, 3 and 5 would not exempt from the shave the 219 facilities that tend to be smaller and use more labor-intensive production technologies than, for example, those used by the refineries.

The table below illustrates the job impacts on all facilities needing to purchase additional RTCs.

Table 25: Average Annual Jobs Foregone as a Result of RTC Purchases

All Facilities	**Average Annual Job Impact (2023-2035)**				
	Current Market Price	**100 percent increase**	**200 percent increase**	**300 percent increase**	**$22,499**
Proposed Rule Amendments	+1	-6	-14	-21	-36
Alternative 1	-2	-13	-25	-36	-58
Alternative 2	-2	-13	-24	-35	-57
Alternative 3	-2	-13	-24	-35	-57
Alternative 4	0	0	0	0	0
Alternative 5	-2	-13	-24	-35	-57

9.6 Value of Shaved Excess RTCs

SCAQMD staff believes the proposed shave of 14 tpd is necessary in order to induce the 20 facilities with identified control equipment to upgrade their control equipment and achieve programmatic BARCT equivalency. This is especially likely given that about 60 percent of the 2.7 tpd of RTCs traded for compliance in Compliance Year 2011 were made by the 20 affected facilities.

Some stakeholders commented that the shave should be divided into 8.79 tpd[30] of a BARCT shave and 5.21 tpd of an excess RTC shave. Staff does not agree with this division because 14 tpd of NOx RTC shave is necessary to induce a BARCT-equivalent level of *actual* NOx emission reductions. Moreover, at the outset of RECLAIM, RTCs were allocated to RECLAIM facilities free of charge, yet they now have value to the facilities as a commodity that can be bought and sold. While RTCs have value, they are not a property right. The proposed amendments to RECLAIM will reduce the number of RTCs. Since there was no cost associated with allocated RTCs for a facility, there should be no financial loss to the RECLAIM universe as the SCAQMD retires them. Staff's analysis of the RECLAIM data revealed that only 3.33 tpd out of the proposed 14 tpd shave would affect additional acquisitions of NOx RTCs that were used to expand a facility's NOx RTC holdings beyond the original free-of-charge allocations. These 3.33 tpd of NOx RTCs are spread across 24 RECLAIM facilities, and more than three quarters of these shaved credits would be concentrated in the refinery sector. If a value is estimated for the 3.33 tpd of shaved credits, it is $4.6 million annually, applying the base price of $3,779 per ton.

However, the choice between additional RTC purchase and emission control installation is solely a business decision to comply with RECLAIM requirements, and the decision to purchase RTCs in lieu of installing emission controls is most likely made to minimize overall compliance cost. Therefore, it is expected to generate an expected stream of cost-savings afforded only by the RECLAIM program and not available under command-and-control. Therefore, any RTC investment loss should not be considered as a compliance cost to be compared to the compliance cost under command-and-control regulations (Section 11 includes further explanations on this topic). Moreover, this loss may be offset by any potential increase in RTC price due to a decreased RTC supply, which would subsequently raise the market value of a facility's remaining RTC holdings. Finally, any loss of "value" of shaved RTCs cannot be compared to command and control, because in that case, there are no RTCs and thus no similar "value" was ever created.

10. NEW REVISIONS TO THE PROPOSED RULE AMENDMENTS

The Revised Draft Socioeconomic Report (released on October 6, 2015) was based on the version of the rules presented at the July 22, 2015 Public Workshop. Since then, there have been revisions made to the Proposed Rule Amendments. The revisions that were already incorporated in the Revised Draft Staff Report (released on October 6, 2015) have been reflected in the analysis presented in the previous sections. The potential socioeconomic impacts of the newer revisions are discussed below.

[30] As of the Revised Draft Staff Report released on November 5th, this number is now 8.77.

10.1 Option to Exit for Electricity Generating Facilities

Under the Proposed Amendments to Rule 2001, an electricity generating facility (EGF)—excluding cogeneration plants—would be allowed to exit the RECLAIM program, provided that at least 99 percent of the facility's NOx emissions for the most recent three full compliance years are from equipment that meets current BACT or BARCT for NOx. If an EGF decides to opt out from RECLAIM, it would need to surrender a pre-defined amount of NOx RTCs to be retired from the NOx RTC market. For existing EGF RECLAIM facilities as defined by the rule, the amount to be surrendered would be equivalent to the amount of NOx RTC holdings as of September 22, 2015, as adjusted by the proposed shaves; for other EGFs, the amount would be equivalent to the quantity required to be held by the facility pursuant to Rule 2005 – New Source Review.

Since the ability to exit RECLAIM is an option, it will be a business decision made by an EGF to exit RECLAIM, and therefore, it can be reasonably assumed that the business decision to exit the program would generate potential cost-savings for the facility; therefore, such a facility is not expected to experience any adverse economic impact due to this proposed rule amendment. However, due to the proposed provisions that a pre-defined amount of NOx RTCs shall be surrendered and retired from the market, this proposed rule amendment could potentially reduce the market supply of NOx RTCs. It should be noted that, while the 21 EGFs together hold more than 20 percent of the current NOx RTCs (or 5.63 tpd as of September 22, 2015), only a very small percentage of these holdings are sold on the NOx RECLAIM market, either as IYB or Discrete NOx RTCs.

To assess the potential impact on both the IYB and Discrete NOx RTC market, staff analyzed the NOx RTC transactions occurring during the period from 2010-2014. To begin, staff eliminated any transaction that did not have a positive market value (which could be due to a business's internal transfers or equal-value swap trades), and therefore might not have reflected real market supply and demand. Infinite-Year-Block (IYB) NOx RTCs sold by any operating EGFs over the five-year period represented less than 0.00001 percent of total IYB NOx RTCs traded in this market. As a result, little impact from EGF opt-out is expected for the IYB market.

Less than half of the EGFs have consistently sold RTCs in the discrete credit market over the past five years. As shown in the table below, during 2010-2014, these EGFs sold an annual average of nearly 1.4 tpd of NOx RTCs to help satisfy the market demand for discrete year NOx RTCs. Many of these facilities would be subject to a 49% shave under the proposed rule amendments and will no longer have that much surplus NOx RTCs for sale on the market. Therefore, in the worst-case scenario if all EGFs decide to exit RECLAIM, the post-shave market supply of NOx RTCs would be decreased by 0.216 tpd, once they have all opted out.[31] The decrease per se may exert an upward pressure on the discrete NOx RTC prices. (The estimated incremental compliance cost associated with market price increases of discrete NOx RTCs can be found in Section 9.) It is also possible that these EGFs choose to opt out during the 2016-2022 period, thus removing more NOx RTCs from the market than would occur after full shave implementation in 2022. Note that EGFs opting-out may also decrease demand for RTCs. Nonetheless, if that happens and credit prices increase

[31] The total projected surplus NOx RTCs for all operating EGFs in 2023 are estimated to be up to 1.5 tpd. However, staff does not expect this full amount of surplus credits would be offered for sale in the NOx RTC market, as a large share of these credits are held by EGFs that typically do not sell their surplus NOx RTCs.

to the level as specified by the Rule 2002 price trigger, the non-tradable/non-usable credits would then be converted to tradable/usable credits, which would be sufficient to temporarily offset the decrease in NOx RTC supply due to any EGF opt-out. (As shown above, the decrease resulting from EGFs opting out is expected to be less than 1.4 tpd while the amount of potential credit conversion would be at least 2 tpd.)

Table 26: Potential Decrease in the Market Supply of Discrete NOx RTCs due to EGF Opt-Out

Electricity Generating Facility Selling NOx RTCs during 2010-2014 (excl. Cogeneration)	Average Annual NOx RTC Sale (tpd)	Proposed Total Shave (tpd)	Estimated Post-Shave Market Supply (tpd) = Min (0, Average Annual NOx RTC Sale - Proposed Total Shave)
A	0.353	0.363	0.000
B	0.347	0.176	0.171
C	0.264	0.330	0.000
D	0.219	0.196	0.023
E	0.087	0.160	0.000
F	0.049	0.077	0.000
G	0.044	0.120	0.000
H	0.017	0	0.017
I	0.006	0	0.006
Total	**1.385**		**0.216**

In a letter dated November 17, 2015, WSPA stated that the Socioeconomic Assessment "does not consider whether such a supply constriction [from EGF opt-out] might actually impair regional economic activity due to a lack of available RTCs. Rather, it assumes that RTC supply will be available at some (presumably higher) cost without providing any evidence to support that assumption." In another letter dated November 17, 2015, Southern California Air Quality Alliance on behalf of the NOx RECLAIM Industry Coalition stated that the Socioeconomic Assessment did not consider the effect of EGF opt-out on the IYB market. Staff believes that these comments are a result of misunderstandings. The analysis presented in the paragraphs above, which is a refinement of the analysis conducted in the Draft Final Socioeconomic Report, clearly represents staff's assessment of the effects of EGF opt-out on the discrete year and IYB NOx RTC market.

The WSPA comment letter dated November 17, 2015 incorrectly claimed that the Socioeconomic Report released on November 4, 2015 acknowledged that "EGFs have been significant sellers of surplus RTCs in the discrete credit market over the past five years to meet market demand; […]." While the 21 EGFs together hold more than 20 percent of the current NOx RTCs (or 5.63 tpd as of September 22, 2015), they rarely offered any IYB RTCs for sale, and are not expected to do so in the future given their NSR holding requirements and/or grid stability considerations. Less than half of the EGFs were regular net sellers of discrete NOx RTCs over the past five years, and they supplied an annual average of 1.4 tpd in total, which is about only 5 percent of the current total NOx RTC holdings. In the post-shave market (i.e., 2023 and beyond.), the estimated 0.216 tpd of remaining market supply among these facilities would account for less than 2 percent of total post-shave market holdings.

10.2 NOx RTC Price Triggers

Under the Proposed Amendments to Rule 2002, the price threshold beyond which the non-tradable/non-usable NOx RTCs would be converted to tradable/usable NOx RTCs is raised to $22,500 from $15,000, on the basis of 12-month rolling average of discrete NOx RTC prices. In order to further ensure price stability during the proposed phased-in period of 2016-2022, an additional stabilization mechanism would be put in place, which constitutes an additional price trigger of $35,000, on the basis of 3-month rolling average of discrete NOx RTC prices. This additional price trigger would assist with shortening the duration of any potential price spikes and containing the magnitude of any potential adverse economic impact on NOx RTC buyers. The estimated incremental compliance cost associated with market price increases of discrete NOx RTCs can be found in Section 9, which contains the price scenario where buyers would need to pay $22,500 per discrete ton of NOx RTC to reconcile their annual NOx emissions.

Proposed Amended Rule 2002 also contains another price trigger—$200,000 per ton (Infinite Year Block) based on the 12-month rolling average—below which the Executive Officer will report the determination to the Governing Board. As the determination is yet to be made and the provision would not be effective until 2019, it is speculative to assess any potentially resultant socioeconomic impact. Moreover, following the 2005 NOx RECLAIM amendments, none of the 51 SCRs identified in the BARCT analysis for refineries have been installed because of RECLAIM, not even in 2008 when the average IYB prices went above $200,000 (in 2008 dollars) per ton of NOx. This suggests that NOx RTC prices could have been historically too low to induce cost-effective control installation, and the 200,000 price trigger floor is conservative.

10.3 Facility Shutdowns

Since the adoption of RECLAIM, facilities which planned to shut down were not restricted from selling off their RTCs prior to facility closures. RTCs resulting from shutdowns are not subject to the best available control technology (BACT) discount that is applicable to non-RECLAIM sources.

As a consequence, staff estimated that a significant portion of the unused RTCs can be traced to the sale of pre-closure RTCs. As shown in Table 2 of this report, facility shutdowns amounted to 2.62 tpd of actual NOx emission reductions between 2006 and 2012, which was just less than two thirds of the 4 tpd actual total reductions over the same period. However, NOx RTCs that were previously held by these shutdown facilities were never removed from the market, thus exerting a downward pressure on the RTC market prices. This, in turn, has dis-incentivized the remaining NOx RECLAIM facilities from installing cost-effective control equipment or making other changes at their facilities.

Under the Proposed Amended Rule 2002, any major NOx-emitting facility (i.e., those listed in Table 7 or 8) permanently shutting down some or all equipment with emissions greater than or equal to 25 percent of the facility emissions for any quarter within the previous 2 compliance years would need to surrender NOx RTCs to be retired from the market. The amount of NOx RTCs to be surrendered would be determined by the maximum quarterly ratio of the average NOx emissions emanating from the shutdown equipment over facility-wide NOx emissions, multiplied by the facility's NOx RTC allocations.

In the Southern California Air Quality Alliance comment letter dated November 17, 2015, it was stated that an analysis should have been conducted to assess the impact of removing RTCs from the market relating to shutdowns. Also in the WSPA comment letter dated November 17, 2015, it was stated that there was no technical analysis in the Draft Final Socioeconomic Report in this topic. Since staff cannot predict which facilities may choose to shut down some or all of their permitted equipment, it would be speculative to predict the magnitude of any impact on the NOx RTC market resulting from future shutdowns. The shut-down provision would not allow large influxes of credits into the RECLAIM market because of shutdowns. However, as discussed previously, staff acknowledges that the provision of surrendering and retiring NOx RTCs from the market could potentially affect the credit market and prices. The magnitude of the potential impact would depend heavily on the usual market behavior of each facility before it decides to shut down. On the one hand, for facilities that regularly sell their surplus NOx RTCs, the provision would exert an upward pressure on NOx RTC prices. On the other hand, if the shutdown facility is a regular buyer on the NOx RTC market or does not participate in the market at all, the retirement of their NOx RTCs would have little, if any, impact on the RTC market supply. In any event, District analyses show that the unrestrained flow of RTCs from shut downs have resulted in an oversupply of RTCs so that BARCT equivalent controls are avoided.

11. COSTS OF COMMAND AND CONTROL (CAC) COMPARED TO RECLAIM

RECLAIM allows facilities to use the least costly option to remain in compliance. Unlike the command-and-control regulations where every source has to be controlled to the same emission standard, RECLAIM facilities can pursue operational changes or purchase RTCs from investors and other facilities with surplus credits in lieu of upgrading existing control equipment or installing new control equipment. This flexibility notwithstanding, RECLAIM ultimately must achieve emissions reductions equivalent to or greater than what would have been achieved under command-and-control regulations. A BARCT assessment is required by H&SC §40440 and BARCT requires actual emission reductions. Based on staff analysis, a reduction of 14 tpd of NOx RTCs is needed to induce actual emission reductions equivalent to BARCT. The 2015 BARCT analysis demonstrated that there would be an actual NOx emission reduction of 8.77 tpd from the 2011-2012 activity levels at 2015 BARCT compared to the same activity levels at 2005 BARCT. This represents 8.77 tpd reductions in actual emissions. If the overall NOx RTC holdings had closely matched the total amount of actual NOx emissions from the NOx universe, the removal of 8.77 tpd of NOx RTCs would likely induce an equivalent amount of actual NOx emission reductions. However, over the past five years, actual NOx emissions from RECLAIM facilities fell below the overall NOx RTC holdings by 21-30%, resulting in approximately 5.45-8.41 tpd of unused NOx RTCs (unused for compliance purposes). Therefore, the removal of 8.77 tpd of NOx RTCs would first eliminate some, if not all, of these excess NOx RTCs from the market and only thereafter result in actual emissions reductions. As a result, total emission reductions would be less than the BARCT-equivalent level of actual NOx emission reductions.

The problem of excess unused RTCs is illustrated by the fact that the 2005 NOx shave did not achieve 2005 BARCT levels for the RECLAIM universe. The 7.7 tpd of NOx shave adopted in the 2005 RECLAIM amendments was phased in over the period of 2007-2011; however, only about 4 tpd of actual NOx emission reductions occurred between 2006 (the year before the 2005 shave began) and 2012 (the year after the 2005 shave was fully phased in).[32] Almost two-thirds of the actual emission reductions resulted from facility shutdowns, not installation of controls or other changes at RECLAIM facilities. Therefore, as long as there are persistently unused RTCs available in the market, the RTC shave would need to be larger than the tons of emission reductions calculated for the BARCT analysis to induce an equivalent level of actual emission reductions.

The proposed phased-in shave of 14 tpd is anticipated to be able to induce sufficient emission reductions by 2023 so that the expected total NOx emissions from the RECLAIM universe in 2023 would be consistent with the projected NOx emissions in 2023 at the 2015 BARCT levels. (Please see the Staff Report for the shave methodology.)

As discussed in the Revised Draft Staff Report, staff has identified and demonstrated that technologically feasible and cost-effective control equipment are commercially available if any of the 20 facilities with identified BARCT chooses to install controls in response to the proposed shave from the NOx RECLAIM universe. The total cost of full BARCT installation was estimated to be between $728 million and $1.1 billion (present worth value in 2014 dollars). However, a RECLAIM facility is expected to retrofit an emission source only when it meets both of the following conditions: first, it does not hold sufficient RTCs to offset facility-wide emissions at the end of the compliance period; second, the cost of control installation per ton of emission reduction is lower than the expected average RTC price over the life of the control equipment.

Even if a facility finds it more cost-effective to install pollution control equipment, it still would not incur the full cost of control installation if control installation results in surplus RTCs that the facility eventually sells to offset the control installation cost. In comparison, command-and-control regulations would require, under all circumstances, that this same facility install the control equipment and incur the full cost of control installation. As a result, total costs to install controls under RECLAIM will always be equal to or less than under command and control. Under command and control, each facility must install the required controls, whereas under RECLAIM, the highest cost option is where each facility installs BARCT controls, because the total actual costs may be lower if a facility identifies any other more cost-effective alternative to remain in compliance. Looking at the RECLAIM program as a whole, the major source of cost-savings potential is precisely the differential in each facility's ability to cost effectively reduce emissions at different points in time. This cost-savings has been studied and quantified in economic research of cap- and-trade market mechanism since the 1970s, and the range of cost-savings was estimated to be between 15% and 90 % of command-and-control costs (Chan et al. 2012).

H&SC §39616 (c) specifies that: "In adopting rules and regulations to implement a market- based

[32] Some of the 4 tpd of actual reductions came from operational changes at refineries, which chose to run gas turbines instead of higher-emitting at various points in time. However, just less than two-thirds of the 4 tpd actual reductions were due to facility shut-downs and not measures taken to reduce actual emissions by facilities in the program. In 2005, the installation of 51 SCR units at refineries. However, not one has been installed due to the RECLAIM program. (Four SCR units were installed only due to orders for abatement.) While that choice did not violate RECLAIM, it resulted in facilities not achieving the level of emissions they would have achieved had they applied BARCT. As a result, there is a need to ensure that the currently proposed shave is sufficient to induce emissions reductions equivalent to 2015 BARCT levels, accounting for growth to 2023.

incentive program, a district board shall, at the time that the rules and regulations are adopted, make express findings." One of those findings pursuant to H&SC §39616 (c)(1) is that emission reduction benefits and the costs of the program shall be compared with those of "current command and control regulations and future air quality measures that would otherwise have been adopted as part of the district's plan for attainment." H&SC §39616 (c) does not refer to "amendments," and therefore, it does not apply to the proposed rule amendments *per se*. Nevertheless, assuming that the finding needed to continue to be made upon amendment of the rules, it makes sense to make that finding with respect to the entirety of the RECLAIM program since its adoption, because the statute repeatedly refers to "the program" in specifying findings that need to be made. Thus, the structure of H&SC §39616 is directed to the program as a whole, which includes the entirety of the program since its adoption. With the exception of the 2000-2001 period when the California energy crisis took place, the historical discrete NOx RTC prices ($5,500 or lower per ton) have consistently been at the lower end of or below the cost- effectiveness range of pollution controls. As a result, many RECLAIM facilities have accrued substantial cost-savings over the years by being able to delay or forego the installation of pollution control equipment that would have been required at different points in time by command-and-control regulations. And even if the H&SC §39616 (c)(1) finding needs to be made for this proposed shave alone, the proposed shave is expected to only reduce the future stream of this cost-savings. Even so, a reduced cost-savings is still a cost- savings compared to command-and-control regulations. Thus, this amendment will clearly not cost more than the projected cost of command and control.

For example, following the 2005 NOx RECLAIM amendments, not one of the 51 SCRs identified in the BARCT analysis for refineries have been installed because of RECLAIM, and 4 SCRs were installed only due to orders for abatement. As a result, refineries have saved approximately $205 million since 2007 by delaying installation of 47 SCRs.[33] The cost-savings would continue to accumulate as long as refineries are able to further delay the installation of SCRs and still remain in compliance under RECLAIM. This continuous stream of cost-saving would only be reduced or even ceased if the currently proposed shave could eventually induce at least some of the 47 SCRs to be installed.

Staff acknowledges that, for a portion of the smaller emitters that have no cost-effective controls identified so far, they may have been affected by past RTC price spikes and could potentially be impacted by future price fluctuations, either due to their RTC holdings or their limited financial capacity to hedge against price volatilities. However, their potential losses would be at the same time economic gains for the RTC sellers; therefore, the resulting net cost, if any, is expected to be zero or negligible to the entire RECLAIM program, particularly compared with the program's cost savings. While individual facilities may experience different costs and savings, H&SC §39616 applies to the RECLAIM universe as a whole.

[33] The total capital and installation cost for 47 SCRs was estimated to be $460 million in 2005 dollars in the 2005 amendments to the RECLAIM program (not counting the operating and maintenance costs). If the facilities invested this money at a 5 percent nominal rate of return over the 8 years, they would have saved a total of $220 million (i.e., $460 million*(1.05)^8 - $460 million, in 2015 dollars), by the end of 2015. Meanwhile, the affected facilities purchased 1.7 tpd of RTCs in lieu of installing 47 SCRs. The cost of purchasing these RTCs over the past 8 years is estimated to be about $15 million (i.e., 1.7 tpd * 365 days *
$3,000 per discrete ton of RTCs * 8 years). The total net cumulative benefits of the program for refineries only would have been about $205 million. (Based on further analysis using internal RECLAIM compliance data, the total cost of RTC purchases by refineries from 2005-2013 was estimated to be between $16 and $18 million.)

In the 2005 RECLAIM amendments, some stakeholders commented that the shaved RTCs would result in real, significant financial cost to companies and should be recognized as a cost. However, staff disagreed at the time RECLAIM was first adopted and still disagrees today that the cost of shaved RTCs should be recognized as a programmatic cost. Staff has never considered the "cost" of the shaved RTC's to be recognized as a "cost" for determining equivalency with command and control. At the outset of RECLAIM, RTCs were allocated to RECLAIM facilities free of charge, yet they now have value to the facilities as a commodity that can be bought and sold. While RTCs have value, they are not a property right. The proposed amendments to RECLAIM will reduce the number of RTCs. Since there was no cost associated with allocated RTCs for a facility, there should be no financial loss to the RECLAIM universe as the SCAQMD retires them. Any additional purchase of RTCs executed by a facility is made in lieu of emission control. The choice between the RTC purchase and emission control is solely a business decision that is made to generate an expected stream of cost-savings afforded only by the RECLAIM program and not available under command-and-control. Therefore, any RTC investment loss should not be considered as a compliance cost to be compared to the compliance cost under command-and-control regulations. Moreover, this loss may be offset by any potential increase in RTC price due to a decreased RTC supply, which would subsequently raise the market value of a facility's remaining RTC holdings. Finally, any loss of "value" of shaved RTCs cannot be compared to command and control, because in that case there are no RTCs and thus no similar "value" was ever created.

To sum up, many factors are in play that may lower the compliance cost of RECLAIM as compared to CAC. They include:

- RECLAIM facilities have many more options for compliance than facilities under traditional command and control rules, including adding control equipment, process changes, and purchasing RTCs.
- Sources subject to Rule 2005—New Source Review for RECLAIM—are not subject to the 1.2 offset factor that is applied to new and modified sources for non- RECLAIM facilities when using emission reduction credits (ERCs).[34]
- Rule 2005 facilities can sell excess RTC offset holdings at the end of each compliance year resulting from installing or modifying existing control equipment. This option is not available under CAC.
- RTCs resulting from shutdowns have not been subject to the best available control technology (BACT) discount that is applicable to non-RECLAIM sources.
- RECLAIM facilities can take advantage of facility or program emission averaging to implement the least cost controls. Cross-cycle trading under RECLAIM provides additional compliance flexibility.
- The non-RECLAIM facilities are subject to source specific standards (e.g. concentration limits or mass emission limits) that cannot be exceeded at any time whereas, for the most part, RECLAIM facilities can operate their equipment with flexibility and reconcile the emissions with the facility caps at the end of the compliance quarter and year.
- RECLAIM facilities have received monetary benefits from trading their RTCs through the past 22-year life of the RECLAIM program to reduce the costs of compliance.

[34] Rule 2005—New Source Review for RECLAIM.

Based on the aforementioned reasons, the compliance costs under RECLAIM are equivalent to or less than what would have occurred under CAC.

14. APPENDIX B: WEEKLY EARNINGS BY OCCUPATIONAL WAGE GROUP BY MEDIAN WEEKLY EARNINGS

Table A

Quintile	Occupational Title	Median Weekly Earnings
1	Media and communication equipment workers	$398
1	Nursing, psychiatric, and home health aides	$457
1	Occupational therapy and physical therapist assistants and aides	$457
1	Other healthcare support occupations	$460
1	Cooks and food preparation workers	$398
1	Food and beverage serving workers	$424
1	Other food preparation and serving related workers	$385
1	Building cleaning and pest control workers	$467
1	Grounds maintenance workers	$445
1	Entertainment attendants and related workers	$361
1	Personal appearance workers	$480
1	Other personal care and service workers	$431
1	Supervisors of farming, fishing, and forestry workers	$448
1	Agricultural workers	$418
1	Fishing and hunting workers	$448
1	Forest, conservation, and logging workers	$448
1	Other construction and related workers	$461
1	Textile, apparel, and furnishings workers	$250
1	Other transportation workers	$236
2	Life, physical, and social science technicians	$571
2	Other education, training, and library occupations	$582
2	Other protective service workers	$534
2	Supervisors of food preparation and serving workers	$529
2	Animal care and service workers	$524
2	Funeral service workers	$481
2	Baggage porters, bellhops, and concierges; Tour and travel guides	$481
2	Retail sales workers	$516
2	Information and record clerks	$603
2	Other office and administrative support workers	$611
2	Helpers, construction trades	$566
2	Extraction workers	$596
2	Assemblers and fabricators	$525
2	Food processing workers	$509
2	Printing workers	$583
2	Plant and system operators	$573
2	Other production occupations	$555

Table A (Continued)

Quintile	Occupational Title	Median Weekly Earnings
2	Rail transportation workers	$619
2	Material moving workers	$486
3	Social scientists and related workers	$640
3	Religious workers	$767
3	Librarians, curators, and archivists	$685
3	Entertainers and performers, sports and related workers	$763
3	Supervisors of building and grounds cleaning, maintenance workers	$684
3	Supervisors of personal care and service workers	$687
3	Other sales and related workers	$659
3	Communications equipment operators	$638
3	Financial clerks	$624
3	Material recording, scheduling, dispatching, and distributing workers	$623
3	Secretaries and administrative assistants	$681
3	Construction trades workers	$680
3	Electrical and electronic equipment mechanics, installers, and repairers	$706
3	Vehicle and mobile equipment mechanics, installers, and repairers	$737
3	Other installation, maintenance, and repair occupations	$761
3	Metal workers and plastic workers	$645
3	Woodworkers	$623
3	Motor vehicle operators	$689
3	Water transportation workers	$620
4	Drafters, engineering technicians, and mapping technicians	$909
4	Life scientists	$960
4	Counselors and Social workers	$864
4	Miscellaneous community and social service specialists	$773
4	Legal support workers	$856
4	Preschool, primary, secondary, and special education school teachers	$935
4	Other teachers and instructors	$905
4	Art and design workers	$969
4	Health technologists and technicians	$768
4	Supervisors of protective service workers	$897
4	Fire fighting and prevention workers	$939
4	Law enforcement workers	$899
4	Supervisors of sales workers	$776
4	Sales representatives, services	$906
4	Supervisors of office and administrative support workers	$772
4	Supervisors of installation, maintenance, and repair workers	$980

Table A (Continued)

Quintile	Occupational Title	Median Weekly Earnings
4	79 Supervisors of production workers	$902
4	88 Supervisors of transportation and material moving workers	$882
4	Military	$904
5	Top executives	$1,729
5	Advertising, marketing, promotions	$1,384
5	Operations specialties managers	$1,320
5	Other management occupations	$1,141
5	Business operations specialists	$1,074
5	Financial specialists	$1,108
5	Computer occupations	$1,367
5	Mathematical science occupations	$1,244
5	Architects, surveyors, and cartographers	$1,016
5	Engineers	$1,384
5	Physical scientists	$1,261
5	Lawyers, judges, and related workers	$1,738
5	Postsecondary teachers	$1,172
5	Media and communication workers	$995
5	Health diagnosing and treating practitioners	$1,267
5	Other healthcare practitioners and technical occupations	$1,065
5	Sales representatives, wholesale and manufacturing	$1,042
5	Supervisors of construction and extraction workers	$990
5	Air transportation workers	$1,131

15. APPENDIX C: RESPONSE TO STAKEHOLDER COMMENTS

Comments Received at the January 8, 2015, CEQA and Socioeconomic Scoping
A combined CEQA and Socioeconomic Scoping was held on January 8, 2015. There were two specific comments regarding the yet to be completed draft socioeconomic analysis which are addressed below.

Comment #1:
Industry would like to request that the impact of an alternative incremental BARCT shave be analyzed in the socioeconomic assessment.

Response:
The draft socioeconomic document analyzed the impact of this proposed alternative in the Draft Socioeconomic Report released on September 9, 2015. This alternative is listed as CEQA alternative #3—Industry Proposal.

Comment #2:
There are at least a dozen facilities with boilers above 40 mmBtu/hr that will not have cost-effective control equipment to install. The cost-effectiveness of this control equipment is $200,000 per ton and higher, and, as a result, these facilities are only left with the option to buy credits at higher prices after the shave.

Response:
The proposed amendments used a cost effectiveness of $50,000 per ton to determine the quantity of equipment estimated to be cost effective and the amount of emission reductions for the program.

If this comment refers to the refinery sector, the incremental cost effectiveness is $28,000 for refinery boilers/heaters above 40 mmBtu/hr (see Table 4.3 of the staff report). Any controls with cost effectiveness above $50,000 were not considered in the BARCT analysis. If this comment refers to the non-refinery sector, the BARCT analysis indeed did not identify any cost-effective controls for boilers/heaters above 40 mmBtu/hr (see Table 4.2 of the staff report); however, there are cost-effective controls identified for other emission sources.

Under the proposed amendments, the proposed BARCT-based shave would be distributed in the fashion that facilities with identified BARCT would see their RTC holdings reduced by the highest percentages. A non-refinery facility with identified BARCT is expected to be able to reduce facility-wide emissions by installing cost- effective controls on emission sources other than boilers/heaters above 40 mmBtu/hr; however, this same facility would also have the flexibility to reconcile their facility-wide emissions by obtaining sufficient NOx RTCs.

The Draft Socioeconomic Report has analyzed the potential incremental costs of purchasing RTCs at higher prices for 45 facilities where no control equipment has been identified for installation, as well as for the 210 facilities exempt from the shave.

Western States Petroleum Association (WSPA) Comment Letter #1 Received January 30, 2015

Socioeconomic Comment Letter #1

WSPA

Patty Senecal
Manager, Southern California Region and Infrastructure Issues

VIA ELECTRONIC MAIL

January 30, 2015

Dr. Elaine Chang
Deputy Executive Officer, Planning, Rule Development & Area Sources
South Coast Air Quality Management District
21865 Copley Drive
Diamond Bar, CA 91765

SUBJECT: WESTERN STATES PETROLEUM ASSOCIATION (WSPA) COMMENTS ON THE SOCIOECONOMIC ASSESSMENT FOR PROPOSED AMENDED REGULATION XX – REGIONAL CLEAN AIR INCENTIVES MARKET (RECLAIM)

Dear Dr. Chang:

The Western States Petroleum Association ("WSPA") is a non-profit trade association representing twenty-five companies that explore for, produce, refine, transport and market petroleum, petroleum products, natural gas and other energy supplies in California, Arizona, Nevada, Oregon, and Washington. WSPA-member companies operate petroleum refineries and other facilities in the South Coast Air Basin that are within the purview of the Regional Clean Air Incentives Market ("RECLAIM") program. 1-1

WSPA supports the scoping comments submitted by the Industry RECLAIM Coalition for the Socioeconomic Assessment for Proposed Amended Regulation XX.[1] WSPA formally offers the following additional comments:

1. *A ten-year useful equipment life would be more appropriate due to the frequency of District rulemakings. AQMD's 25-year useful equipment life assumption is not appropriate and results in an understated BARCT cost effectiveness analysis. Potential stranded asset costs should be considered in the socioeconomic assessment.* 1-2

[1] SCAQMD, Notice of Preparation (NOP) and Initial Study for a Draft Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), 4 December 2014 ("NOP/IS").

970 W. 190th Street, Suite 304, Torrance, California 90502
PHONE: (310) 678-7782 • FAX: (310) 324-9063 • PSenecal@wspa.org • www.wspa.org

For some time, South Coast Air Quality Management District ("AQMD" or "District") has been using a 25-year equipment life assumption to compute emission control cost effectiveness when conducting new Best Available Control Retrofit Control Technology ("BARCT") analyses. This equipment life assumption results in a systemic understatement of emission control costs because BARCT is typically redefined on much shorter terms. To that point, the District established BARCT for all of the source categories being considered under this Regulation XX rulemaking only ten years ago (i.e., 2005). Calculation of control costs of the 25-year term distorts the true cost associated with these rules. 1-2 Concluded

As recommended in ABT Associates' recent evaluation of the District's socioeconomic assessment process,[2] AQMD should ensure that the control costs used in the Regulation XX socioeconomic assessment include the full cost of retrofitting existing controls or installing new controls. This would include consideration of any stranded asset costs, such as when the proposed BARCT determination requires replacement of prior investments for emission control equipment or effectively mandates the replacement of basic equipment (e.g., gas turbines).

2. *The District's capital cost estimates are significantly lower than refiners' estimates; the socioeconomic assessment should consider a scenario based on these higher costs.*

As with past rulemakings, the District's emission control costs for refineries have been underestimated. Norton Engineering Consultants ("Norton") recently concluded a review of the District's BARCT analysis[3] and concluded that emission control costs for most refinery source categories would be significantly higher than those estimated by District staff. For example:

- FCCUs: Norton's Present Worth Value (PWV) estimates for FCCUs were >60% higher than the last PWV estimates presented by AQMD staff to the NOx RECLAIM Working Group (note: range of variance was between -19% and +138% depending on the unit) 1-3
- Refinery Heaters/Boilers: On average, Norton's PWV estimates were >90% higher than the last estimates presented by AQMD staff (note: range of variance was a function of size).[4]
- Coke Calciner: Norton concluded the PWV costs will be >75% higher than the most recent AQMD Staff estimates, and that for BARCT performance in the range of 5-10 ppmv NOx (i.e., not 2 ppmv).[5]
- Sulfur Recovery Units/Tail Gas Treatment Units: Norton concluded that PWV costs will be higher than the AQMD Staff with range of variances between +37% and +267% depending on the unit.[6]

[6] Comparison of data presented in Norton Report (p. 34) to AQMD Staff data presented to the NOx RECLAIM WGM, 31 July 2014.

970 W. 190th Street, Suite 304, Torrance, California 90502
PHONE: (310) 678-7782 • FAX: (310) 324-9063 • PSenecal@wspa.org • www.wspa.org

Based on a confidential and blinded cost survey of WSPA members conducted last year, it appears that the Norton cost estimates may also significantly understate the refinery sector's overall cost of control for this Regulation XX rulemaking. Because RECLAIM is a market-based emission control program, the individual companies have the flexibility to develop their own strategies for complying with their facility-wide emission limits. These strategies can involve emissions control projects or RTC trading and the companies are incentivized under the program to seek the most cost-effective approach for their particular situation. 1-3 Concluded

WSPA, through a third party contractor, conducted a confidential cost survey of the Southern California refineries concerning total capital and operating costs for their compliance strategies for the District's proposed NOx RECLAIM shave.[7] This information is highly proprietary and refiners submitted this information on a confidential basis to the third-party contractor who de-identified and aggregated the compliance costs for the overall industry. The current refining industry forecast suggests the compliance costs of this rulemaking may be nearly twice the most recent cost estimate presented by AQMD staff.[8]

Given the magnitude of this cost variance, WSPA is willing to make its contractor, Stillwater Associates, available to District socioeconomic staff to discuss the aggregated findings of WSPA's confidential survey for the refining industry. In addition, our members, as individual refiners, are willing to discuss with the District staff, individual inputs to the confidential survey to substantiate the methodology and its findings. We respectfully request that the District's socioeconomic assessment consider this higher cost scenario as it would better inform the Governing Board and stakeholders of the true, potential socioeconomic impacts associated with the proposed rulemaking. 1-4

We appreciate your consideration of these comments in the scoping of the socioeconomic assessment for the Regulation XX rulemaking, and will continue working with AQMD staff towards the development of sensible proposal for the RECLAIM program.

Very truly yours,

Patty Senecal

Responses to WSPA – Socioeconomic Letter #1

1-1. Thank you for the comments provided.

1-2. Although the Bay Area AQMD and EPA OAQPS assume an SCR lifespan of 20 years, staff used a 25-year equipment life for SCRs to be installed based on the profiles of SCRs used by refineries in the Basin. Nearly 30 percent of the refinery combustion equipment in the Basin has SCRs that were installed more than 25 years ago, and more than 60 percent of the refinery combustion equipment has SCRs that were installed more than 20 years ago. These units are still in operation and thus support the assumption of a 25-year useful life in the cost analysis.

In addition, there is no demonstration that assets have been stranded as a result of advancements in BARCT, since such advancements may be based on improvements in the earlier air pollution control technology. Thus, to artificially reduce equipment life based on the potential for new BARCT requirements in the future is speculative, and will be addressed at the time of any rulemaking.

1-3. The cost estimates used in the staff report are what is used in the socioeconomic analysis. Please see the Staff Report for more information regarding the difference between staff estimates and NEC estimates.

1-4. As indicated in Response 1-3, please refer to the Staff Report for cost estimates and related assumptions. In a comment letter dated August 21, 2015, Western States Petroleum Association (WSPA) stated, "WSPA believes that the District's cost effectiveness calculations significantly understate the costs associated with achieving the proposed BARCT levels. We believe that even the Norton analysis underestimates actual costs. WSPA is currently developing additional information based on detailed engineering assessments that more accurately represent the costs associated with the proposed BARCT. We will submit this information to the record as it becomes available." WSPA also stated in a working group meeting that their cost estimates were 2 to 3 times higher than those estimated in the Staff Report. Staff has met with three refineries who provided varying levels of detail regarding their projected costs that would occur for these facilities to comply with the proposed amendments. There is not sufficient information for staff to verify the WSPA cost estimates. Some of the difference related to staff using an incremental cost-effectiveness calculation, which assumes that 2005 BARCT levels are in place, which may or may not be the case for individual facilities, but is needed for a programmatic evaluation. The individual facilities include total costs, and often include full costs for additional equipment such as substations that may support the new control equipment, as well as other operations at the facility.

Diamond Bar, CA 91765

SUBJECT: INDUSTRY COMMENTS ON THE SOCIOECONOMIC ANALYSIS FOR PROPOSED AMENDED REGULATION XX – REGIONAL CLEAN AIR INCENTIVES MARKET (RECLAIM)

Dear Dr. Chang:

These comments are presented on behalf of the members of leading Southern California businesses represented by the California Council for Environmental and Economic Balance ("CCEEB"), the Regulatory Flexibility Group ("RegFlex"), the Southern California Air Qaulity Alliance ("SCAQA"), and Western States Petroleum Association ("WSPA"). The members of these business groups are major Southern California employers who own and operate facilities that comprise most of the Regional CLean Air Incentives Market ("RECLAIM") program. 2-1

This "Industry RECLAIM Coalition" formally offers the following scoping comments on Socioeconomic Analysis for Proposed Amended Regulation XX.[1]

1. *The socioeconomic analysis should incorporate the procedural improvements recommended under the ABT study;[1] these are important enhancements to the District's socioeconomic analysis process.* 2-2

The District recently commissioned ABT Associates to conduct an evaluation of the SCAQMD's socioeconomic assessment process.[2] ABT made a number of recommendations relevant to this rulemaking which SCAQMD committed to implement.[3] This included but was not limited to the following:

[1] SCAQMD, Notice of Preparation (NOP) and Initial Study for a Draft Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), 4 December 2014 ("NOP/IS").
[2] ABT Associates, Review of the SCAQMD Socioeconomic Assessments, Documentation, Task 1-4 Final, 14 August 2014.
[3] AQMD, Summary of ABT Recommendations & SCAQMD Staff Response, presented to Governing Board, 7 November 2014.

Dr. Elaine Chang, SCAQMD
30 January 2015

- Appropriately consider useful life of pollution control equipment; need to consider stranded costs where early replacement is required
- Present both DCF and LCF methods" with appropriate thresholds
- Ensure control costs of new regulations include complete estimate of retrofitting existing controls. Clearly cite and include all sources of control cost estimates.
- Improve transparency through external peer reviews

2-2 Concluded

While these recommendations were agreed to by AQMD Staff in the context of the 2016 Air Quality Management Plan ("AQMP"),[4] the Industry RECLAIM Coalition believes they are more broadly important than just for the AQMP. The proposed revisions to Regulation XX represent a significant rulemaking which could have significant socioeconomic impacts to the Southern California regional economy. We recommend that these process improvements recommended by ABT Associates should be fully incorporated into the socioeconomic analysis for the Regulation XX rulemaking.

2. *The socioeconomic analysis should fully consider the comparative economic impacts of project Alternatives presented in the Draft Program Environmental Assessment ("PEA") for Proposed Amended Regulation XX, including the Industry Coalition's alternative proposal.*

Under the 2012 AQMP, the Governing Board approved control measure CMB-01 which authorized further reductions from the NOx RECLAIM program. The control measure authorized by the Governing Board was based on a range of 3-5 tons per day ("TPD") of RECLAIM Trading Credits ("RTCs") being removed from the program. While stakeholders understood the eventual rulemaking could differ, the current Staff proposal as presented in the NOP/IS would be substantially larger at nearly 13 TPD.

2-3

This Industry RECLAIM Coalition has presented an alternative methodology for demonstrating command-and-control equivalency which would reduce the program's quantity of RTCs by an amount limited to only those reductions that can be directly attributed to the advancement of Best Available Retrofit Control Technology ("BARCT"). While the industry proposal could also result in RTC reductions greater than the approved AQMP control measure, it would be less than what has been presented by the AQMD Staff.

Given the significant differences between the Proposed Project and project Alternatives, we recommend that the socioeconomic analysis quantify the potential economic impacts of each policy option (i.e., the Proposed Project and all project Alternatives) for the Governing Board and stakeholders.

3. *The socioeconomic analysis should consider total costs associated with the Proposed Project and project Alternatives.* 2-4

Dr. Elaine Chang, SCAQMD
30 January 2015

While the BARCT technical analysis being conducted by AQMD Staff is being based on incremental cost effectiveness,[5] the actual economic impacts associated with this rulemaking will be based the total costs for compliance. To understand the potential economic impacts of this rulemaking, the socioeconomic analysis should consider the total capital cost and total increased operating costs as compared to the current baseline condition.

Furthermore, the socioeconomic analysis should consider the cost to RECLAIM program participants for RTC reductions which cannot be directly attributed to the advancement of technology (i.e., BARCT). The AQMD Staff proposal would appear to cause RTC reductions beyond those directly attributable to new BARCT.[6] RECLAIM program members will bear the costs for new capital and operating expenses associated with new BARCT, and they will also be collectively impacted by potential RTC reductions which are not tied to BARCT. These impacts may be regionally significant. 2-5

The socioeconomic analysis should fully quantify all these costs in assessing the potential economic impacts for the Proposed Project and each project Alternative to ensure the Governing Board and stakeholders are informed of the socioeconomic impacts associated with the different policy options.

The RECLAIM program remains vitally important to the health of Southern California's economy and environment. The members of this coalition have actively participated in this rulemaking through the NOx RECLAIM Working Group over these last two years, and we look forward to continuing to work with you and the District's Staff on the significant rulemaking.

Very truly yours,

Bill Quinn
California Council for Environmental and Economic Balance

Michael Carroll
Regulatory Flexibility Group

Curtis Coleman
Southern California Air Quality Alliance

Patty Senecal
Western States Petroleum Association

[5] For this rulemaking, incremental cost effectiveness is based on the cost and emissions benefit differences that would theoretically be observed between the new 2015 BARCT technology and emissions performance level as compared to the prior 2000/2005 BARCT technology and emissions performance level.
[6] AQMD NOx RECLAIM Working Group Meetings, 7 January 2015 and 31 July 2014.

Responses to CCEEB, RegFlex, SCAQA, and WSPA – Socioeconomic Letter #2

2-1. Thank you for the comments provided.

2-2. The Socioeconomic analysis of the proposed amendments to the NOx RECLAIM has implemented, to the extent possible, methodological and procedural improvements based on the recommendations put forward by Abt Associates in their 2014 report. These improvements include:

- Conducting Socioeconomic Scoping Session with CEQA Scoping on January 8, 2015
- Providing a more-than-45-day review period for the Draft Socioeconomic Report (Draft released on September 9, 2015)
- Identifying key socioeconomic issues and assumptions
- Analyzing the impacts of potential alternatives, including the Industry Proposal
- Providing a range of costs and job impacts to reflect different assumptions
- Clearly citing and including all sources of control cost estimates
- Conducting sensitivity analysis by analyzing a scenario in which no control installation spending occurs in the Basin
- Providing better documentation of assumptions and methodologies

Finally, although not included in the socioeconomic analysis, the staff report presents cost-effectiveness analysis results both LCF and DCF methodologies.

2-3. The Draft Socioeconomic Report has analyzed the potential economic impacts of four policy alternatives (and no impacts under the “No Project” alternative), including an Industry Proposal, which is represented as CEQA alternative #3.

2-4. The draft socioeconomic impact assessment estimated total compliance costs associated with the proposed rule amendments and CEQA alternatives. In addition to the potential compliance cost of control equipment installation and operation for these 20 facilities, the proposed amendments may potentially result in incremental costs for some of the 45 facilities where no BARCT was identified, and some of the 210 facilities that are not shaved but would need to continue purchase RTCs which may increase in price. These incremental costs would be the result of both additional RTCs that would be purchased from the market and due to potential RTC price increases after the shave. However, the total cost to RTC buyers is at the same time an economic gain for RTC buyers; therefore, the net compliance cost related to RTC transactions would cancel out.

2-5. As discussed in Response 2-4, the draft socioeconomic economic report considers the total compliance costs associated with the proposed NOx RECLAIM amendments and also with each CEQA alternatives. This is done by comparing the proposed amendments against a baseline of “business as usual”.

Based on staff's analysis, a shave of 14 tpd from current RTC levels of 26.51 tpd is necessary to attain the 12.51 tpd (26.51 tpd – 14 tpd = 12.51 tpd) of remaining NOx emissions in 2023. This level includes installation of 2015 BARCT, an allowance for growth, a compliance margin, and adjustments to account for uncertainties in the BARCT analysis. The cost of full BARCT installation represents the most conservative (i.e., maximum) cost estimate because, under RECLAIM, the total actual costs may be lower if a facility identifies any other more cost-effective alternative to remain in compliance.

The draft socioeconomic report also included discussion of the value of shaved RTCs (Please see Section 9—Market Analysis for more details). At the outset of RECLAIM, RTCs were allocated to RECLAIM facilities free of charge, yet they now have value to the facilities as a commodity that can be bought and sold. While RTCs have value, they are not a property right. The proposed amendments to RECLAIM will reduce the number of RTCs. Since there was no cost associated with allocated RTCs for a facility, there should be no financial loss to the RECLAIM universe as the SCAQMD retires them. Any additional purchase of RTCs executed by a facility is made in lieu of emission control. The choice between the RTC purchase and emission control is solely a business decision that was made to generate an expected stream of cost-savings afforded only by the RECLAIM program and not available under command-and-control. Therefore, any RTC investment loss should not be considered as a compliance cost to be compared to the compliance cost under command-and- control regulations. Moreover, this loss may be offset by any potential increase in RTC price due to a decreased RTC supply, which would subsequently raise the market value of a facility's remaining RTC holdings. Finally, any loss of "value" of shaved RTCs cannot be compared to command and control, because in that case there are no RTCs and thus no similar "value" was ever created.

ELECTRONIC SUBMISSION

RE: Revised Draft Socioeconomic Report for Proposed Amendments to Regulation XX-Regional Clean Air Incentive Market (RECLAIM) NO_x RECLAIM

Dear Dr. Dabirian:

At the request of the Western States Petroleum Association (WSPA), we were asked to review the October, 2015 draft "Socioeconomic Report for Proposed Amendments to Regulation XX-Regional Clean Air Incentive Market (RECLAIM) NO_x RECLAIM" prepared by the South Coast Air Quality Management District (SCAQMD.) Specifically, we were asked to review the draft analysis as regards methodology, implementation of the economic model supplied by Regional Economic Models, Inc. (REMI), and to offer relevant comments that have a bearing on the adequacy or accuracy of the economic analysis given in the draft report. We note that we posed a number of questions during a teleconference on October 7, 2015 that included a number of the SCAQMD staff, as well as WSPA representatives. Some of what we learned during that discussion has carried through to comments we make here and there are a number of questions that remain unresolved. Below, we offer our questions and comments under each of the three categories.

I. METHODOLOGY

a. Omission of RTC Costs in Macroeconomic Impact Estimates

In the revised draft report, it is noted that the proposed best available retrofit control technology (BARCT) shave will produce annualized capital and operating cost changes of $72 million per year at a 4% discount rate (see ES-3 and later). These estimated BARCT costs are then used in estimating the macroeconomic impact on the regional economy. However, it appears as though compliance costs involving RTC allowances were excluded from the macroeconomic impact analysis. We note that firms with inadequate allowances after the shave will face higher production costs when securing *additional* RTCs. The argument that SCAQMD offers, if we understand it correctly, is that the RTC allowances were made available freely at the start of the program and that any subsequent trading of allowances merely represents a shift in asset values between seller and buyer with no economic gain or loss to the region. We agree with this view so long as the sole function of the RTC is limited to a bookkeeping store of value. However, RTC's are not merely abstract assets: Very much like certain metal commodities such as gold and silver, RTCs are at once both assets with a market-determined value and a critical production input in the manufacture of certain goods. When a firm decides to offset an excess of emissions at a particular level of output, there must be seller of RTCs that has surplus allowances at its own level of emissions to sell. Note that carrying surplus RTC allowances does not change the seller's production costs, but does represent an opportunity cost that affects its current net income if the market value of its RTCs is greater than zero. On the other hand, the buyer must pay the current market cost for each additional RTC that it requires, and this cost is *incremental* to all other costs in their production function. These costs will be incurred by any facilities when their RTC holding levels fall below their emissions levels, which can occur for a number of reasons, including mandated allowance reductions. This production cost increase is by design, intended to create an incentive to reduce emissions by investment in improved control or combustion technology or by reducing production volumes if this reduces emissions. Were it the case that the shave had no effect on operating costs, no incentive would exist to alter emitters' production technologies or output. I-A

We note that you have already estimated the total RTC allowance cost changes for 255 facilities (see ES-5 "Market Analysis, para. 2) as ranging from $14 to $365 million. We do not see why the addition of the RTC costs to the production cost policy variable in the REMI model cannot be included to complete the total program cost macroeconomic impact. On p.40, you note that because actual RTC price changes cannot be accurately predicted, you cannot include market effects in the REMI macroeconomic simulation. We contend that a reasonable range of value could be applied to develop a range of total macroeconomic impact. I-A

By ignoring the RTC price changes on production costs, this analysis implicitly sets the RTC price change to be zero, a value that seems unreasonable.

b. **Growth Assumptions**

For determining which firms will need to acquire additional RTC allowances in the future, it is stated on p. 42, paragraph 2 that you have applied an industry specific annual growth rate to the 2011 actual emissions to project when and by how much a facility will exceed its RTC holdings. These growth rate assumptions are fundamental to estimating the RTC market impact component. It was noted during the teleconference that three different growth rate assumptions were used and that these are shown in the footnotes found on p. 45 and 47 of the revised draft report. Also during the phone conference, it was noted that the industry projections used are mandated in State legislation. Could we please have a complete citation for the industry-level projections that were used? (We note that although the REMI model is not a forecasting model per se, its baseline economic projection is derived from known and credible macroeconomic forecasts and the implicit growth rates for each of the industries in the model could certainly function develop a medium-run economic outlook for SCAQMD's purposes.) We contend that a three-sector scheme for estimating future RTC allowance requirements is far too aggregate and may misrepresent the severity of the proposed regulatory change on industries that are important to the regional economy. I-B

c. **Industry-Level Data**

When projecting future demand for RTC allowances, we suggest that it would be very useful for SCAQMD to aggregate facilities to a NAICS 6-digit industry-level or REMI 70 sector level for an appropriate time interval and produce data files of output, emissions, employment, and RTC holdings. Such information would allow the SCAQMD and public to directly identify which industries are more or less affected by the non-BARCT market effects and which are greater or lesser contributors to overall regional economic activity and emissions. This information is entirely missing in the analysis despite the need for such information being listed as a report requirement on pp. 5-6 of the draft. I-C

II. REMI IMPLEMENTATION QUESTIONS

a. Classification of BARCT Compliance Costs

In Table 17, we see both BARCT compliance costs and compliance spending listed as inputs to the REMI model. We do not see the specific REMI "policy variables" (as they are known in the model) listed or described in even a general context. However, we do see that one-time capital costs are entered into the REMI model as Machinery Manufacturing and installation costs entered as Construction costs. We would also expect that operating costs for the new capital equipment would be entered into the REMI model as changes in the production costs for the affected industry, and that the suppliers of the goods and services required to run the new capital equipment would see a change in appropriate industry sales values in the REMI model. Is this how compliance costs were entered into the model? What were the job and output impacts of the compliance costs? These can be presented separately from RTC allowance job and output impact. For the compliance spending, how were the machinery manufacturing and installation costs entered? II-A

b. BARCT Installation Costs as Construction Industry Spending

During the phone conference, one SCAQMD representative (apologies for not noting who the speaker was at the time) stated that the installation costs associated with the BARCT capital equipment entered into the REMI model as construction sector spending. We contend that this should have been entered using the wage payments policy variable for the construction sector or the employee compensation policy variable for construction sector (i.e., fully-loaded labor costs including wages, fringes, and benefits.) If entered as general construction sector spending, the REMI model will divide-up the spending over a multitude of inputs: Approximately 20 percent of the total amount will be classified as labor costs, 60 percent will assigned to materials and services expenditures (including amounts for lumber, gypsum board, glass and glazing products, lighting products, flooring products, concrete products, etc.) things unlikely to be purchased for installing refinery equipment, and the last 20 percent will be classified as overhead and profits which would have already been included in the equipment purchase. This appears to be incorrect to us. II-B

c. **Production Location of BARCT Capital Equipment**

Also during the phone conference, we established that SCAQMD knows the manufacturer of capital goods and can determine location of manufacture for that equipment. In that case, it is always recommended that we use this knowledge and avoid use of the general regional purchase coefficient that is included in the REMI model. The regional purchase coefficients are, at best, an approximation of a general regional production pattern and if one knows the actual geographic source, there is no point in allowing large errors to reduce the impact estimation quality. The same can be said of the installation labor, if the manufacturer requires that its own labor be used. II-C

d. **BARCT Equipment Purchases as Increment to the Regional Capital Stock**

We determined that SCAQMD did not increment the regional capital stock in the REMI model. This is not automatically done with investment expenditures in the REMI model, despite what one SCAQMD representative said during the phone conference. The user must specifically enter the value of the BARCT capital equipment and installation costs to the regional nonresidential capital stock policy variable. The consequence of omitting this step is having slightly overstated aggregate capital investment. The BARCT investment will offset implicit future investment, resulting in higher future net job-creation impact. II-D

e. **Review of REMI Input File**

To assure ourselves that the REMI model was correctly implemented, we submitted a public records request, at SCAQMD's suggestion, to obtain a copy of the relevant worksheets and REMI input files. We received these data on October 14th and will review to see specifically what direct impact data were entered into the model, and how they were entered in terms of specific policy variable categories. We will submit comments, if needed, at a later date to address any specific concerns. II-E

III. GENERAL QUESTIONS AND/OR COMMENTS

a. At no point in the draft analysis is there a figure that represents the total cost of the proposed regulatory change. It would be very helpful if SCAQMD can develop such a figure (or a value range) that allows the reader to know the potential total. III-A

b. The "Short-Term Economic Outlook" section (starting on p.6) offers no insights into the industries of the regulated facilities. It offers a two year forecast (of which ¾ of a year is now history and not outlook), which is of limited value in the context of 10 year projection period for emissions and economic activity. Since we are not given an economic outlook for markets that can change significantly over the next 10 years, we do not know how South Coast believes events will unfold and have no basis to assess the reasonability of the cost estimates for RTC allowances and effect on specific industries. III-B

c. We attempted to verify the short-run "outlook" figures using the cited sources, i.e., the California State University at Fullerton, Wells Fargo California Economic Outlook, and the Los Angeles Economic Development Corporation. We could not match- up table data from the draft with (several of) the cited sources. We suggest that a full citation of the source used for this section would be helpful. III-C

d. In the "Competitiveness: section, p. 34 it is stated, "The proposed amendments are not expected to impose discernable impacts relative to the cost of services or delivered prices of the affected facilities." Given the incomplete macroeconomic analysis with respect to RTC allowance pricing impacts, we think this conclusion is premature. If you add the allowance price effects into production cost estimates, REMI can solve for price and interregional trade changes that will inform us whether the effects are significant or not. These cannot be dismissed out-of-hand. III-D

e. Regarding ability to bear the costs of required investments, references are made on P. 34 to the refining industries gross revenues of the corporate owners of the facilities. This is an entirely inappropriate metric when conducting a regional economic evaluation as to whether the change in regulation is burdensome. The refineries do not operate in a national or international market reflected by total international corporate revenues. Rather, they operate in a regional market where the burden of the mandated and market changes should be measured against a figure such as regional refinery non-labor value added, which measures the value produced by capital net of depreciation, retained earnings, and earnings distributed to owners (i.e., shareholders), excluding raw material input costs and labor input. The change in non-labor value added will inform us as to whether the regulation change is burdensome. III-E

f. The second paragraph and footnote given on p. 34 offers an estimate for determining the cost-per-gallon of gasoline due to the proposed regulatory changes. Since, once again, these ignore RTC acquisition costs; the figures are likely to be low. Furthermore, it ignores the natural forces of the transportation fuel markets and it assumes that the region faces no outside competition from gasoline imports. This leads to the misleading conclusion that refineries can fully pass on all costs associated with the revised regulations. For example, the calculation ignores known gasoline imports to region via the Port of Los Angeles, which amounted to $2.9 billion in 2012, a relatively small amount compared to the $70 billion of regional refinery output[1], but proof that the market is not closed to competitors and that not all costs can be assumed to be passed on to consumers. III-F

Please let us know if you have questions regarding the specific points we have raised. We look forward to your reply and thank you for your assistance.

Sincerely,

cc: Dr. Phil Fine, SCAQMD
Sue Gornick, WSPA

I. METHODOLOGIES

Response to Comment I-A:

The commenter noted that, in the Revised Draft Socioeconomic Report released in October 2015, staff already estimated that potential incremental compliance cost for the projected NOx RTC buyers. The incremental cost for an affected facility is estimated as the difference in its current compliance cost and the projected higher compliance cost, which would be the result of either the proposed NOx RTC shave per se or any increase in NOx RTC prices due to a potentially decreased supply of NOx RTCs in the market.

Since any incremental compliance cost paid to obtain NOx RTCs would benefit NOx RTC sellers, the incremental compliance cost on the net for the entire RECLAIM universe would be by far lower than the gross compliance cost incurred by NOx RTC buyers. Any positive net compliance cost would be equivalent to the financial gains accrued to NOx RTC brokers. As the commenter noted, the Revised Draft Socioeconomic Report does state that, "[b]ecause the RTC price scenarios were set arbitrarily at various price points for illustrative purposes only, and any actual price increase cannot be accurately predicted, staff did not include the result of price analysis as an input for the REMI model to assess the macroeconomic impacts that could be potentially generated due to a redistribution of wealth within the RECLAIM universe as a result of RTC transactions." Staff did not assume the RTC price changes on production costs to be zero. In fact, in the Final Socioeconomic Report, job impacts have been estimated using REMI for the incremental compliance costs related to NOx RTC transactions. Please see Section 9.59.5 REMI Job Impacts of RTC Purchases for more details.

Response to Comment I-B:

The growth factors used in projecting the 2023 NOx emissions are the same set of growth factors used in the 2012 Air Quality Management Plan (AQMP), with the base year set in 2011. Nearly all of the growth factors were based on the growth projections made in the 2012 Regional Transportation Plan/Sustainable Community Strategies (RTP/SCS) prepared by the Southern California Association of Governments (SCAG). The only exception is for Electricity Generating Facilities (EGFs). EGF emissions were projected using 2012 as the base year and with updated growth factors based on the 2014 Gas Fuel Report published by the Southern California Gas Company. (See Appendix W of the October 6, 2015 Draft Staff Report for more details).

In order to project the overall 2023 NOx emissions among current NOx RECLAIM facilities, SCAQMD staff began by projecting the 2023 emissions for each facility, based on the aforementioned growth factors that vary by county and by 3-digit North American Industry Classification System (NAICS) code. The projected emissions at the facility level were then aggregated to the group level to arrive at the composite growth factors referenced in the Revised Socioeconomic Report (i.e., those noted by the commenter). Therefore, the projected total NOx emissions for any of the groups analyzed in the Report are consistent with the summation of projected NOx emissions across all facilities in a group.

When it comes to analyzing the potential buyers of NOx RTCs and the additional credits that will be needed in the post-shave market, staff acknowledges that the use of the group-level composite growth factors can potentially generate somewhat different estimates than using the more disaggregate growth factors that vary by county and by 3-digit NAICS. The difference would be larger, with greater within-group variations of projected NOx emissions and RTC holdings; however, the magnitude and even the direction of this difference is a priori unclear. If, as reasonably expected, the projected NOx emissions mostly occur at facilities with higher levels of post-shave RTC holdings, then the projected total additional NOx RTCs that will need to be purchased, and thus the associated incremental compliance cost, will have been overestimated in the Report. In a letter from Kavet, Rockler & Associates dated November 19, 2015, it is stated that "it would be preferable to provide NAICS-3 estimates for industry growth accompanied by estimates for industry emissions and allowance balance at same NAICS-3 level." Staff continues to believe that presenting the potential incremental compliance cost for the two major groups of facilities that are distinguished by whether they would be shaved or not (and both without identified cost-effective controls) is a more appropriate method to illustrate overall impacts. Staff is working to compile this information and will respond to the commenter.

It should also be noted that, to be conservative about compliance cost estimates, staff assumes that all facilities with identified cost-effective controls would install such devices and incur the associated compliance costs. In reality, the installation of all cost-effective controls will not likely come true unless NOx RTC prices would rise to a sufficiently high level to make control installation a more economical compliance option. In fact, the estimated cost-effective values of several categories of cost-effective control equipment lie well above the proposed price trigger of $22,500 per ton (based on a 12-month rolling average of discrete NOx RTC prices), above which all non-usable/non-tradable NOx RTCs would be converted to usable/tradable RTCs to stabilize market prices.

Response to Comment I-C:

As mentioned in the previous response, the growth factors used to project the 2023 NOx emissions vary by county and by 3-digit NAICS. The REMI 70-sector model used by the SCAQMD staff has a similar level of industry aggregation and the same geographical breakdown.

The growth factors used for point sources in the 2012 AQMP are directly based on industry output, employment, or population growth projections made by SCAG. (The only exception is for EGFs, whose growth factors were based on the 2011 Gas Fuel Report. For details, please refer to the 2012 AQMP: Table III-2-5 in Appendix III available at http://www.aqmd.gov/docs/default-source/clean-air-plans/air-quality-management-plans/2012-air-quality-management-plan/final-2012-aqmp-(february-2013)/appendix-iii-final-2012.pdf.) Therefore, it appears redundant to additionally report the underlying growth projections used to generate the growth factors. Moreover, the data files, which contain NOx emission and RTC holding projections and were used to generate estimates reported in Section 9: Market Analysis, can be requested via a public records request, similar to the commenter's previous request for REMI data files used in the Revised Draft Socioeconomic Report.

Furthermore, the socioeconomic assessment has met the legal requirements listed on pp. 5-6 of the Revised Draft Socioeconomic Report. Industry distribution was not included explicitly for the 219 facilities, because facilities in this group represent a range of industries, but are largely comprised of manufacturing, mining, oil and gas exploration, and utilities industries. Cost impacts on these facilities individually are expected to be small (if not zero). Any cost impacts that could potentially occur would be the result of any NOx RTC price increases due to the proposed amendments, and they are expected to be proportional to the amount of NOx RTCs currently needing to be purchased by these facilities. This information has now been included in Section 6: Affected Facilities.

II. REMI IMPLEMENTATION QUESTIONS

Response to Comment II-A:

Table 17 lists the industry sectors modeled in REMI that would either incur cost or benefit from the compliance expenditures. A full lists of policy variables are beyond level of detail needed for the average reader and thus are not presented in the report. (Policy variables are the channels through which the estimated economic changes due to the proposed amendments—for example, changes in production costs and market demand for goods or services—are inputted into REMI to generate macroeconomic impacts.) However, they are available to the public, and as requested by the commenter in his Public Records request, staff has prepared and sent REMI RWB files with a complete list of policy variables on October 14, 2015.

The operating and maintenance costs of the new capital equipment were modeled in REMI as a change in production cost for the RECLAIM facilities with identified cost-effective controls. The suppliers of the goods and services of these new equipment would receive additional spending, modeled as an increase in industry specific exogenous final demand. Please note that not all the additional spending would benefit the local economy, as the affected facilities may purchase the control equipment and the related goods and services from outside the region. The distribution of these additional spending within and outside the region is determined internally by the REMI model's Regional Purchase Coefficients. As a sensitivity test to this implicitly assumed spending distribution, staff also conducted a worst-case scenario where no additional spending would occur within the region.

As noted by the commenter, in the Draft Socioeconomic Report, staff did not enter into the REMI model the incremental compliance cost due to either additional RTC purchases or any increases in NOx RTC price. For the specific response to this comment, please see the response to Comment I-A.

Response to Comment II-B:

The installation costs associated with the BARCT capital equipment were entered into the REMI model as an increase in exogenous final demand in the construction sector. The commenter recommended that staff use the wage payments policy variable instead. However, it should be noted that, first, the increased exogenous final demand in the construction sector (the policy variable that staff used) automatically adds labor income based on the underlying Input-Output table and labor productivity. Second, after consultation with REMI staff and conducting several simulations, staff confirmed that the wage payments variable is an inappropriate policy variable to use. The most important reason is that it would inappropriately ignore the direct job creation impact due to construction labor demands by control installation. As a result, an excessively small job impact would be observed in the construction sector, mainly due to indirect effects such as those working through increased labor income that would drive up residential construction labor demand. In fact, the largest impact of increased wage payments in the construction sector would be, literally, a higher average wage per worker in the construction sector. Staff does not consider this as the most appropriate modeled impact in the context of control installation.

Staff acknowledges that, when entered as an exogenous demand in the construction sector, the additional spending associated with control installation would result in increases in intermediate goods and services in the REMI model that, in reality, are remotely related to control installation. However, this result is largely related to the level of industry aggregation in the REMI model and, as advised by REMI staff, may be partially mitigated by choosing an appropriate translator policy variable that will constrain the direct effect to fewer, more disaggregate construction industries that are a subset of the broader construction sector. However, the use of this translator variable mitigates but does not completely resolve this issue. Moreover, the use of wage payments variable, as recommended by the commenter, would not be the solution to this problem.

In a comment letter sent by Kavet, Rockler & Associates on November 19, 2015, the commenter maintained the opinion that control installation cost should be entered into REMI as “Wage Bill-Construction” or “Compensation (amount)-Construction”. Staff does not agree with this opinion as already explained in Response to Comment II-B. A simple exercise of entering the same amount of construction spending using the three different policy variables showed that the two policy variables suggested by the commenter generated an unreasonably low share of construction jobs among total jobs created. For example, in a simple exercise where a same amount of construction spending was increased in the region in one single year, more than 50 percent of total jobs projected to be created that year was concentrated in the construction sector when entered as “Exogenous Final Demand-Construction”. In comparison, only 7-11 percent of jobs created was in the construction sector when entered as “Compensation (amount)-Construction” or “Wage Bill-Construction”.

Response to Comment II-C:

Please see the response to Comment II-A.

Response to Comment II-D:

While the REMI model models capital investment using optimal capital stock theory, staff disagrees with its applicability for modeling the potential impact on current and future capital investment due to these proposed air pollution control amendments. Increments to capital investment, operating through the optimal capital stock mechanism, results in an appropriate modeled effect only when a facility is reasonably expected to lower its level of capital investment in the future by a similar amount spent on installing pollution control equipment. This can be the case in the situation where the affected facility has already planned on installing controls even without any policy interventions, and the effect of policy interventions would be to induce this investment made earlier in time. In terms of control installation under the RECLAIM program, staff does not consider this to be the appropriate situation, because absent clean air regulations and programs, a facility is not expected to make capital investments on pollution abatement. Staff also consulted with REMI staff, who agreed with staff's assessment.

In a letter from Kavet, Rockler & Associates dated November 19, 2015, the commenter maintained the opinion that "the nonresidential capital stock requires that the incremental value be included." Staff has already responded with the reasons why this is not always the case, especially not when it comes to capital spending on pollution control. Staff did not claim that the effect is insignificant, as incorrectly suggested by the commenter, but that it is an inappropriate modeling approach based on the theoretical foundation of optimal capital stock.

Response to Comment II-E:

REMI input files as requested were delivered via public record request on October 14, 2015. Kavet, Rocker, and Associates, LLC followed-up on this data request with a letter dated November 19, 2015 that presented their cost estimates using the REMI data sheets requested.

According to staff's estimates, the present worth value of control installation under the proposed rule amendments would amount to $728 million to $1.1 billion (in 2014 dollars). The high-end cost estimate (i.e., $1.1 billion) was used to annualize compliance costs and project macroeconomic impacts using the REMI model. However, it was not clear to staff how the commenter arrived at the conclusion that the total cost for the 2018-2035 period would be as high as $2.1 billion (in 2009 dollars) under the proposed rule amendments, or the "Proposed Project". One plausible explanation was that the commenter may have inadvertently double counted the compliance cost by adding up the same values assigned to both "Production Cost" and "Exogenous Final Demand" variables, which is a usual modeling practice to reflect the fact that one industry's compliance cost spending will benefit other industries that either manufacture control equipment or provide control installation related services.

III. GENERAL QUESTIONS AND/OR COMMENTS

Response to Comment III-A:
Staff believes that the compliance cost of control installation and the incremental compliance cost due to the effect of the NOx RTCs shave on the credit market are not the same in nature and should not be simply added. For example, the incremental compliance cost of purchasing additional RTCs could result in financial gains to a facility that installs cost-effective controls and thus has surplus NOx RTCs for sale. The financial gains would then offset the compliance cost of control installation. Therefore, simply adding up both categories of compliance costs could result in double counting.

Response to Comment III-B:

The Short-Term Economic Outlook section was provided at the request of stakeholders in order to assess the current state and overall health of the regional economy. This section presents the latest and credible economic forecast available by local economic development agencies and universities. Staff has also included a 10-year employment forecast by industry in Section 5: Short-term/Long-term Economic Outlook.

Response to Comment III-C:

Please see the following link for the 2015-2016 Economic Forecast and Industry Outlook from the Los Angeles Economic Development Corporation (LAEDC).
http://laedc.org/2015/02/18/2015-2016-economic-forecast-published/

Please use the following link for the report published by the California State University, Fullerton. The commenter may need to contact the department to receive the full report.
http://business.fullerton.edu/Center/EconomicAnalysisAndForecasting/#Default

Response to Comment III-D:

Staff will present the impacts of the proposed amendments on the relative cost of production and relative delivered prices in the Final Socioeconomic Report. Regarding the macroeconomic impact associated with the projected NOx RTC transaction, please see the response to Comment I-A.

Response to Comment III-E:

Staff has removed the reference to the refineries' global revenue.

Response to Comment III-F:

Regarding the comment on RTC acquisition cost, please see the response to Comment III-A.

Staff has added a caveat, stating that refineries may not be able to pass on the full cost of the proposed amendment to consumers due to possible outside competition from gasoline imports. However, it should be noted that due to clean air regulations, the gasoline blends sold in this region are different from those permitted in other parts of the country. Therefore, any outside competition, if any, is expected to be very limited.

PAST STATIONARY SOURCE COMMITTEE PRESENTATIONS

SEPTEMBER 23, 2015 (SPECIAL SESSION)

RECLAIM BARCT

Special Stationary Source Committee
September 23, 2015

Barbara Baird
Chief Deputy Counsel

RECLAIM BARCT

SCAQMD must adopt rules to require "best available retrofit control technology" (BARCT) for existing sources.

H & S Code § 40440(b)(1)

RECLAIM BARCT

BARCT is defined as:
an emission limitation based on the "maximum degree of reduction achievable" considering "environmental, energy and economic impacts. . ."

H & S § 40406

3

CARB Legal Opinion, 1992

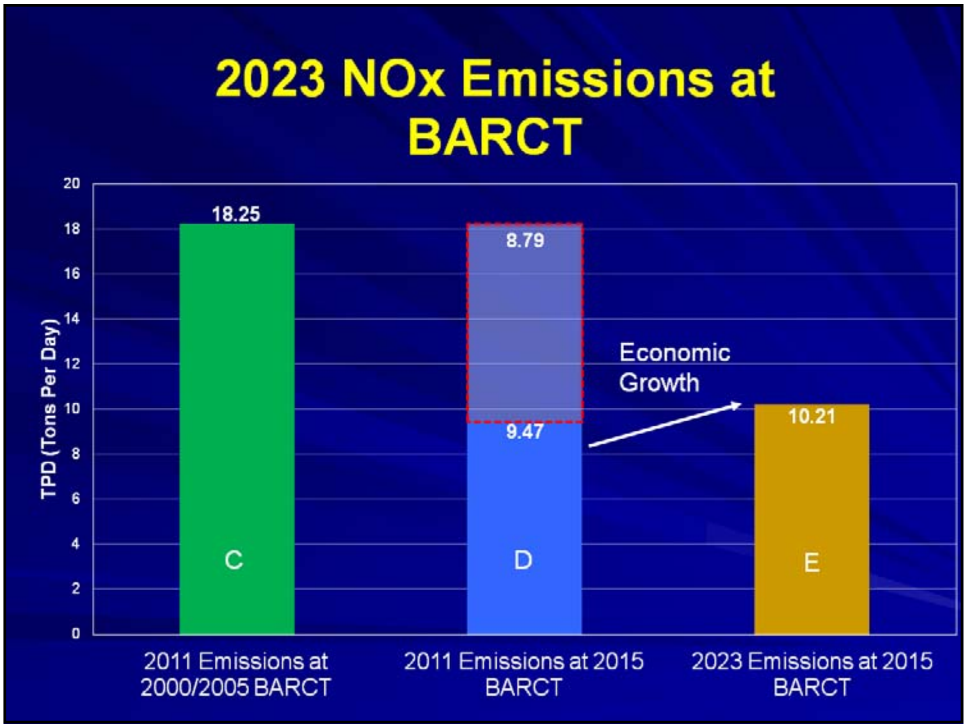
- BARCT can be met in the aggregate, including emissions trading
- But must be equivalent to what command-and-control would achieve
- Must be updated as technology advances

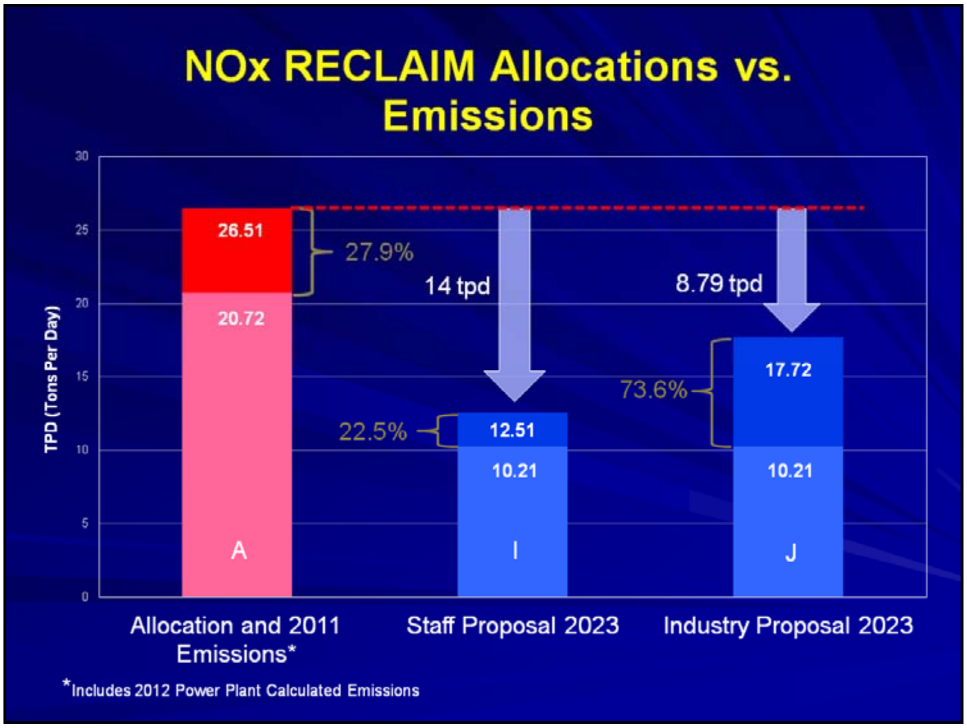
4

Industry Proposal

- Takes a goal derived from actual emission reductions, but then subtracts from allowable emissions
- Only guarantees small amount of actual reductions; rest are "paper reductions"

5





South Coast AQMD

Industry Proposal (cont'd)

- Is not designed to attain "maximum reductions achievable" as required by H & S § 40406
- Is not equivalent to levels that would be achieved under command-and-control
- Does not meet legal requirements

8

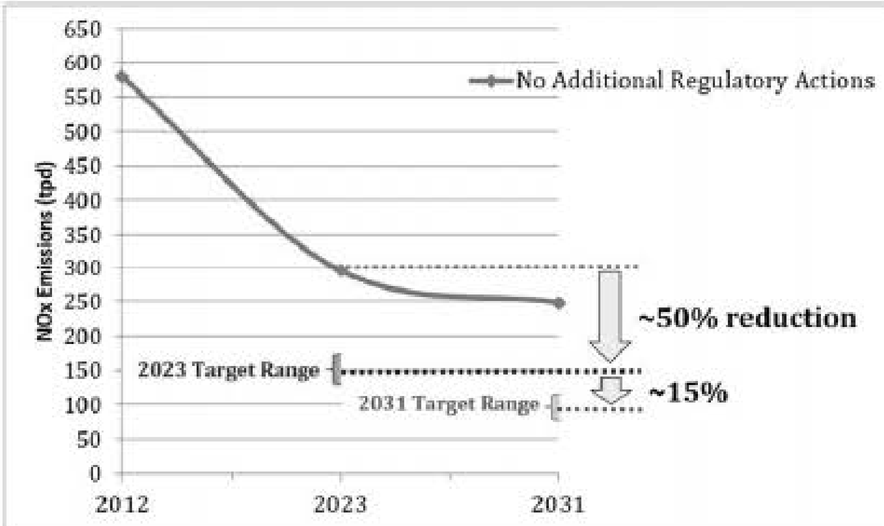
Proposed Amendments to Regulation XX – NOx RECLAIM Special Stationary Source Committee Meeting

September 23, 2015
SCAQMD
Diamond Bar, CA

Background – RECLAIM

- RECLAIM originally adopted in 1993
  - Establishes annual facility-wide emission limits for NOx and SOx
  - Allows emission trading amongst facilities
  - Subject to reduction of limits over time
- Compliance options
  - Install air pollution controls
  - Process changes
  - Purchasing of RECLAIM Trading Credits (RTCs) from other facilities and investors
- Last shave amendment was in 2005

Significant NOx Reductions Needed for Ozone and PM 2.5 Attainment



Equipment Categories Identified with Potential Further NOx Reductions

- Refinery Gas Turbines
- Metal Heat Treating Furnaces >150 MMBTU/hr
- Sodium Silicate Furnace
- Glass Melting Furnaces
- Non-Refinery Internal Combustion Engines (Non-Power Plant)
- Cement Kilns
- Refinery Fluid Catalytic Cracking Units
- Non-Refinery Gas Turbines (Non-Power Plant)
- Coke Calciner
- Refinery Boilers/Heaters
- Refinery Sulfur Recovery Units/Tail Gas Units

Working Group Meetings*

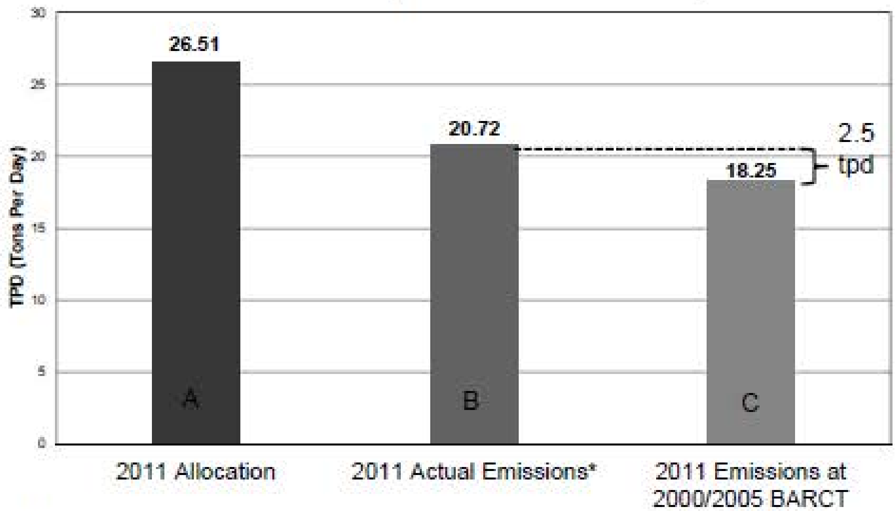
- January 31, 2013
- March 20, 2013
- June 13, 2013
- September 19, 2013
- January 22, 2014
- March 18, 2014
- July 31, 2014
- January 7, 2015
- April 29, 2015
- June 4, 2015
- July 9, 2015
- July 22, 2015 (Public Workshop)
- August 19, 2015

*Rulemaking Analysis initiated over 3 years ago

Major Proposed RECLAIM Amendments

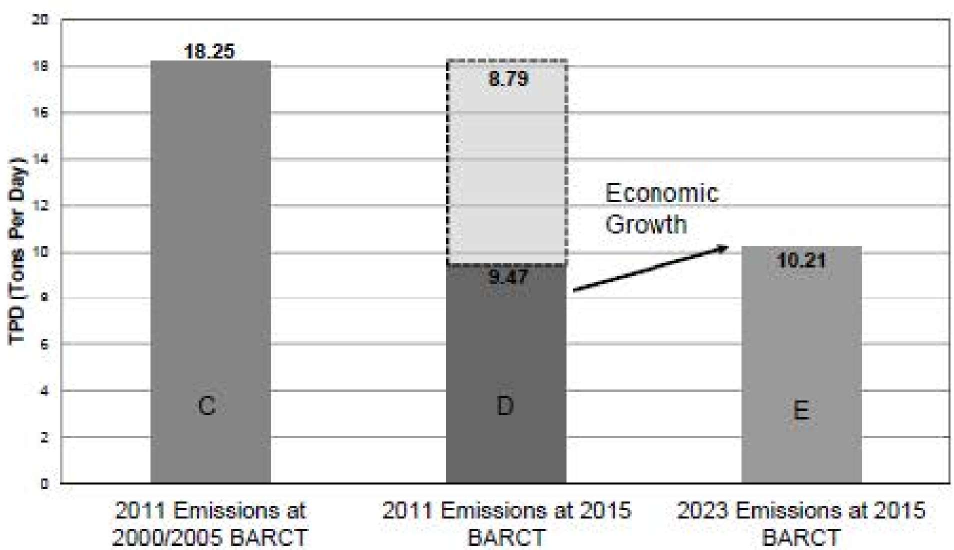
- BARCT Equivalency required by State law (H&SC § 40440 and § 40914)
- Total proposed RTC reductions = 14 tons per day based on BARCT analysis
- Updated BARCT emission factors
- Timing and distribution of shave
- Establishment of Adjustment Account for Power Plants

Comparison of NOx RECLAIM Emission Levels Relative to Total Allocation (2011 Base Year)

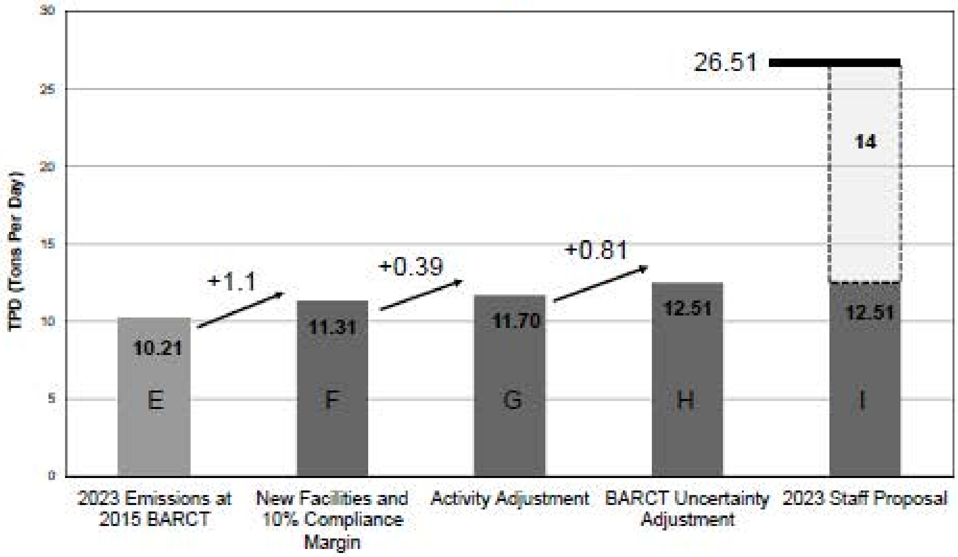


*Includes 2012 Power Plant Calculated Emissions

2023 NOx Emissions at BARCT



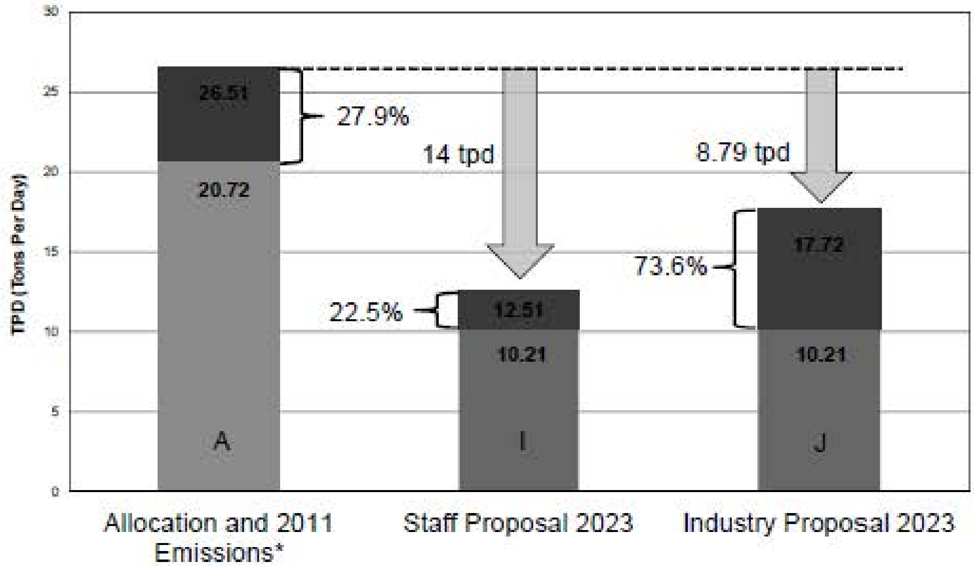
2023 Adjustments and Allocation Target



Key Issue: Amount of Shave

- BARCT Analysis
  - NEC Assumptions for Refinery Sector
  - SCAQMD Responses
    - Different approaches and engineering assumptions
    - No impact on proposed RTC reduction
    - Resulting 0.33 tpd difference less than proposed 0.81 tpd adjustment
- Industry proposal for shave amount (8.79 tpd)

NOx RECLAIM Allocations vs. Emissions



*Includes 2012 Power Plant Calculated Emissions

Timing/Distribution of Shave

- Staff Proposal: 14 ton per day RTC reduction
  - 4 tons per day reduced in 2016
  - Remainder to be reduced equally from 2018 to 2022
  - Proposed reductions based on share of BARCT opportunities
    - Refineries and Investors: 66%
    - Non-Refinery facilities and power plants among the top 90% of RTC holders: 47%
    - 210 facilities not among the top 90% of RTC holders: 0% Facilities)
- Key Issues
  - Sufficient time for engineering, permitting, procurement, and construction
  - Equity of shave distribution
  - Addressing refinery turnaround schedules

NSR for Natural Gas Power Plants

- Newer power producing facilities required by federal NSR regulations to hold RTCs to offset their potential to emit (PTE), even though actual emissions are well below this level
- Adjustment Account for newer power producing facilities (already required to be at BACT or BARCT)
  - Assist compliance with NSR holding requirements
  - To be held by SCAQMD regionally
  - Difference between pre- and post- shave holdings
  - Not to be used to offset actual emissions unless state of emergency regarding power supply is declared by the Governor

Key Issues regarding Adjustment Account

- Regional account or held by individual facilities
- Criteria to access RTCs to offset actual emissions

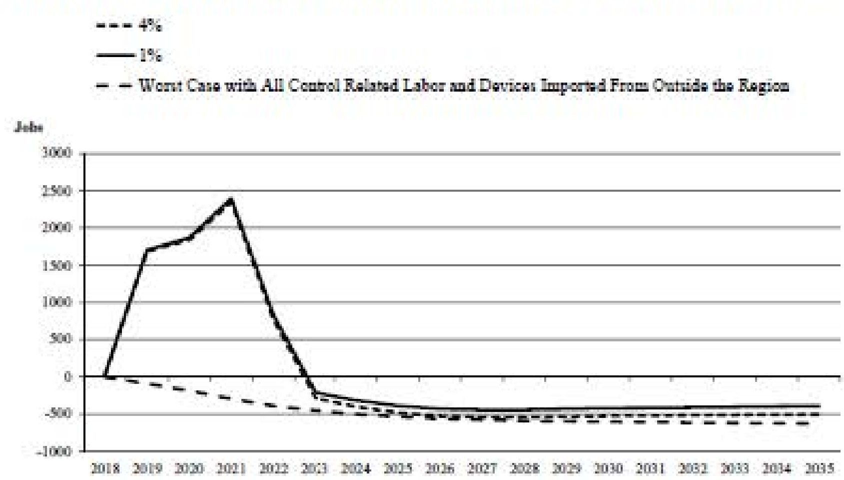
10-Year Equipment Life

- Industry believes 10-year equipment life is appropriate given frequency of RECLAIM amendments
- Equipment lasts 25 years, thus 25-year life is appropriate and consistent with SCAQMD past practices
- Little or no equipment was identified as obsolete or a stranded asset from the last shave in 2005
- Even with future NOx shaves, not all equipment becomes obsolete / stranded assets

15

Costs and Job Impact of BARCT Installation

- **Total Potential Cost: $0.62 – 1.09 Billion** **(100% control installation)**
- **Average Annual Costs: $52 – $63 MM**
- **Average Annual Job Impact: +13 to +90 (over 2018-2035)**
- **Not Expecting Shift from High-Pay to Low-Pay Jobs**



16

ATTACHMENT L
PAST STATIONARY SOURCE COMMITTEE PRESENTATIONS

OCTOBER 16, 2015

Amendments to NOx RECLAIM Program

Stationary Source Committee

October 16, 2015

Purpose of Proposed NOx RECLAIM Amendments

1. Protect Public Health
   - Significant NOx reductions needed to attain Ozone and PM2.5 standards (50% additional reductions by 2023)
   - RECLAIM sources account for ~40% of all non-mobile source emissions
   - Proposed shave is a critical step towards healthful air quality and attainment
2. Meet Requirements of State Law (H&SC §40919)
   - All sources to implement BARCT

Approach

1. Technology Assessment - BARCT Analysis
   - Feasible and cost-effective controls
   - Consultants' review of staff analysis
2. Achieve equivalent emissions outcome as BARCT under Command-and-Control Regulations
   - Assume all feasible/cost-effective controls are implemented by 2023, including economic growth projections
   - BARCT-equivalent allowable NOx emissions in 2023 = 10.21 tpd
   - Add compliance margin, BARCT uncertainty adjustments, + 2.3 tpd
   - Total remaining NOx holdings in 2023 = 12.51 tpd
   - Current Holdings (26.51) - Shave (14) = Remaining (12.51)

Approach

3. Apply shave proportionate to identified BARCT opportunities
4. Implementation schedule considering the time needed to install equipment
5. Considerations for unique circumstances of Electrical Generating Facilities

SCAQMD Consultants' Analyses

- Two consultants (NEC and ETS) retained to review staff BARCT analysis
- Confirmed staff analysis and BARCT levels with few exceptions
- Staff adjusted approach based on consultants' findings
  - Coke Calciners (10 ppm), Cost Factors for boilers/heaters and SRU/TGU incinerators
- Only one exception (boilers and heaters) led to a 0.33 tpd difference
  - Staff included an adjustment (0.79 tpd) to the shave that more than covers the different engineering opinions for boilers and heaters

Industry Comments

Issue	Industry Claim	Staff Response
Proposal Goes "Beyond BARCT"	14 tpd emissions reduction goes beyond the BARCT analysis • 8.79 tpd is the BARCT adjustment • 5.21 tpd is Beyond BARCT 14 tpd	• Command and Control equivalency is 10.21 tpd remaining emissions in 2023 • A shave to achieve this level is BARCT, not "beyond BARCT"
Equipment Life	• Use of DCF method and 25-years useful life overstates cost effectiveness of controls • 10 years more appropriate	• Staff provides both DCF and LCF cost effectiveness estimates • Refineries acknowledge equipment lasts 25-years • Lifespan consistent with other agencies and EPA assessments • 10-year life assumes IF rule is amended in 10 years that ALL investments are stranded assets

Industry Comments

Issue	Industry Claim	Staff Response
RECLAIM Effectiveness	RECLAIM responsible for more NOx emissions reductions than non-RECLAIM sources: 6.4 TPD since 2005	• Past NOx reductions depend on where the feasible, cost-effective opportunities are • ~1/3 of these RECLAIM reductions derive from shut down facilities • Under command and control, shut downs result in very limited ERCs

Cost Effectiveness Threshold	CE threshold of $50,000/ton is more than twice that used for command and control rules	• Used same CE threshold for SOx RECLAIM, not adjusted for inflation over 7 years
		• Average Incremental CE:
		  • Refinery Sector : $ 10,000/ton - $17,000/ton
		  • Non-Refinery Sector: $9,000/ton - $14,000/ton

Industry Comments

Issue	Industry Claim	Staff Response
The Gap Between Allocations and Actual Emissions Should be Much Larger than the Staff Proposal	Gap important for market function, includes compliance margin, growth, investor holdings, & RTCs for new facilities and structural buyers	• Staff proposal includes 10% compliance margin, adjustments, and growth projections for existing and new businesses • Resulting 23% gap is sufficient and consistent with past gaps in a functioning market

General Industry Comment:
Too Much, Too Fast, for the Market to Function

- Rule has safeguards to ensure market functioning
- Staff continuing work with industry on
  - Implementation schedule
  - Temporary off-ramp based on shorter-term price trigger
  - Access to credits for power plants during power crisis
  - Resolution language to track electricity supply/demand relative to increased renewables and electrified transportation sector
  - Lower emission rates for R219 exempt equipment

Proposal Comparison

Staff Proposal	Industry Proposal (10/14/15)
• 14 TPD shave • 12.51 TPD remaining RTCs	• 10.3 TPD • 16.21 TPD remaining RTCs
Implementation Schedule 4, 0, 2, 2, 2, 2, 2	Delayed Implementation Schedule Less in first year, weighted towards end years
$22,500/ton Running Annual Average threshold	Shorter trigger time necessary (e.g. six months, ….)

Summary

- Primary issue is size and schedule of shave
- Continue working with stakeholders to finalize provisions for program safeguards
- Staff is prepared for November Public Hearing

ATTACHMENT M
PAST STATIONARY SOURCE COMMITTEE PRESENTATIONS

NOVEMBER 20, 2015

Proposed Amendments to Regulation XX – NOx RECLAIM Stationary Source Committee Meeting

November 20, 2015

Purpose

- Meet requirements of state law
  - SCAQMD shall require BARCT for existing sources(H&SC § 40440)
  - All feasible measures (H&SC § 40914)
- 2012 AQMP control measure CMB-01
- Significant NOx reductions needed for ozone and PM 2.5 attainment
- Level the playing field
  - RTC price significantly lower than C&C control costs for mobile sources and other stationary sources
- To demonstrate our fair share reductions while demanding CARB & EPA to do their fair share

Market Program vs. Command & Control

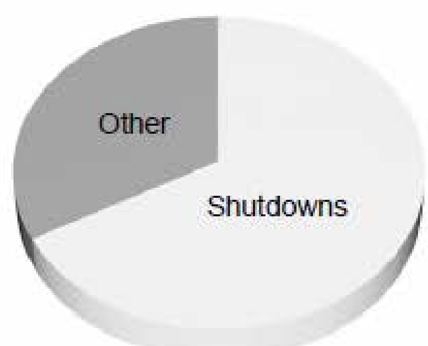
- Market Program
  - Low hanging fruit picked first
  - Flexibility/Options
  - Cost savings
- Command and Control:
  - All the fruit gets picked
  - Limited flexibility

In SCAQMD, eventually, both approaches converge.
All the fruit is gone

Emission Reductions From 2005 Amendment

NOx shave target = 7.7 tpd

- Actual emission reductions between 2006-2012 = 4 tpd
  - 2.6 tpd (65%) from shutdowns
  - 1.4 tpd (35%) from controls, process changes, recessionary production levels
- If C&C, all reductions would have occurred



Why Retire RTCs from Shutdowns?

- Command and Control Shutdowns
  - Credits discounted to BACT and based on last 2 yrs. of operation
- RECLAIM Shutdowns
  - No discount of credits
  - Financial incentive for shutdowns and job loss
  - Reduces incentive to implement cost-effective controls that would be required under command and control

Why Allow EGFs to Opt-out of RECLAIM?

- Electrical grid system has changed over time
- EGFs are unique
  - Once-Through Cooling Regulation – older units repowered with cleaner, more efficient units
- EGFs highly regulated
- Most units already at BARCT or BACT
- Provide essential public service
  - Other essential public services exempt from RECLAIM
- Need to hold extra RTCs for NSR and/or to meet resource adequacy

WSPA Comments

- Staff did not address discrepancies identified in NEC Report
  - Incorrect understanding of staff approach
  - 0.33 tpd difference
  - 0.8 tpd adjustment included in proposal
- $2.3 Billion vs. $0.7 – $1.1 Billion Cost
  - Insufficient details provided to assess validity
  - Incremental cost vs. total cost
    - Staff assumed controls from last shave in place
    - Significant accrued cost savings from delayed controls

WSPA Comments

- 10 year equipment life, DCF vs LCF
  - Staff provides both DCF and LCF cost effectiveness estimates
  - Refineries acknowledge equipment lasts 25-years
  - Lifespan consistent with other agencies and EPA assessments
  - 10-year life assumes IF rule is amended within 10 years that ALL investments are stranded assets *(impossible outcome)*

Proposed Regulation XX

- Stakeholder Comment
  - Recent changes to the rule (opt-out for EGFs and shutdown provisions) have not been analyzed for impacts and necessitates a delay in the rule amendment

Proposed Regulation XX: Staff Response

- EGF opt-out
  - EGFs will only opt out if it is to their advantage and are at BARCT or BACT
  - Better grid reliability
- Shutdowns
  - Removal of shutdown credits needed to achieve BARCT equivalency
  - Under command and control, shutdown credits are deeply discounted and restricted

Proposed Regulation XX: Staff Response

- Both provisions
  - Not expected to have environmental or economic impacts beyond those already analyzed
  - Already conducted multiple meetings with stakeholders
  - Working Group Meeting next week
  - Beneficial for AQMP
  - Safety valves in rule if RTC price reaches trigger levels

14 tpd Feasible and Necessary

NOx RECLAIM Shave

23 September 2015

1

Industry Coalition's Objectives

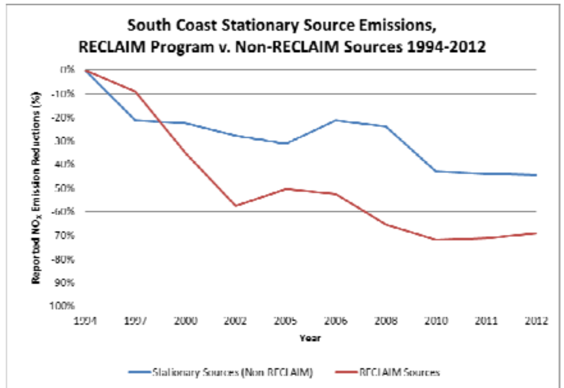
- Preserve a successful program and a healthy RECLAIM market
- Reflect the emission reductions possible from advancements in BARCT between 2005 and 2015 (Technology Shave)
- Fulfill obligations in H&SC §39616(c) as opposed to the District's proposal which goes **beyond BARCT**
- Fulfill at a minimum the 2012 AQMP commitments to the State Implementation Plan (SIP) and USEPA
  - 3 to 5 tons per day NOx
- Recognize successful emission reductions from RECLAIM Program's 2005 shave

2

Emissions for RECLAIM facilities have declined faster than South Coast facilities under command & control rules (i.e., non-RECLAIM sources)

RECLAIM program's emissions have been reduced 69% since 1994

Non-RECLAIM stationary source emissions declined by about 44% during that same period



Sources: "RECLAIM Sources" data is reported (audited) emissions from SCAQMD RECLAIM Audit Report (March 2015). "Stationary Sources (Non-RECLAIM)" is taken from SCAQMD Air Quality Management Plans (1997, 2003, 2007, 2012) and AQMP Working Group Meeting #5, Agenda Item #3.

Legal Requirements

- Allows facilities the "flexibility to achieve emission reductions using methods which include, but are not limited to: add-on controls, equipment modifications, reformulated products, operational changes, shutdowns, and the purchase of excess emission reductions." [1]
- CA Health & Safety Code (H&SC) §39616(c) requires on a program basis:
  - equal or greater emission reductions than command-and-control
  - equal or less cost than command-and-control
- Under the 2005 market adjustment, a 23% reduction in RTCs resulted in a 24% reduction in NOx RECLAIM emissions [2]
- The District is going **BEYOND BARCT**

[1] Source: SCAQMD Rue 2000(a).
[2] Source: SCAQMD Annual RECLAIM Audit Report, March 2015.

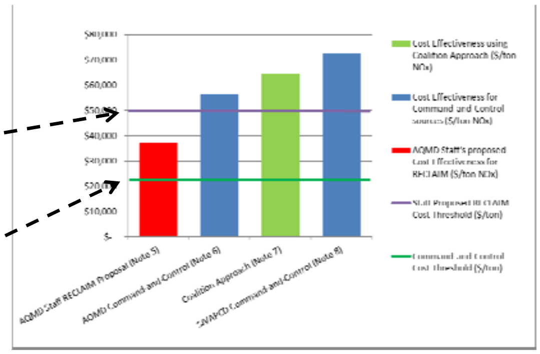
Staff Proposal would treat RECLAIM disproportionately as compared to Command-and-Control

RECLAIM program is required to be equivalent or less costly than command-and-control rules [1]

AQMD use of DCF method and 25-year useful life overstates cost-effectiveness of controls [2]

Staff are proposing a cost effectiveness threshold that is twice that used for AQMD's command-and-control rules [3]

Cost effectiveness threshold for this rule should be the same one used for command-and-control rules; $22,500 per ton [4]



Example is $5M emission control project with 25 tpy NOx reduced. Notes: (1) H&SC 39616(c)(1). (2) Comparison of AQMD Staff method proposed v. AQMD BACT method. (3) Comparison of SCAQMD cost threshold in 2012 AQMP and 2015 RECLAIM. (4) SCAQMD 2012 AQMP. (5) AQMD Staff method proposed for RECLAIM in Preliminary Draft Staff Report (July 2015) using DCF method, 25-year Useful Life assumption, and 4% interest rate. (6) AQMD BACT Guidelines, Part C (2006) using DCF method, 10-year Useful Life assumption, and 4% interest rate. (7) Industry Coalition proposed method using LCF method, 10-year Useful Life, and 4% interest rate. (8) SJVAPCD BACT Guidelines.

5

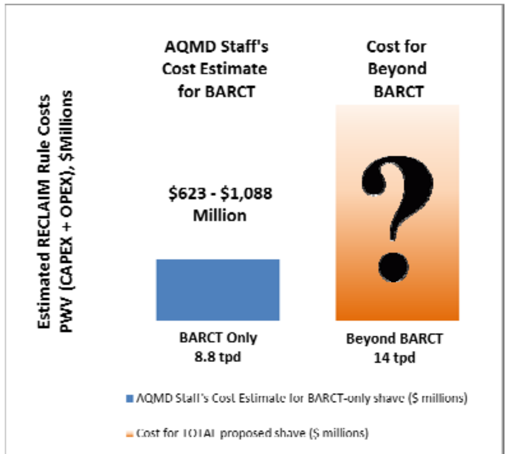
Command and Control Equivalency is not more than 6.6 TPD

- AQMD Staff's current analysis only demonstrates 7.9 TPD of reductions can be justified by technology advancement (i.e. BARCT) [1]
- AQMD Staff have not reconciled the discrepancies between their cost analysis and the recommendations of the third-party expert, Norton Engineering
- The Industry Coalition further believes corrections to the AQMD Staff's cost effectiveness methodology would trim BARCT reductions by an estimated 1.3 tpd [2]
- A reduction greater than 6.6 TPD would be **BEYOND BARCT**

1 AQMD Preliminary Draft Staff Report, Proposed NOx RECLAIM Amendments, July 2015, p. 18. Presented BARCT reduction adjusted pursuant Staff's 0.85 TPD adjustment factor to account for discrepancies between Staff analysis and third-party expert, Norton Engineering.
2 Industry Coalition/ERM analysis of AQMD BARCT calculations assuming a 10-year useful equipment life (Sept 2015).

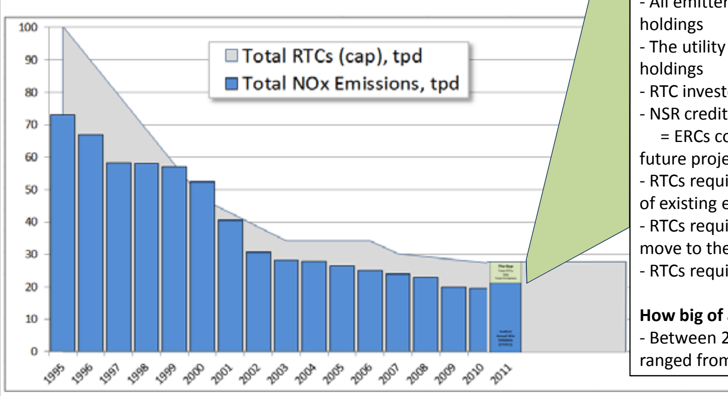
6

BARCT $ ≠ BARCT $ + BEYOND BARCT



Sources: "AQMD Staff's Estimate for BARCT-Only Shave taken from SCAQMD Preliminary Draft Staff Report, Proposed NOx RECLAIM Amendments, July 2015, p. 23-24. To date, AQMD Staff have not provided a "Cost Estimate for the TOTAL proposed shave" of 14 tpd.

Mind the "Gap"



What is The Gap?
- The difference between the total RTCs issued and the total actual emissions.

What is in the Gap?
- All emitter's compliance margin holdings
- The utility sector's potential-to-emit holdings
- RTC investors' holdings
- NSR credits
  = ERCs converted to RTCs for future projects
- RTCs required for economic growth of existing emitters
- RTCs required for new businesses to move to the South Coast
- RTCs required for structural buyers

How big of a Gap is needed?
- Between 2005 – 2013, unused RTCs ranged from 5.1 to 9.1 tpd

[1] Source: SCAQMD, Annual RECLAIM Audit Report

Arbitrary Removal of RTCs

- CMB-01 Phase 1 (approved in the 2012 AQMP) explicitly considered and rejected removal of all RTCs in excess of actual emissions, except what was needed for the $PM_{2.5}$ contingency measure (2 tpd)[1]
- The proposed "compliance margin" of 10% is not adequate to meet the market's historical need for RTCs which have averaged in the 15-30% (5 to 9 TPD) range (except for the early 2000's power crisis) [2]
- The Industry Coalition approach negates the need for a "compliance margin"

[1] Source: SCAQMD, 2012 AQMP. Page 4-9 states: "The control measure will seek further reductions of 2 tpd of NOx allocations if triggered." Appendix A, page IV-A-13 presents rationale for that conclusion.

[2] Source: SCAQMD, Annual RECLAIM Audit Report for 2013 Compliance Year, 6 March 2015. See Table 3-2.

Shave Implementation Schedule

- A shave of 4 TPD in 2 months does not allow adequate time for industry to install emission control projects which take several years to design, permit and implement[1]
- It also conflicts with CMB-01 Phase 1 which explicitly considered and rejected removal of all RTCs in excess of actual emissions, except what was needed for the $PM_{2.5}$ contingency measure (2 tpd)[2]
- The Industry Coalition supports a schedule consistent with approved Control Measure CMB-01 Phase 1, which begins with 2 tpd in the first year

[1]Source: Industry Coalition letter to SCAQMD, August 21, 2015, p. 2.

[2]Source: SCAQMD, 2012 AQMP. Page 4-9 states: "The control measure will seek further reductions of 2 tpd of NOx allocations if triggered." Appendix A, page IV-A-13 presents rationale for that conclusion.

Summary of Concerns

- Size of the proposed District shave could imperil the RECLAIM program
  - Shave is well beyond amount indicated by BARCT analysis
  - Depth of District's proposed shave potentially requires market to function with amount of "unused" RTCs only seen during the power crisis
- Shave Implementation schedule is too aggressive
- District BARCT analysis is flawed
  - Staff has selectively disregarded the recommendations of Norton Engineering, the AQMD's third-party consultant
  - Inappropriately equates BARCT with BACT
  - Assumes technology will develop in extremely short timeframe and w/o safeguards provided under command and control rules
  - Understates true cost by assuming 25-year equipment life
  - Corrections to the BARCT analysis could reduce the 8.8 TPD by approximately 2 TPD

Please support:

- The Industry Coalition alternative technology shave
- A feasible and cost effective BARCT assessment including a 10 year useful life
- A reasonable and achievable implementation schedule

ATTACHMENT O
PAST STATIONARY SOURCE COMMITTEE PRESENTATIONS
ENVIRONMENTAL COMMUNITY

SEPTEMBER 23, 2015 (SPECIAL SESSION)

South Coast AQMD Rule XX

Stationary Source Committee

September 23, 2015

Health Advocates Position

- Rule is a good step towards fixing a flawed program
- Strong rule realizes a previous commitment to near term reductions.
- Emission reductions should total *at least* 14.85 tons.
- Timeline for reductions should be faster
- Focus on refineries and power plants
- Industry concerns don’t hold water

Background

- South Coast facing steep reductions to meet 2023, 2032 NOx standards
- Missed 2010 1-hr standard
- Dirty air still plagues region
  - 1.1 million missed school days
  - 5,000 premature deaths
- Impact of dirty air inequitable

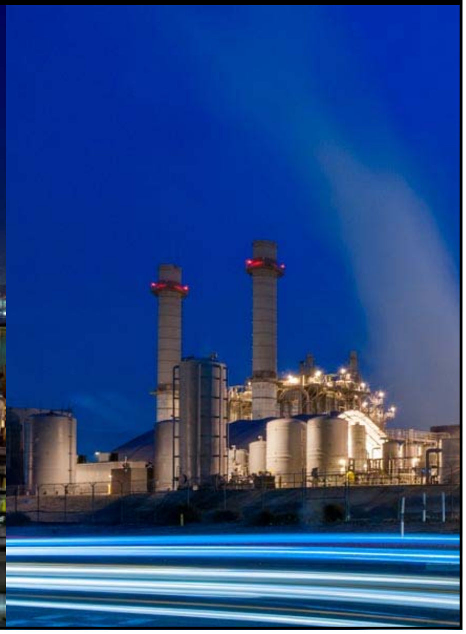
Cal. Health & Safety Code §39616.

- *"The program will result in an equivalent or greater reduction in emissions at equivalent or less cost compared with current command and control regulations and future air quality measures that would otherwise have been adopted as part of the district's plan for attainment."*
- Proposal should shave *at least* 14.85 tons per day.

The need for reductions is urgent

Year	Current Proposal	Health Advocates Proposal
2016	4 tpd	5 tpd
2018	2 tpd	3 tpd
2019	2 tpd	3 tpd
2020	2 tpd	2 tpd
2021	2 tpd	1.85 tpd
2022	2 tpd	0 tpd

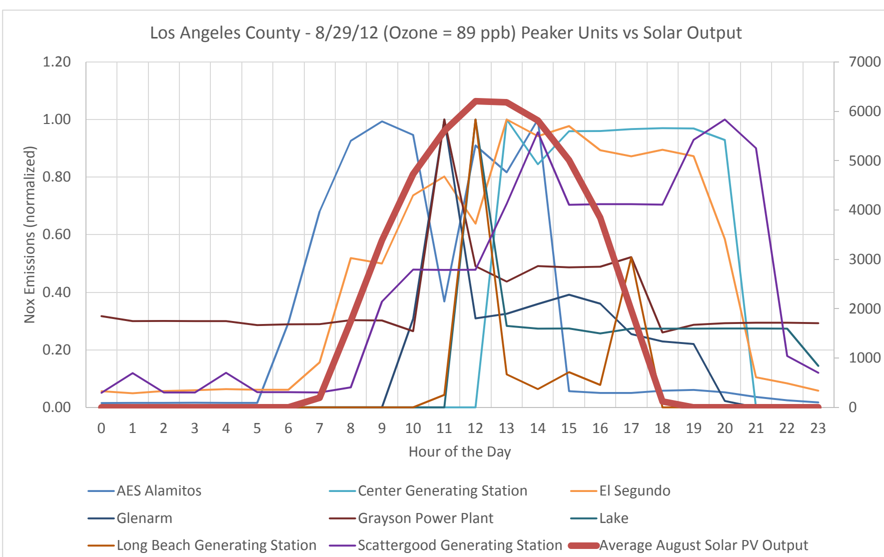
Focus on refineries & power plants



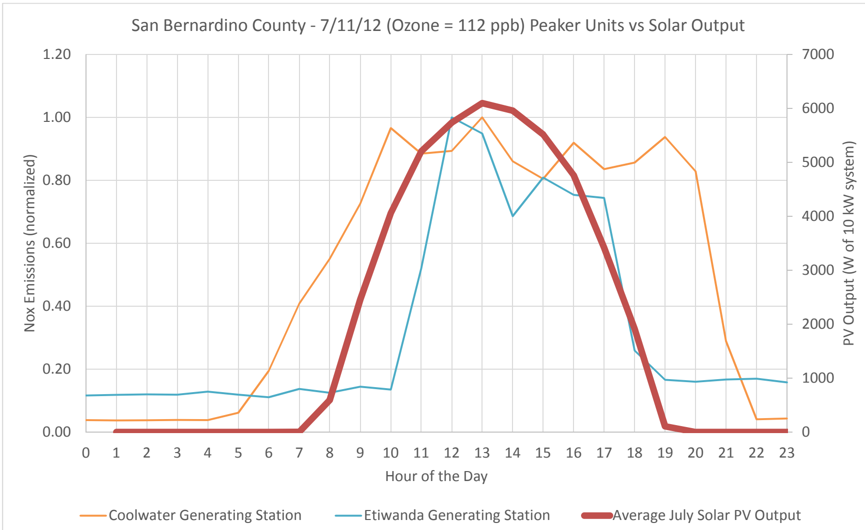
The Current Gas Boom

- Many power projects proposed for region:
  - Stanton Energy Reliability Center (98 MW)
  - Haynes (600 MW)
  - Harbor (449 MW)
  - Scattergood Generating Station (830 MW)
  - San Gabriel Generating Station (656 MW)
  - Huntington Beach/Alamitos (1,234 MW)
  - Sun Valley Energy Project (500 MW)

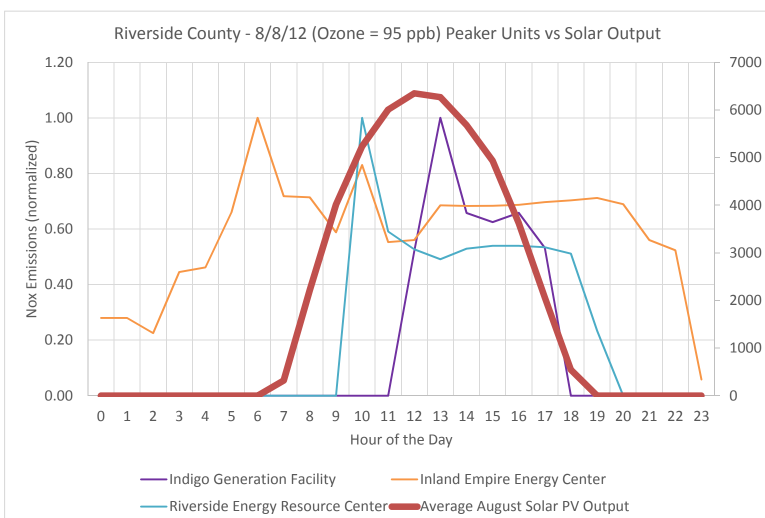
NOx, Gas Plants, and Solar Potential



Ozone, Gas, and Solar (cont'd)



Ozone, Gas, and Solar (cont'd)



Thank You

Addendum to Item #30 –
Amend Regulation XX - Regional Clean Air Incentives Market (RECLAIM)

This item includes:

1. Staff Report – The copies of Comment Letters that were part of the 30-day Set Hearing package were inadvertently omitted from the package that was released on Saturday, November 28th. Nonetheless, the responses to these comments were correctly included in both the 30-day Set Hearing package and the package released on Saturday, November 28th. The comment letters are attached.
2. Final Program Environmental Assessment – The online version of some CEQA comment letters is missing brackets from seven pages of the CEQA document (Appendix I: pages I-11, I-15, I-31, I-43, I-44, I-129 and I-130). The comment letters and responses to these comments were correctly included in the package released on Saturday, November 28th. These pages are attached with the brackets inserted.

Attachment to Appendix Z

Comments on Preliminary Draft Staff Report
Proposed Amendments to Regulation XX
Regional Clean Air Incentives Market (RECLAIM)
NOx RECLAIM – SCRs for FCCUs
Document No. 14-045-7

Dear Mr. Fine,

We have completed a first pass review of the above captioned report's discussion of SCR applications to district SCRs and have identified several misstatements and/or misunderstandings of the information provided by our company, under contract from SCAQMD, which may have material impact on the conclusions drawn by staff in the report. It is my intent in this letter to clarify the most glaring misstatements/misunderstandings of the information we provided to the district both in our final report (Doc. No. 14-045-4, Nov. 26, 2014) which summarized the data on a non-confidential basis, and the details provided on a confidential basis to the district and individually to each of the refineries.

We stated, quite clearly, in the final report and in subsequent discussions with staff, that we agree that 2 ppmvd (3% O_2) NOx emissions is a justifiable emission level for SCR applications to FCCUs, Fired Heaters, Boilers, Gas Turbines and TGU/SRUs, with caveats. While a few existing units can meet this guideline under current operating conditions, many more, similarly designed units have not demonstrated similar low emissions capabilities. With the exception of Gas Turbine installations (which have an equivalent emission level of 6 ppmv @ 3% O_2) most low emission SCRs in service today, being built today and even those being designed today carry manufacturer's guarantees to meet a NOx limit of 5 vppm @ 3% O_2. In spite of the limited number of units (other than gas turbines) operating at or below 2 vppm NOx, we believe that it is possible to achieve these levels, but to guarantee long term reliable performance (refineries typically operate 24/7 for periods of 4 to 6 years) it is prudent and quite possibly necessary to design future SCRs to increase residence time, improve NH_3 distribution, improve overall flue gas flow distribution, add catalyst, etc. SCAQMD staff agrees with this concept but we have strong disagreement as to how much change from current SCR designs will be required to achieve the sought after NOx reductions not only on day one but at the end of year one and year five and beyond.

NEC's engineers have extensive experience in process development, equipment development and project development for the refining and petrochemical industry in the manufacturing and air pollution control areas. The experience level of the engineers who completed our technology and project cost evaluations is 51, 37 and 8 years. It is exactly this experience base, and past successful work with the district, that caused you to look to NEC to develop "cost guidance" for evaluating the refining sector. We find it very surprising therefore, that staff essentially ignored our recommendations and continued to use what we feel are unrealistically low costs for NOx control projects for district refineries.

Comments on FCCU SCR Costs

Appendix F presents a review of NEC's analysis for FCCU SCR costs by SCAQMD staff. It concludes that NEC's estimated costs for NOx control are excessive and gives the following reasons for this assessment:

- NEC recommends using three catalyst beds and designing for superficial gas velocities of 10 ft/sec vs SCR vendor proposals which have less catalyst and 20% higher superficial velocities.

- NEC conditions budgetary quotations from manufacturers for the accuracy of the quote, the accuracy of the project basis and for the application of refining industry standards for construction of the equipment. This is characterized by staff as: "Adding a "mark-up" factor, or a bid conditioning factor of 1.35 to increase the costs".

- NEC includes the cost of installation of the SCR in its estimate to arrive at a direct material and labor cost for the SCR component of a project at 75% of the equipment cost. Characterized by staff as: "Adding another 75% increase in labor to the costs of the manufacturer's SCR.".

- NEC used incorrect FCCU feed rates in developing comparisons to AQMD PWVs.

The following paragraphs address each of staff's objections and provide additional information and clarifications to address what we perceive as staff's misunderstanding of the information presented in our final report.

Basis for Catalyst Addition and
Velocity Reductions vs Vendor Budget Quotes

All FCCU SCR catalyst beds are in the range of 3 - 4' deep, all are prone to plugging by catalyst and/or ABS and all have limitations on allowable pressure drop, so superficial velocity is a good basis for comparison between units. The district has three operating FCCU SCRs. All units have two catalyst beds and operate at superficial gas velocities in the range of 8 to 13 ft/sec. Two of the three units, operating at superficial velocities of 12 and 13 ft/sec do not achieve emissions of 2 vppm @ 3% O_2. The other unit, highlighted in the draft report, achieves less than 2 vppm @ 3% O_2 operating at a superficial velocity of 7.7 ft/sec. The "good" unit is operating with inlet NOx levels which are 50%

of design or lower and at lower than design flue gas flows. There are several ways to bring the two "non-performing" units into compliance with the revised standard, each with different costs and different overall performance impacts. NEC was not commissioned to do an evaluation of individual units and propose improvement options, but rather to make an assessment of what it would take, cost wise, to reliably achieve the 2 ppmv limit for grass roots SCR installations. Based on the experience of operating units in the district, and our direct experience with FCCU units for other clients (due to confidentiality agreements we cannot divulge client identities and specific locations) reliably achieving 2 vppm NOx emissions in an FCCU over a five year run will require the addition of catalyst and will be designed for superficial velocities of 10 ft/sec or less. Considering that SCR catalyst vendors have not developed and guaranteed a specific SCR design for 2 ppmvd @ 3% O_2 NEC feels that it is prudent to assume that a third bed of catalyst (SCR or ASC) and cross section designed to achieve a maximum superficial velocity of 10 ft/sec is sufficient to characterize the most likely cost of a SCR unit capable of achieving 2 ppmvd in a typical refinery FCCU environment. *The impact of the increased cross sectional area and the addition of a third bed of catalyst on the cost of an SCR installation has been overstated by district staff as a 284% increase in catalyst volume over manufacturer's estimates. The increase over manufacturer's budget estimates/proposals is actually 92%, one half of staff's reported delta.*

Staff's SCR Design Comparison Did Not Accurately Reflect NEC's "Typical" FCCU SCR Design

Staff used an incorrect basis for comparing NEC's typical FCCU SCR with district units in Table F.3. A revised comparison, using data from Refineries 1, 5 and 6 is shown below.

Table 1 (F. 3 Showing NEC Typical SCR)
Performance Information of Existing SCRs

	Refinery 1	Refinery 5	Refinery 6	NEC Typical
FCC Feed Rate, kBPD	95	71	84	55
SCR Inlet Flue Gas Flow, ACFS	6,585	5,525	9,685	3,848
SCR Manufacturer	1	3	2	--
No. Catalyst Layers	2	2	2	3
Catalyst Volume, ft^3	6,200	2,975(1)	6,200(5)	4,600
Design Inlet NOx, ppmv	133(2)/40-80(3)	150	35	45
Design Outlet NOx, ppmvd	--	17	6	2
NOx Measured, ppmvd	<2	15-17	5.6 – 6.4	1.5 (Est.)
Superficial Gas Velocity, fps	7.4	13.3	11.6	10.0
Space Velocity, 1/hr	3,823(6)	6,686(4)	5,624(5)	3,011
Removal Efficiency	95 - 97%(3)	89%	83%	97%

Notes:

1. Staff incorrectly stated catalyst volume as 2,391 ft^3 in Table F.3. 2,975 ft^3 catalyst volume confirmed by NEC with Refinery 5 and via review of SCR data provided by Refinery 5 to SCAQMD.
2. Design value reported as 155 ppmv @ 0% O_2. Value presented in table is corrected to 3% O_2.

3. Measured outlet NOx value of <2 ppmv corresponds to operation of unit with inlet NOx in the range indicated. Removal efficiency based on range of actual operation.
4. Staff reports space velocity value of 2,974/hr in table F.3.
5. Confidential data provided by SCAQMD staff is insufficient to calculate the catalyst volume for this unit without making the following assumption on the depth of a catalyst module which we assume to be 45". Staff used ½ of this value in Table F.3 corresponding to catalyst bed depth (catalyst element height) of 22.5". Recommend staff confirm catalyst volume with Refinery 6.
6. Confidential data on unit design and performance, provided by SCAQMD staff, used to calculate inlet volumetric flow and space velocity. Values differ from staff's entries in Table F.3.

In their review, staff is suggesting that NEC's typical SCR is overdesigned and as a result overpriced. Staff's comparisons suggest an overdesign factor of as much as 284%. We do not agree with this assessment. As can be seen in Table 1, NEC's typical SCR should be able to achieve 97% NOx reduction by virtue of the addition of catalyst at higher gas velocities than the SCR operating at Refinery 1. The typical SCR design provides an approximate 21% margin in space velocity over the Refinery 1 SCR design primarily due to the addition of a third catalyst bed. The addition of a third bed has inherent performance advantages in that it provides for partial redistribution of unreacted NH_3 and NOx versus further cross sectional area additions. If it is determined that the incremental cost of specially fabricated catalyst modules (shorter depth) is low, some further optimization may be possible to reduce SCR cost. It is worth noting that the ~21% catalyst margin will have a 12% overall TIC and PWV cost impact.

Basis of the: ***"mark-up" factor, or a bid conditioning factor of 1.35 to increase the costs"***

The following paragraphs provide background for NEC's use of a 35% conditioning factor for vendor equipment quotes at early stages of projects. These concepts were discussed with SCAQMD staff during reviews of our report and in subsequent follow-up phone conversations and e-mails. Due to the extensive discussion around this topic we are mystified by staff's characterization of this "bid conditioning factor" as, and here I paraphrase, 'an undefined and therefore invalid cost increase'.

Obtaining budgetary quotations from vendors for their equipment is part of the process of developing cost estimates for any project. At the early stages of projects, or when general information is sought, vendors are not provided comprehensive design basis information and therefore do not have a complete picture of the operating envelope for their proposed equipment. In these instances, some vendors will use costs from recent projects and "factor" them to the provided process conditions, other vendors may develop estimates based on equipment designed specifically to meet the provided process conditions. In either eventuality, the vendor is providing a quality estimate with reasonable accuracy (about +/- 10%) for the specified process conditions, without providing a performance guarantee and without review of the specific codes and standards applicable to refinery installations.

As project definition improves the process basis becomes fixed, equipment sizes become more reliable, performance guarantees are finalized, and vendor quote accuracy improves. Industry experience shows that at the early stages of a project, basis uncertainty alone, necessitates the addition of a 15 – 25% conditioning factor to a vendor's budget quote, in addition to other bid conditioning factors, to account for the difference seen between early equipment bids and final, full definition, performance guaranteed, equipment bids based on a definitive project basis.

Refineries are built to a more rigorous set of standards than typical air pollution control equipment which makes projects in the refining sector slightly more expensive than typical industrial projects. Standards which will have an impact on either the SCR design, the structural support design, location of equipment, internal and external maintenance access, etc., are likely to increase Direct SCR M&L costs. At this stage of project definition a factor of 10% is added to a vendor's equipment bid to account for the cost of meeting local plant standards.

The 1.35 "mark-up" or bid conditioning factor used in NEC's cost work-up for all SCR projects (FCCU, Heaters/Boilers, etc.) is not an arbitrary factor used to inflate costs, as implied in Appendix F, but is actually the low end of a time tested and proven means to determine the actual cost of a piece of equipment after full project definition is complete, including application of local industry standards to the design of the equipment, performance guarantees are offered and firm pricing for equipment components is provided by the vendor.

Basis for: ***"Adding another 75% increase in labor to the costs of the manufacturer's SCR."***

Another cost factor discussed with SCAQMD staff, and apparently dismissed as a simple adder to make costs appear high, is the cost of actually installing the equipment supplied by the SCR vendor in the plant. The vendor does not do construction and does not quote the cost of field assembly in their quote which only covers fabrication and supply of the equipment, in this case the SCR catalyst, support frames, ammonia injection grid and the carbon steel box.

The labor cost factor used in NEC's development of project costs is applied to the SCR vendor's factored estimate to account for the labor required to install the manufacturer's equipment at the site, transportation, taxes, tie-ins, insulation, access, structural steel, etc. Installation labor for equipment can range from a low of about 30% of the equipment cost to as much as 200% of direct equipment cost depending on the complexity of the equipment, the material it is made of and other equipment specific factors. In general, low cost equipment manufactured of low cost materials have higher installation percentages than highly complex equipment made of high cost materials. As a reference point, "Applied Cost Engineering", Clark F. D. and Lorenzoni A. B.; Marcel Decker Inc., 1978, uses a factor of 2.2 times direct material costs to estimate the direct M&L cost of a fired heater installation, a factor of 3.0 times direct material costs to estimate the direct M&L cost of a pump installation and a factor of 2.9 to estimate the direct M&L cost of a distillation tower. Due to the simplicity of the SCR equipment and its use of low cost materials we have used an installation labor cost factor of 0.75 (75%) to account for physical installation of the SCR, structural steel, fit-up of ducting, connection of piping, foundations, excavation, instrumentation, insulation, equipment storage, etc. This factor does not account for any costs associated with: demolition of existing equipment, modification of existing equipment, labor inefficiencies attributed to working in an operating plant, relocation and/or modification to underground utilities, piping, piping supports, ammonia storage facilities, control system additions, instrumentation wiring, conduit, power wiring, area paving, area lighting, area utilities, safety facilities, sootblowers, etc.. The cost of these items is rolled up into the overall TIC factor applied to escalate SCR M&L costs to a total project cost.

TIC Factor

SCAQMD staff disputes NEC's use of a TIC factor of 4.5 to convert direct M&L costs for the SCR into TIC for the SCR PROJECT. This factor is a reasonable estimate for project items not specifically identified in the direct M&L costs (indirect costs, engineering and owner's costs, labor productivity, ancillary equipment and systems, revamp items, duct work, area paving, lighting, utilities, safety systems, control system connections and programming, instrumentation, sootblowers, etc.) As a point of reference, the TIC factor used by NEC, in this analysis, is 90% of the average TIC factor of 4.9 used to estimate SOx control costs in NEC's SOx RECLAIM report.

NEC Estimated FCCU Feed Rates from
Flue Gas Rate Data Provided by SCAQMD
Correction of NEC PWVs Required

SCAQMD staff is correct in pointing out that NEC used incorrect design capacities in developing the FCCU SCR costs shown in section 1.2 of NEC's non-confidential report (14-045-4, November 26, 2014). NEC back calculated expected FCCU rates from flue gas flow rate data provided by AQMD staff to obtain estimated FCCU sizes. The following table presents a revision to the report table based on corrected FCCU sizes as indicated by district staff. Also included in the table is an update to the cost of a Grass Roots SCR for Refinery 6 based on a comparison of flue gas rates to the SCR versus the typical (base case) SCR. Revised NEC estimates provided in Table 2 do not include any reduction to NEC's original cost estimate model.

Table 2 (Restatement of Table F.2)
Estimates of PWV Correcting NEC Values for FCCU Feed Rates

Facility	FCCU Feed, kBPD	AQMD's Estimate, $M	Revised NEC Estimate, $M	Ratio: NEC/AQMD
5	71	33	43(2)	1.3
6	90	57	62(1)(2)	1.09
7	55	27	37	1.37
4	34/36(3)	16	28	1.75
9	55	19	37	1.95
Total		152	207	1.36

Notes:

1. The PWV shown includes the impact of additional flue gas from a CO boiler but does not include the incremental flue gas from another source which is fed to the existing SCR.
2. Costs shown are for grass roots (new) SCR additions to existing FCCUs. Existing units may be modified to reduce compliance costs below those indicated.
3. Staff report throughput is 34 kBPD. Published unit capacity is 36 kBPD.

**Staff Evaluation of NEC PWVs vs. Refinery 1 SCR Costs
Does Not Factor In Project Scope Differences**

Staff provided a review of NEC's cost estimates based on a comparison to the cost provided for Refinery 1's SCR to demonstrate that NEC's estimating method is overly conservative. In this comparison staff claims that NEC's cost tool over predicts the cost of this installation by $11M (27%). The difficulty in comparing a specific project to a generalized curve is that the project has a specific scope which in most cases is different than the assumed scope of the "typical" project. This is the case for the SCR installation at Refinery 1 which, according to Refinery 1 personnel, did not include the cost for waste heat boiler modifications. Subtracting this component from the TIC for a typical FCCU SCR installation and recalculating PWV yields a cost of $45.45M which is 10.8% higher than staff's cost work-up on this project of $41M, not the 26% difference indicated in Appendix F. Staff had the WHB cost information NEC used in our estimates, we do not understand why they did not make the PWV comparison on the same basis.

**Staff Evaluation of NEC PWVs vs. Refinery 9 SCR Costs
Misstates Vendor and NEC Information**

Staff also provided a review of NEC's cost estimates based on staff's assessment of differences between the data provided by an SCR vendor to staff and NEC for an installation at Refinery 9. In staff's evaluation of the data provided by the vendor they incorrectly calculate the total catalyst volume to be 3,100 ft^3 vs the actual vendor proposal which provided only 2,400 ft^3. Staff also incorrectly calculates NEC's estimated catalyst volume at 12,697 ft^3 vs an actual value of 4,600 ft^3 (1.92 x vendor proposal, see previous discussion on catalyst volumes and specification of a third bed).

**Comments on Staff's Determination of
PWVs for FCCU SCRs**

I would like to take the opportunity to provide a few comments on SCAQMD staff's determination of PWVs for FCCU SCRs.

1. In using the costs provided for Refinery 1's SCR staff is assuming that all district SCRs can be installed without any impact on upstream equipment and that installation of the SCR can be executed in an open, non congested area. Refinery 1's SCR was installed prior to the installation of a large ESP, which occurred around 2006. If the SCR was to be installed today, or at any time after installation of the large ESP, costs would be higher due to productivity debits associated with working in a congested area and quite possibly even higher due to the need to move or modify some equipment to make the installation possible. In the most extreme case the SCR and ducting may have to be field erected from small fabricated assemblies due to access constraints.

2. Staff used a 0.7 power factor to scale the costs for Refinery 1's SCR project to different sizes. Costs for FCCU regenerator flue gas systems scale more accurately when a figure of around 0.6 is used. The effect of using a larger scale factor is a greater reduction in project costs for all projects with the differences getting proportionately greater the further one gets from the base case unit size. In essence using the 0.7 factor instead of 0.6, in this particular evaluation, will decrease costs for all units and will disproportionately decrease the cost of smaller units.

3. In using vendor budget quotes for SCRs, staff needs to add erection labor to the vendor quote. There is no indication that this is done in staff's analysis.

4. Staff does not condition the vendor's quotes to account for operational conditions, including unit upsets, and other project unknowns which will have direct bearing on SCR design details, performance and costs. An allowance must also be made for the accuracy inherent in vendor's budget quotations, which does not appear anywhere.

5. The PWVs provided for Refinery 7 and Refinery 9 are $27M and $19M respectively. There is an apparent inconsistency in these numbers as the stated capacity for each of these units is 55 kBPD. Units of the same capacity should have PWVs close to one another not differing by 42%. Staff should check these numbers and ensure that the SCR project scope differences between these two units can explain the large difference in cost.

In the interest in getting our comments into your hands as soon as possible we will provide comments on Staff's review of our SCR estimates for other applications in the district in one or more separate letters.

I am looking forward to discussing the items identified in this letter with SCAQMD staff and invite them to meet with us at our office in Montville, NJ.

Sincerely,

James P. Norton
President & CEO

Comments on Preliminary Draft Staff Report
Proposed Amendments to Regulation XX
Regional Clean Air Incentives Market (RECLAIM)
NOx RECLAIM – SCRs for Fired Heaters & Boilers
Document No. 14-045-8

Dear Mr. Fine,

We have completed a review of the above captioned report's discussion of SCR applications to district Refinery Fired Heaters and Boilers and have identified several misstatements and/or misunderstandings of the information provided by our company, under contract from SCAQMD, which may have material impact on the conclusions drawn by staff in the report. It is my intent in this letter to clarify the most glaring misstatements/misunderstandings of the information we provided to the district both in our final report (Doc. No. 14-045-4, Nov. 26, 2014) which summarized the data on a non-confidential basis, and the details provided on a confidential basis to the district and individually to each of the refineries.

We stated, quite clearly, in the final report and in subsequent discussions with staff, that we agree that 2 ppmvd (3% O_2) NOx emissions is a justifiable emission level for SCR applications to FCCUs, Fired Heaters, Boilers, Gas Turbines and TGU/SRUs, with caveats. While a few existing units can meet this guideline under current operating conditions, many more, similarly designed units have not demonstrated similar low emissions capabilities. With the exception of Gas Turbine installations (which have an equivalent emission level of 6 ppmv @ 3% O_2) most low emission SCRs in service today, being built today and even those being designed today carry manufacturer's guarantees to meet a NOx limit of 5 vppm @ 3% O_2. In spite of the limited number of units (other than gas turbines) operating at or below 2 vppm NOx, we believe that it is possible to achieve these levels, but to guarantee long term reliable performance (refineries typically operate 24/7 for periods of 4 to 6 years) it is prudent and quite possibly necessary to design future SCRs to increase residence time, improve

NH_3 distribution, improve overall flue gas flow distribution, add catalyst, etc. SCAQMD staff agrees with this concept but we have strong disagreement as to how much change from current SCR designs will be required to achieve the sought after NOx reductions not only on day one but at the end of year one and year five and beyond.

NEC's engineers have extensive experience in process development, equipment development and project development for the refining and petrochemical industry in the manufacturing and air pollution control areas. The experience level of the engineers who completed our technology and project cost evaluations is 51, 37 and 8 years. It is exactly this experience base, and past successful work with the district, that caused you to look to NEC to develop "cost guidance" for evaluating the refining sector. We find it very surprising therefore, that staff essentially ignored our recommendations and continued to use what we feel are unrealistically low costs for NOx control projects for district refineries.

Comments on Heater SCR Project Costs

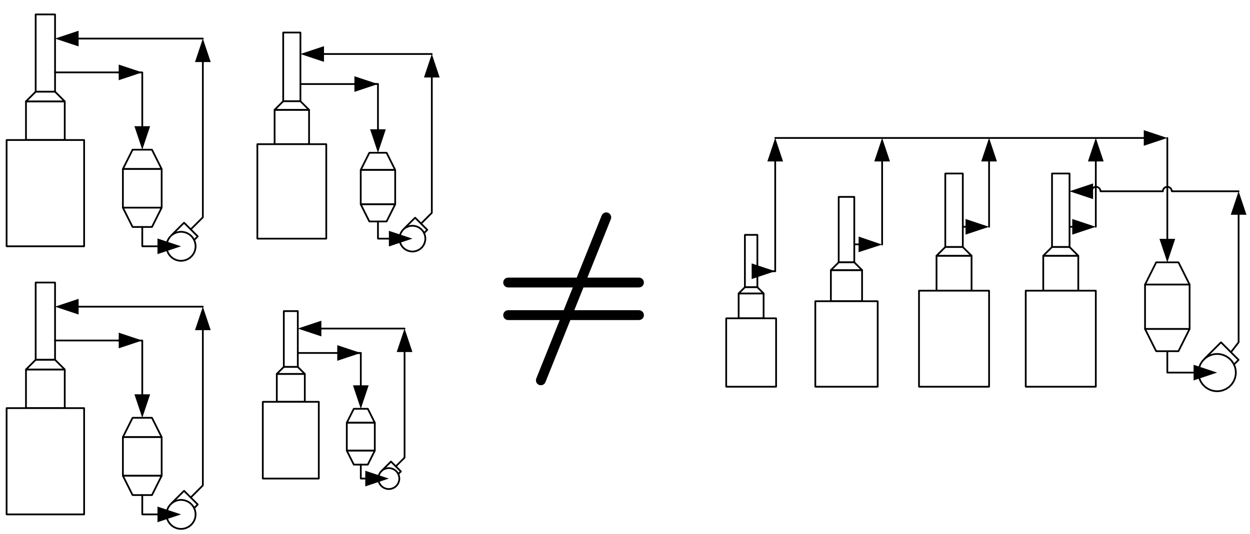
Appendix G to Staff's Draft Report presents a review of NEC's analysis of Heater and Boiler SCR costs by SCAQMD staff. It concludes that NEC's estimated costs for NOx control are excessive and gives the following reasons for this assessment:

- NEC recommendations did not include an assessment of the efficacy and cost of alternative NOx control technologies.
- NEC developed TIC estimates using a direct M&L multiplier of 4.5 vs staff's use of a TIC factor of 3.87.
- NEC used SCR catalyst and enclosure costs, obtained from SCR suppliers, for FCCU applications and used these costs as a basis for estimating the cost of heater and boiler SCRs.
- NEC recommends including space for four catalyst beds and designing for superficial gas velocities of 10 ft/sec.
- NEC included costs for new CEMS in their project cost estimates.
- NEC's costs estimates for smaller heaters and boilers are biased high by specification of ammonia systems which are too large for these small units.
- NEC's operating costs are biased high due to the cost of catalyst replacement which is higher if/when with higher installed catalyst volumes.
- NEC's estimates are skewed high because they are higher than staff's estimates which are conservative in the base case.
- NEC conditioned budgetary quotations from manufacturers for the accuracy of the quote, the accuracy of the project basis and for the application of refining industry standards for construction of the equipment.

- NEC includes the cost of installation of the SCR in its estimate to arrive at a direct material and labor cost for the SCR component of a project at 75% of the equipment cost. Characterized by staff as: "additional labor".

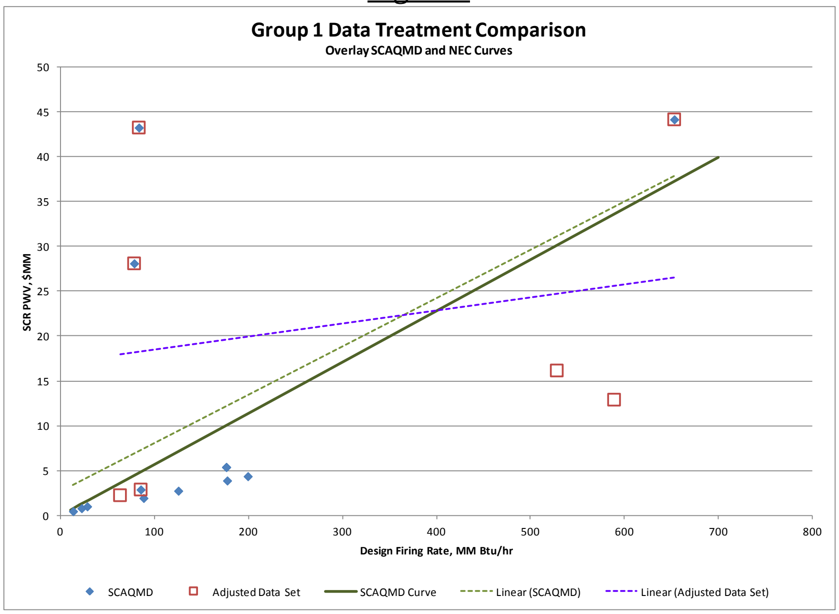
Before getting caught up in the minutia of Appendix G, I want to first present an overall picture of the PWV estimates developed by AQMD staff and those developed by NEC. The first thing we noticed in reviewing staff's use of refinery cost survey data, was that PWVs for SCR installations servicing multiple heaters were broken down and allocated to each heater based on design firing rate. This was done to obtain data points for SCR installation costs for individual heaters as a function of heater design firing rate. The problem with parsing the data in this manner is that it assumes that project costs for multiple heater installations and single heater installations are equivalent. They are not. Sharing an SCR between heaters is always lower cost than installing an SCR on each heater. We estimate that multiple heater SCR installations can cost as much as 30 to 70% of single heater installations with the savings coming from a reduction in SCR box steel and structural support, a reduction in the number of fans required for the installation, a reduction in foundations, ammonia distribution piping, controls, etc.

I believe that the following sketch provides a much better explanation of the difference between multiple and single heater SCR installations:



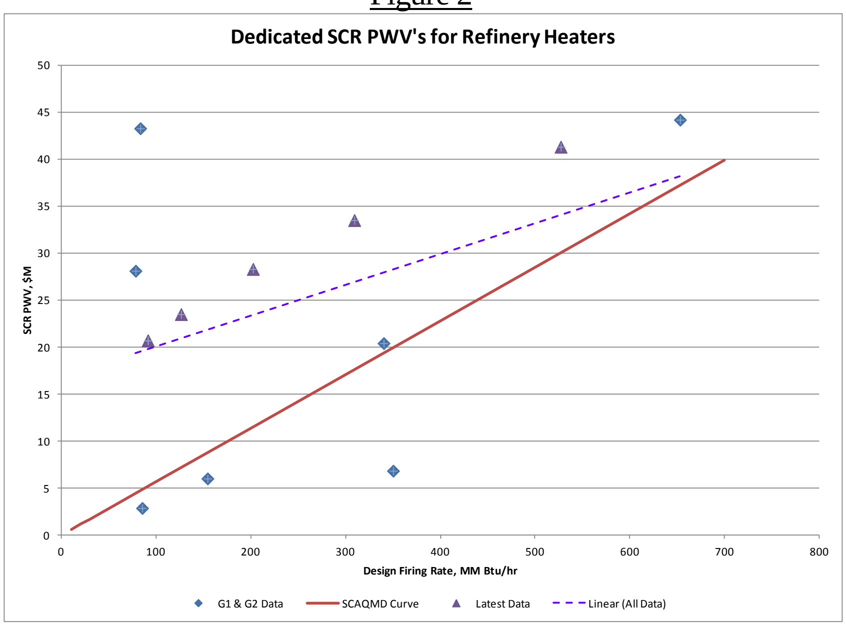
The following figures provide an illustration of the effect of staff's cost allocation assumption on the estimated PWVs of small heaters. Figure 1 presents two sets of survey cost data denoted as Group 1 data in the draft report. The data set named SCAQMD includes the parsed PWV data for three of the seven best performing SCRs in the district resulting in a total of fourteen data points. The data set named "Adjusted Data Set" combines the duties of the seven heaters which share SCRs into three data points yielding a total of seven data points. The revised data points represent SCR systems designed for a heater with a size equal to the combined firing rate of all the heaters sharing the SCR. Linear regressions of the parsed and non-parsed data are shown as dashed lines in the figure. The solid line is staff's PWV relationship. While the data is widely scattered and does not curve fit very well (R^2 = 0.3 for curve fit of parsed data and 0.05 for non-parsed data) the slopes of the two curves are very different and indicate that staff's correlation likely under predicts PWVs for heaters smaller than 400 MM Btu/hr; quite a different conclusion than that drawn in the draft report.

<u>Figure 1</u>



Norton Engineering understands that the number of survey project and operating cost data points on high performing SCR units is both limited and scattered and that additional information is needed and has been used by staff to generate more representative PWVs for refinery heaters. Figure 2 provides a comparison of staff's PWV correlation with available Group 1, Group 2 and additional SCR project cost estimate data provided to AQMD by a district refinery during NEC's review. All data are for dedicated SCR installations.

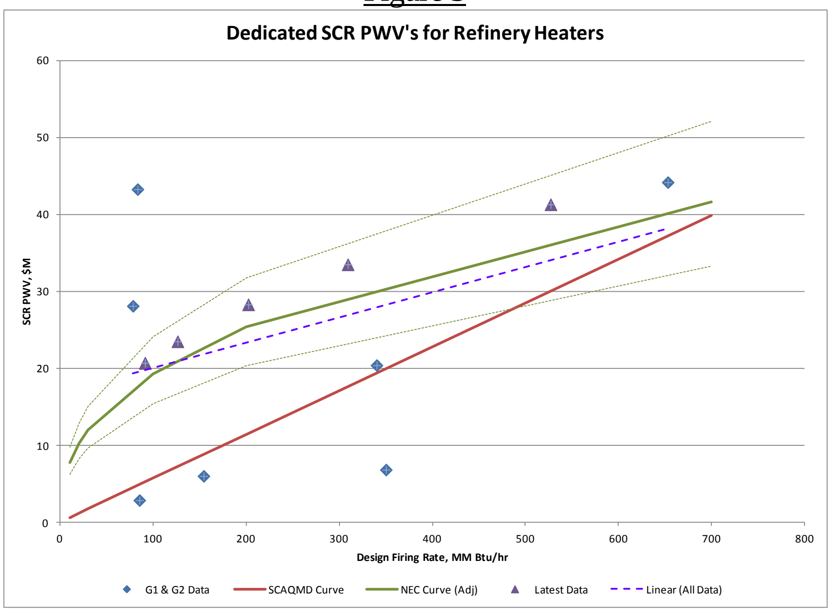
<u>Figure 2</u>



The purple dashed line in the figure represents a linear regression line for all the chart data. As with Figure 1, the large scatter in the data makes the correlation, any correlation, almost meaningless. The conclusion we can reliably draw from this chart is that staff's PWV correlation under predicted PWVs (based on actual and estimated TICs) in eight out of twelve instances, over predicted PWVs in one out of twelve instances and was accurate in three out of twelve instances. If staff's correlation was conservative we would expect that it would over predict PWVs more often than it under predicted PWVs. That is clearly not the case.

Figure 3 is a repeat of Figure 2 including NEC's proposed PWV correlation and the cost bands recommended for use in estimating complex and simple, single heater – single SCR PWVs.

Figure 3



NEC's proposed correlation provides PWV estimates for dedicated SCR projects which are more representative that staff's proposed correlation, matches up pretty well with the linear correlation of all data and, is not overly conservative. Six data points are higher cost than predicted by NEC's correlation, four are lower cost and two are predicted pretty accurately. When the complexity bands are used, the correlation under predicts in two of 12 cases, over predicts in four of twelve cases and is "accurate" in six of twelve cases.

For the specific case of smaller heaters (<100 MMBtu/hr heat release) NEC's correlation shows a very steep slope indicating that costs for small heater SCR installations rapidly increase with increasing heater size. This size sensitivity is expected as fixed project costs and non-size dependent project costs are normally a higher percentage of small projects than they are of larger projects. Staff's proposed correlation does not show this trend and therefore can be expected to significantly under predict PWVs for smaller heaters.

The following paragraphs address each of staff's comments and objections and provide additional information and clarifications to address what we perceive as staff's misunderstanding of the information presented in our final report. While the items covered in the following paragraphs may be open to interpretation, our previous analysis of available cost data indicates that any changes SCAQMD staff might want to make to NEC's "typical fired heater and boiler project basis" will likely necessitate changes to equipment definition, equipment cost or estimate cost factors to improve the cost correlation with Group 1, Group 2 and subsequent project cost data.

Scope of NEC's Review of AQMD Staff's
Preliminary Draft Report – September 23, 2014

This comment seems irrelevant to the current discussion as Staff's entire discussion on refinery heaters and boilers is focused on SCR installations as BARCT for the 2 vppm emission limit. We discussed this with staff during our work and staff agreed that any dilution of our effort to evaluate these alternative technologies would not be desirable.

Using FCC SCR Costs Increased Heater &
Boiler SCR Cost Estiamtes

Staff provided NEC with heater and boiler SCR cost data from vendors for review. In our discussions with SCR vendors we focused on the more severe FCC applications and obtained detailed information on SCR costs for these applications. Much less data was available from staff's contact with SCR vendors. Attempts were made to obtain clarifications from SCR vendors which were either not received or received after issuance of NEC's report. In reviewing the design and operation of the best heater in the district (1.6 vppm outlet NOx) we found that inlet gas velocities were similar to our recommendations for FCCU SCRs while catalyst volumes were significantly less. Using the FCCU SCR cost as a basis NEC estimated and added the cost of and ID fan, an ammonia storage tank, and a new CEMS for each SCR project. We then factored the cost as described previously to arrive at a total project cost. We then compared the result of this method to available data on past and planned projects, Group 1, Group 2 and recent refinery estimates, and found the accuracy of this method to be reasonable and more accurate than staff's PWV correlation. Considering the scatter in the data and the relative good accuracy of the methodology we did not go further in refining any underlying assumptions or our cost estimating technique.

NEC TIC Factor of 4.5 vs.
Staff TIC Factor of 3.87

Details of how NEC developed the factored estimates we used to generate TICs and ultimately PWVs for heater and boiler SCR installations have been described at length in our SOx RECLAIM cost review report (Non-Confidential Report No. SCAQMD 10-014-04 dated June 10, 2010). All of the factors used in this analysis are consistent with those used for our SOx RECLAIM assessment. Additional discussion is also available in our letter of August 10, 2015 commenting on AQMD staff's assessment of NEC's FCC SCR PWVs.

It appears that staff relied on SCR vendor cost data (Group 3 data) to generate SCR project costs for heaters and boilers without adjusting vendor costs for the budgetary nature of the estimates, the screening level of the process data provided to the vendor, the cost of equipment installation or the need for ancillary equipment such as ducting, fans and controls. All of these components are typically included in a cost estimate before the addition of TIC factors which cover, undefined equipment and systems, indirect project costs, engineering, project management, operator training, start-up spares, civil works and site preparation, project contingency, shipping and taxes. Staff's use of a TIC factor of 4.0 applied to the budget cost of the SCR provided by a vendor is not adequate to cover the cost of the entire SCR project.

Basis for SCR Catalyst Increase and Velocity Reductions vs Vendor Budget Quotes

The district has 7 SCRs installed on 14 fired heaters, achieving 1.6 to 3.5 ppmv NOx @ 3% O_2. The best performing unit treats flue gas from four heaters with a combined total design firing rate of 589 MM Btu/hr and is designed to treat flue gas to achieve 5 vppm NOx at this rate. Reported operation of this unit is 65% of design when achieving <2 vppm NOx emissions. Low firing rate operation decreases superficial and space velocities across/through the SCR versus design conditions (lower flue gas mass flows and lower flue gas temperatures vs design) lower velocities and space velocities translate into improved unit performance. In addition, lowering heater firing rates cools the heater firebox which also decreases inlet NOx levels to the SCR.

More important to the current discussion on SCR application to achieve 2 vppm emissions limits is the use of design data for this unit by staff, to extrapolate catalyst volumes and system costs for design of new units. Since the "base" unit is operated at 65% of design, any use of this data in an extrapolation to other applications needs to account for the lower than design operating conditions. It is not apparent from our review of staff's assessments if they have made this adjustment which will be a minimum 54% increase in the costs of the base unit.

NEC looked at the available operating data and the SCR manufacturer's information provided by staff for our assessment. We interviewed the SCR owners and made the assessment, based on information obtained during these interviews and our experience in developing oil processing, infrastructure and environmental control projects for over 20 years in the US and International refining industry, that estimating typical SCR sizes, based on the design conditions for the best SCR in the district, which isn't operating anywhere near its design condition would result in specifying/costing units which were too small. The question of catalyst volume then became one of how much additional catalyst might be needed to ensure long term reliable operation of an SCR. For refiners this translates into an SCR design which does not limit refinery or unit operation at any time between scheduled turnarounds.

Final determination of SCR catalyst volume for a typical refinery heater application requires making a flue gas throughput correction to the base case design, as note above, and making adjustment to catalyst volumes quoted by vendors where catalyst change out times are shorter than five to six years. To achieve the long run lengths required in refinery applications, refiners will increase catalyst volumes to offset declining catalyst performance. This is done in the design of every fixed catalyst bed system in the refinery. Based on the vendor information provided by AQMD staff a doubling of vendor catalyst volumes would be needed to ensure reliable operation in excess of five years. The minimum adjustment to achieve 2 vppm NOx and long unit operating life is therefore 3x (1/0.65 * 2) typical vendor specified or currently installed catalyst volumes.

NEC included a total of four catalyst beds for 2vppm NOx designs when three beds will likely prove adequate. Our inclusion of the fourth bed was to provide operating flexibility to ensure long term compliance while burning variable composition refinery fuel gas. This bed added 11 ft to the height of a typical SCR compared with a three bed unit. Elimination of this bed will reduce proposed SCR height by less than 20% and will not have any impact on the cross sectional area of the catalyst bed. Adjusting the SCR cost to reflect this change will necessitate a change in TIC estimating methodology to improve the correlation with Group 1, Group 2 and subsequent project cost data (Figure 3).

Cost of New CEMS vs Upgrade

NEC did not have any data on the status/condition of existing CEMS and therefore included the cost of a new CEMS, CEMS enclosure, stack platforms, access, etc. in the heater and boiler SCR project TIC estimates. A reduction in this cost will necessitate a change in estimating methodology to improve the correlation with Group 1, Group 2 and subsequent project cost data (Figure 3).

Specification of "Large" Ammonia Storage Tanks Biases Costs for Small Heaters High

A stand alone ammonia storage system will include a storage tank with sufficient volume to receive a full truck load of ammonia while operating with a heel sufficient to run the associated SCR for a defined, short, period of time. Local bulk ammonia suppliers suggest a minimum tank size of 11,000 gallons. NEC used this tank size as the basis for all district SCRs without increasing size for larger heaters which will receive ammonia deliveries more frequently.

NEC did not include the likely cost savings impact of centralized ammonia storage and distribution systems in our analysis. While on the surface it appears that significant savings can be gained from such systems, the need for long runs of small bore piping on existing pipe racks, through operating units, with frequent pipe supports (small bore piping cannot span typical pipe rack supports and needs multiple intermediate supports) and requiring significant scaffolding to be erected, makes ammonia distribution from centralized storage facilities nearly as costly as dedicated storage, and in some cases more expensive. For this reason, dedicated storage is a more reasonable option during early stages of project definition.

High Catalyst Replacement Costs Skewed NEC PWVs High

Staff is correct in their assessment that high catalyst volumes (FCCU SCR basis) in NEC's basis yielded high catalyst replacement costs and increased PWVs for heaters and boilers. A correction to annual operating costs should be made to correct this error. When this is done PWVs estimated by NEC's correlation will drop and will under predict Group 1, Group 2 and subsequent project cost data. An adjustment in NEC's TIC estimating method will be required to reestablish prediction accuracy for PWV (Figure 3).

NEC's Estimates are Higher Than Staff's "Conservative" PWVs

Staff has incorrectly used NEC's PWV correlation to demonstrate a reported 250+% difference in cost for a refinery SCR. Table G. 8 is recreated below with an additional column showing the correct use of NEC's correlation for PWV.

Table G. 8A – SCR Costs Estimated by Staff and NEC for Four Process Heaters Vented to a Common Stack (Shared SCR)

Heater	Rating MM Btu/hr	Staff's Approach Upperbound PWV	NEC's Approach PWV	Corrected NEC Approach PWV
D471	177	$11 M	$27 M	--
D472	125	$11 M	$23 M	--
D473	88	$5.5 M	$20 M	--
D3031	199	$11M	$28 M	--
Total	589	$38.5 M	$99 M	$43.2 M

As discussed previously in this letter we expect the SCR project cost for shared units to be less than what would be calculated for each individual unit. Costs should be more in line with the cost of an SCR for the total fired duty of the heaters feeding the SCR. In this case the difference between staff and NEC is 12% not 250+%.

Based on the data which staff purports to use to "calibrate" their conservative PWV correlation for fired heaters and boilers, staffs correlation is neither calibrated nor conservative. NEC has provided AQMD with a reasonable correlation for estimating the cost of SCR installations on refinery heaters and boilers as validated by the same data set staff is using. We agree that operating costs for heater and boiler SCRs should be reduced in the PWV calculation to correct the operating cost impact of over specification of catalyst volume. After making this correction (staff has the TIC correlation) we recommend staff use the resulting PWV correlation to estimate the cost of heater and boiler NOx control.

It is a shame that NEC and AQMD find themselves disagreeing on so many items in a public forum. I wish that we had discussions on more of the specifics of our review of AQMD's draft report and our recommendations for changes to the way cost estimates were prepared between November 2014 and July 2015. Perhaps we could have clarified and/or resolved some of these issues prior to AQMD staff developing the draft report and the recommendations which are based on the cost evaluations in question. It would have certainly made everyone's life a little easier.

I am looking forward to discussing the items identified in this letter with SCAQMD staff and invite them to meet with us at our office in Montville, NJ.

Sincerely,

James P. Norton
President & CEO

August 21, 2015

Dr. Philip Fine
Deputy Executive Officer
South Coast Air Quality Management District
21865 Copley Drive
Diamond Bar, CA 91765

SUBJECT: NOx RECLAIM INDUSTRY COALITION COMMENTS ON CURRENT DISTRICT STAFF PROPOSED AMENDMENTS TO REGULATION XX DATED JULY 21, 2015

Dear Dr. Fine:

The following trade associations in representing their members have joined together to form the NOx RECLAIM Industry Coalition ("the Coalition"):

California Asphalt Pavement Association (CalAPA)
California Construction & Industrial Materials Association (CalCIMA)
California Council for Environmental and Economic Balance (CCEEB)
California Manufacturers and Technology Association (CMTA)
California Metals Coalition (CMC)
California Small Business Alliance (CSBA)
Regulatory Flexibility Group (RFG)
Southern California Air Quality Alliance (SCAQA)

Western States Petroleum Association (WSPA)
Los Angeles Business Federation (BizFed)

Members of the Coalition have been actively following the District staff proposals regarding a NOx RECLAIM shave ostensibly being proposed to reflect advances in Best Available Retrofit Control Technology ("BARCT") between 2005 (the last NOx RECLAIM shave) and today. Following the release of the preliminary draft staff report and the proposed amendments to Regulation XX on July 22, 2015, the Coalition members believed it necessary to make these written comments and ensure that staff is fully aware of our concerns and that those concerns are included in the administrative record.

PROPOSED SHAVE AMOUNTS AND TIMING

District staff has proposed the following shave implementation schedule:

Year	Shave amount (tons/day)
2016	4
2017	0
2018	2
2019	2
2020	2
2021	2
2022	2

A shave of 4 tons per day in 2016 does not allow any time whatsoever for facilities to develop and implement emission reduction measures. Indeed, it could potentially put many of the RECLAIM facilities at risk of non-compliance with their respective RECLAIM caps, resulting in deductions from their 2017 RTC allocations. Moreover, the District expects that the bulk of the BARCT emission reductions will be made at the refineries[1]. At NOx RECLAIM Working Group meetings, staff has conceded that those reductions will not be achievable for several years into the future, at the earliest, due to the complexity of the permitting and siting issues and the magnitude of the construction activities necessary to achieve the BARCT levels projected by District staff. Thus, it is illogical to require the largest shave amount to occur at the earliest possible date.

The Coalition understands that the District has committed itself in the currently operative AQMP to implement a certain level of NOx reductions from the RECLAIM universe as a contingency measure if the District failed to attain the 24 hour PM2.5 NAAQS by the end of 2014. However, there is no commitment in the AQMP to make a 4-ton per day shave in 2016. Indeed, the AQMP contemplated a 2-3 ton per day reduction in Phase I and another 1-2 tons per day in Phase II. (Preliminary Draft Staff Report, page 2). Moreover, the AQMP specifically considered <u>and rejected</u> whether such an early action shave should remove all "excess" RTCs (i.e., the entire

[1] SCAQMD PDSR, Proposed Amendments to NOx RECLAIM, July 21, 2015, page 18.

"gap"). Rather, it was determined that only a 2-ton per day reduction was appropriate. Accordingly, the Coalition believes that the shave amount for the period 2016-2017 should be no more than 2 tons per day, and that there is no reason that all two tons have to be shaved in 2016. In fact, given that 2016 is almost upon us, and certainly will be by the time the amendments are adopted, it may be appropriate not to make any adjustments to 2016 allocations. Finally, we believe that the public record supports the view that the Governing Board approved the AQMP and CMB-01 with the understanding that if the 24 hour PM2.5 NAAQS was not attained, no more than 2 tons per day would be removed and that additional NOx reductions from RECLAIM would not be needed as a contingency measure to meet this purpose.

With respect to the total amount of the shave, the Coalition continues to believe that shaving a total of 14 tons per day of RTCs from the RECLAIM market in order to achieve the 8.79 tons per day reductions the District seeks to obtain as a BARCT adjustment is neither necessary nor justified.[2] We understand that District staff believes that the BARCT reductions won't occur unless almost the entire "gap" between RTC holdings and reported NOx emissions has been eliminated. History has shown that the staff is incorrect on this assessment. As shaves have been implemented, emissions have gone down to reflect past BARCT adjustments, even as the "gap" has remained relatively stable at 5-9 tons per day. A shave of 14 tons per day is excessive and risks destroying the RECLAIM market.

Finally, when implementing the shave, the amounts in the early years should be smaller and larger increments should be reserved for later years, to allow the BARCT installations to be implemented.

COST EFFECTIVENESS

The Coalition continues to believe that a 25 year useful life assumption (used consistently for all equipment in this proposed rulemaking) is not appropriate for all equipment. Additionally, we believe that the District staff has underestimated the cost for several equipment categories. District staff minimizes control costs by using a cost-effectiveness calculation[3] that is not used by the California Air Resources Board and most other major California air districts. Additionally, the use of a $50,000 per ton figure as the cost threshold is more than twice the $22,500 per ton threshold applied to command-and-control regulated sources. This is inconsistent with Health and Safety Code Section 39616 which requires that the RECLAIM program "not result in disproportionate impacts, measured on an aggregate basis, on those stationary sources included in the program compared to other permitted stationary sources in the district's plan for attainment."

We also note that Norton Engineering (the third party independent contractor retained by the District to review and assess the District staff's cost effectiveness determinations) has raised

[2] The Coalition does not believe that the 8.79 tons per day figure is necessarily the correct number. We continue to take issue with the SCAQMD staff's cost-effectiveness calculations for a number of source categories and understand that Norton Engineering, the SCAQMD's third party BARCT evaluator, continues to have issues with the staff analysis as well. This will be discussed separately in this letter.

[3] The use by SCAQMD of the discounted cash flow (DCF) method as well as generous assumptions regarding useful life and interest rates result in cost effectiveness figures that show lower costs per ton of emissions reduced than other, more accepted, calculation methods.

questions regarding the District staff's cost effectiveness determinations and its dismissal of Norton Engineering's analyses when those analyses showed higher costs than the District staff's evaluation showed[4].

NEED FOR THE "GAP"

Our analysis has shown that even if the District staff concluded that NO BARCT improvements had been made between 2005 and today, the staff's methodology would result in 6 tons per day of NOx RTCs being removed from the program. RTCs being removed under the District's methodology would include those needed for:

- NSR Holding Requirements
- Electric Grid Reliability and Implementation of AQMP Attainment Strategies (i.e., large scale electrification to replace current combustion processes)
- Post-2023 Growth
- Investor Holdings
- Shutdowns
- ERC Conversions

Additionally, there are significant questions regarding whether the District staff's proposed 10% compliance margin is sufficient. A 10% compliance margin will likely be insufficient to assure sufficient liquidity to maintain a functioning market in light of the removal of the above listed RTCs from the program.

We are also concerned that RTCs reflecting investor holdings and ERC conversions are proposed to be "taken" by the District as a result of the District's BARCT shave methodology with no analysis of the financial impact or the costs associated with such a taking[5].

We understand that District staff is working with electric power generators to address the NSR holding requirement issue[6]. While the Coalition agrees that something must be done to address the NSR holding requirement, the current proposal is a complicated attempt to address a problem that only arises because the District staff is trying to eliminate the "gap" altogether. One of the complicating factors associated with the current staff proposal is that it would allow the Adjustment Account to be utilized both to address the NSR holding requirement and to cover actual emissions from power plants under certain contingencies. This brings into question whether or not the Adjustment Account will be adequately funded to cover potential demand. Furthermore, the proposal is fraught with risk because it needs EPA approval, which is not assured. The Coalition believes that the size of the shave should not include RTCs that are required to be held for NSR holding purposes. However, if the District insists on going forward with its proposal, no amounts of RTCs held by electric power generators to satisfy their NSR holding requirements should be shaved unless and until EPA approval is finalized.

---

[4] NEC-SCAQMD letter dated August 10, 2015.
[5] SCAQMD PDSR, Proposed Amendments to NOx RECLAIM, July 21, 2015, Chapter 4.
[6] SCAQMD Staff stated meetings were being held with power-related stakeholders at the June 4 and July 9, 2015 working group meetings.

In summary, the District's proposed shave goes way beyond what is required to comply with the Health and Safety Code requirements with respect to a BARCT adjustment and runs the risk of repeating the program "meltdown" of 2000-2001 during the power crisis when insufficient RTCs were available.

ENERGY EFFICIENCY PROJECTS

As we stated in our June 19, 2015 comment letter, the Coalition strongly opposes any effort to further reduce RTC allocations due to "energy efficiency projects" that have or would reduce NOx emissions. Any reduction in NOx emissions not strictly required by BARCT should be encouraged and the benefits of making those reductions retained by the facility operator making them. For the District to consider taking away RTCs due to reductions in emissions occurring from efforts to improve energy efficiency would be a true manifestation of "no good deed goes unpunished."

CONCLUSION

We look forward to continuing to work with the District staff to develop a RECLAIM shave that represents a true BARCT adjustment while not endangering the life of the RECLAIM program. RECLAIM has been extremely successful in reducing NOx emissions from stationary sources while providing them the flexibility to make reductions in the most cost effective manner. We are very concerned that the severe reductions in RTCs currently being proposed by District staff go beyond adjusting for new BARCT and will result in facilities being subjected to the same RTC shortages that plagued the program in 2000-2001.

Respectfully,

Curtis L. Coleman

August 20, 2015

Mr. Joe Cassmassi
Planning & Rules Director
Planning, Rule Development & Area Sources
South Coast Air Quality Management District
21865 Copley Drive
Diamond Bar, CA 91765

Re: Comments on Proposed Amendments to Regulation XX, NOx RECLAIM

Dear Mr. Cassmassi:

We are writing on behalf of Southwest Generation Operating Company, LLC ("SWG") and its subsidiary Harbor Cogeneration Company, LLC ("HCC"), which owns a power plant located at the Port of Long Beach at 505 Pier B Street, Wilmington, California (Harbor Cogeneration Plant). The plant is listed as one of the top 90 percent of RTC holders that would be subject to a 47% "shave" in NOx RECLAIM Trading Credit ("RTC") holdings under the proposed amendments to South Coast Air Quality Management District (the "District") Regulation XX released by staff on July 20-22, 2015.

Basis for HCC Comments

The stated purpose of the proposed amendments to Regulation XX is to reduce NOx emissions from the universe of RECLAIM facilities by 2022 in line with current best available retrofit control technology (BARCT). The District staff has decided that the best way to achieve this goal is by reducing the holdings of the largest RECLAIM NOx holders in the basin. This includes the Harbor Cogeneration Plant and over 50 other power plants, refiners, industrial facilities and investors.

As HCC has discussed with District staff, its primary concern and the basis for submitting this comment letter is the District's proposal that the baseline date from which the "shave" will be taken be retroactive to RTC holdings as of March 20, 2015. The first time HCC was made aware that staff was proposing the March 20, 2015 baseline date was just prior to the public workshop on July 22, 2015. We understand the desire to establish a baseline to prevent manipulation through multi-step disposition and re-acquisition strategies. However, the current staff proposal to establish a retroactive baseline date without prior advance notice constitutes an unprecedented *ex post facto* action that unfairly disadvantages entities that have made good faith trades subsequent to the proposed baseline date.

Relevant Rule Language

In its rollout of the proposed amendments to Regulation XX, the District issued proposed revisions to Rules 2002 and 2005 on July 20, 2015, followed by proposed revisions to Rules 2011 and 2012 on July 21, 2015. The primary amendments are in Proposed Amended Rule (PAR) 2002. In paragraph (f), Annual Allocations for NOx and SOx and Adjustments to RTC Holdings, the proposed amendments to subparagraph (f)(1)(C) would apply to the Harbor Cogeneration Plant. The relevant proposed amended text of subparagraph (f)(1)(C) states:

> (C) The Executive Officer will adjust NOx RTC holdings, as of (Date of Amendment) for compliance years 2016 and thereafter by multiplying the amount of RTC holdings as of *March 20, 2015* by the following adjustment factors for the relevant compliance year to each of the Facility Permit Holder listed in Table 8 to obtain tradable/usable and non-tradable/non-usable holdings: . . . (emphasis added)

We understand the need to set a baseline date in order to establish the inventory and identify potentially affected sources. However, choosing a retroactive baseline date without prior advance notice of the proposed date would be an *ex post facto* action that unfairly disadvantages entities, like HCC, that made good faith economic decisions in reliance on the rules in place at the time.

An *ex post facto* law or regulation is one that retroactively changes the legal consequences or status of actions that were committed, or relationships that existed, before the enactment of the law or regulation. Article I, Sec. 9 of the California Constitution prohibits the passage of *ex post facto* laws. Furthermore, in In re Lomax, 66 Cal. App. 4th 639, 643 (1st Dist. 1998) (citing *People v. Armitage*, 194 Cal. App. 3d 405, 414 (1987); *Flemming v. Oregon Bd. of Parole*, 998 F.2d 721, 726 (9th Cir. 1993), the court held that "Regulations have the force and effect of law and thus are subject to ex post facto prohibitions" of the state constitution. It is therefore unambiguous that the Constitutional prohibition on *ex post facto* laws applies to agency regulations, such as those of the District. The current proposal runs afoul of that prohibition by retroactively changing the legal consequences and status of trades that were made in good faith and without advance notice of the proposed March 20, 2015 baseline date.

Impact on Facility Planning and Engineering

The District's proposed retroactive baseline date of March 20, 2015 frustrates plans that HCC, and perhaps others, have developed and begun to implement to achieve early emission reductions, thereby undermining the purpose of the RECLAIM program and the proposed amendments. HCC's planning window for engineering upgrades and plant performance improvements is a multi-year exercise. In order to accomplish their business goals, they implemented trades of their NOx RTC holdings this year that were completed after March 20,

2015. These trades were made to fund planned plant upgrades, including emission reduction strategies and possible plant expansions. This strategy is completely consistent with the market concept of the RECLAIM program. If the District were to retroactively reduce HCC's NOx RTC holdings, it would also retroactively alter the premises upon which they based their decisions to improve the plant during 2016 to 2020 such that those decisions may not make financial sense.

We are aware that other facilities in the basin have sold RECLAIM NOx perpetuity streams after the March 20, 2015 date. Presumably, the sales were used to finance upgrades to their facilities which would reduce emissions in the future (the fundamental purpose of this rule). The way PAR 2002 currently stands, like HCC, these entities would be penalized for their early actions to become more efficient and less polluting. The examples provided below illustrate some of the adverse consequences associated with the District's proposed action.

Example 1: A non-refining facility that held 100,000 pounds of NOx perpetuity RTCs on March 19, 2015 would be subject to a 47% shave. If this entity sold 50,000 pounds of NOx RTCs on March 25, 2015 to finance an upcoming project to reduce emissions, it would still be shaved 47,000 pounds based on its holdings of 100,000 pounds as of March 20, 2015. This would leave that facility with an allocation of only 3,000 pounds in 2022, far less than the facility originally planned. In this example the facility expected to reduce its emissions by half, finance a project with the proceeds from the sale of their future excess credits, and retain an allocation of emissions for future use. This example describes an action that should be applauded, rather than penalized, by the District because the facility is cutting its emissions.

Example 2: A facility may have sold all of its RTC holdings after the proposed baseline date, but before the shave date. For example, a facility may have held 100,000 pounds of NOx perpetuity RTCs on March 19, 2015 and sold all RTCs on March 25, 2015. The entity would be shaved 47,000 pounds of RTCs, but it has no remaining RTCs in its account. How would the District implement the shave? Would the District follow the RTCs and apply the shave to the purchaser, or would the facility "owe" 47,000 pounds of RTCs?

These are just a couple of examples of the potential consequences of the District's proposed action. We would expect the trading, selling and buying examples to be as numerous as the varied operations of the affected sources.

Baseline Date for RTC Holdings Should Be Date of Amendment

We urge the District to work with the affected sources to establish a baseline date that is not earlier than the date of adoption of the rule amendments. This would provide clarity to businesses making financial and operational decisions, and stability to the District in establishing a credible inventory. In no case should the effective date to determine baseline RTC holdings be earlier than the effective date of amendment.

LATHAM&WATKINS LLP

We appreciate the opportunity to submit these comments and look forward to working with the District to refine and implement the proposed amended rules. If you have any questions please contact me or Bob Louallen, HCC's Senior Environmental Compliance Engineer at (702) 239-3712.

Kind regards,

Michael Carroll
of Latham & Watkins LLP

Subject: Comments on Proposed NOx RECLAIM Amendments

Dear Mr. Orellana and Ms. Pham:

Please find herein comments on the draft RECLAIM Rule language dated July 22, 2015.

NEW EMISSION FACTORS FOR RULE 219 EXEMPT EQUIPMENT

We support the District's August 19th proposal for new provisions in Rule 2012 Chapter 4 to allow equipment certified by either U.S. EPA, CARB, or SCAQMD to use an emission factor other than the default factor of 130 lb/mmscf to report NOx emissions.

Currently, when a RECLAIM facility installs an SCAQMD Rule 1146.2 certified hot water heater, they are directed by District staff to report their RECLAIM and Annual Emissions Report (AER) emissions using a default emission factor of 130 lbs NOx/MMscf natural gas (equivalent to ~102 ppm of NOx), even though the unit has been certified by the SCAQMD to be "less than or equal to 20 ppm of NOx emissions (at 3% O2, dry)…" per Rule 1146.2. The estimated emissions factor associated with 20 ppm is approximately 25 lbs/MMscf, which is less than the 2010 ending emission factor. Manufacturers may not sell heaters for use in the District unless it complies with Rule 1146.2. We support that the RECLAIM rules are proposed to be modified to allow accurate reporting of emissions for R219 exempt equipment.

RULE 219 EXEMPT EQUIPMENT REPORTING

The District's August 19th proposal for certified Rule 219 exempt equipment indicates source tests may be required to verify lower emissions. We request that no source test shall be required for certified equipment. The SCAQMD specifies the emission certification process and accepts the documentation provided by the manufacturer as adequate to demonstrate compliance with the emission standards of Rule 1146.2. Certified heaters/boilers have been available on the market for years, tested by the manufacturers, low NOx combustion technology is achieving well under 30 - 55 ppmv, and the heat input ratings of Rule 219 equipment are small. Moreover, facilities may have multiple small boilers onsite, and given the unit cost to source test is approximately $3,000-$4,000, this presents an unnecessary cost burden on these facilities. We request that the SCAQMD forego the requirement to source test small boilers and accept the emission certifications as adequate to document NOx emission concentrations for use in the RECLAIM program.

RTU REPORTING

We do not see that the District is proposing any changes to the electronic reporting requirements for NOx Major Sources. The current requirements are specified in 2012 Appendix A, Chapter 7 – Remote Terminal Unit (RTU) Electronic Reporting. This section of the rule requires facilities to use dial-up modem technology to transmit a text string that must be very specifically formatted. The use of dial up modems as telecommunication devices is woefully outdated. It is becoming difficult even to find dial-up modem systems and components since their functionality has been replaced by better technology. Moreover, the very specific text file formatting is very challenging and error prone whenever text files must be written for transmittal to correct previously reported emissions. We have wasted hours of time working with this antiquated system which is still required by the regulation. We urgently request that the District update their electronic reporting system to allow more modern and easy to use technology.

CONCLUSION

Thank you for considering these comments. We would be glad to meet with you and the RECLAIM team to discuss these important issues. Should you have any questions or concerns, please contact me at (949) 248-8490 x511.

Sincerely,

Kathy Prokey

Re: Comment Letter on NOx RECLAIM Shave Proposal; Cities of Burbank and Pasadena

Dear Dr. Fine:

On behalf of the City of Burbank, Department of Water and Power ("BWP"), and the City of Pasadena, Water and Power Department ("PWP) (collectively "the Cities"), we are submitting the following comments on your staff's draft proposed amendments to Regulation XX, Regional Clean Air Incentives Market ("RECLAIM") ("NOx shave proposal"), published on July 21, 2015. While the NOx shave proposal appears to include provisions that would mitigate some of its worst impacts on the Cities' well-controlled power plants, it still does not provide the needed certainty that adequate RECLAIM Trading Credits ("RTCs") will be available at a reasonable price to cover these plants' anticipated emissions and other needs related to resource adequacy and utility-specific operating contingencies. We would like to suggest some improvements to the proposal that would provide the needed certainty and address other issues.

Both Cities operate their own power plants containing peaking units, and BWP also operates the Magnolia Power Plant ("MPP"), a baseload unit, on behalf of the Southern California Public Power Authority ("SCPPA"). Participants in MPP include Burbank, Pasadena, and four other municipalities. The Cities operate these power plants to serve their municipal customers. RTCs are required not only to cover anticipated annual emissions, but also to meet resource adequacy needs and prepare for utility-specific operating contingencies, such as grid reliability, increased cycling to support integration of renewables, and potential electrification of the transportation system. Unlike other industrial facilities operating under the RECLAIM program, the Cities' power plants are obligated to operate to serve load. If they are unable to serve load, there may be blackouts with serious adverse economic and other consequences.

The staff proposal would require a 47% reduction in the NOx RTC allocations for these power plants. The proposed reductions are so severe that insufficient RTCs would remain to cover Pasadena's and MPP's anticipated emissions, not to mention RTCs needed for resource adequacy and utility-specific operating contingencies.

As you know from our discussions during the Working Group process preceding the proposal, the Cities have requested that their power plants be excluded from the proposed NOx shave. This request is rooted in history and fairness. The Cities have already achieved the goals of the RECLAIM program, and more should not be asked of them.

The Cities have already reduced NOx emissions as much as feasible with the installation of Best Available Control Retrofit Technology ("BARCT") at their existing units, at a cost of over $28 million. In fact, these reductions were achieved over ten years ago pursuant to a command-and-control rule, Rule 2009. These reductions were required in the wake of the energy crisis of 2001, which led to an increase in power plant operation for which adequate RTCs were not available. BWP also has installed Best Available Control Technology ("BACT") at its Lake 1 unit and at MPP, and PWP has under construction a boiler replacement project that also will have BACT installed. The Cities cannot make any further cost-effective NOx emissions reductions. When and if the shave results in a shortage of RTCs to cover operating needs, the Cities would not have the option of installing more control equipment. Instead, all they could do is purchase additional RTCs, if available, or fail to meet load.

Moreover, the Cities are ahead of schedule in meeting the state's requirement that all electricity retailers serve at least 33% of their load with renewable energy no later than 2020. Burbank is already at 34% renewables, and Pasadena is at 28% renewables with a goal of reaching 40% by 2020.

While the Cities therefore believe they should not be subject to the proposed NOx shave, they acknowledge that with appropriate safeguards, the potential adverse impacts of the proposed shave on the Cities' power plants could be substantially avoided. It appears that the staff proposal addresses one important adverse impact: the requirement that MPP hold enough NOx RTCs to cover its maximum rated capacity at the beginning of each compliance year ("NSR holding requirement"), in the face of a 47% reduction in its NOx allocations. The proposal would apparently relieve MPP and other "new," post-1993 facilities from that requirement by providing for an "Adjustment Account" that will meet this requirement on a programmatic basis [see Proposed Amended Rule ("PAR") 2002(f)(4)]. But the proposal only partly addresses the other major potential adverse impact: the prospect that adequate NOx RTCs will not be available at a reasonable price to cover these power plants' anticipated emissions and other needs related to resource adequacy and utility-specific operating contingencies.

In the remainder of this letter, we will address these potential adverse impacts, and other issues as well.

1. Power Plants Need Quicker Access to Non-tradable/Non-usable NOx RTCs If Needed to Cover Annual Emissions

The staff proposal provides for a non-tradable/non-usable adjustment factor to be reflected in the permit for each facility subject to the 47% shave, including power plants, topping out at 0.335 in 2022 [PAR 2002(f)(1)(C)]. As we understand the proposal, it means that up to a 0.335 fraction of each facility's current allocation of RTCs would be made usable and tradable, and therefore available to cover annual emissions, in the event that the Executive Officer determines that the 12-month rolling average price of NOx RTCs exceeds $15,000 per ton (or $7.50 per pound) and after the Governing Board concurs in that determination [PAR 2002(f)(1)(F)]. No fee would be charged for these additional RTCs.

Based on the experience of power plants during the energy crisis of 2000-2001, this cumbersome, two-step process for releasing these RTCs to cover annual emissions appears to be too slow to avoid skyrocketing spot prices or an outright shortage of RTCs for power plants to either cover annual emissions or demonstrate resource adequacy. We understand that the Los Angeles Department of Water and Power will be presenting a more detailed description of how the two-step process for releasing RTCs during the energy crisis of 2000-2001 did not avoid high prices and shortages of RTCs at that time.

The Cities therefore suggest that a provision be added allowing power plants to request that some or all of this pool of non-tradable, non-usable RTCs be converted to usable but non-tradable RTCs, in exchange for a fee of $7.50 per pound. Once converted, the RTCs could be used to cover annual emissions or meet resource adequacy needs for the year in which the request is made, but they could not be traded. In addition, the power plant also would not be allowed to trade any of its own RTC allocation for the year in which the request to convert is made.

The fee serves two purposes. First, it gives power plants the incentive to rely on the RTC market if the spot price remains below $7.50 per pound. As long as the spot price of RTCs remains below that level, power plants will not have an economic incentive to make a request to convert. Instead, they will rely on the RTC market to acquire additional needed RTCs. But if the spot price rises above $7.50 per pound, then they will have an incentive to make a request, if they deem it prudent to do so. Of course, power plants would be free to wait for the slower two-step process to unfold regarding the 12-month rolling average price, and obtain additional unrestricted RTCs without a fee, if they deem that to be the more prudent course.

The fee also serves the purpose of providing the District with funds to achieve additional NOx reductions from other sources, including mobile sources, for which cost-effective reductions cannot otherwise be obtained.

We understand that in response to questions posed at the Working Group meeting on August 19, District staff indicated it is their intention that the non-tradable, non-usable RTCs be removed from each facility's permit after 2022. If these RTCs are indeed removed from the permits, then the suggested provision discussed above would be of little or no use to the Cities, because it is precisely in the last year or two of the NOx shave, and in later years, that these RTCs are most likely to be needed. The Cities therefore also suggest that these non-tradable, non-usable RTCs, or some significant portion of them, remain on power plant permits after 2022.

Attachment 1 to this letter contains an example of rule language that might be used for a provision allowing the conversion of non-tradable, non-usable RTCs to usable but non-tradable status.

2. Power Plants Should Have Access to the "Adjustment Account" to Cover Annual Emissions

As mentioned earlier, the staff proposal contains an "Adjustment Account" enabling post-1993 power plants to meet the NSR holding requirement on a programmatic basis. We understand that staff estimates that 1 to 1 ½ tons of RTCs will be needed for this account [see Draft Staff Report at p. 33]. We suggest that the RTCs in this account also be made available to affected facilities to cover their annual emissions, in exchange for a fee of $7.50 per pound. There does not appear to be any impediment to allowing the RTCs involved to serve both purposes.

As in the case of a request to convert non-tradable, non-usable RTCs to usable but non-tradable RTCs, the fee serves the dual purpose of giving power plants the incentive to rely on the RTC market if the spot price remains below $7.50 per pound, and also providing the District with funds to achieve additional NOx reductions from other sources for which cost-effective reductions cannot otherwise be obtained.

This use of the "Adjustment Account" could be viewed as an alternative to the suggested provision regarding the non-tradable, non-usable RTCs discussed above.

Attachment 2 to this letter contains an example of rule language that might be used to allow RTCs in the "Adjustment Account" to both meet the NSR holding requirement and be available to cover annual emissions.

3. Provisions Involving Delayed RATA Tests Due to Extenuating Circumstances

The Cities appreciate the staff proposal to allow postponement of a relative accuracy test audit ("RATA") when a major source is physically incapable of being operated. [PAR 2012, Appendix A, Attachment C, Section (B)(2)] Allowing postponement by rule provision would make it unnecessary for the Cities to incur the expense of petitioning the Hearing Board for a variance to allow postponement of the test. However, the Cities would like to suggest two changes to the conditions that apply to the postponement.

First, the due date for performing the RATA should be 30 days, rather than 14 days, from the re-firing of the major source. The additional time is needed in some circumstances to perform tests on the source to ensure reliable and safe operation. [See PAR 2012, Appendix A, Attachment C, Section (B)(2)(c)]

Second, the proposed requirement to disconnect and flange the fuel feed lines is unnecessary and costly. The proposed requirement is unnecessary because the fuel meters are required to be maintained, associated fuel records are required to be kept, and stack emissions are continuously monitored and recorded. So there are multiple sources of data to rely on to verify that the source is not operating. The proposed requirement is costly and time consuming because significant manpower and equipment would be needed to meet it. There also may be health and safety risks if asbestos-containing materials are encountered in the work. The Cities therefore suggest that this requirement be deleted. [See PAR 2012, Appendix A, Attachment C, Section (B)(2)(c)]

4. Other Comments and Questions

a. Provisions Involving the Non-tradable, Non-usable Adjustment Factor

i. The staff proposal should be clarified to provide that the 12-month rolling average RTC price that may trigger release of the non-tradable, non-usable RTCs is the "weighted" average. [PAR 2002(f)(1)(E)]

ii. The staff proposal speaks of determining the 12-month rolling average RTC price for all trades in the "current compliance year." It is not clear how this language would apply to a 12-month rolling average price when the 12 months in question straddle two adjacent compliance years. [PAR 2002(f)(1)(E)]

iii. In PAR 2002(f)(1)(F), the correct cross-reference appears to be to PAR 2002(f)(1)(E), not PAR 2002(f)(1)(F).

b. Provisions Involving the "Adjustment Account"

i. The staff proposal includes a provision allowing access to "Adjustment Account" RTCs for the purpose of compliance with annual emissions during a State of Emergency as declared by the Governor. [see PAR 2002(f)(5)] This provision raises several questions:

(1) How is the account to be funded for this purpose, and with what quantity of RTCs? As we indicated earlier, we understand that staff estimates that 1 to 1 ½

tons will be needed to meet the NSR holding requirement. Will additional amounts be added to fund the account to allow compliance with annual emissions?

(2) Why is access to RTCs limited to a State of Emergency declared by the Governor, as opposed to a State of Emergency declared by a local government official, such as a Mayor?

(3) We understand that in response to questions raised at the Working Group meeting on August 19, District staff indicated that RTCs in this account can be used both to meet the NSR holding requirement and to cover annual emissions. If our understanding is correct, then the rule language needs to be clarified.

(4) It may not be appropriate for the Executive Officer to have unfettered discretion to determine the amount and distribution of RTCs. By making these determinations, he would in effect decide which power plants generate electricity during a State of Emergency. Such decisions may be beyond his authority and expertise. It is important, moreover, that every power plant have access to the RTCs it needs to meet its operating requirements.

The Cities appreciate your consideration of these comments. Please let us know if you have any questions.

Sincerely,

Charles F. Timms, Jr.

cc: Jill Whynot, Assistant Deputy Executive Officer (via email)

ATTACHMENT 1

Proposed Amended Rule 2002(f)(1)(G) shall be added to read as follows:

"Notwithstanding the provisions of subparagraph (f)(1)(F), upon the request of a Power Producing Facility, all or a portion of the facility's non-tradable/non-usable NOx RTCs specified in subparagraph (f)(1)(C) shall be converted to usable but non-tradable NOx RTCs for the purpose of compliance with the facility's emissions, or to meet resource adequacy needs, for the year for which the request is made, for a user fee of $7.50 per pound (or $15,000 per ton) of NOx RTCs. Any facility making such a request shall not sell any of its NOx RTC allocation for the year for which the request is made."

Later subparagraphs will need to re-numbered to accommodate this new subparagraph.

ATTACHMENT 2

Proposed Amended Rule 2002(f)(6) shall be added to read as follows:

"Notwithstanding the provisions of subparagraph (f)(5), upon the request of a Power Producing Facility, the Executive Officer shall allow the facility access to Adjustment Account RTCs for the purpose of compliance with the facility's annual emissions, or to meet resource adequacy needs, for a user fee of \$7.50 per pound (or \$15,000 per ton) of NOx RTCs. These Adjustment Account RTCs are non-tradable. Any facility making such a request shall not sell any of its NOx RTC allocation for the year for which the request is made."

Subject: Backstop Measures for Municipal Utilities Operating Under RECLAIM SCEC 2564.2001

Dear Dr. Fine:

South Coast Environmental Company (SCEC) offers the following comments on behalf of the Cities of Anaheim, Colton and Riverside. All three Cities operate power generating stations that are regulated under RECLAIM.

The Cities of Anaheim, Colton and Riverside (the Cities) operate modern facilities that already incorporate Best Available Control Technology (BACT) or Best Available Retrofit Control Technology (BARCT). Municipal power generators have an obligation to provide power to the communities they serve and cannot simply cut back operations due to SCAQMD policies or the implications of SCAQMD's actions on RTC costs and availability. Unlike many facility operators in the South Coast Air Basin that can respond to the proposed NO_X shave by installing new technology or reducing operations, these municipal utilities can only purchase additional NO_X RTCs in order to operate at permitted levels should their existing inventory of credits be discounted. Because of the limited compliance strategies available to municipal utilities and the unique circumstances we face in a regulatory program that is dominated by private sector operators, the Cities feel that they should have been excluded from the RTC reduction proposed by SCAQMD, but we also understand that safeguards can be built into Regulation XX to reduce the impacts of RTC reduction for municipal utilities.

Throughout the rule development process the Cities have stressed that safeguards proposed by SCAQMD to counter the impacts of the RTC reduction must offer certainty that credits will be available when needed, and that those credits can be obtained swiftly and efficiently. The Cities' concerns stem from the uncertainties we will face in the upcoming years as our peaking units are called upon for more frequent run sequences in support of the increased reliance upon renewable resources in the region.

Given that SCAQMD continues to propose a reduction of the Cities' RTC holdings, complementing rule language to ease the burden of the NSR holding requirement for new facilities and to ensure that credits are easily available in the event of RECLAIM or power market upset are critical to the Cities' continued ability to meet their mission as municipal power generators. The Cities appreciate the steps that SCAQMD has taken so far toward meeting the unique needs of municipal power generators, but also recognize that additional thought must be given to several concepts already laid out in Rule 2002. The Cities encourage SCAQMD to continue to refine proposed amendments to Rule 2002 with due consideration of the Cities' needs and we offer these comments for SCAQMD's consideration as it proceeds with its rule development effort.

<u>Rule 2002 (f)(1) - Non-tradable / Non-usable Holdings</u>

SCAQMD proposes to reestablish a non-tradable / non-usable holding account to complement the reduction of available RTCs. Permit holders would be able to access the holding account only after two conditions are met. First the 12-month rolling average RTC price must exceed \$15,000 per ton. Second, the SCAQMD Governing Board must direct staff to convert the holdings to tradeable / usable credits.

Responsiveness of Mitigating Actions

The Cities are concerned that rolling average RTC price may trail too far behind sudden RTC price increases and the requirement to obtain Governing Board authorization to convert the holdings to tradeable and useable credits may not be suitably responsive to our needs as municipal utilities. In other words, the Cities' need for certainty and swift access to RTCs may be jeopardized and we will be forced to participate in a market with escalating costs and limited RTC availability until the point that the \$15,000 threshold is reached. By the time the SCAQMD responses are implemented, it will be too late to undo the damage to the utilities and local communities.

Request for Flexibility in Accessing Non-tradeable / Non-useable Holdings

The Cities understand that other municipal utilities have suggested to SCAQMD that we should have discretionary use of our non-tradeable / non-usable credits for our own use, but not to be sold or transferred to other entities. Those proposals vary from making the credits available at no cost to making them available for a mitigation fee of \$7.50 per pound, which is equivalent to the trigger price of \$15,000 per ton. The fee would be paid only if the holdings are accessed prior to the rolling average price being reached. If the \$7.50 fee were to be assessed, municipal utilities would in effect, access their non-tradeable / non-useable credits only if spot market prices escalate above that rate and would otherwise rely upon the market for any required RTCs.

The Cities are supportive of the proposals to expand access to credits and believe that they would be beneficial to the utilities, SCAQMD and the RECLAIM program in general. By providing access to these credits in advance of a market upset, SCAQMD would provide municipal utilities the certainty needed to meet our mission at a reasonable cost and the limited access of utilities to their non-tradeable credits may actually prevent market upsets that would trigger the widespread release of non-tradeable / non-useable credits to all RECLAIM operators. Finally, if utilities are assessed a fee of for their use of their non-tradeable / non-useable credits in advance of the 12-month price trigger being reached, the proceeds would be available to SCAQMD to facilitate voluntary NOx emission reductions. Those reductions may be more cost-effective than what would otherwise be obtained within the RECLAIM program.

Sunset of Non-tradeable / Non-useable Holdings

The Cities understand that SCAQMD proposes to discontinue the non-tradeable / non-useable holdings in the year 2022. Given the uncertainty presented by increased integration of renewable resources and regional electrification, the Cities ask SCAQMD to provide for continued utilization of the non-tradeable / non-useable holdings, at least for municipal utilities.

Rule 2002 (f)(4) & (5) RTC Adjustment Account

SCAQMD proposes to establish an RTC adjustment account that would serve two purposes. The first is to provide a store of credits that new power generating facilities can use to demonstrate compliance with the NSR holding requirement of Rule 2005 (Rule 2002 (f)(4)). The second purpose of the adjustment account is to make credits available to all power generators in response to an electrical emergency (Rule 2002 (f)(5)). During the August 19 public consultation, SCAQMD indicated that it plans to further refine the provisions of Rule 2002 that deal with the proposed adjustment account. The Cities suggest that the following concepts be given additional consideration.

Compatibility of Dual Purposes

The Cities appreciate that SCAQMD is proposing alternatives that would ease the NSR holding requirement burden and also provide additional RTCs in the event of an emergency. However, it is not clear that both purposes can be simultaneously served, given the amount of RTCs that SCAQMD proposed to allocate to the account. The Cities ask that SCAQMD clarify how the account can be available for emergency use by all power producers, without jeopardizing the ability of new facilities to make the NSR holding demonstration.

During the working group meeting, SCAQMD advised that the proposed funding level of 1 – 1.5 tons/day reflects the amount of reduced RTCs that are currently held by new facilities for the offset demonstration. If the funding of the account reflects the reduced RTCs, rather than the entire PTE for these facilities, it is unclear how the adjustment account can be used by existing facilities (pre 1993 installations) during an emergency without jeopardizing the ability of new facilities to make the NSR demonstration.

Authority to Declare an Energy Emergency

SCAQMD initially proposed that RTCs in the adjustment account would be available to power generators upon an emergency declaration made by the Governor of California, but has committed to investigate concepts that would allow other parties to make such declarations.

Additional entities or authorities should be allowed to declare the presence of an energy emergency at both a regional and local level. Many emergencies requiring local power generation may exist within the boundaries of a city and state or regional authorities may not be able to investigate and make the necessary declaration quickly. Local authorities, such as a City Manager or Mayor, should also be allowed to make a declaration that would allow for the release of RTCs from the adjustment account.

Dispersing Credits from the Adjustment Account

It is unclear how access to RTCs would be granted or how competing applicants would be prioritized by SCAQMD to receive RTCs. SCAQMD must further define its role in the process of granting access to the adjustment account if the Cities are to be assured that credits are available not only for the NSR holding demonstration, but also for easy access in case of an emergency.

RTC Management Flexibility

The Cities ask SCAQMD to clarify how the adjustment account would affect the way in which new power producing facilities would manage the remaining RTCs listed in their facility permits, with respect to the Rule 2005 (f) holding requirement. Ideally, provisions to accommodate the holding requirement would also allow facility operators to sell the remaining unused RTCs listed in their permit in advance of compliance year closure. We also ask SCAQMD to give consideration to the same discretionary use of the adjustment account by municipal utilities that is proposed within this letter for the non-tradeable / non-useable holdings.

Thank you for considering these comments. The Cities of Anaheim, Colton and Riverside welcome the opportunity to further discuss SCAQMD's RECLAIM proposal and I am available should you require additional information regarding the Cities' comments.

Sincerely,
SCEC

RE: PROPOSED AMENDMENTS TO REGULATION XX:
NOx SHAVE FOR RECLAIM SOURCES

Dear Mr. Cassmassi:

Eco Services Operations LLC (Eco Services) is again writing to express its concerns with the South Coast Air Quality Management District's (SCAQMD's) proposed amendments to Regulation XX to implement the latest round of NO_x emissions reduction for RECLAIM sources ("NO_x shave"). Eco Services owns and operates a sulfuric acid regeneration plant located at 20720 South Wilmington Ave in City of Carson (Dominguez Plant). Eco Services provided comments to you by letter dated April 27, 2015 and is attaching a copy of our prior comments for your reference.

As we previously advised, the Dominguez Plant has been an active supporter and participant of the RECLAIM program. In 2010, Eco Services worked cooperatively with the SCAQMD to identify the Best Available Retrofit Control Technology (BARCT) for the control of SOx emissions and installed a caustic scrubber to greatly reduce SOx emissions at a substantial cost. Eco Services is committed to environmental compliance as demonstrated through our implementation of BARCT for SOx.

As the SCAQMD develops amendments to the RECLAIM program for NOx, Eco Services reiterates its commitment to environmental compliance and working cooperatively towards a common sense and practical solution. Eco Services believes that implementation of technically feasible and cost-effective measure is appropriate. Eco Services is amenable to implement any such measures as we have done with SOx emissions. However, based on the SCAQMD's BARCT analysis, there are no technologies that qualify as BARCT for the NOx emissions sources at the Dominguez Plant. Accordingly, Eco Services is left in the unenviable position of having no practical means of complying with RECLAIM other than purchasing additional allowances at a substantial cost.

Eco Services is very concerned with the prospect of having no control over its ability to comply with RECLAIM. Importantly, we have been advised by RECLAIM brokers that the drastic across the board shave being contemplated by the SCAQMD will result in NOx credits being rendered extremely scarce and accordingly, cost prohibitive. In order for a cap-and-trade program to function properly, there must be a reasonable amount of credits available for trading at a reasonable cost. It is our understanding that NOx credits, if available for trading at all, will be exorbitantly priced.

Eco Services simply does not support a program that leaves no reasonable means of complying other than to put us at the mercy of what we believe will be a dysfunctional trading program. Instead, as we have demonstrated with respect to the SOx RECLAIM program, we support revisions to the RECLAIM program that rely on implementation of feasible and cost-effective controls. Sources that can implement BARCT can and should do so as a first step towards additional reductions. We strongly urge the SCAQMD to consider this approach which will result in a reduction of NOx emissions based on cost-effective controls which will not cripple the RECLAIM trading program and leave smaller emitters no real cost-effective option for compliance. If the SCAQMD pursues the across the board shave, it will effectively be imposing cost-effective requirements on the BARCT sources but not considering cost-effectiveness at all for non-BARCT sources. Eco Services believes that is inequitable and inappropriate.

If the SCAQMD does pursue an across the board NOx shave, Eco Services recommends that the changes to RECLAIM include some type of measure to limit the costs of NOx credits in addition to the current $15,000 per ton annualized average cost, particularly for small emitters. An equitable rule should provide the regulated community with a cost-effective means of complying. We request that the SCAQMD somehow provide a ceiling on the financial impact it will have on RECLAIM participants in terms of cost-effectiveness. BARCT sources will be subjected to cost-effective controls. Similarly, the financial impact to non-BARCT sources should also be based on cost-effectiveness.

It is our understanding that Non-Tradable/Non-Useable allocations will be issued to emitters, and that these "safety valve" allocations can be used as compliance instrument when the average cost of annual NOx RTC exceeds $15,000 per ton (or $7.50 per pound). However, we believe that the time for cost averaging should be significantly shortened to prevent the repeat of situation similar to year 2000 when the value of annual NOx RTC went far above the $7.50 per pound threshold. Also, additional safe guards should be considered to prevent non-compliance for non-BARCT sources if the NOx RECLAIM market fails such that no NOx RTCs are available to be purchased.

If you have any questions or need additional details regarding the information contained in this letter, please contact me at (925) 313-8221.

Sincerely,

Anthony Koo

RE: PROPOSED AMENDMENTS TO REGULATION XX:
NOx SHAVE FOR RECLAIM SOURCES

Dear Mr. Cassmassi:

Eco Services Operations LLC (Eco Services) is writing to express its concerns with the South Coast Air Quality Management District's (SCAQMD's) proposed approach to amending Regulation XX to implement the latest round of reductions in NO_x emissions allowances for RECLAIM sources ("NO_x shave").

Eco Services owns and operates a sulfuric acid regeneration plant (Dominguez Plant) located at 20720 South Wilmington Ave. in City of Carson. The Dominguez Plant's sulfuric acid product is primarily used in petroleum refineries as alkylation catalyst to produce high octane, low vapor pressure, and clean burning gasoline blending stock.

The Dominguez Plant has been an active supporter and participant of the SCAQMD RECLAIM Program. During the 2010 SO_x RECLAIM rulemaking process, Eco Services worked closely and cooperatively with SCAQMD in identifying feasible Best Available Retrofit Control Technology (BARCT) for the Plant. In 2012, the facility became the world's first double absorption sulfuric acid plant to be retrofitted with a caustic scrubber to reduce SO_x emissions. The scrubber has been in operation since November of 2012 and has since been consistently removing approximately 1 ton of SO_x per day from the South Coast Air Basin. These examples serve as a clear indication of Eco Services' commitment to environmental compliance and air quality improvement.

We understand that the SCAQMD is implementing its Air Quality Management Plan (AQMP) and plans to reduce NO_x emissions from its Air Basin. SCAQMD is contemplating on reducing as much as 50% of the currently-available NO_x credit from the Regional Trading Credit (RTC) universe. More importantly, SCAQMD is in the process of evaluating various options on how the reductions will be implemented, including an across-the-board shave approach that would uniformly remove RTCs without consideration of an individual source's operational characteristics or its ability to implement BARCT fundamentally developed for other types of sources.

In 2014, SCAQMD conducted a detailed BARCT study of the major NO_x emitting sources within the South Coast Air Basin. The study did not include the Dominguez Plant because there is no known BARCT available to reduce NO_x emissions at sulfuric acid plants. Furthermore, the study also concluded that the other two natural gas burning sources (the preheater and package boiler) at the Dominguez Plant were not cost-effective for BARCT implementation due to their low usage and NOx emissions.

The Dominguez Plant emits about 0.0685 tons per day of NO_x, which matches its RTC allocations without any surplus. This total represents 0.258% of the entire current NO_x RTC market. Eco Services is concerned that if a 50% across-the-board shave is implemented, it will severely inhibit the Dominguez Plant's ability to comply with the RECLAIM Program. Without a viable BARCT and limited RTC supply, Eco Services is concerned that it will be difficult, if not impossible, for the Dominguez Plant to comply with the post-shave allocation. Assuming that NO_x credits will be available, based on the current credit value of $90 per pound, this translates to an exorbitant minimum of $4,500,000 in compliance costs for the Dominguez Plant.

Eco Services respectfully asks SCAQMD to seriously consider the huge negative impacts to small emitters like the Dominguez Plant, which have no viable options to comply with the proposed NO_x reductions if implemented. Instead, Eco Services urges SCAQMD to consider achieving this round of NO_x reductions by using the sector and subsector approach in lieu of an across-the-board shave. In particular, Eco Services believes that this iteration of the NO_x shave should only be applied to sectors which have viable BARCTs that were identified in the recent BARCT study conducted by the SCAQMD. Applying such an approach, Eco Services respectfully requests that the District remove the Dominguez Plant from the list of facilities subject to this round of the NOx shave.

If you have any questions or need additional details regarding the information contained in this letter, please contact me at (925) 313-8221.

Sincerely,

Anthony Koo

Re: Follow-up to Comment Letter on NOx RECLAIM Shave Proposal; Cities of Burbank and Pasadena

Dear Dr. Fine:

On behalf of the City of Burbank, Department of Water and Power ("BWP"), and the City of Pasadena, Water and Power Department ("PWP) (collectively "the Cities"), we are submitting this follow-up letter to our August 21, 2015, comment letter on your staff's draft proposed amendments to Regulation XX, Regional Clean Air Incentives Market ("RECLAIM") ("NOx shave proposal"), published on July 21, 2015.

We have identified some additional rule language that would need to be amended to facilitate our proposal that power plants be provided with quicker access to non-tradable/non-usable NOx RTCs, and/or access to RTCs in the Adjustment Account, if needed to cover annual emissions. This additional language will ensure that the relevant RTCs are only credited to the SIP on a year-by-year basis to the extent they are not needed for power plant compliance purposes. See Attachment 1 to this letter.

In addition, the Cities support the proposal of the Los Angeles Department of Water and Power to expand the emergency provisions in the staff proposal to allow power plants to access RTCs in the Adjustment Account if an energy emergency alert is declared by the relevant electrical "Reliability Coordinator." See Attachment 2 for proposed rule language.

The Cities appreciate your consideration of these additional comments. Please let us know if you have any questions.

Sincerely,

Charles F. Timms, Jr.

cc: Jill Whynot, Assistant Deputy Executive Officer (via email)
Attachments.

ATTACHMENT 1

Proposed Amended Rule 2002(f)(1)(J) shall be amended to read as follows:

"The NOx RTC adjustment factors for compliance years 20019 through 2021 shall not be submitted for inclusion into the State Implementation Plan until the adjustments have been in effect for one full compliance year. The 2022 NOx RTC adjustment factors shall not be submitted for inclusion in the State Implementation Plan until 12-months after the adjustments have been in effect for one full compliance year. At the end of each compliance year reconciliation period from 2022 and each year thereafter, the Power Producing Facility shall surrender unused non-tradable RTCs to the District for inclusion into the State Implementation Plan."

ATTACHMENT 2

Proposed Amended Rule 2002(f)(5) shall be amended to read as follows:

"During a State of Emergency as declared by the Governor or an Energy Emergency Alert as declared by the Reliability Coordinator, the Executive Officer will allow Power Producing Facilities access to Adjustment Account RTCs for the purpose of compliance with the annual emissions. ~~These available RTCs will be limited to those that are in excess of those specified for use in paragraph (f)(4).~~ The amount and distribution of the RTCs will be determined by the ~~Executive Officer~~ Power Producing Facilities based on the ~~impact that~~ amount of energy they produce during the State of Emergency ~~has on the RECLAIM program~~ or the Energy Emergency Alert."

'Reliability Coordinator' means the entity that is the highest level of authority who is responsible for the reliable operation of the Bulk Electric System as defined in the North American Electric Reliability Corporation Glossary."

RE: 2015 RECLAIM

Dear Mr. Cassmassi:

Southern California Edison (SCE) appreciates the opportunity to comment on the South Coast Air Quality Management District's (District) proposed reduction of Reclaim Trading Credits (RTCs). Moving the District's air basins into attainment is a step toward improved air quality and improved economic growth by increasing the ability of businesses to operate in this region. The District's proposed reduction in the RTC market should act to drive stationary sources under the RECLAIM program to install Best Available Retrofit Control Technology (BARCT) for control of NOx emissions. SCE recognizes the need to make reductions in NOx in order to assist in the effort to achieve attainment with the National Ambient Air Quality Standards.

The shave should drive sources towards BARCT
The shave, as proposed, would constitute a 53% reduction in the total number of RTCs in the market. 67% would be taken from the refinery sector while 47% would be taken from the non-refinery sector, including electric generation facilities. While this would be better than an outright across-the-board shave, it still would trigger costs for the electric generation sector that would have no commensurate impact on reducing air emissions. The electric generation facilities are already at Best Available Control Technology (BACT) with no existing opportunity to reduce emissions (other than curtailing operation, which is not feasible for electric generation facilities since electric demand will dictate operating times). While there is recognition there will have to be some reduction of RTCs from electric generation facilities, the shave should cause facilities not currently at BARCT to install better controls. With the proposed percentages, the costs will disproportionally impact facilities that are already at BACT and result in a subsidization by those at BACT of facilities not yet utilizing the best controls.

The proposed shave amount on the Electric Generation Facilities in effect caps the amount of fuel we can use
As stated above, SCE's electric generation facilities are already at BACT or BARCT, with no currently feasible opportunity, from a control standpoint, to reduce emissions further. With no advancements in control technology, the only way to further reduce emissions is by curtailing operation (i.e. limiting fuel usage). Thus, if no credits were available for purchase on the open market, which is a possibility given the proposed size of the shave, the only way to stay in compliance would be by reducing fuel usage.

P. O. Box 800
2244 Walnut Grove Ave.
Rosemead, CA 91770

Limiting operations might be an option in other industries where production can be outsourced to different sites, but this is not an option for electric generation facilities, as local demand for electricity dictates when these facilities must operate, as ordered by the California Independent System Operator (CAISO). Existing contracts with the California Public Utilities Commission (CPUC) also require the facility to operate when the grid demands it, meaning that when this equipment will run, is effectively out of SCE's control. In other words, if system demand requires SCE to turn on a unit, the facility must do so. SCE will not violate the air permit conditions. But failure to operate when needed for system demand could result power outages.

It should also be noted that under the California Health & Safety Code for market-based programs [§39616(c)], a program must not result in disproportionate impacts to stationary sources in the program as compared to other permitted stationary sources not in the program. A typical permitted source not in the RECLAIM program is subject to rule-based command and control regulations. Were SCE's facilities not in the RECLAIM program, command and control regulations would require BACT concentration limits with no further limits on operation or fuel use, unless such further limits were agreed to for PTE or CEQA limit purposes. However, because the facilities are in RECLAIM, not only are they subject to BACT, but also to the holding requirement and the potential surrender of RTCs. The result is that if there aren't enough RTCs in the market, this proposed shave would effectively cap fuel use. By setting a concentration limit as well as a fuel use limit, this proposed shave would go beyond command and control regulations.

The amount of the shave could have impacts on grid reliability during emergency situations.

The current proposal contemplates what amounts to a 53% shave in the existing RTC market. While action must be taken to reduce current NOx emissions, this action must not result in a situation where generating facilities are unable to operate during emergency situations. The electric grid is a complex, interrelated system. All components work together to generate and ultimately distribute electric power to end users. If, for example, a major transmission line were to go down, there would be an immediate need for local, dispatchable generation to begin operating. If these facilities don't have sufficient RTCs to operate in these circumstances, the system would be faced with energy resources that could not be operated under SCAQMD rules, which would result in load curtailment. Because of the complexity of the system, there is no bright line that can be drawn. The District must therefore exercise caution and not bring about a market that is incapable of responding to emergency situations.

Changes to the RATA testing requirements are supported

Thank you for meeting previously with SCE and DWP on this matter and recognizing that there was a legitimate need to change the rule language regarding postponement of RATAs. In the past, SCE has experienced multiple incidents where equipment has failed in the quarter in which a RATA was due, and found that the District's options for RATA postponement were impractical. With no reasonable alternative to postpone testing, and in order to avoid enforcement, the facilities were forced to petition the SCAQMD Hearing Board for variances. SCE believes the proposed language addresses this issue and now provides a legitimate alternative for RATA postponement without variance relief.

While we fully support the option presented, we are requesting an increase of the 14 unit operating day extension to 30 unit operating days. The main concern is with SCE's Pebbly Beach Generating Station on Catalina Island. Due to its remote location, weather related delays of transportation options to the island, and the high work load schedule of our source testing firm, it can be difficult to organize a RATA test in a short timeframe. The testing firm must separately schedule a time to barge its equipment out to the island, and if power demand on the island were high, the engines may need to run as soon as possible when they return to service, which could impact the test protocol This is especially true for the cleaner engines, as they must operate more frequently in order to comply with facility-wide emission limits. If the source testing firm could not schedule a visit to the island and the engines had to operate to support the power demand, 14 operating days might not be enough time to complete an appropriate RATA. As an alternative, if staff is not open to extending the 14 unit operating day window, SCE suggests having an equivalent operating hour limit. This could give the facility more time to schedule a test without increasing the overall operating time of the unit. Whether there are 14 days or 30 days to complete a RATA, a facility has plenty of incentive to complete the RATA as soon as possible so as to minimize the use of missing data procedures. We ask that the District consider this extension. But other than this amendment, we fully support the rule language as presented by the District and we appreciate the work done by staff to address this issue.

SCE Supports the adjustment account for compliance with Rule 2005 Subdivision (f). Existing USEPA interpretation of the NSR requirements hold that a facility in RECLAIM must obtain sufficient RTCs at the beginning of the calendar year to cover the total potential to emit (PTE) for the year notwithstanding that most facilities do not operate at or near their PTE. This results in a substantial procurement of RTCs that are necessarily bought at a time they are most expensive, but if not used are then sold off when they are of little value. Further, there is no environmental benefit created by what is, in effect, an over-procurement of credits. SCE supports the proposal by the District to create an adjustment account that would cover this RTC requirement. It would eliminate the costly procurement of RTCs beyond what is really needed to cover actual emissions and, quite simply, it makes sense. We urge the District to continue to seek EPA concurrence with this proposal.

As stated above. SCE appreciates the opportunity to provide these comments and we can make ourselves available, if needed, to further clarify our positions. We look forward to working with the District on this important issue.

Sincerely,

Thomas Gross

Subject: **Inland Empire Energy Center, LLC Request to Change Designation from Investor Category to the Power Plant Category**
RECLAIM XX Rule Making

Dear Mr. Cassmassi:

Inland Empire Energy Center, LLC (IEEC, LLC), a wholly-owned subsidiary of General Electric (GE), is the permit holder for the Inland Empire Energy Center (IEEC). GE partnered with Calpine in 2005 to bring the H-technology gas turbine to life as a demonstration project at the IEEC. For business reasons that existed at the time, GE purchased all NOx RECLAIM Trading Credits (RTCs) required for the IEEC instead of having them purchased directly by IEEC, LLC. The NOx RTCs were acquired specifically and solely to meet the RECLAIM compliance obligations of IEEC, and have been used for no other purpose throughout the life of the project. GE has no interest in any other RECLAIM facility. The GE RTC account is, and always has been, 100% dedicated to the IEEC (please see attachments for evidence of past account transfers).

The current staff proposal for amending South Coast Air Quality Management District (District) Regulation XX incorrectly categorizes the IEEC RTCs held by GE in the Investor category. As the name suggests, the Investor category includes entities that buy and sell RTCs with the objective of making a profit based on fluctuations in market price. The Investor held RTCs are disassociated from any RECLAIM facility. This is clearly not the situation with respect to the IEEC RTCs held by GE.

We suspect that this error occurred because IEEC, LLC is the permit holder for the IEEC, not GE. However, this legal distinction does not change the fact that the subject RTC account is exclusively associated with the IEEC, and is not an Investor account. Because all of the GE owned NOx RTCs were acquired and are used solely for IEEC compliance purposes, GE's NOx RTC account should be designated as a Power Plant (non-refinery) account for purposes of the allocation "shave" in the proposed amendments to Regulation XX.

Failing to correctly categorize the allocations held by GE for IEEC would result in a double digit multi-million dollar impact on our business. IEEC, LLC and GE could have never known that the means by which they chose to acquire and hold the RTCs for the IEEC could have such serious implications, and we do not believe that the District intends such an unforeseen consequence. We therefore request that the GE RTC account be correctly categorized as a Power Plant (non-refinery) account by changing Table 8 in proposed Rule 2002 from Inland Empire Energy Center, LLC to "General Electric Company, Inland Empire Energy Center, LLC

Thank you for your attention to this matter. If necessary to resolve this matter, we would be happy to meet with you and your team to discuss the details of our request. Please coordinate directly with Alisa Moretto at 951-226-4553.

Diamond Bar, CA 91765-0830

SUBJECT: INLAND EMPIRE ENERGY CENTER (IEEC) – 2014 RTC TRANSFER FROM GE ACCT #700126 TO IEEC ACCT #129816

To Whom It May Concern:

Attached is our completed form 2007-2 for the transfer of internal RTC's from the General Electric account #700126 to the Inland Empire Energy Center account #129816. This internal transfer is for the following single year trades:

- 96,380 lbs of Cycle 1, Coastal zone, RTC's Expiring December 31, 2015 at $0.00/lb/year
- 12,340 lbs of Cycle 2, Coastal zone, RTC's Expiring June 30, 2015 at $0.00/lb/year
- 23,600 lbs of Cycle 1, Inland zone, RTC's Expiring December 31, 2014 at $0.00/lb/year
- 35,000 lbs of Cycle 1, Inland zone, RTC's Expiring December 31, 2015 at $0.00/lb/year
- 82,923 lbs of Cycle 2, Inland zone, RTC's Expiring June 30, 2015 at $0.00/lb/year

Since this is an internal transfer, the price is not applicable and there is no purchase agreement or transaction confirmation required.

If you have any questions or need further information, please don't hesitate to contact me at (951) 928-5941.

Sincerely,

Francisco Escobedo

1	12/31/2015	Single Year Trade	Coasta	96,380	N/A	01	N/A	B	REGXX	N/A
1	12/31/2015	Single Year Trade	Inland	35,000	N/A	01	N/A	B	REGXX	N/A

* In the "From Compliance Year" Column, fill in the expiration date of the first compliance year RTCs. The "To Compliance Year" Column is used to enter (1) single year transaction, (2) perpetual stream transaction, or (3) multiple year transaction of RTCs of same zone, quantity, and price in a single line. For a single year transaction, mark this column "Single Year Trade". For a perpetual stream transaction, mark this column "All Years After". For a multiple year transaction, fill in the expiration date of the last compliance year. Use separate lines for transactions of different RTCs, quantities or prices. Transactions for all inclusive years between these two columns will be registered. **See reverse side for examples.**

Buyer Use Codes *(only one code per transaction)*

- 01 Increase RTC Allocation account balance to satisfy annual compliance
- 02 Use under Rule 2005 - New Source Review for RECLAIM
- 03 Increase RTC certificate account balance without issuance of physical certificate.
- 04 Increase RTC certificate account balance with issuance of physical certificate
- 05 Retire RTCs from market without issuance of physical certificate
- 06 Retire RTCs from market with issuance of physical certificate
- 07 Facility Acquisition (Change of Ownership)

NOTE: RTCs in Certificate or Printed Certificate Account must be transferred to Allocation Account to be eligible for compliance use.

Seller Generation Codes

- 01** Process Change
- 02** Addition of Control Equipment
- 03** Production Decrease
- 04** Equipment or Facility Shutdown
- 06 Facility Acquisition (Change of Ownership)
- 07 RTCs for Future Compliance Year, cause of generation not yet been determined

***** Selection of this Generation Code must be accompanied by the selection of Account Source Code "A" - Allocation Account.***

Seller Account Source Code *(only one code per transaction)*

- A Allocation Account
- B*** Certificate Account
- C*** Printed Certificate (must list Certificate Serial number and attach certificate to this form)

****** If this Account Source Code is selected, then select "N/A" from Generation Code field.***

Origin of Credits
State Rule Number from which the credits were originally issued (e.g. Reg XX, R1631, R2506, etc.)

Answer the following Questions:

A. Is this transaction part of a pooled transactions or market?

( ) Yes → Attach Form 2007-3 to identify participants (Part A Only)

(•) No → Go to Question B

B. Is seller an agent, broker, or other intermediary representing the owner of RTC ?

( ) Yes → Attach Form 2007-3 to identify Owner of RTC (Part B Only)

(•) No → Complete this form only

Date when this transaction was agreed upon (trading transaction date): 6/10/2014 → Attach purchase agreement or transaction confirmation

I certify that I am authorized to make this submission on behalf of the affected registered holders of the RTCs listed herein. I certify that the statements are true, accurate, and complete to the best of my knowledge.

Ref. No. GE/IEEC – 0787

Reclaim Administration – RTC Transfer
South Coast Air Quality Management District
21865 Copley Dr.
Diamond Bar, CA 91765-0830

SUBJECT: **INLAND EMPIRE ENERGY CENTER (IEEC) – 2013 RTC TRANSFER FROM GE ACCT #700126 TO IEEC ACCT #129816**

To Whom It May Concern:

Attached is our completed form 2007-2 for the transfer of internal RTC's from the General Electric account #700126 to the Inland Empire Energy Center account #129816. This internal transfer is for the following single year trades:

- 23,380 lbs of Cycle 1, Coastal zone, RTC's Expiring December 31, 2013 at $0.00/lb/year
- 12,340 lbs of Cycle 2, Coastal zone, RTC's Expiring June 30, 2014 at $0.00/lb/year
- 96,380 lbs of Cycle 1, Coastal zone, RTC's Expiring December 31, 2014 at $0.00/lb/year
- 11,400 lbs of Cycle 1, Inland zone, RTC's Expiring December 31, 2014 at $0.00/lb/year
- 82,923 lbs of Cycle 2, Inland zone, RTC's Expiring June 30, 2014 at $0.00/lb/year

Since this is an internal transfer, the price is not applicable and there is no purchase agreement or transaction confirmation required.

If you have any questions or need further information, please don't hesitate to contact me at (951) 928-5941.

Sincerely,

Francisco Escobedo

jcassmassi@aqmd.gov

Re: Amendments to Regulation XX – NOx RECLAIM

Dear Dr. Fine and Mr. Cassmassi:

On behalf of Communities for a Better Environment, Earthjustice, Natural Resources Defense Council and Sierra Club ("Health Advocates"), we submit these comments on amendments to Regulation XX, which is slated to go to the Governing Board this fall. We are filing these comments based on the presentation that was provided at June 4, 2015 Working Groups Meeting (hereinafter "Staff Presentation"). At the outset, we remind the South Coast Air Quality Management District ("District") of the urgent ozone and particulate matter problems facing the region. Reducing pollution from the sources in the NOx Regional Clean Air Incentives Market ("RECLAIM") program is essential to achieving our air quality goals and attaining ozone and particulate matter standards. The following sections outline our positions on various issues raised at the last Working Group meeting.

I. The Cap Shave for the Program Should be a Minimum of 14.85 Tons Per Day ("tpd"), Not 14 tpd.

We do not agree with the decision to reduce the total shave amount by .85 tpd, from the required 14.85 tpd to 14 tpd. California's Health & Safety Code is abundantly clear that trading programs must "result in an equivalent or greater reduction in emissions at equivalent or less cost compared with current command and control regulations. . . ." Cal. Health & Safety Code § 39616. In reviewing the materials produced through this rulemaking, the Best Available Retrofit Control ("BARCT") assessments show that a BARCT-equivalent program would result in 14.85

tpd fewer emissions. Accordingly, to comply with Health & Safety Code section 39616, the shave for the RECLAIM program must also be at least 14.85 tpd. We also suggest shaving even more from the program given the large size of the "black box" that must be reduced to meet ozone standards.

II. The Implementation Schedule is Weak.

We are deeply concerned that the schedule for implementation for the shave is too protracted. *See* Slide 4 of the Staff Presentation. Given recent difficulties in meeting various air quality standards, including the 1997 and 2006 standards for fine particle pollution ("PM2.5"), it would be prudent to move up some of the latter year reductions. In fact, we suggest amending the schedule to the following to ensure reductions on the front end in time for compliance with standards.

Year	Current Proposal	Health Advocates Proposal
2016	4 tpd	5 tpd
2018	2 tpd	3 tpd
2019	2 tpd	3 tpd
2020	2 tpd	2 tpd
2021	2 tpd	1.85 tpd
2022	2 tpd	0 tpd

We believe our proposed schedule represents an approach more in line with the directive of the California Health & Safety Code than the implementation schedule proposed in Slide 4 of the Staff Presentation.

III. The District Should Not Establish a New Source Review ("NSR") Set Aside.

Health Advocates do not support the implementation of a District-operated set-aside for New Source Review ("NSR") holdings. There is no basis for the District to undertake this task. In fact, this provision exists to ensure the program does not erode air quality progress in the region. We think this is a necessary safeguard, and we have not heard a compelling reason why the District should take on this duty. Industries have complied with this provision for decades, and it makes sense to continue to place this duty on industry.

IV. The California Environmental Quality Act Analysis Should Examine a Command and Control Alternative.

It is important that the Governing Board and the public receive full information on the environmental landscape of this action. In particular, through the California Environmental Quality Act ("CEQA") process, an assessment of a Command and Control alternative will be important to understand how quickly desperately needed reductions could be implemented in the

South Coast under a regulatory program requiring implementation of readily available technologies, many of which have not been installed at the largest NOx emitters in the South Coast. Under the currently proposed approach, clean up would be protracted for many years as the shave is implemented. A Command and Control Alternative would achieve reductions sooner than this compliance schedule.

V. Industry's Critique on Credit Prices Carries No Water.

At the workshop, representatives for NOx emitters suggested that environmental interests were naïve in solely looking at the prices of short term credits in asserting that NOx RECLAIM credits are priced too low. They claimed that environmental interests failed to look at the price of Infinite Year Block ("IYB") credits. Rather than rebut the claims environmentalists have made that the NOx RECLAIM system is broken because credits prices are too low, the IYB credits only help boost the environmentalists claim. Even with the recent doubling of IYB NOx credits in 2014, the value of IYB credits has been excessively low for over a decade. The following chart from the March 5, 2015 Annual NOx RECLAIM report reprinted below confirms this:

Table 2-5
IYB NOx Pricing (Excluding Swaps)

Calendar Year	Total Reported Value ($ millions)	IYB RTC Traded with Price (tons)	Number of IYB Registrations With Price	Average Price ($/ton)
1994*	$1.3	85.7	1	$15,623
1995*	$0.0	0	0	N/A
1996*	$0.0	0	0	N/A
1997*	$7.9	404.6	9	$19,602
1998*	$34.1	1,447.6	23	$23,534
1999*	$18.6	438.3	19	$42,437
2000*	$9.1	184.2	15	$49,340
2001*	$34.2	416.9	25	$82,013
2002	$5.5	109.5	31	$50,686
2003	$14.3	388.3	28	$36,797
2004	$12.5	557.0	52	$22,481
2005	$43.1	565.3	71	$76,197
2006	$65.2	432.9	50	$150,665
2007	$45.4	233.5	25	$194,369
2008	$49.7	245.6	27	$202,402
2009	$16.7	134.2	14	$124,576
2010	$14.3	149.0	13	$95,761
2011	$9.1	160.7	29	$56,708
2012	$2.2	46.6	13	$48,146

2013	$12.0	260.9	17	$45,914
2014	$99.7	902.2	49	$110,509

District, Staff Report, 2-24, March 6, 2015, *available at* http://www.aqmd.gov/docs/default-source/Agendas/Governing-Board/2015/2015-mar6-029.pdf?sfvrsn=2.

The claims of industry lobbyists that the IYB credits are appropriately priced are not true. In fact, like the short term credits, these credits are exceptionally low. Even with a more than doubling of the IYB prices in 2014 compared to 2013, these credits are only 18% of the $609,187 cost established by the District pursuant to section 39616(f) of the California Health & Safety Code, which is set to ensure credit prices do not go too high. That the failure of these IYB credits to even approach 1/5 of the District's ceiling for credit costs just bolsters the excessive number of credits in the NOx RECLAIM system. Overall, the evidence conclusively suggests that the credits are not priced correctly to push for pollution reductions at a level commensurate with what command and control would achieve, which is borne out in the District's BARCT assessments.

VI. The Shave Approach Must Ensure Reductions from Refineries and Powerplants.

The evidence presented by the District in this rulemaking indicates that refineries have used the NOx RECLAIM system as a shield from actually installing pollution control equipment like Selective Catalytic Reduction ("SCR"). Given this past behavior, we suggest that the best path forward is that refineries be taken out of the NOx RECLAIM program and be required to install pollution control equipment.

If this cannot happen, we support the shave approach number 4 on slide 2 of the Staff Presentation, which focuses on large emitters like refineries and natural gas powerplants. Absent removing those facilities unwilling to install pollution controls, this methodology appears to be the most sound approach to allocating the shave of those presented at the June 4, 2015 working group meeting.

Overall, we are deeply committed to ensuring stationary sources clean up harmful NOx emissions in the South Coast. As it stands now, the NOx RECLAIM program has failed to spur adoption of available pollution technologies for many large facilities, and has accordingly failed to adequately reduce NOx emissions. In addition, it has continued to allow high NOx emissions in the disproportionately impacted neighborhoods near refineries and powerplants, raising substantial environmental justice issues. Thus it has dramatically displayed one of the major flaws of a trading system.

We therefore support efforts to retool the program, but urge SCAQMD to do so in a way that meets the urgent need of South Coast residents for clean air and clean energy.

Please do not hesitate to contact us if you have questions.

Sincerely,

Adrian L. Martinez

Subject: Re: **SAVE THE DATE** SCAQMD NOx RECLAIM Working Group Meeting
Attachments: AACE_CLASSIFICATION_SYSTEM.pdf

Hi Kevin -

I wanted to share with you this document produced by the Association for the Advancement of Cost Estimating (AACE):

This document highlights the deliverables generated in a gated/phased project development and the corresponding estimate detail and accuracy expected. This is followed by **all** major refining and chemical companies when appraising, selecting, and defining projects for internal funding or external financing. **All** of the major EPCs follow process this as well. Fluor and many other EPCs - and the operating companies - have developed proprietary design manuals that address gated process development and we all follow these very rigorously.

So how does this apply to a NOx RECLAIM Program?

For each potential project, a screening level study estimate (Class 5) is developed for each possible solution for a heater's NOx emissions, for example. Screening whether (1) newer/better burners would be a good choice for NOx mitigation, whether (2) improving the refinery fuel gas for lower NOx generation due to heavy hydrocarbon removal or hydrogen removal, whether (3) improved SCR catalysts would be effective, whether (4) new and/or larger SCR systems are required, or whether (5) the heater should be replaced altogether.

The same would apply to FCC regenerator emissions, but from a slightly smaller list of technical choices.

A variation would apply to sulfur plant incinerators with the caveat that the mitigation system cannot interfere with H_2S destruction during an emergency release.

Following a positive outcome of the screening level study, a more detailed look is undertaken to better define the scope and improve the cost estimate. This estimate is usually an equipment factored or Class 4 estimate.

Following a positive outcome of the more detailed study, the refiner would receive internal funding for a Front End Engineering Design effort, which is of sufficient detail and completeness that external financing could be sought or an internal AFE is pursued. The decision to proceed following a FEED effort is serious since it will involve equipment and construction commodity purchased.

With external financing or an internal AFE, the project can now proceed into the detailed design, procurement, and construction effort.

All this takes time:

- Studies take from weeks to several months to complete, depending on the scope of the problem.
- FEEDs tend to take 6 to 12 months, depending on the project complexity and the impacts to offsites and utility systems.
- EPC is usually 18 to 30 months when new equipment is involved and will depend greatly on the project complexity and its impacts on other systems in the refinery.

In between each of the steps is a review and approval period by the client - likely 1 to 3 months, depending on project complexity and the financial analysis required to move forward.

This disciplined decision making approach is driven by refining being a "commodity" business and one that is extremely capital intensive. Shortcuts do not save time or money. An incomplete technology assessment or rushed project development can lead to regretful choices and inadequate mitigation.

At this point, we are probably one to two months away from having finalized NOx RECLAIM rules. Then, we are only another two months from the beginning of the first compliance year. There will be inadequate time for project development with any results in 2016/2017 - even for simpler scopes like burner replacements in existing heaters or catalyst upgrades in existing SCRs. But, new scrubbers or new SCRs would not be able to provide any mitigation benefit until 2018/2019.

The ongoing SOx RECLAIM Program had a gap of 26 months from the end of rule-making to the beginning of compliance - which would allow for some mitigation to be realized in the first compliance year. A three year gap would have insured an even stronger result.

A three year gap between rule-making and the first compliance year for NOx RECLAIM would have provided a better start for a real NOx reduction.

I am available anytime if you wish to discuss this further.

Thanks and best regards -

Arnie

Subject: PAR 2002 RECLAIM and Rule 1146.2 Boilers (Rule 219 exempt)
Attachments: Karl Lany.vcf

Thanks for taking the steps you have to accommodate Rule 219 boiler technology into the proposed RECLAIM amendments. After giving the concept more consideration, I continue to question the proposed requirement that such boilers be subject to testing requirements in order to qualify for RECLAIM reporting factors that reflects certification standards.

Several people at yesterday's meeting raised concerns about the need for, and practicality of, such tests (cost, the presence of certification data, and the way in which certification data supports SIP credit). SCAQMD's position is that certification is for a family of boilers or boiler models, rather than each individual boiler. I understand that concept because of my experience with diesel engine certification programs. There are many parallels that I expect to exist and those parallels lead one to shy away from a testing requirement.

Even though boilers may be certified in groupings, if the boiler program is anything at all like the engine certification program, those groupings are based upon similarity of the equipment, combustion technology and the reasonable expectation that the environmental performance of the lead device truly reflects the environmental performance of the entire family of devices. It seems to me that groups of boilers being certified have very few technological variables. In fact, Rule 1146.2 requires certification based upon each boiler model, which appears to be more restrictive than the engine certification program which includes many different engine ratings and applications in a single family.

As we debate the need for small boiler testing, we should pay close attention to the equity of SCAQMD policy, relative to other certified equipment such as diesel emergency engines that are brought into the RECLAIM program. I recognize I am comparing process units that go through district permitting with Rule 219 permit exempt units, but the comparison is valid because the technology analysis performed by SCAQMD when permitting diesel emergency engines is rather simple.

SCAQMD makes all NSR determinations, including BACT and offset, for certified emergency engines based upon engine certification standards unless the applicant proposes unit-specific certified rates or manufacturer data. SCAQMD does not question the legitimacy of EPA or CARB's certification. Instead SCAQMD makes a very basic determination of the engine certification status and the emission rates to which the engine is certified. SCAQMD then uses the certification status to determine NSR compliance. Then, because Rule 2002 allows, SCAQMD uses the certification standard to determine a RFECLAIM process unit emission factor. The entire SCAQMD program for certified diesel engines rests upon certification standards and excludes any emissions testing. It makes sense that the benefits of certification (exclusion from unnecessary emissions tests) that are extended to process unit diesel engines in RECLAIM would also be extended permit exempt natural gas boilers that arte subjected to a similar certification program.

I sincerely hope that SCAQMD reconsiders its proposed testing requirements for Rule 219 boilers in RECLAIM and instead provides a more practical solution that reflects the legitimacy of its boiler certification program I'm always happy to discuss further at your convenience.

Thanks.

Subject: RE: RECLAIM Rulemaking Follow up

Hello Jill and Joe,

I appreciate the time you spent with me last month. I am unclear whether I will be able to make the August 19 RECLAIM Working Group meeting, but nonetheless, we continue to be engaged with the developments of the rulemaking/shave. I have a couple points to consider. I am not considering this formal written comments; just some follow up thoughts. I can give you a call or we can discuss at the August 19 meeting if I can make it.

1. In Rule 2005, will there be proposed language to address annual holding limit requirements for a facility like Walnut Creek. I did not see it, unless I missed it.
2. During our meeting, I may have understated the financial impact to a new facility like Walnut Creek that is different than an existing RECLAIM facility or new plant at an existing RECLAIM facility. In satisfying NSR (unlike a legacy RECLAIM facility), we purchased IYB Cycle 1 and 2 RTCs from the market. Demonstration that we satisfied the RTCs for annual NOx PTE was not only necessary for the Permit to Construct and annual Permit to Operate but also for the financing of the WCEP. We would now represent that the asset has lost the equivalent of 47% of its NOx IYB RTCs at the current rate of say $115/lb-yr and address the means to which we can demonstrate our continued holding and/or access to these RTC for the lenders. While not obvious, the financial implications are different than a facility that has relied on an existing RECLAIM account or the ability to reconcile its emissions for the respective year. It is the difference between losing the unrealized value of IYB RTCs in a legacy RECLAIM account versus the purchase, shave and possible replacement of them at the new market condition (or from the Adjustment Account?) to meet its PTE. This is one of the reasons why we believe WCEP should be exempt from the shave. More food for thought.
3. Any concern about challenges to removal of the annual holding limit requirement by the environmental community?

Thanks for the time. And we can discuss these thoughts soon.

Best Regards,

Kevin,
On behalf of the City of Riverside, City of Anaheim and City of Colton, thank you for your time yesterday regarding an audit of the Preliminary Draft Report – NOx RECLAIM July 21, 2015 Table U.1 "*List of 65 Affected Facilities and Investors.*" The draft report states "*Additionally, all power plants would be included in this option*." (pg 210) but in fact all power plants are NOT included on table U.1.

Attached are the Facilities' "NOx Information" sheets from the AQMD website which appear to hold RTCs and are "power plants" therefore it's a assumed, as per your draft report, would be included on the list but in fact are not. The attachments include power plants such Corona Energy Partners, Wheelabrator Norwalk Energy Co, OLS Energy – CHINO, Carson Cogeneration Company, NP Cogen Inc, Thumbs Long Beach, Harbor Cogeneration Co, and Altagas Pomona Energy inc.

You and I covered a wide range of thoughts yesterday including; ALL power plants are on the list, cogeneration facilities are excluded from the list, "new" power plants are on the list, companies without NSR requirements are excluded, and power plants without any RTCs are not on the list. But in each of these cases I showed how your list contradicts the statement.

For example, you said the list may not include cogeneration facilities even though one of my facilities (facility ID 164204) is on the list and is a cogeneration. Additionally, your familiar with the inclusion of power plants (facility ID 132191 and 132192 for example) with zero RTCs who are on the U.1 list.

In summary, the list as provided in table U.1 needs to be audited with a full explanation of who is included or excluded and the reason for each. The NOx shave percentage adjusted for non-refinery RTC holders' weighted reduction, currently 47%, would require adjustment if the list changes.

Thank you. Please let me know if you have any questions,

Mr. Joe Cassmassi

Los Angeles Department of Water & Power

August 14, 2015

Philip M. Fine, Ph.D., Deputy Executive Officer
South Coast Air Quality Management District
21865 Copley Drive
Diamond Bar, CA 91765

L:

Dear Dr. Fine:

Subject: Los Angeles Department of Water & Power's (LADWP) Comments on Proposed Amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM) NOx RECLAIM

The LADWP appreciates the opportunity to provide comments on the proposed amendments to Regulation XX – NOx RECLAIM and its accompanying Preliminary Draft Staff Report. LADWP remains committed to working with South Coast Air Quality Management District (SCAQMD) to further develop efficient and effective policies to reduce NOx emissions from RECLAIM facilities in order to meet the federal ozone standards in the South Coast Air Basin.

Serving approximately 1.4 million customers in Los Angeles with a generating capacity of over 7,300 megawatts, LADWP is the largest municipal electric utility in the nation, and the third largest electric utility in California. LADWP is a vertically integrated utility, owning and operating a diverse portfolio of generation, transmission, and distribution assets spanning several states.

All of LADWP's generating units are equipped with Best Available Retrofit Control Technology (BARCT) or Best Available Control Technology (BACT) and have reduced NOx emissions by 90 percent. As part of its modernization efforts, since the 1990s, LADWP has been replacing its existing, less efficient utility boilers in the South Coast Air Basin with new, state-of-the-art combined-cycle and simple cycle turbine systems equipped with selective catalytic reduction technology to minimize NOx emissions. During this modernization process, LADWP's generating facilities have been subject to New Source Review and are equipped with BACT.

LADWP also continues to make unprecedented investments in renewable energy resources, energy efficiency and transportation electrification to improve the environment. LADWP is on track to meet 33 percent of its energy sales from renewable energy resources by 2020, has a goal to achieve 15 percent energy savings by 2020, and is continuing to implement programs to support the electrification of the transportation sector to reduce greenhouse gases and criteria pollutants, including NOx, and as a potential solution to absorb over-generation from solar renewable sources.

LADWP's provides comments on SCAQMD's proposed regulatory language and draft preliminary draft staff report below. In addition, LADWP offers a simpler alternate regulatory approach (Pgs. 10 through 14) for the Power Producing Facility sector that is structured to support clean generation and renewable energy while enabling the sector to meet native load and reliably operate.

Comments on the Proposed Amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM)

1) Proposed Amended Rule 2002(f) – Annual Allocations for NOx and SOx and Adjustments to RTC Holdings

   a) LADWP is generally supportive of SCAQMD's inclusion of non-tradable RTCs in a Facility Permit Holder's RECLAIM facility account. However, LADWP believes that the current proposed mechanism for accessing the RTCs in a facility's non-tradable account would be costly and inequitably treats Power Producing Facilities that are operating at NOx BARCT levels.

      The proposed rule contains a two-step process before the non-tradable/non-usable RTCs can be converted to tradable/usable RTCs. First, the 12-month rolling average RTC price for all trades (with the exception of transactions at no price or RTC swap transactions) must exceed $15,000 per ton. Second, the SCAQMD Executive Officer would be required to report to the Governing Board at a Board Meeting on the RTC market price. Only upon Board determination that the price threshold of $15,000 per ton was exceeded would the non-tradable RTCs be converted to tradable and usable RTCs. LADWP recommends an alternative approach applicable to Power Producing Facilities such that the non-tradable/non-usable RTCs continue to be deemed non-tradable but *usable* for compliance *without* the price threshold trigger for the following reasons: 18-1

      - All of LADWP's generating facilities have been retrofitted with selective catalytic reduction technology (BARCT/BACT) and have reduced NOx emissions by 90 percent. Thus, LADWP has implemented all feasible NOx controls on-site to control its NOx emissions to the maximum extent feasible.

- As provided in the Los Angeles City Charter, LADWP has the obligation and duty to serve its native load customers. With SCAQMD's proposed 47 percent shave in current RTC holdings, if LADWP were to be short of RTCs, the only compliance option would be to purchase (if available) RTCs at the market price – at whatever that price happens to be. Reducing electricity production at LADWP's Los Angeles basin generating facilities may likely not be an option due to the following operational constraints and needs:
    - Transmission constraints
    - Need for local dispatchable generation to support local renewables
    - Certain minimum amounts of inertia in-basin that are required to import out-of-basin generation 18-1 cont
    - "Reliability Must Run" generation that is needed in-basin
- Although widespread electrification of the transportation sector would result in a *significant net decrease in NOx* emissions in the South Coast Air Basin, there would be a relatively minor increase in NOx emissions at LADWP's generating facilities due to increased electricity demand.
    - SCAQMD, as noted in its 2016 Air Quality Management Plan draft white papers, has stated that there is a need to expand zero-emission technologies in the transportation sector for the South Coast Air Basin to attain the 8-hour ozone standards in 2023 and 2032.
    - The SCAQMD's draft *Residential and Commercial Energy 2016 AQMP* white paper states, "A rough estimate of the NOx emission resulting from upstream power plants providing electricity to the residential and commercial sectors is an additional 1.4 tons per day." This increase in NOx does not include the impacts of electrification of other sectors such as the Goods Movement sector.
    - Having to procure RTCs on the open market to meet native load until the price threshold of $15,000 per ton is reached after investing over

two billion dollars on new advanced gas turbine technology control technology could result in significant additional costs for LADWP.

- These additional costs would likely be, by far, in excess of the proposed $15,000 per ton threshold based on our experience and information in SCAQMD's Annual RECLAIM Report.[1] In particular, RECLAIM RTC prices can be volatile and the market price of RTCs can be significantly high by the time the $15,000 per ton 12-month rolling average price is reached. For example, the average price 1999 NOx RTCs traded in 2000 (1999 cycle 2 RTCs which are valid from July 1, 1999 to June 30, 2000) was $15,369 per ton although 1999 cycle 2 NOx RTCs transacted at significantly higher prices (e.g. $70,000 per ton in the summer of 2000). The average price for NOx RTCs for compliance year 2000 RTCs traded during 2000 increased to $45,609 per ton although there were transactions at the $100,000 per ton level. 18-1 cont.

Thus, the imposition of these incremental costs does not represent an efficient way to achieve the additional NOx reductions needed for meeting the air quality goals in the air basin. In fact, the proposal's process would penalize the Power Producing Facilities which have met NOx BARCT requirements and are making investments in energy efficiency, demand response, energy storage, renewable energy and electric transportation to help meet California's environmental goals as well as help attain the federal ozone standard.

As an alternative to address this concern, LADWP recommends that the non-tradable/non-usable RTCs be deemed non-tradable/usable RTCs such that they are available for Power Producing Facility compliance with NOx RECLAIM. There would be no need for the non-tradable RTCs to be tradable as they would be used strictly for compliance purposes by the affected Power Producing Facility to which the non-tradable RTCs would be allocated. Thus, Power Producing Facilities at BARCT levels would not be subject to the provisions of Rule 2002(f)(D) through (I). To summarize, LADWP would only use the non-tradable RTCs for compliance purposes and allocated tradable RTCs would be used first for compliance and never sold to another electric utility or other entity.

LADWP recommends the addition of the following subparagraph Rule 2002(f)(1)(G) with proposed subparagraphs (G) through (T) renumbered accordingly to (H) to (U):

[1] Annual RECLAIM Audit Report for the 1999 Compliance Year, March 16, 2001

18-1 cont.

> Power Producing Facility Permit Holders listed in Table 8 will obtain tradable/usable NOx RTCs and non-tradable/usable NOx RTCs as listed in subparagraph (f)(1)(C) and shall not be subject to subparagraphs (f)(1)(D) through (F) and (H) through (J). In this subparagraph, a Facility Permit Holder may use its non-tradable/usable NOx RTCs for a compliance year so long as the tradable NOx RTCs were not sold or transferred to another facility not under common ownership during that compliance year.

b) Rule 2002(f)(1)(J) states, "The 2022 NOx RTC adjustment factors shall not be submitted for inclusion into the State Implementation Plan until 12-months after the adjustments have been in effect for one full compliance year." For the 2011 compliance year, SCAQMD submitted the non-tradable/non-usable RTCs for 2011 and all years after to the State Implementation Plan such that RECLAIM facility permit holders' non-tradable RTCs were zeroed out for 2011 and all years thereafter. As mentioned previously, LADWP has an obligation to serve its native load customers and anticipates increased electricity demand in the future due to electrification of the transportation sector. Part of serving native load reliably entails having its in-basin generating facilities available to integrate intermittent renewable energy. LADWP recommends that subparagraph (f)(1)(J) not apply to power producing facilities as they are at BARCT levels and SCAQMD's analysis concluded that there is no new BARCT for the power producing facility sector. Recommended language is in underline/strikeout format: 18-2

> ...The 2022 NOx RTC adjustment factors shall not be submitted for inclusion into the State Implementation Plan until 12-months after the adjustments have been in effect for one full compliance year.
> At the end of each compliance year reconciliation period from 2022 and each year thereafter, the power producing facility shall surrender unused non-tradable RTCs to SCAQMD for inclusion into the State Implementation Plan.

c) Proposed Rule 2002(f)(4) and (5) creates an Adjustment Account for Power Producing Facilities for the purpose of complying with the RECLAIM New Source Review requirements in Rule 2005(f) and compliance with annual emissions. The Power Producing Facilities' ability to access RTCs in the Adjustment Account for the purposes of compliance is constrained such that the RTCs would be released only under the following conditions – the Governor declared a State of Emergency and SCAQMD Executive Officer determination on the impact the State of Emergency has on the RECLAIM program. The suggested language 18-3 also states that the available RTCs for Power Producing Facilities to fulfill compliance with RECLAIM would be limited to the RTCs remaining in the Adjustment Account after Power Producing Facilities' New Source Review offset needs are fulfilled. This introduces great uncertainty whether there will be sufficient RTCs in the Adjustment Account.

LADWP is subject to mandated and enforceable North American Electric Reliability Corporation (NERC) standards which ensure reliability of the bulk power system in North America. LADWP is concerned with respect to its ability to both comply with the reliability standards and the RECLAIM program using the mechanism as proposed. Compliance with NERC standards requires a Power Producing Facility such as LADWP's power plants to respond quickly, as soon as fifteen minutes. Waiting for the Governor to declare a State of Emergency and for the SCAQMD Executive Officer to determine the impacts RECLAIM has on the emergency jeopardizes LADWP's compliance with NERC standards and its ability to reliably deliver electricity to its customers. 18-3 cont.

NERC Reliability Standard EOP-002-3.1 (Enclosure 1) ensures that Reliability Coordinators and Balancing Authorities such as LADWP are prepared for capacity and energy emergencies. Under this reliability standard, the Reliability Coordinator has the authority to initiate an Energy Emergency Alert, as defined, to mitigate the emergency condition.

There are also instances when LADWP, as a balancing authority, must have its Los Angeles basin generating units available for operation to meet NERC standards; if the units are constrained by the unavailability of RTCs, LADWP may face noncompliance with additional NERC standards. For example, there is operational variability in LADWP's current fleet of renewable resources. By late 2016, LADWP will be subject to as much as a 1000 MW sudden drop in output from renewable resources (e.g. due to cloud cover at solar facilities). In order to comply with NERC Reliability Standard BAL-001-2 (which replaces BAL-001-1 on July 1, 2016), LADWP must respond to this variability by dispatching its local generation facilities. That is, as the renewable production (e.g. wind, solar) suddenly decreases, local generation must be rapidly increased, and vice versa. Starting in July 1, 2016, BAL-001-2 (Enclosure 2) will allow only 30 minutes for LADWP to respond to the renewable variability so its Los Angeles basin generating units will be critical resources planned to be used for compliance with this reliability standard.

Also, if LADWP lost a conventional resource, it would have only fifteen minutes to bring up remaining generation to replace the loss. If generation from LADWP's pumped storage hydroelectric generating facility is unavailable, Los Angeles basin generating units would need to come on-line within this fifteen minute time period.

NERC Reliability Standard FAC-011-2, Requirement 2.2 and LADWP's Transmission Reliability Criteria (Enclosure 3) govern transmission operations with respect to system operating limits. Systems such as LADWP's must demonstrate transient, dynamic and voltage stability, facilities must be in operating within their Facility Ratings and within their thermal, voltage and stability limits such that cascading or uncontrolled separation does not occur. LADWP's local transmission system cannot meet this requirement in the absence of local Los Angeles basin generation. Reliability Must Run local generation is required to be either on-line or available to be quickly put on-line to meet the requirement. The only alternative to increasing or turning on the additional generation to meet this reliability requirement would be to shed customer load if insufficient RTCs are unavailable. 18-3 cont.

LADWP recommends the following language in underline/strikeout format:

> During a State of Emergency as declared by the Governor or Reliability Coordinator, the Executive Officer will allow Power Producing Facilities access to Adjustment Account RTCs for the purpose of compliance with the annual emissions. ~~These available RTCs will be limited to those that are in excess of those specified for use in paragraph (f)(4).~~ The amount and distribution of the RTCs will be determined by the Power Producing Facility ~~Executive Officer~~ based on the impact that the State of Emergency has on compliance with North American Electric Reliability Corporation standards and the RECLAIM program.
>
> "Reliability Coordinator" means the entity that is the highest level of authority who is responsible for the reliable operation of the Bulk Electric System as defined in the North American Electric Reliability Corporation Glossary."

The draft preliminary staff report states that the Adjustment Account RTCs "would be derived from the proposed programmatic 14 tons per day in NOx reductions." In previous NOx RECLAIM working group meetings, SCAQMD stated that Adjustment Account RTCs derived from the 14 tons per day NOx reductions would not be submitted to the State Implementation Plan. LADWP recommends that the preliminary staff report explicitly state that the Adjustment Account RTCs would not be submitted to the State Implementation Plan. 18-3 cont.

2) Table 6 RECLAIM NOx 2021 Ending Emission Factors
LADWP recommends that the description "Gas Turbines" under the Nitrogen Oxide Basic Equipment column be amended to read "Refinery Gas Turbines" to distinguish that the Power Producing Facility gas turbines are not subject to BARCT in this rule amendment process. 18-4

3) Proposed Amended Rule 2012 – Appendix A: Protocol for Monitoring, Reporting and Recordkeeping of Oxides of Nitrogen (NOx) – Attachment C – Quality Assurance and Quality Control Procedures

a) Semi-Annual Assessments
The proposal's 14 unit operating day time window for conducting a RATA in the case where a major source is physically incapable of being operated is insufficient at LADWP generating facilities when a unit is inoperable for an extended period of time. The draft preliminary staff report includes additional information by stating that the "proposed 14 operating day RATA postponement for unforeseen equipment failure would apply separately for each unrelated, independent event." LADWP supports the clarification in the draft staff report and LADWP recommends that this clarification be reflected in the rule language. LADWP offers the following added language to subparagraph B.2.c after clause B.2.c.ii.: 18-5

> The 14 unit operating day RATA postponement for unforeseen equipment failure applies separately for each unrelated, independent event.

Subparagraph B.2.d. - Due Date for RATAs

LADWP appreciates SCAQMD's efforts to consistently treat facilities under contract with the California Independent System Operator (CalISO) as well as electric generating facilities owned and operated by municipalities that have difficulties in meeting RATA deadlines because their equipment does not operate long enough, or not at all, to conduct a RATA in the quarter in which the RATA is due. 18-6

The proposed rule language states that the electric generating facility can postpone the RATA if it was scheduled to be performed during the first 45 days of the calendar quarter in which the assessment is due. This means that if the RATA was scheduled during the second 45 days of the calendar quarter, then the RATA cannot be postponed. The draft preliminary staff report does not provide an explanation as to why the RATA must be scheduled the first 45 days of the calendar quarter. There could be situations where a source tester is not available or a unit has not been capable of operating until the second 45 days of the calendar quarter. Thus, the proposed requirement to schedule the RATA during the first 45 days of the calendar quarter does not resolve the availability issues. In both cases, the facilities would need to schedule the RATA in the second 45 days of the calendar quarter to meet compliance. Therefore, so long as the RATA is performed within the required timeframe, facilities should be able to have flexibility with respect to schedule of a RATA. 18-6 cont.

LADWP recommends the following language changes to Clause B.2.d.i. in underline/strikeout format:

> The semi-annual or annual assessment was scheduled to be performed during ~~the first 45 days of~~ the calendar quarter in which the assessment was due

b) Clauses B.2.c.i. and ii – Proposed requirement to disconnect and flange the fuel feed lines when a unit is physically incapable of operation and maintain operational fuel meters introduces health and safety issues, compromises structural integrity of the pipelines and would be costly at steam generating units scheduled to be replaced.

The proposed language requires that:

i. All fuel lines to the major source are disconnected and either flanges or equivalent sealing devices are placed at both ends of the disconnected lines

ii. The fuel meter(s) for the disconnected fuel feed lines are maintained and operated and associated fuel records showing no fuel flow are maintained on site 18-7

Over the next decade, LADWP's steam generating units will be repowered with a combination of more efficient combined cycle units and quick start combustion turbines. These steam generating units have been constructed such that there are no pipe segments of the fuel lines that could be readily removed. To do so, the lines must be cut at two locations and a removable spool would need to be fabricated at significant costs in order to further prove that a unit is inoperable. Also, this requirement would unnecessarily create a health and safety risk as the fuel lines are insulated with asbestos-containing materials (ACM) at two of LADWP's generating stations. The intact ACM would have to be removed to gain access to the fuel pipelines which would be against the general plant operating and maintenance practice and EPA's recommendation to leave intact ACM alone.

LADWP surveyed all of its generating units that are currently in operation. The survey presented technical difficulties of creating air gaps by cutting into the fuel lines or removing certain piping equipment including valves, strainers, or meters to create the gaps. LADWP has considered alternative methods to pipe cutting and removing equipment such as opening access to the piping and equipment. 18-7 cont.

LADWP recommends the following changes to Clauses B.2.c.i. and ii:

i. All fuel lines to the major source are disconnected or opened and either flanges or equivalent sealing devices are placed at both ends of the disconnected or opened lines

ii. The fuel meter(s) for the disconnected or opened fuel feed lines are maintained and operated and associated fuel records showing no fuel flow are maintained on site

Alternative Regulatory Approach

As discussed above, reducing NOx emissions at in-basin plants may not be feasible due to the fact that the only way to achieve additional reductions from these well-controlled plants is by reducing their generation output. As discussed above, reducing the utilization of in-basin gas-fired generation is not a viable option given the essential role these units play in ensuring a reliable supply of electricity in the basin.

Furthermore, an essential part of the strategy to reduce NOx emission levels in the South Coast Air Basin will be to electrify the transportation sector and other major source categories of NOx emissions. Specifically, the increased electricity generation will result in small increases in NOx emissions by affected electric generating units, but those emission increases will be more than offset by substantial NOx emission reductions achieved by the newly electrified sources. Electrification of even a portion of these sources will result in substantial overall net NOx emission reductions in the SCAB region. 18-8

LADWP has identified a possible regulatory credit mechanism that could be developed to ensure that affected power plant facilities would not be penalized for increased NOx emissions resulting from an increased demand in electricity due to native load needs and increased transportation electrification. Such a crediting mechanism would incentivize the development and implementation of renewable energy and transportation electrification. This approach would be consistent with SCAQMD's position as described in its comment letter to U.S. Environmental Protection Agency (EPA), which states that "It is important that the 111(d) regulation recognizes California's unique situation and does not hinder the introduction of additional renewable energy generation." "The proposed regulation must be structured to support clean generation and renewable energy."[2]

In addition, this proposed regulatory mechanism is consistent with the federal Clean Air Act framework for achieving expeditiously the air quality goals established under the Act. Most importantly, the establishment of a mechanism to enable the achievement of substantial overall net NOx reductions in the South Coast Air Basin region will provide an effective strategy for the SCAQMD to meet its "reasonable further progress" reduction goals for the current 2008 ozone standard as well as any additional NOx reductions that may be necessary for meeting upcoming more stringent ozone standard. 18-8 cont.

The discussion below describes how a similar credit mechanism might be developed to ensure affected electric generating facilities had sufficient RTCs in the event that SCAQMD decides to impose an across-the-board RTC reduction on all affected RECLAIM facilities.

1. <u>Quantify the amount of RTCs needed to support native load and transportation electrification</u>

   The first step of the process would involve each affected electric utility quantifying the amount of NOx RTCs that it would need to cover its projected NOx emissions. The process for calculating each unit's generation level would be based on the amount of electricity that the utility would need to

[2] November 26, 2014 letter to EPA regarding *Carbon Pollution Emission Guidelines for Existing Stationary Sources: Electric Utility Generating Units – Proposed Rule*

generate in order to meet its native load, along with the expected electricity demand increase resulting from the transportation electrification. This determination would likely be based on an Integrated Resource Plan (IRP) or similar process for estimating the utility's native load and the expected transportation electrification for the next 10 to 15 years. With respect to transportation electrification, the utility would need to work with the SCAQMD and the California Air Resources Board (CARB) to estimate the level of transportation electrification in the basin in order to determine the resulting increased electricity demand.

Based on this quantification of future electricity demand and NOx emissions (which could be updated on an annual basis), the SCAQMD would allow the affected electric utilities to hold in their accounts sufficient number of NOx RTCs to cover their emissions on a system-wide basis. This amount of each utility's RTCs would not be deducted from its RECLAIM account and consequently remain available for use in meeting its RECLAIM credit-holding requirements.

2. <u>Determine the amount of RTCs used for electrification of major NOx emission source categories</u> 18-8 cont

Each utility sector would quantify the number of RTCs that are actually used to generate electricity for electrification of mobile sources and other major NOx source categories in the South Coast Air Basin region.

In the case of electric vehicles, this quantification would be performed for each compliance year based on a method similar to CARB's Low Carbon Fuel Standard approach. A combination of meter kWh data and estimated kWh data applied to the number of EVs that a utility reports would be used to quantify the emissions due to the increase in electricity demand from electric transportation.

In the case of the other major NOx source categories, the quantification would be performed based on the estimated NOx emission reductions that would occur from mandatory electrification measures established by the CARB and SCAQMD as well as non-mandatory electrification measures and incentives that CARB, SCAQMD and electric utilities may promote.

3. <u>Label unused RTCs designated to cover electrification as non-tradable</u>

The RTCs that an electric utility retains based on the quantification of future electricity demand due to electrification would be put into a utility's account and labeled non-tradable. The non-tradable RTCs could be used for compliance purposes only and allocated tradable RTCs would be used first for compliance. Thus, if a utility has NOx emissions that are lower than expected such that its non-tradable RTCs are unused, the utility would not be able to sell them to entities outside of the utility's system. At the end of the reconciliation period, the utility would surrender unused non-tradable RTCs to SCAQMD for credit toward reducing NOx emissions through the RECLAIM program and meeting attainment of the ozone standard. Enclosed is a more detailed description of this regulatory approach (Enclosure 4).

<u>State Implementation Plan crediting with respect to design of the NOx RECLAIM program to accommodate transportation electrification</u>

18-8 cont.

There are uncertainties with respect to the level of electrification and the level of in-basin generation needed to support future renewables which creates uncertainties as to the number of RTCs that electric generating facilities would need. LADWP believes that SCAQMD has the discretion to develop its NOx RECLAIM program to accommodate such uncertainties without having to determine the exact amount of the NOx reductions upfront for SIP credit purposes. Enclosed for your review is a white paper that outlines the key elements of an emission reduction crediting mechanism that SCAQMD could use to account for and provide the appropriate emission reduction credit to electric utilities for the overall net NOx emission reductions achieved by the electrification of other source categories in order to meet its "reasonable further progress" goals under the Clean Air Act (Enclosure 5). Among other things, the paper presents the key design elements of a crediting mechanism that is modeled after approaches that EPA has developed for promoting energy efficiency and renewable energy measures under the Clean Air Act.

LADWP is ready and willing to work with SCAQMD, CARB, and EPA to explore opportunities in creating an approach to include the benefits of transportation electrification as well as support clean generation and renewable energy. Development of an EPA-recognized SIP crediting mechanism will address the regulatory uncertainty that would otherwise result from this paradigm shift and thereby encourage the implementation of policies to reduce emissions from the transportation and major source categories of emissions through electrification in the South Coast Air Basin and other urban ozone nonattainment areas.

Finally, in the NOx RECLAIM working group meeting on July 9, SCAQMD stated that resolution language would be included in this NOx RECLAIM rulemaking package to address the impacts of transportation electrification on the RECLAIM program. LADWP offers that resolution language to address this issue (Enclosure 6). 18-8 cont.

Again, LADWP appreciates the opportunity to provide comments on the NOx RECLAIM proposed amended rules and draft preliminary staff report. If you have any questions or would like additional information, please contact Ms. Jodean Giese of my staff at (213) 367-0409.

Sincerely,

Mark J. Sedlacek

A. Introduction

1. **Title:** **Capacity and Energy Emergencies**
2. **Number:** EOP-002-3.1
3. **Purpose:** To ensure Reliability Coordinators and Balancing Authorities are prepared for capacity and energy emergencies.
4. **Applicability**
   4.1. Balancing Authorities.
   4.2. Reliability Coordinators.
   4.3. Load-Serving Entities.
5. **(Proposed) Effective Date:** First day of the first calendar quarter six months following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter six months following Board of Trustees adoption.

B. Requirements

R1. Each Balancing Authority and Reliability Coordinator shall have the responsibility and clear decision-making authority to take whatever actions are needed to ensure the reliability of its respective area and shall exercise specific authority to alleviate capacity and energy emergencies.

R2. Each Balancing Authority shall, when required and as appropriate, take one or more actions as described in its capacity and energy emergency plan to reduce risks to the interconnected system.

R3. A Balancing Authority that is experiencing an operating capacity or energy emergency shall communicate its current and future system conditions to its Reliability Coordinator and neighboring Balancing Authorities.

R4. A Balancing Authority anticipating an operating capacity or energy emergency shall perform all actions necessary including bringing on all available generation, postponing equipment maintenance, scheduling interchange purchases in advance, and being prepared to reduce firm load.

R5. A deficient Balancing Authority shall only use the assistance provided by the Interconnection's frequency bias for the time needed to implement corrective actions. The Balancing Authority shall not unilaterally adjust generation in an attempt to return Interconnection frequency to normal beyond that supplied through frequency bias action and Interchange Schedule changes. Such unilateral adjustment may overload transmission facilities.

R6. If the Balancing Authority cannot comply with the Control Performance and Disturbance Control Standards, then it shall immediately implement remedies to do so. These remedies include, but are not limited to:

R6.1. Loading all available generating capacity.

R6.2. Deploying all available operating reserve.

R6.3. Interrupting interruptible load and exports.

R6.4. Requesting emergency assistance from other Balancing Authorities.

R6.5. Declaring an Energy Emergency through its Reliability Coordinator; and

R6.6. Reducing load, through procedures such as public appeals, voltage reductions, curtailing interruptible loads and firm loads.

R7. Once the Balancing Authority has exhausted the steps listed in Requirement 6, or if these steps cannot be completed in sufficient time to resolve the emergency condition, the Balancing Authority shall:

R7.1. Manually shed firm load without delay to return its ACE to zero; and

R7.2. Request the Reliability Coordinator to declare an Energy Emergency Alert in accordance with Attachment 1-EOP-002 "Energy Emergency Alerts."

R8. A Reliability Coordinator that has any Balancing Authority within its Reliability Coordinator area experiencing a potential or actual Energy Emergency shall initiate an Energy Emergency Alert as detailed in Attachment 1-EOP-002 "Energy Emergency Alerts." The Reliability Coordinator shall act to mitigate the emergency condition, including a request for emergency assistance if required.

R9. When a Transmission Service Provider expects to elevate the transmission service priority of an Interchange Transaction from Priority 6 (Network Integration Transmission Service from Non-designated Resources) to Priority 7 (Network Integration Transmission Service from designated Network Resources) as permitted in its transmission tariff:

R9.1. The deficient Load-Serving Entity shall request its Reliability Coordinator to initiate an Energy Emergency Alert in accordance with Attachment 1-EOP-002 "Energy Emergency Alerts."

R9.2. The Reliability Coordinator shall submit the report to NERC for posting on the NERC Website, noting the expected total MW that may have its transmission service priority changed.

R9.3. The Reliability Coordinator shall use EEA 1 to forecast the change of the priority of transmission service of an Interchange Transaction on the system from Priority 6 to Priority 7.

R9.4. The Reliability Coordinator shall use EEA 2 to announce the change of the priority of transmission service of an Interchange Transaction on the system from Priority 6 to Priority 7.

C. Measures

M1. Each Reliability Coordinator and Balancing Authority shall have and provide upon request evidence that could include but is not limited to, job descriptions, signed agreements, authority letter signed by an appropriate officer of the company, or other equivalent evidence that will be used to confirm that it meets Requirement 1.

M2. If a Reliability Coordinator or Balancing Authority implements one or more actions described in its Capacity and Energy Emergency plan, that entity shall have and provide upon request evidence that could include but is not limited to, operator logs, voice recordings or transcripts of voice recordings, electronic communications, computer printouts or other equivalent evidence that will be used to determine if the actions it took to relieve emergency conditions were in conformance with its Capacity and Energy Emergency Plan. (Requirement 2)

M3. If a Balancing Authority experiences an operating Capacity or Energy Emergency it shall have and provide upon request evidence that could include, but is not limited to operator logs, voice recordings or transcripts of voice recordings, electronic communications, or other equivalent evidence that will be used to determine if it met Requirement 3.

M4. The Balancing Authority shall have and provide upon request evidence (such as operator logs, work orders, E-Tags, or other evidence) that it took the actions described in R4 in response to anticipating a capacity or energy emergency.

M5. The Balancing Authority shall have and provide upon request evidence (such as operator logs, dispatch instructions, or other evidence) that it only used the assistance provided by the Interconnection frequency bias for the time needed to implement corrective actions and did not attempt to return Interconnection frequency to normal through unilateral adjustment of generation beyond that supplied through the frequency bias action and Interchange Schedule changes. (Requirement 5)

M6. The Balancing Authority shall have and provide upon request evidence (such as operator logs, dispatch instructions, or other evidence) that it took actions such as those listed in R6 to comply with CPS and DCS.

M7. The Balancing Authority shall have and provide upon request evidence (such as operator logs, voice recordings, or other evidence) that it took the actions listed in R7 when unable to resolve an emergency condition.

M8. If a Reliability Coordinator has any Balancing Authority within its Reliability Coordinator Area that has notified the Reliability Coordinator of a potential or actual Energy Emergency, the Reliability Coordinator involved in the event shall have and provide upon request evidence that could include, but is not limited to operator logs, voice recordings or transcripts of voice recordings, electronic communications, or other equivalent evidence to determine if it initiated an Energy Emergency Alert as specified in Requirement 8 and as detailed in Attachment 1-EOP-002 "Energy Emergency Alerts."

M9. If a Transmission Service Provider expects to elevate the transmission service priority of an Interchange Transaction from Priority 6 (Network Integration Transmission Service from Non-designated Resources) to Priority 7 (Network Integration Transmission Service from designated Network Resources), the Reliability Coordinator involved in the event shall have and provide upon request evidence that could include, but is not limited to, NERC reports, EEA reports, operator logs, voice recordings or transcripts of voice recordings, electronic communications, or other equivalent evidence that will be used to determine if that Reliability Coordinator met Requirements 9.2, 9.3 and 9.4.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

1.2. Compliance Monitoring Period and Reset Timeframe

Not Applicable.

1.3. Compliance Monitoring and Enforcement Process

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

1.4. Data Retention

For Measure 1, each Reliability Coordinator and Balancing Authority shall keep The current in-force documents.

For Measure 2, 8 and 9 the Reliability Coordinator shall keep 90 days of historical data.

For Measure 3, 4, 5, 6, and 7 the Balancing Authority shall keep 90 days of historical data.

If an entity is found non-compliant the entity shall keep information related to the noncompliance until found compliant or for two years plus the current year, whichever is longer.

Evidence used as part of a triggered investigation shall be retained by the entity being investigated for one year from the date that the investigation is closed, as determined by the Compliance Monitor.

The Compliance Monitor shall keep the last periodic audit report and all requested and submitted subsequent compliance records.

1.5. Additional Compliance Information

None.

E. Regional Differences

None identified.

Attachment 1-EOP-002
Energy Emergency Alerts

Introduction

This Attachment provides the procedures by which a Load Serving Entity can obtain capacity and energy when it has exhausted all other options and can no longer provide its customers' expected energy requirements. NERC defines this situation as an "Energy Emergency." NERC assumes that a capacity deficiency will manifest itself as an energy emergency.

The Energy Emergency Alert Procedure is initiated by the Load Serving Entity's Reliability Coordinator, who declares various Energy Emergency Alert levels as defined in Section B, "Energy Emergency Alert Levels," to provide assistance to the Load Serving Entity.

The Load Serving Entity who requests this assistance is referred to as an "Energy Deficient Entity."

NERC recognizes that Transmission Providers are subject to obligations under FERC-approved tariffs and other agreements, and nothing in these procedures should be interpreted as changing those obligations.

A. General Requirements

1. **Initiation by Reliability Coordinator.** An Energy Emergency Alert may be initiated only by a Reliability Coordinator at 1) the Reliability Coordinator's own request, or 2) upon the request of a Balancing Authority, or 3) upon the request of a Load Serving Entity.

   1.1. Situations for initiating alert. An Energy Emergency Alert may be initiated for the following reasons:

   - When the Load Serving Entity is, or expects to be, unable to provide its customers' energy requirements, and has been unsuccessful in locating other systems with available resources from which to purchase, or
   - The Load Serving Entity cannot schedule the resources due to, for example, Available Transfer Capability (ATC) limitations or transmission loading relief limitations.

2. **Notification.** A Reliability Coordinator who declares an Energy Emergency Alert shall notify all Balancing Authorities and Transmission Providers in its Reliability Area. The Reliability Coordinator shall also notify all other Reliability Coordinators of the situation via the Reliability Coordinator Information System (RCIS). Additionally, conference calls between Reliability Coordinators shall be held as necessary to communicate system conditions. The Reliability Coordinator shall also notify the other Reliability Coordinators when the alert has ended.

B. Energy Emergency Alert Levels

Introduction

To ensure that all Reliability Coordinators clearly understand potential and actual energy emergencies in the Interconnection, NERC has established three levels of Energy Emergency Alerts. The Reliability Coordinators will use these terms when explaining energy emergencies to each other. An Energy Emergency Alert is an emergency procedure, not a daily operating practice, and is not intended as an alternative to compliance with NERC reliability standards or power supply contracts.

The Reliability Coordinator may declare whatever alert level is necessary, and need not proceed through the alerts sequentially.

1. **Alert 1 — All available resources in use.**

Circumstances:

- Balancing Authority, Reserve Sharing Group, or Load Serving Entity foresees or is experiencing conditions where all available resources are committed to meet firm load, firm transactions, and reserve commitments, and is concerned about sustaining its required Operating Reserves, and
- Non-firm wholesale energy sales (other than those that are recallable to meet reserve requirements) have been curtailed.

2. **Alert 2 — Load management procedures in effect.**

Circumstances:

- Balancing Authority, Reserve Sharing Group, or Load Serving Entity is no longer able to provide its customers' expected energy requirements, and is designated an Energy Deficient Entity.
- Energy Deficient Entity foresees or has implemented procedures up to, but excluding, interruption of firm load commitments. When time permits, these procedures may include, but are not limited to:
  - Public appeals to reduce demand.
  - Voltage reduction.
  - Interruption of non-firm end use loads in accordance with applicable contracts[1].
  - Demand-side management.
  - Utility load conservation measures.

During Alert 2, Reliability Coordinators, Balancing Authorities, and Energy Deficient Entities have the following responsibilities:

2.1 Notifying other Balancing Authorities and market participants. The Energy Deficient Entity shall communicate its needs to other Balancing Authorities and market participants. Upon request from the Energy Deficient Entity, the respective Reliability Coordinator shall post the declaration of the alert level along with the name of the Energy Deficient Entity and, if applicable, its Balancing Authority on the NERC website.

2.2 Declaration period. The Energy Deficient Entity shall update its Reliability Coordinator of the situation at a minimum of every hour until the Alert 2 is terminated. The Reliability Coordinator shall update the energy deficiency information posted on the NERC website as changes occur and pass this information on to the affected Reliability Coordinators, Balancing Authority, and Transmission Providers.

2.3 Sharing information on resource availability. A Balancing Authority and market participants with available resources shall immediately contact the Energy Deficient Entity. This should include the possibility of selling non-firm (recallable) energy out of available Operating Reserves. The Energy Deficient Entity shall notify the Reliability Coordinators of the results.

2.4 Evaluating and mitigating transmission limitations. The Reliability Coordinators shall review all System Operating Limits (SOLs) and Interconnection Reliability Operating Limits (IROLs) and transmission loading relief procedures in effect that may limit the Energy Deficient Entity's scheduling capabilities. Where appropriate, the Reliability Coordinators shall inform

[1] For emergency, not economic, reasons.

the Transmission Providers under their purview of the pending Energy Emergency and request that they increase their ATC by actions such as restoring transmission elements that are out of service, reconfiguring their transmission system, adjusting phase angle regulator tap positions, implementing emergency operating procedures, and reviewing generation redispatch options.

2.4.1 Notification of ATC adjustments. Resulting increases in ATCs shall be simultaneously communicated to the Energy Deficient Entity and the market via posting on the appropriate OASIS websites by the Transmission Providers.

2.4.2 Availability of generation redispatch options. Available generation redispatch options shall be immediately communicated to the Energy Deficient Entity by its Reliability Coordinator.

2.4.3 Evaluating impact of current transmission loading relief events. The Reliability Coordinators shall evaluate the impact of any current transmission loading relief events on the ability to supply emergency assistance to the Energy Deficient Entity. This evaluation shall include analysis of system reliability and involve close communication among Reliability Coordinators and the Energy Deficient Entity.

2.4.4 Initiating inquiries on reevaluating SOLs and IROLs. The Reliability Coordinators shall consult with the Balancing Authorities and Transmission Providers in their Reliability Areas about the possibility of reevaluating and revising SOLs or IROLs.

2.5 Coordination of emergency responses. The Reliability Coordinator shall communicate and coordinate the implementation of emergency operating responses.

2.6 Energy Deficient Entity actions. Before declaring an Alert 3, the Energy Deficient Entity must make use of all available resources. This includes but is not limited to:

2.6.1 All available generation units are on line. All generation capable of being on line in the time frame of the emergency is on line including quick-start and peaking units, regardless of cost.

2.6.2 Purchases made regardless of cost. All firm and non-firm purchases have been made, regardless of cost.

2.6.3 Non-firm sales recalled and contractually interruptible loads and demand-side management curtailed. All non-firm sales have been recalled, contractually interruptible retail loads curtailed, and demand-side management activated within provisions of the agreements.

2.6.4 Operating Reserves. Operating reserves are being utilized such that the Energy Deficient Entity is carrying reserves below the required minimum or has initiated emergency assistance through its operating reserve sharing program.

3. Alert 3 — Firm load interruption imminent or in progress.

Circumstances:

- Balancing Authority or Load Serving Entity foresees or has implemented firm load obligation interruption. The available energy to the Energy Deficient Entity, as determined from Alert 2, is only accessible with actions taken to increase transmission transfer capabilities.

3.1 Continue actions from Alert 2. The Reliability Coordinators and the Energy Deficient Entity shall continue to take all actions initiated during Alert 2. If the emergency has not already been posted on the NERC website (see paragraph 2.1), the respective Reliability Coordinators will, at this time, post on the website information concerning the emergency.

3.2 Declaration Period. The Energy Deficient Entity shall update its Reliability Coordinator of the situation at a minimum of every hour until the Alert 3 is terminated. The Reliability Coordinator shall update the energy deficiency information posted on the NERC website as changes occur and pass this information on to the affected Reliability Coordinators (via the RCIS), Balancing Authorities, and Transmission Providers.

3.3 Use of Transmission short-time limits. The Reliability Coordinators shall request the appropriate Transmission Providers within their Reliability Area to utilize available short-time transmission limits or other emergency operating procedures in order to increase transfer capabilities into the Energy Deficient Entity.

3.4 Reevaluating and revising SOLs and IROLs. The Reliability Coordinator of the Energy Deficient Entity shall evaluate the risks of revising SOLs and IROLs on the reliability of the overall transmission system. Reevaluation of SOLs and IROLs shall be coordinated with other Reliability Coordinators and only with the agreement of the Balancing Authority or Transmission Operator whose equipment would be affected. The resulting increases in transfer capabilities shall only be made available to the Energy Deficient Entity who has requested an Energy Emergency Alert 3 condition. SOLs and IROLs shall only be revised as long as an Alert 3 condition exists or as allowed by the Balancing Authority or Transmission Operator whose equipment is at risk. The following are minimum requirements that must be met before SOLs or IROLs are revised:

3.4.1 Energy Deficient Entity obligations. The deficient Balancing Authority or Load Serving Entity must agree that, upon notification from its Reliability Coordinator of the situation, it will immediately take whatever actions are necessary to mitigate any undue risk to the Interconnection. These actions may include load shedding.

3.4.2 Mitigation of cascading failures. The Reliability Coordinator shall use its best efforts to ensure that revising SOLs or IROLs would not result in any cascading failures within the Interconnection.

3.5 Returning to pre-emergency Operating Security Limits. Whenever energy is made available to an Energy Deficient Entity such that the transmission systems can be returned to their pre-emergency SOLs or IROLs, the Energy Deficient Entity shall notify its respective Reliability Coordinator and downgrade the alert.

3.5.1 Notification of other parties. Upon notification from the Energy Deficient Entity that an alert has been downgraded, the Reliability Coordinator shall notify the affected Reliability Coordinators (via the RCIS), Balancing Authorities, and Transmission Providers that their systems can be returned to their normal limits.

3.6 Reporting. Any time an Alert 3 is declared, the Energy Deficient Entity shall submit the report enclosed in this Attachment to its respective Reliability Coordinator within two business days of downgrading or termination of the alert. Upon receiving the report, the Reliability Coordinator shall review it for completeness and immediately forward it to the NERC staff for posting on the NERC website. The Reliability Coordinator shall present this report to the Reliability Coordinator Working Group at its next scheduled meeting.

4. Alert 0 - Termination. When the Energy Deficient Entity believes it will be able to supply its customers' energy requirements, it shall request of its Reliability Coordinator that the EEA be terminated.

4.1. Notification. The Reliability Coordinator shall notify all other Reliability Coordinators via the RCIS of the termination. The Reliability Coordinator shall also notify the affected Balancing Authorities and Transmission Operators. The Alert 0 shall also be posted on the NERC website if the original alert was so posted.

C. Energy Emergency Alert 3 Report

A Deficient Balancing Authority or Load Serving Entity declaring an Energy Emergency Alert 3 must complete the following report. Upon completion of this report, it is to be sent to the Reliability Coordinator for review within two business days of the incident.

Requesting Balancing Authority:

Entity experiencing energy deficiency (if different from Balancing Authority):

Date/Time Implemented:

Date/Time Released:

Declared Deficiency Amount (MW):

Total energy supplied by other Balancing Authority during the Alert 3 period:

Conditions that precipitated call for "Energy Deficiency Alert 3":

If "Energy Deficiency Alert 3" had not been called, would firm load be cut? If no, explain:

Explain what action was taken in each step to avoid calling for "Energy Deficiency Alert 3":

1. **All generation capable of being on line in the time frame of the energy deficiency was on line (including quick start and peaking units) without regard to cost.**

2. **All firm and nonfirm purchases were made regardless of cost.**

3. **All nonfirm sales were recalled within provisions of the sale agreement.**

4. **Interruptible load was curtailed where either advance notice restrictions were met or the interruptible load was considered part of spinning reserve.**

5. **Available load reduction programs were exercised (public appeals, voltage reductions, etc.).**

6. **Operating Reserves being utilized.**

Comments:

Reported By: **Organization:**

Title:

A. Introduction

1. **Title:** **Real Power Balancing Control Performance**

2. **Number:** **BAL-001-2**

3. **Purpose:** To control Interconnection frequency within defined limits.

4. **Applicability:**

 4.1. Balancing Authority

  4.1.1 A Balancing Authority receiving Overlap Regulation Service is not subject to Control Performance Standard 1 (CPS1) or Balancing Authority ACE Limit (BAAL) compliance evaluation.

  4.1.2 A Balancing Authority that is a member of a Regulation Reserve Sharing Group is the Responsible Entity only in periods during which the Balancing Authority is not in active status under the applicable agreement or the governing rules for the Regulation Reserve Sharing Group.

 4.2. Regulation Reserve Sharing Group

5. **(Proposed) Effective Date:**

 5.1. First day of the first calendar quarter that is twelve months beyond the date that this standard is approved by applicable regulatory authorities, or in those jurisdictions where regulatory approval is not required, the standard becomes effective the first day of the first calendar quarter that is twelve months beyond the date this standard is approved by the NERC Board of Trustees, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

B. Requirements

R1. The Responsible Entity shall operate such that the Control Performance Standard 1 (CPS1), calculated in accordance with Attachment 1, is greater than or equal to 100 percent for the applicable Interconnection in which it operates for each preceding 12 consecutive calendar month period, evaluated monthly. *[Violation Risk Factor: Medium] [Time Horizon: Real-time Operations]*

R2. Each Balancing Authority shall operate such that its clock-minute average of Reporting ACE does not exceed its clock-minute Balancing Authority ACE Limit (BAAL) for more than 30 consecutive clock-minutes, calculated in accordance with Attachment 2, for the applicable Interconnection in which the Balancing Authority operates. *[Violation Risk Factor: Medium] [Time Horizon: Real-time Operations]*

C. Measures

M1. The Responsible Entity shall provide evidence, upon request, such as dated calculation output from spreadsheets, system logs, software programs, or other evidence (either in hard copy or electronic format) to demonstrate compliance with Requirement R1.

M2. Each Balancing Authority shall provide evidence, upon request, such as dated calculation output from spreadsheets, system logs, software programs, or other evidence (either in hard copy or electronic format) to demonstrate compliance with Requirement R2.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

As defined in the NERC Rules of Procedure, "Compliance Enforcement Authority" means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

1.2. Data Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The Responsible Entity shall retain data or evidence to show compliance for the current year, plus three previous calendar years unless, directed by its Compliance Enforcement Authority, to retain specific evidence for a longer period of time as part of an investigation. Data required for the calculation of Regulation Reserve Sharing Group Reporting Ace, or Reporting ACE, CPS1, and BAAL shall be retained in digital format at the same scan rate at which the Reporting ACE is calculated for the current year, plus three previous calendar years.

If a Responsible Entity is found noncompliant, it shall keep information related to the noncompliance until found compliant, or for the time period specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all subsequent requested and submitted records.

1.3. Compliance Monitoring and Assessment Processes

Compliance Audits

Self-Certifications

Spot Checking

Compliance Investigation

Self-Reporting

Complaints

1.4. Additional Compliance Information

None.

2. Violation Severity Levels

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The CPS 1 value of the Responsible Entity, for the preceding 12 consecutive calendar month period, is less than 100 percent but greater than or equal to 95 percent for the applicable Interconnection.	The CPS 1 value of the Responsible Entity, for the preceding 12 consecutive calendar month period, is less than 95 percent, but greater than or equal to 90 percent for the applicable Interconnection.	The CPS 1 value of the Responsible Entity, for the preceding 12 consecutive calendar month period, is less than 90 percent, but greater than or equal to 85 percent for the applicable Interconnection.	The CPS 1 value of the Responsible Entity, for the preceding 12 consecutive calendar month period, is less than 85 percent for the applicable Interconnection.
R2	The Balancing Authority exceeded its clock-minute BAAL for more than 30 consecutive clock minutes but for 45 consecutive clock-minutes or less for the applicable Interconnection.	The Balancing Authority exceeded its clock-minute BAAL for greater than 45 consecutive clock minutes but for 60 consecutive clock-minutes or less for the applicable Interconnection.	The Balancing Authority exceeded its clock-minute BAAL for greater than 60 consecutive clock minutes but for 75 consecutive clock-minutes or less for the applicable Interconnection.	The Balancing Authority exceeded its clock-minute BAAL for greater than 75 consecutive clock-minutes for the applicable Interconnection.

E. Regional Variances

None.

0	July 24, 2007	Corrected R3 to reference M1 and M2 instead of R1 and R2	Errata
0a	December 19, 2007	Added Appendix 2 – Interpretation of R1 approved by BOT on October 23, 2007	Revised
0a	January 16, 2008	In Section A.2., Added "a" to end of standard number In Section F, corrected automatic numbering from "2" to "1" and removed "approved" and added parenthesis to "(October 23, 2007)"	Errata
0	January 23, 2008	Reversed errata change from July 24, 2007	Errata
0.1a	October 29, 2008	Board approved errata changes; updated version number to "0.1a"	Errata
0.1a	May 13, 2009	Approved by FERC	
1		Inclusion of BAAL and WECC Variance and exclusion of CPS2	Revision
1	December 19, 2012	Adopted by NERC Board of Trustees	
2	August 15, 2013	Adopted by the NERC Board of Trustees	
2	April 16, 2015	FERC Order issued approving BAL-001-2	

Attachment 1
Equations Supporting Requirement R1 and Measure M1

CPS1 is calculated as follows:

$$CPS1 = (2 - CF) * 100\%$$

The frequency-related compliance factor (CF), is a ratio of the accumulating clock-minute compliance parameters for the most recent preceding 12 consecutive calendar months, divided by the square of the target frequency bound:

$$CF = \frac{CF_{12\text{-month}}}{(\varepsilon 1_I)^2}$$

Where $\varepsilon 1_I$ is the constant derived from a targeted frequency bound for each Interconnection as follows:

- Eastern Interconnection $\varepsilon 1_I$ = 0.018 Hz
- Western Interconnection $\varepsilon 1_I$ = 0.0228 Hz
- ERCOT Interconnection $\varepsilon 1_I$ = 0.030 Hz
- Quebec Interconnection $\varepsilon 1_I$ = 0.021 Hz

The rating index $CF_{12\text{-month}}$ is derived from the most recent preceding 12 consecutive calendar months of data. The accumulating clock-minute compliance parameters are derived from the one-minute averages of Reporting ACE, Frequency Error, and Frequency Bias Settings.
A clock-minute average is the average of the reporting Balancing Authority's valid measured variable (i.e., for Reporting ACE (RACE) and for Frequency Error) for each sampling cycle during a given clock-minute.

$$\left(\frac{RACE}{-10B}\right)_{\text{clock-minute}} = \frac{\left(\dfrac{\sum RACE_{\text{sampling cycles in clock-minute}}}{n_{\text{sampling cycles in clock-minute}}}\right)}{-10B}$$

And,

$$\Delta F_{\text{clock-minute}} = \frac{\sum \Delta F_{\text{sampling cycles in clock-minute}}}{n_{\text{sampling cycles in clock-minute}}}$$

The Balancing Authority's clock-minute compliance factor ($CF_{\text{clock-minute}}$) calculation is:

$$CF_{\text{clock-minute}} = \left[\left(\frac{RACE}{-10B} \right)_{\text{clock-minute}} * \Delta F_{\text{clock-minute}} \right]$$

Normally, 60 clock-minute averages of the reporting Balancing Authority's Reporting ACE and Frequency Error will be used to compute the hourly average compliance factor ($CF_{\text{clock-hour}}$).

$$CF_{\text{clock-hour}} = \frac{\sum CF_{\text{clock-minute}}}{n_{\text{clock-minute samples in hour}}}$$

The reporting Balancing Authority shall be able to recalculate and store each of the respective clock-hour averages ($CF_{\text{clock-hour average-month}}$) and the data samples for each 24-hour period (one for each clock-hour; i.e., hour ending (HE) 0100, HE 0200, ..., HE 2400). To calculate the monthly compliance factor (CF_{month}):

$$CF_{\text{clock-hour average-month}} = \frac{\sum_{\text{days-in-month}} [(CF_{\text{clock-hour}})(n_{\text{one-minute samples in clock-hour}})]}{\sum_{\text{days-in month}} [n_{\text{one-minute samples in clock-hour}}]}$$

$$CF_{\text{month}} = \frac{\sum_{\text{hours-in-day}} [(CF_{\text{clock-hour average-month}})(n_{\text{one-minute samples in clock-hour averages}})]}{\sum_{\text{hours-in day}} [n_{\text{one-minute samples in clock-hour averages}}]}$$

To calculate the 12-month compliance factor ($CF_{\text{12 month}}$):

$$CF_{\text{12-month}} = \frac{\sum_{i=1}^{12} (CF_{\text{month-i}})(n_{(\text{one-minute samples in month})-i})]}{\sum_{i=1}^{12} [n_{(\text{one-minute samples in month})-i}]}$$

To ensure that the average Reporting ACE and Frequency Error calculated for any one-minute interval is representative of that time interval, it is necessary that at least 50 percent of both the Reporting ACE and Frequency Error sample data during the one-minute interval is valid. If the recording of Reporting ACE or Frequency Error is interrupted such that less than 50 percent of the one-minute sample period data is available or valid, then that one-minute interval is excluded from the CPS1 calculation.

A Balancing Authority providing Overlap Regulation Service to another Balancing Authority calculates its CPS1 performance after combining its Reporting ACE and Frequency Bias

Settings with the Reporting ACE and Frequency Bias Settings of the Balancing Authority receiving the Regulation Service.

Attachment 2

Equations Supporting Requirement R2 and Measure M2

When actual frequency is equal to Scheduled Frequency, $BAAL_{High}$ and $BAAL_{Low}$ do not apply.

When actual frequency is less than Scheduled Frequency, $BAAL_{High}$ does not apply, and $BAAL_{Low}$ is calculated as:

$$BAAL_{Low} = \left(-10B_i \times \left(FTL_{Low} - F_S\right)\right) \times \frac{\left(FTL_{Low} - F_S\right)}{\left(F_A - F_S\right)}$$

When actual frequency is greater than Scheduled Frequency, $BAAL_{Low}$ does not apply and the $BAAL_{High}$ is calculated as:

$$BAAL_{High} = \left(-10B_i \times \left(FTL_{High} - F_S\right)\right) \times \frac{\left(FTL_{High} - F_S\right)}{\left(F_A - F_S\right)}$$

Where:

$BAAL_{Low}$ is the Low Balancing Authority ACE Limit (MW)

$BAAL_{High}$ is the High Balancing Authority ACE Limit (MW)

10 is a constant to convert the Frequency Bias Setting from MW/0.1 Hz to MW/Hz

B_i is the Frequency Bias Setting for a Balancing Authority (expressed as MW/0.1 Hz)

F_A is the measured frequency in Hz.

F_S is the scheduled frequency in Hz.

FTL_{Low} is the Low Frequency Trigger Limit (calculated as $F_S - 3\varepsilon1_I$ Hz)

FTL_{High} is the High Frequency Trigger Limit (calculated as $F_S + 3\varepsilon1_I$ Hz)

Where $\varepsilon1_I$ is the constant derived from a targeted frequency bound for each Interconnection as follows:

- Eastern Interconnection $\varepsilon1_I$ = 0.018 Hz
- Western Interconnection $\varepsilon1_I$ = 0.0228 Hz
- ERCOT Interconnection $\varepsilon1_I$ = 0.030 Hz
- Quebec Interconnection $\varepsilon1_I$ = 0.021 Hz

To ensure that the average actual frequency calculated for any one-minute interval is representative of that time interval, it is necessary that at least 50% of the actual frequency sample data during that one-minute interval is valid. If the recording of actual frequency is interrupted such that less than 50 percent of the one-minute sample period data is available or valid, then that one-minute interval is excluded from the BAAL calculation and the 30-minute clock would be reset to zero.

A Balancing Authority providing Overlap Regulation Service to another Balancing Authority calculates its BAAL performance after combining its Frequency Bias Setting with the Frequency Bias Setting of the Balancing Authority receiving Overlap Regulation Service.

A. Introduction

1. **Title:** **System Operating Limits Methodology for the Operations Horizon**

2. **Number:** FAC-011-2

3. **Purpose:** To ensure that System Operating Limits (SOLs) used in the reliable operation of the Bulk Electric System (BES) are determined based on an established methodology or methodologies.

4. **Applicability**

   4.1. Reliability Coordinator

5. **Effective Date:** April 29, 2009

B. Requirements

R1. The Reliability Coordinator shall have a documented methodology for use in developing SOLs (SOL Methodology) within its Reliability Coordinator Area. This SOL Methodology shall:

R1.1. Be applicable for developing SOLs used in the operations horizon.

R1.2. State that SOLs shall not exceed associated Facility Ratings.

R1.3. Include a description of how to identify the subset of SOLs that qualify as IROLs.

R2. The Reliability Coordinator's SOL Methodology shall include a requirement that SOLs provide BES performance consistent with the following:

R2.1. In the pre-contingency state, the BES shall demonstrate transient, dynamic and voltage stability; all Facilities shall be within their Facility Ratings and within their thermal, voltage and stability limits. In the determination of SOLs, the BES condition used shall reflect current or expected system conditions and shall reflect changes to system topology such as Facility outages.

R2.2. Following the single Contingencies[1] identified in Requirement 2.2.1 through Requirement 2.2.3, the system shall demonstrate transient, dynamic and voltage stability; all Facilities shall be operating within their Facility Ratings and within their thermal, voltage and stability limits; and Cascading or uncontrolled separation shall not occur.

R2.2.1. Single line to ground or 3-phase Fault (whichever is more severe), with Normal Clearing, on any Faulted generator, line, transformer, or shunt device.

R2.2.2. Loss of any generator, line, transformer, or shunt device without a Fault.

R2.2.3. Single pole block, with Normal Clearing, in a monopolar or bipolar high voltage direct current system.

R2.3. In determining the system's response to a single Contingency, the following shall be acceptable:

R2.3.1. Planned or controlled interruption of electric supply to radial customers or some local network customers connected to or supplied by the Faulted Facility or by the affected area.

---

[1] The Contingencies identified in FAC-011 R2.2.1 through R2.2.3 are the minimum contingencies that must be studied but are not necessarily the only Contingencies that should be studied.

R2.3.2. Interruption of other network customers, (a) only if the system has already been adjusted, or is being adjusted, following at least one prior outage, or (b) if the real-time operating conditions are more adverse than anticipated in the corresponding studies

R2.3.3. System reconfiguration through manual or automatic control or protection actions.

R2.4. To prepare for the next Contingency, system adjustments may be made, including changes to generation, uses of the transmission system, and the transmission system topology.

R3. The Reliability Coordinator's methodology for determining SOLs, shall include, as a minimum, a description of the following, along with any reliability margins applied for each:

R3.1. Study model (must include at least the entire Reliability Coordinator Area as well as the critical modeling details from other Reliability Coordinator Areas that would impact the Facility or Facilities under study.)

R3.2. Selection of applicable Contingencies

R3.3. A process for determining which of the stability limits associated with the list of multiple contingencies (provided by the Planning Authority in accordance with FAC-014 Requirement 6) are applicable for use in the operating horizon given the actual or expected system conditions.

R3.3.1. This process shall address the need to modify these limits, to modify the list of limits, and to modify the list of associated multiple contingencies.

R3.4. Level of detail of system models used to determine SOLs.

R3.5. Allowed uses of Special Protection Systems or Remedial Action Plans.

R3.6. Anticipated transmission system configuration, generation dispatch and Load level

R3.7. Criteria for determining when violating a SOL qualifies as an Interconnection Reliability Operating Limit (IROL) and criteria for developing any associated IROL T_v.

R4. The Reliability Coordinator shall issue its SOL Methodology and any changes to that methodology, prior to the effectiveness of the Methodology or of a change to the Methodology, to all of the following:

R4.1. Each adjacent Reliability Coordinator and each Reliability Coordinator that indicated it has a reliability-related need for the methodology.

R4.2. Each Planning Authority and Transmission Planner that models any portion of the Reliability Coordinator's Reliability Coordinator Area.

R4.3. Each Transmission Operator that operates in the Reliability Coordinator Area.

R5. If a recipient of the SOL Methodology provides documented technical comments on the methodology, the Reliability Coordinator shall provide a documented response to that recipient within 45 calendar days of receipt of those comments. The response shall indicate whether a change will be made to the SOL Methodology and, if no change will be made to that SOL Methodology, the reason why. (Retirement approved by FERC effective January 21, 2014.)

C. Measures

M1. The Reliability Coordinator's SOL Methodology shall address all of the items listed in Requirement 1 through Requirement 3.

M2. The Reliability Coordinator shall have evidence it issued its SOL Methodology, and any changes to that methodology, including the date they were issued, in accordance with Requirement 4.

M3. If the recipient of the SOL Methodology provides documented comments on its technical review of that SOL methodology, the Reliability Coordinator that distributed that SOL Methodology shall have evidence that it provided a written response to that commenter within 45 calendar days of receipt of those comments in accordance with Requirement 5. (Retirement approved by FERC effective January 21, 2014.)

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Regional Reliability Organization

1.2. Compliance Monitoring Period and Reset Time Frame

Each Reliability Coordinator shall self-certify its compliance to the Compliance Monitor at least once every three years. New Reliability Authorities shall demonstrate compliance through an on-site audit conducted by the Compliance Monitor within the first year that it commences operation. The Compliance Monitor shall also conduct an on-site audit once every nine years and an investigation upon complaint to assess performance.

The Performance-Reset Period shall be twelve months from the last non-compliance.

1.3. Data Retention

The Reliability Coordinator shall keep all superseded portions to its SOL Methodology for 12 months beyond the date of the change in that methodology ~~and shall keep all documented comments on its SOL Methodology and associated responses for three years~~. In addition, entities found non-compliant shall keep information related to the non-compliance until found compliant. (Deleted text retired-Retirement approved by FERC effective January 21, 2014.)

The Compliance Monitor shall keep the last audit and all subsequent compliance records.

1.4. Additional Compliance Information

The Reliability Coordinator shall make the following available for inspection during an on-site audit by the Compliance Monitor or within 15 business days of a request as part of an investigation upon complaint:

1.4.1 SOL Methodology.

1.4.2 Documented comments provided by a recipient of the SOL Methodology on its technical review of a SOL Methodology, and the associated responses. (Retirement approved by FERC effective January 21, 2014.)

1.4.3 Superseded portions of its SOL Methodology that had been made within the past 12 months.

1.4.4 Evidence that the SOL Methodology and any changes to the methodology that occurred within the past 12 months were issued to all required entities.

2. Levels of Non-Compliance for Western Interconnection: (To be replaced with VSLs once developed and approved by WECC)

2.1. Level 1: There shall be a level one non-compliance if either of the following conditions exists:

2.1.1 The SOL Methodology did not include a statement indicating that Facility Ratings shall not be exceeded.

2.1.2 No evidence of responses to a recipient's comments on the SOL Methodology (Retirement approved by FERC effective January 21, 2014.)

2.2. Level 2: The SOL Methodology did not include a requirement to address all of the elements in R3.1, R3.2, R3.4 through R3.7 and E1.

2.3. Level 3: There shall be a level three non-compliance if any of the following conditions exists:

2.3.1 The SOL Methodology did not include a statement indicating that Facility Ratings shall not be exceeded and the methodology did not include evaluation of system response to one of the three types of single Contingencies identified in R2.2.

2.3.2 The SOL Methodology did not include a statement indicating that Facility Ratings shall not be exceeded and the methodology did not include evaluation of system response to two of the seven types of multiple Contingencies identified in E1.1.

2.3.3 The System Operating Limits Methodology did not include a statement indicating that Facility Ratings shall not be exceeded and the methodology did not address two of the six required topics in R3.1, R3.2, R3.4 through R3.7.

2.4. Level 4: The SOL Methodology was not issued to all required entities in accordance with R4.

3. Violation Severity Levels:

Requirement	Lower	Moderate	High	Severe
R1	Not applicable.	The Reliability Coordinator has a documented SOL Methodology for use in developing SOLs within its Reliability Coordinator Area, but it does not address R1.2	The Reliability Coordinator has a documented SOL Methodology for use in developing SOLs within its Reliability Coordinator Area, but it does not address R1.3.	The Reliability Coordinator has a documented SOL Methodology for use in developing SOLs within its Reliability Coordinator Area, but it does not address R1.1. OR The Reliability Coordinator has no documented SOL Methodology for use in developing SOLs within its Reliability Coordinator Area.
R2	The Reliability Coordinator's SOL Methodology requires that SOLs are set to meet BES performance following single contingencies, but does not require that SOLs are set to meet BES performance in the pre-contingency state. (R2.1)	Not applicable.	The Reliability Coordinator's SOL Methodology requires that SOLs are set to meet BES performance in the pre-contingency state, but does not require that SOLs are set to meet BES performance following single contingencies. (R2.2 – R2.4)	The Reliability Coordinator's SOL Methodology does not require that SOLs are set to meet BES performance in the pre-contingency state and does not require that SOLs are set to meet BES performance following single contingencies. (R2.1 through R2.4)
R3	The Reliability Coordinator's SOL Methodology includes a description for all but one of the following: R3.1 through R3.7.	The Reliability Coordinator's SOL Methodology includes a description for all but two of the following: R3.1 through R3.7.	The Reliability Coordinator's SOL Methodology includes a description for all but three of the following: R3.1 through R3.7.	The Reliability Coordinator's SOL Methodology is missing a description of four or more of the following: R3.1 through R3.7.
R3.6	N/A	N/A	N/A	N/A
R4	The Reliability Coordinator failed to issue its SOL Methodology and/or one or more changes to that methodology to one of the required entities specified in R4.1, R4.2, and R4.3.	The Reliability Coordinator failed to issue its SOL Methodology and/or one or more changes to that methodology to two of the required entities specified in R4.1, R4.2, and R4.3.	The Reliability Coordinator failed to issue its SOL Methodology and/or one or more changes to that methodology to three of the required entities specified in R4.1, R4.2, and R4.3.	The Reliability Coordinator failed to issue its SOL Methodology and/or one or more changes to that methodology to four or more of the required entities specified in R4.1, R4.2, and R4.3

Requirement	Lower	Moderate	High	Severe
	OR For a change in methodology, the changed methodology was provided to one or more of the required entities before the effectiveness of the change, but was provided to all the required entities no more than 10 calendar days after the effectiveness of the change.	OR For a change in methodology, the changed methodology was provided to one or more of the required entities more than 10 calendar days after the effectiveness of the change, but less than or equal to 20 days after the effectiveness of the change.	OR For a change in methodology, the changed methodology was provided to one or more of required entities more than 20 calendar days after the effectiveness of the change, but less than or equal to30 days after the effectiveness of the change.	OR For a change in methodology, the changed methodology was provided to one or more of the required entities more than30 calendar days after the effectiveness of the change.
R5 (Retirement approved by FERC effective January 21, 2014.)	The Reliability Coordinator received documented technical comments on its SOL Methodology and provided a complete response in a time period that was longer than 45 calendar days but less than 60 calendar days.	The Reliability Coordinator received documented technical comments on its SOL Methodology and provided a complete response in a time period that was 60 calendar days or longer but less than 75 calendar days.	The Reliability Coordinator received documented technical comments on its SOL Methodology and provided a complete response in a time period that was 75 calendar days or longer but less than 90 calendar days. OR The Reliability Coordinator's response to documented technical comments on its SOL Methodology indicated that a change will not be made, but did not include an explanation of why the change will not be made.	The Reliability Coordinator received documented technical comments on its SOL Methodology and provided a complete response in a time period that was 90 calendar days or longer. OR The Reliability Coordinator's response to documented technical comments on its SOL Methodology did not indicate whether a change will be made to the SOL Methodology.

Regional Differences

1. The following Interconnection-wide Regional Difference shall be applicable in the Western Interconnection:

   1.1. As governed by the requirements of R3.3, starting with all Facilities in service, shall require the evaluation of the following multiple Facility Contingencies when establishing SOLs:

   1.1.1 Simultaneous permanent phase to ground Faults on different phases of each of two adjacent transmission circuits on a multiple circuit tower, with Normal Clearing. If multiple circuit towers are used only for station entrance and exit purposes, and if they do not exceed five towers at each station, then this condition is an acceptable risk and therefore can be excluded.

   1.1.2 A permanent phase to ground Fault on any generator, transmission circuit, transformer, or bus section with Delayed Fault Clearing except for bus sectionalizing breakers or bus-tie breakers addressed in E1.1.7

   1.1.3 Simultaneous permanent loss of both poles of a direct current bipolar Facility without an alternating current Fault.

   1.1.4 The failure of a circuit breaker associated with a Special Protection System to operate when required following: the loss of any element without a Fault; or a permanent phase to ground Fault, with Normal Clearing, on any transmission circuit, transformer or bus section.

   1.1.5 A non-three phase Fault with Normal Clearing on common mode Contingency of two adjacent circuits on separate towers unless the event frequency is determined to be less than one in thirty years.

   1.1.6 A common mode outage of two generating units connected to the same switchyard, not otherwise addressed by FAC-011.

   1.1.7 The loss of multiple bus sections as a result of failure or delayed clearing of a bus tie or bus sectionalizing breaker to clear a permanent Phase to Ground Fault.

   1.2. SOLs shall be established such that for multiple Facility Contingencies in E1.1.1 through E1.1.5 operation within the SOL shall provide system performance consistent with the following:

   1.2.1 All Facilities are operating within their applicable Post-Contingency thermal, frequency and voltage limits.

   1.2.2 Cascading does not occur.

   1.2.3 Uncontrolled separation of the system does not occur.

   1.2.4 The system demonstrates transient, dynamic and voltage stability.

   1.2.5 Depending on system design and expected system impacts, the controlled interruption of electric supply to customers (load shedding), the planned removal from service of certain generators, and/or the curtailment of contracted firm (non-recallable reserved) electric power transfers may be necessary to maintain the overall security of the interconnected transmission systems.

   1.2.6 Interruption of firm transfer, Load or system reconfiguration is permitted through manual or automatic control or protection actions.

1.2.7 To prepare for the next Contingency, system adjustments are permitted, including changes to generation, Load and the transmission system topology when determining limits.

1.3. SOLs shall be established such that for multiple Facility Contingencies in E1.1.6 through E1.1.7 operation within the SOL shall provide system performance consistent with the following with respect to impacts on other systems:

1.3.1 Cascading does not occur.

1.4. The Western Interconnection may make changes (performance category adjustments) to the Contingencies required to be studied and/or the required responses to Contingencies for specific facilities based on actual system performance and robust design. Such changes will apply in determining SOLs.

2	February 24, 2014	Updated VSLs based on June 24, 2013 approval.	

AUGUST 18, 2015

Framework for NO_x RTC Allocations

This paper provides an informal outline of a possible framework for the allocation of NO_x RTCs to the electric generating units (EGUs) under the RECLAIM program. The objective of this proposed framework is to establish an effective regulatory approach for AQMD to meet its ozone reasonable further progress goals for reducing NO_x emissions under the Clean Air Act. The NO_x emissions for EGUs represent a very small share (less than 3 tons per day during 2011-2013) of the total NO_x emissions in the region (about 550 tons per day estimated for 2016). Part of the strategy to reduce NO_x levels in the region is to electrify sources that are currently burning fossil fuels. Specifically, the increased electricity generation will result in small increases in NO_x at EGU, but those emissions will be more than offset by substantial NO_x emission reductions at the newly electrified sources. Several of those source categories provide large opportunities to reduce overall NO_x emissions: off road equipment, locomotives, ships and commercial boats, and passenger vehicles, SUVs and light duty trucks. Electrification of even portion of these sources will result in substantial overall NO_x reductions. The AQMD's forecasts indicate NO_x reductions in excess of 200 tons per day from forecast 2023 levels are required to keep the region on track for attainment of the current 2008 ozone standard. Notably, electrification of sources that currently burn fossil fuels also increases efficiency so it will be an important tool in achieving the ozone NAAQS as well as the California's CO_2 emission goals under federal and state regulatory programs.

As reflected in the matrix below, the proposed approach would establish the following three "building blocks" for the allocation of NO_x RTCs to affected EGUs: (1) Tradable RTCs allocated to serve native load (forecast demand absent additional electrification programs); (2) Non-tradable RTCs allocated to cover increased generation resulting from mandatory electrification measures established by the ARB or AQMD; and (3) Non-tradable RTCs allocated to cover increased generation resulting from non-mandatory electrification measures and incentives that the ARB, AQMD or electric utilities may promote. Under the proposed approach, RTCs allocated under building block 1 cannot be reduced under any circumstances given that they need to cover native load, while RTCs allocated under building blocks 2 and 3 can be adjusted to reflect the actual amount of increased demand that results from electrification measures actually implemented.

There are several ways that the AQMD could incorporate the non-mandatory electrification measures and incentives into its SIP and receive NO_x emission reduction credit for meeting its ozone reasonable further progress goals under the Clean Air Act. One such approach is the "state measure" approach[1] that EPA has established for a state to meet its applicable CO_2 emission rate target under the Clean Power Plan. In so doing, EPA states that the state plan would include an enforceable commitment by the state itself to implement state-enforceable (but not federally enforceable) measures that would achieve specified portion of the required emission performance level on behalf of affected EGUs. The key difference between the traditional federal-state regulatory approach and EPA's "state measures" approach is that instead of private entities, such as affected EGUs, being responsible for obtaining specific emission reductions, the state adopts a plan that makes itself responsible for ensuring the implementation of the particular state measures in order to meet its federal emission reduction obligations. A similar regulatory approach could be implemented by the AQMD in order to meet its ozone reasonable further progress goals for reducing NO_x emissions under the Clean Air Act.

Finally, it should be noted that EPA has suggested that a "state measure" approach should include a number of key measures in order to guarantee the achievement of the targeted emissions reductions. In particular, it may be necessary for a state to support its state measures with clear initial demonstrations that the required reductions will be achieved, regular reporting during the compliance period, and clear contingency and federally enforceable backstop measures if the expected emission reductions are not achieved by the state. In the case of the non-mandatory electrification measures, AQMD may need to include backstop provisions that automatically place a federally enforceable control measures on NO_x sources in the region to secure any reductions that the state plan commitments do not deliver. The AQMD would choose the appropriate backup reduction measures. However those federally enforceable measures should most likely apply to sources other than power plants given that EGUs are regulated to the maximum extent feasible under AQMD's plan (*i.e.*, EGUs are operating to meet native load or supply electricity for electrification measures that are achieving a net NO_x reduction.)

[1] Another approach not discussed in this paper to provide SIP credit for non-mandatory electrification measures based on the guidance that EPA has developed for how states can earn SIP credit for state implementation of energy efficiency and renewable energy measures under its SIPs.

	RTC Allocation	Types of Credits	SIP Implications
Building Block 1	RTCs are allocated at sufficient levels to cover NO_x emissions from affected EGUs that operate at levels necessary to serve electricity demand within the South Coast Air Basin. RTC allocations are based on stringent NO_x BARCT emission rates set for highly efficient gas-fired generation. RTC allocations are based on utilization levels that are necessary for affected EGUs to meet forecast demand absent additional electrification programs. RTC allocation is sufficient to cover NO_x emissions attributable for startups and shutdowns.	The RTCs are tradable. The RTCs cannot be reduced given that they are essential for EGUs meeting electricity demand and doing so at the lowest feasible NO_x emission rate.	Since BARCT is imposed on all affected EGUs, they are already well-controlled sources that are doing their share to meet RFP goals for reducing NO_x emissions in the South Coast Air Basin.
Building Block 2	An incremental allocation of RTCs is allocated to cover NO_x emissions attributable to incremental electricity demand (beyond Building Block 1) for the implementation of mandatory electrification measures under the state implementation plan.	The RTCs are non-tradable. The number of RTCs can be adjusted to reflect the actual amounts of increased electricity demand attributable to the mandatory electrification	Federally enforceable SIP measure Because the NO_x reductions result from mandatory electrification measures, incremental RTCs to EGUs will not result in a net NO_x emission increase. Furthermore,

	RTC Allocation	Types of Credits	SIP Implications
	For example, an incremental allocation of RTCs could be allocated for the increased generation attributable to mandatory requirements to electrify additional operations at the Port of Los Angeles, LAX, or other significant sources of NO_x emissions.	measures. This incremental allocation of RTC will result in a net reduction in NO_x emissions in the South Coast Air Basin due to offsetting NO_x emission reductions achieved from the mandatory electrification measures.	there is no question on whether there will be a net NO_x reduction, but rather only a question on how many reductions will be achieved (dependent on the source converting to electricity).
Building Block 3	An additional allocation of RTCs is allocated to cover NO_x emissions attributable to incremental electricity demand (beyond Building Blocks 1 and 2) that result from non-mandatory (voluntary) electrification measures. For example, there are many possible policies, incentives, and other measures that the State, City, AQMD, or electric utilities may undertake to encourage the electrification of the transportation or other NO_x emitting sectors. To the extent that these efforts result in the electrification, then there will be a net NO_x emission	The RTCs are non-tradable. The number of RTCs can be adjusted to reflect the electricity demand attributable to the mandatory electrification measures	There are several possible ways to reflect the non-mandatory electrification measures in the SIP. One possible way is to follow the "state measure" approach proposed by EPA in the Clean Power Plan. Under this approach, the AQMD or the State would make a commitment to achieve a specific amount of NO_x reductions through the implementation of voluntary measures referenced in the SIP. Although further EPA guidance is needed, it is likely that AQMD will need to provide enforceable

	RTC Allocation	Types of Credits	SIP Implications
	reduction even though NO_x emissions from affected EGUs will slightly increase.		regulatory backstop measures that would be activated in the event that the NO_x reductions are not achieved. However, the backstop provisions would apply to sources other than power plants given that EGUs are regulated to the maximum extent feasible (i.e., EGUs are operating to meet native load or supply electricity for electrification measures that are achieving a net NO_x reduction.) Another possible way to include non-mandatory measures in the SIP is through existing EPA policy guidance that allows the use of energy efficiency measures and renewable energy generation to achieve emissions reductions under certain situations.

AUGUST 18, 2015

SIP CREDITING MECHANISM TO PROVIDE CREDIT FOR REDUCTIONS ACHIEVED THROUGH ELECTRIFICATION

OUTLINE OF KEY ELEMENTS

The objective of this white paper is to outline the key elements of an emission reduction crediting mechanism that state or local regulatory authorities, such as the South Coast Air Quality Management District (AQMD or District), can use to account for and provide the appropriate emission reduction credit to electric utilities for the overall net NO_x emission reductions achieved by the electrification of other source categories under their state implementation plan (SIP). The paper begins with a brief discussion on the need for the Environmental Protection Agency (EPA) to establish such a SIP crediting mechanism and then presents the key design elements of a crediting mechanism that is modeled after approaches that EPA has developed for promoting energy efficiency and renewable energy measures under the Clean Air Act (CAA).

Need for SIP Crediting Mechanism

The attainment and maintenance of the current 2008 national ambient air quality standard for ozone will require substantial NO_x emission reductions from the largest source categories of NO_x emissions in the South Coast Air Basin (SCAB). As a result, AQMD is examining various NO_x emission reduction strategies, including a substantial reduction in the NO_x RTC holdings for all affected RECLAIM facilities, in order to meet its "reasonable further progress" (RFP) goals for reducing NO_x emissions under the CAA. This need for NO_x emission reductions in the SCAB will only increase when EPA adopts (as expected) final rules to tighten the current ozone standard in October 2015.

According to the District, an essential part of the strategy to reduce NO_x emission levels in the SCAB region will be to electrify the transportation sector and other major source categories of NO_x emissions. Specifically, the increased electricity generation will result in small increases in NO_x emissions by affected electric generating units (EGUs), but those emission increases will be more than offset by substantial NO_x emission reductions achieved by the newly electrified sources. Electrification of even portion of these sources will result in substantial overall net NO_x emission reductions in the SCAB region.

One key implementation issue relates to how the AQMD can account for and provide appropriate emission reduction credit to electric utilities for the net NO_x emission reductions achieved by the electrification of other source categories under the District's ozone attainment SIP. At present, there does not exist an EPA-recognized SIP crediting mechanism for electrification that the District could use for meeting its ozone RFP reduction obligations under the CAA. Without such a crediting mechanism, it is difficult for the AQMD to allocate in advance an additional amount of NO_x RTCs to affected EGUs – even though this increased RTC allocation is necessary for the electrification of the other major sources that will achieve an overall net NO_x reduction within the SCAB region.

The establishment of such a SIP crediting mechanism for electrification is needed not only for the SCAB region, but other major urban areas with significant ozone nonattainment problems for which electrification of major NO_x source categories will likely become an important ozone attainment strategy. Furthermore, the need for such a SIP crediting mechanism is particularly important given that many of the measures for promoting electrification may be non-mandatory policies and incentives that are not federally enforceable under the CAA. The use of non-mandatory policies and incentives in SIP attainment strategies is major shift in the typical CAA regulatory paradigm of states developing SIP control strategies that impose federally enforceable emissions reduction requirements on affected emission sources. The establishment of EPA-recognized SIP crediting mechanism will therefore address the regulatory uncertainty that would otherwise result from this paradigm shift and thereby encourage the implementation of policies to reduce emissions from the transportation and major source categories of emissions through electrification in the SCAB and other urban ozone nonattainment areas.

Key Design Elements of SIP Crediting Mechanism

The purpose of this paper is to identify the key design elements of a SIP crediting mechanism that state or local regulatory authorities, such as AQMD, can use to account for and provide appropriate emission reduction credit to electric utilities for emission reductions achieved by the electrification of other source categories with the same region under their SIP attainment strategies. This proposed SIP crediting mechanism is based on similar approaches that EPA has developed for incorporating energy efficiency and renewable energy strategies into SIP attainment strategies under CAA section 110[1] and state plans for meeting its applicable CO_2 emission reduction targets under CAA section 111(d).[2]

---

[1] *See* Guidance by EPA Office of Air Quality Planning and Standards, entitled: *Roadmap for Incorporating Energy Efficiency/Renewable Energy Policies and Programs into State and Tribal Implementation Plans* (July 2012) (hereinafter referred to as "*EPA Roadmap*").
[2] *See* Proposed Clean Power Plan, 79 Fed. Reg. at 34,902.

As a general matter, EPA has interpreted the CAA to require that four criteria must be satisfied in order for an emission control measure to generate creditable emission reductions that can be used for meeting its RFP goals in the SIP attainment strategy. These criteria are that the emission reductions are: quantifiable, permanent, surplus, and enforceable. The discussion below presents the design elements of a SIP crediting mechanism that would satisfy each of these criteria.

Quantifiable. In order for a policy or measure to be quantifiable, the state or local regulatory authority must quantify the overall net emission reductions that would result from the implementation of the policy or measure for electrification. This analysis would require a quantification of the NO_x emission reductions that are projected to occur as a result of the electrification of existing sources of NO_x emissions in the nonattainment area. One challenge would be the quantification of NO_x emission reductions resulting from the implementation of non-mandatory policies and incentives to encourage electrification. In addition, the analysis should include a quantification of projected NO_x emission increases that would likely occur due to the increased generation of electricity by EGUs located in the nonattainment area. EPA guidance should be developed on each of these steps of analysis in order to ensure consistency among states on how to quantify the overall net reductions that result from electrification policies and measures.

Permanent. The state or local regulatory authority must show that the emission reductions from the electrification policies and measures will not be temporary, but will continue through the future attainment date. To that end, the regulatory authority should develop policies and measures that reflect long-term commitments for electrification and include in its SIP control plan a demonstration on why these commitments will yield extended emissions reductions that satisfy the criterion for permanency.

Surplus. The electrification policies and measures must not be otherwise required under the CAA.[3] To meet this criterion, the state or local regulatory authority would need to demonstrate in its SIP submission that these policies and measures are additional to the control measures included in the baseline emissions projections for the SIP attainment strategy so that there will be no double counting of emission reductions. One element of this demonstration should include a certification that the regulatory authority has reviewed the electrification control strategies and confirms that these strategies are not being used to claim emission reduction credits in any of control strategies included in the SIP attainment strategy, as well as a description of specific

[3] Section 173 (c)(2) of the CAA (providing that "Emission reductions otherwise required by this chapter shall not be creditable as emissions reductions for purposes of any such offset requirement").

steps that the regulatory authority is taking to ensure that there is no double counting of emission reductions.

Enforceable. There would be two pathways from demonstrating compliance with this criterion. The first, and most straightforward, pathway would be the adoption of mandatory control measures that would directly or indirectly require the electrification of the affected sources of NO_x emissions in the nonattainment area. Such mandatory measures would be federally enforceable against specific entities which must be able to verify compliance with the specific control requirements and be subject to enforcement for the failure to comply with those requirements, including civil penalties and corrective action.

The second pathway would be the adoption of non-mandatory policies and incentives for encouraging electrification. Under this alternative approach, the regulatory authority would have the option of meeting the criterion for enforceability through the adoption of an enforceable commitment requiring the regulatory authority to evaluate the effectiveness of the non-mandatory electrification policies or incentives and, if these measures do not achieve the projected emission reductions, to remedy any SIP reduction shortfall. This remedy may involve the implementation of contingency control measures to achieve the necessary emission reductions or demonstrating that the emission reductions are not needed to achieve the RFP reduction requirements for attaining the ozone standard.

Such an approach, as noted above, is modeled after the federal guidance that EPA has developed for incorporating energy efficiency and renewable energy strategies into SIP attainment strategies under CAA section 110.[4] Importantly, the EPA guidance describes four possible implementation pathways for incorporating energy efficiency and renewable energy policies and programs into SIP control strategies. One such pathway involves the adoption of non-mandatory policies and programs to encourage the use of energy efficiency and renewable energy.[5] To meet the enforceability criterion, the state or regulatory authority must make an enforceable commitment to:

- Implement those parts of the policies or measures for which the agency are responsible;
- Monitor, evaluate, and report at least every three years on progress toward emission reductions; and

[4] *See EPA Roadmap*. Notably, this guidance draws from previously issued EPA guidance documents that seek to encourage states to incorporate energy efficiency and renewable energy measures into their SIP control strategies.
[5] *See EPA Roadmap* at pages 9 and 30-32.

- Remedy any SIP credit shortfall if the policies or measures do not meet the projected emission reductions.[6]

In addition, this approach for meeting the enforceability criterion is consistent with the "state measure" approach that EPA has proposed for a state to meet its applicable CO_2 emission rate target under the Clean Power Plan. In this case, EPA has proposed to allow a state to achieve a portion of its CO_2 emission reduction obligation through enforceable requirements to increase renewable energy, energy efficiency, and perhaps other control methods that do not apply directly to EGUs. In so doing, EPA states that the state plan would include an enforceable commitment by the state itself to implement state-enforceable (but not federally enforceable) measures that would achieve specified portion of the required emission performance level on behalf of affected EGUs. The key difference between the traditional federal-state regulatory approach and EPA's proposed state measure approach is that instead of private entities, such as affected EGUs, being responsible for obtaining specific emission reductions, the state adopts a plan that makes itself responsible for ensuring the implementation of the particular measures in order to meet its federal emission reduction obligations.

[6] *See EPA Roadmap* at page 37.

RESOLUTION NO. 15-XXX

A Resolution of the South Coast Air Quality Management District Board Recognizing the Need to Increase the NO_x RTCs Allocations for Affected Electric Generating Units in order to Achieve National Ambient Air Quality Standards

WHEREAS, the attainment and maintenance of the national ambient air quality standards for ozone will require substantial NO_x emission reductions from the largest source categories of NO_x emissions in the South Coast Air Basin (SCAB).

WHEREAS, the largest source categories of NO_x emissions in the SCAB include off road equipment (43 tons per day), locomotives (22 tons per day), ships and commercial boats (41 tons per day), and passenger vehicles, sport utility vehicles, and light duty trucks (24 tons per day);

WHEREAS, the District is currently examining possible regulatory strategies for achieving NO_x reductions from these and other source categories through the electrification of combustion sources;

WHEREAS, the regulatory strategies under consideration include both mandatory and voluntary measures for electrification of combustion sources that would be incorporated into the state implementation plan and achieve substantial NO_x emission reductions that are required for meeting the obligations of the South Coast Air Quality Management District under the federal Clean Air Act; and

WHEREAS, the electrification of these other source categories will require substantial increases in electricity generation from affected electric generating units (EGUs) within the SCAB and that such increases in electricity generation will result in a corresponding increase in NO_x emissions from affected EGUs.

THEREFORE, BE IT RESOLVED that the Board of the South Coast Air Quality Management District commits to provide in the future an additional allocation of NO_x RECLAIM Trading Credits (RTCs) to affected EGUs in order to cover the additional NO_x emissions attributable to such increased electricity generation.

BE IT FURTHER RESOLVED that this future increased allocation of NO_x RTCs to affected EGUs does not constitute a change to the New Source Review regulations that is prohibited under the provisions of Senate Bill 288, entitled *The Protect California Air Act of 2003* and codified at Health and Safety Code §§ 42500-42507, but rather is fully consistent with the goals and protections afforded under Senate Bill 288 given that—

- any additional NO_x emissions from affected EGUs in the SCAB would be offset by a significantly greater reduction in NO_x emissions from other sources within SCAB for an overall net air quality improvement; and

- affected EGUs have already installed the most stringent NO_x control technologies currently available and, consequently, that the NO_x emissions from such EGUs comprise only a very small share (less than 3 tons per day during 2011-2013) of the total NO_x emissions in the SCAB (about 550 tons per day estimated in 2016).

Subject: Proposed Amendments to Regulation XX – NOx Reclaim

This letter includes Shell Energy's comments to the proposed amendments to Regulation XX – NOx RECLAIM. Shell Energy and Wildflower Energy are parties to an Energy Conversion Agreement dated July 26, 2004 (the "ECA"). Under the ECA, Shell Energy has the right to direct that fuel be converted into energy by the Indigo Generated Units that are located in SCAQMD territory.

After analyzing the Draft Rule Language released on July 22, 2015 and participating in the public workshop about this topic we would like to submit the following comments for your consideration:

- The Indigo Facility was built in response to the California Energy crisis in 2001. Indigo was constructed with BACT - best available control technology – including a CO catalyst and SCR to limit NOx to 5 ppm. It operates at a very low capacity factor as this technology is only needed during periods of high demand on the grid, although the SCAQMD permit requirements obligate the facility to hold offsets for significantly greater operational hours. Typically, SCAQMD considers the cost effectiveness of emission reductions, and will evaluate a cost benefit analysis. To meet the proposed requirements in Rule XX, the facility would need to make significant modifications to the SCR, CO catalyst and to the exhaust modules housing the catalyst, far exceeding typical cost benefit ratios. The alternate emissions reduction choice would be to replace the combustor on the gas turbine, also cost prohibitive. There is no further cost effective NOx reduction technology for this facility. The only way that such Facilities can comply with the current proposed rule is to purchase additional NOx RTCs. This represents a significant expense for generating facilities especially considering the current market conditions in California, including the recent decommissioning of San Onofre Nuclear Generating Station. We request that SCAQMD consider that peaking generation facilities with lower capacity factor built to BACT should not be obligated under the proposed rule to make further emissions reductions, and allow the emissions offsets previously procured for the unit to meet current and future SCAQMD requirements.

1C1-1

- Rule 2002 Section PAR 2002(f)(1)(B) and (C) state that the Executive Officer will adjust NOx RTC holdings, as of (Date of Amendment) for compliance years 2016 and thereafter by multiplying the amount of RTC holdings as of March 20, 2015 by adjustment factors for the relevant compliance year. Setting the Amendment Date after it had passed is equivalent to retroactive ratemaking and could have unintended economic consequences. We believe that the Date of Amendment should be set closer to or upon the actual date when the final Rule is published. Additionally, it is not clear how the March 20, 2015 date was established and does not address how NOx RTCs that were transferred between March 20, 2015 and the date of the implementation of the Proposed Rule will be treated. We request the SCAQMD act prospectively; the NOx RTC holdings should be the quantity as of the date of the implementation of the Proposed Rule. 19-2

- Additional information and clarification is needed regarding the Proposed Adjustment Account for Generators PAR 2000 (f) (4). 19-3

We appreciate your consideration of the comments above and look forward to continuing this conversation. Please don't hesitate to contact me at (858) 526-2103 if you would like to discuss our comments.

Yours truly,

Manuel Robin for Michael D. Evans

Bracketed Pages from Final PEA

Ms. Barbara Radlein
October 6, 2015
Page 2

Attachment 1 to this letter provides more detailed comments on this draft PEA from WSPA's technical consultant, and are hereby incorporated by reference. ("Attachment 1"). 2-3

WSPA has previously submitted numerous comments on the proposed regulation itself, as well as the notice of preparation and initial study ("NOP/IS") for the draft PEA, but these comments have received insufficient attention from the District in its environmental analyses.[1] The District responds to the NOP/IS Letter by claiming that technical analyses have been considered, when an in-depth evaluation of the industry's technical concerns has not been performed. 2-4

WSPA has serious concerns with both the proposed rule amendments and the draft PEA, and believe that the requirements under the California Environmental Quality Act ("CEQA") have not been satisfied. Furthermore, both the proposed amendments and the draft PEA must be revised and recirculated to address the comments raised by WSPA and the numerous other commenters in order to correct errors, disclose all significant impacts, and allow the consideration of feasible mitigation measures or project alternatives to reduce or avoid these impacts. 2-5

I. Fundamental Problems With The Draft PEA Undermine The Environmental Analysis

Under CEQA, an EIR is an informational document designed to provide public agencies and the public with detailed information about the impacts that a proposed project is likely to have on the environment, analyze the ways in which the significant effects of a project might be minimized, and identify alternatives to the project.[2] The District's draft PEA, as a substitute EIR under its certified regulatory program, is also subject to the substantive provisions of CEQA.[3] 2-6

Fundamental flaws in the draft PEA's project description and objectives, the scope of review, and the selection and analysis of alternatives, pervade the document, ultimately resulting in a misleading document in specific resource areas as well. Many of the errors in the draft PEA are related to problems with the methodology, assumptions,

Page 6

The draft PEA should identify realistic assumptions based on facts to properly evaluate potential environmental effects of construction activities, and a one-size fits all approach that dismisses the potential for environmental effects based on the industrial locations of the facilities is not sufficient. 2-14

In short, the PEA makes unsubstantiated industry-wide generalizations in determining that technology is feasible, implementation timeframes are reasonable, the site specific impacts will be negligible, and the individual businesses will perform as expected. These generalizations cannot support the PEA's assumptions, particularly in light of the District's own third party expert's efforts to correct the errors in its technical analysis. If an EIR is "so fundamentally and basically inadequate and conclusory in nature" that public comment on the draft is essentially meaningless, or if significant new information is added to an EIR, it must be recirculated for further public review.[15] The PEA should be revised to substantiate its assumptions and reevaluate its conclusions accordingly, and should then be recirculated for further public review and comment. 2-15

B. The PEA Purports To Be A Program-Level Document, But Construction Activities Generally Require Project-Level Review

The draft PEA is described as a "program CEQA document" ostensibly because it consists of proposed amendments to Regulation XX.[16] As noted above, however, the draft PEA appears to evaluate BARCT construction activities, and specific construction projects generally require a project-level analysis. This distinction is important because a program-level review can be more abbreviated and the District apparently seeks to utilize that approach, but it has now embarked on a partial project-level review of BARCT construction activities. As noted above, noise is dismissed in the PEA and not evaluated at all, even though noise is an environmental topic commonly reviewed in a project level EIR for a construction project. If the District seeks to transform a rule-making into a construction project, it needs to do so in compliance with CEQA. 2-16

Furthermore, the draft PEA, which is a "substitute CEQA document" pursuant to the District's certified regulatory program, states that the "program" CEQA document may be used by other agencies for "future related actions." Section 15253 of the CEQA Guidelines addresses use of a substitute CEQA document by responsible agencies, and the District should clarify how the provisions of that Section have been satisfied. 2-17

The draft PEA's insufficient project level analysis for BARCT construction activities reinforces WSPA's main critique of the District's proposed amendments to Regulation XX—the technical analysis to support the proposed amendments is 2-18

ATTACHMENT 1

ADDITIONAL WSPA COMMENTS ON
DRAFT PROGRAM ENVIRONMENTAL ASSESSMENT (PEA)
FOR NO_X RECLAIM AMENDMENTS

Page/Section	WSPA Comment	
Page 1-1, 3rd paragraph	This paragraph describes the project as "amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM) to achieve additional NOx emission reductions to address best available retrofit control technology (BARCT) requirements <u>and to modify the RECLAIM trading credit (RTC) "shaving" methodology</u>." [emphasis added] This description is not consistent with the project description contained in the AQMD's Notice of Preparation issued 4 December 2014,[1] nor is the description consistent with Project Description contained in the Initial Study.[2] Specifically, neither the NOP Project Description nor the Initial Study Project Description includes any reference to modifying "the RECLAIM trading credit (RTC) "shaving" methodology" in the description of the project or the project objectives.	2-49
Page 1-1, 4th paragraph	The Draft PEA states that "further analysis of the actual BARCT NOx emission control opportunities for the various equipment/process categories demonstrated that the proposed project could achieve 14 tons per day of NOx emission reductions by 2023 which is much higher than estimates provided in the 2012 AQMP." While this value is certainly much higher than contemplated in the 2012 AQMP, it is also <u>not supported</u> by the AQMD Staff's technical analysis.[3] The Staff's analysis does not support a 14 ton per day (TPD) shave as necessary for BARCT equivalency. Rather, the Preliminary Draft Staff Report (PDSR) very clearly demonstrates that not more than 8.79 TPD of emission reductions from the RECLAIM program can be attributed to BARCT advancement; a conclusion that is later echoed in the Draft PEA.[4] Furthermore, a 14 TPD shave reduction of the RECLAIM market may violate the project objectives under the California Health & Safety Code (H&SC). Contrary to H&SC §40406, Staff have failed to take into account the economic impacts for each class or category of source. The Staff analysis only considers costs and cost effectiveness for the BARCT equivalency amount of 8.79 TPD (i.e., advancement from 2005 BARCT to 2015 BARCT). There is absolutely no consideration of the economic impacts which would be incurred by RECLAIM facilities under a 14 TPD market adjustment that goes beyond BARCT.	2-50

[4] AQMD, Draft Program Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM), 15 August 2015. See Table 1-3.

1

Page 2-6, 4th paragraph	The Draft PEA states "the proposed project is estimated to reduce four tons per day of NOx emissions starting in 2016 because the amount of unused RTCs in the NOx RECLAIM program over the past five years (e.g., from 2009 to 2013) ranged from five tpd to eight tpd, demonstrating that there is enough cushion to support reduction of four tpd in 2016." While the quantities of "unused" RTCs are a matter of historical record, Staff has provided no evidence to support that supposition that the RECLAIM market has "enough cushion to support reduction of four tpd in 2016." And if this was just a reduction of unused RTCs, that would not equate to an emissions reduction in 4 TPD. The Draft PEA needs to be revised to include a market analysis to support that supposition or this statement should be deleted.	2-69
Page 2-6, 4th paragraph (continued)	The Draft PEA goes on to state "it could take from two to four years for the affected facilities to plan, obtain permits, and install air pollution control equipment or modify existing equipment in response to the proposed project." According to information from WSPA members, this estimate is too short.[26] While some individual projects might be complete able in 2-4 years, the proposed project would require dozens and dozens of emission control projects to be completed. For the refinery sector, such projects would need to be planned, engineered, and sequenced for construction in consideration of unit turnaround schedules. WSPA members report that completion of all needed projects for the proposed project would likely require not less than eight (8) years. The Draft PEA should be revised to reflect this timetable and the Proposed Amended Rules and PDSR should be similarly adjusted.	2-70
Page 2-9, PAR 2005 Requirements for New or Relocated RECLAIM Facilities – Subdivision (b)	The AQMD Staff have yet to provide a complete description of the amendments to this rule. AQMD Staff have also not obtained U.S. EPA approval that such amendments would even be approvable into the State Implementation Plan (SIP). The Draft PEA and PAR 2005 should be revised to reflect these important details after AQMD Staff have obtained the U.S. EPA approval needed for such amendments to be legal.	2-71
Page 2-10, top of page	The Draft PEA states "Further, only 44 facilities are expected to comply with the proposed NOx RTC shave through the purchase of RTCs which will have no environmental impact." The Draft PEA should be revised to present supporting analysis demonstrating how this conclusion was reached.	2-72
Page 3.2-34, 2nd paragraph, GHG Tailoring Rule	This section should be revised to note that the courts vacated significant portions of the GHG Tailoring Rule. The applicability criteria as described in the Draft PEA are not consistent with current regulations.	2-73
Page 4.1-3, Section 4.1.3.1	The Draft PEA states "Because each affected facility is located in heavy industrial areas, the construction equipment is not expected to be substantially discernable from what exists on-site for routine operations and maintenance activities. Further, the construction activities are not expected to adversely impact views and aesthetics resources since most of the heavy equipment and activities are expected to occur within the confines of each existing facility and are expected to introduce only minor visual changes to areas outside each facility, if at all, depending on the location of the construction activities within the facility."	2-74

[26] WSPA/ERM confidential survey of WSPA members concerning refinery heaters/boilers, March 2015.

13

	This statement oversimplifies the range of physical settings existent for RECLAIM facilities. In actuality, some refinery or non-refinery RECLAIM facilities are located areas where additional vertical obstructions from cranes or new emission control structures could be "discernable" and may adversely impact views and aesthetics resources for adjacent communities. The Draft PEA should be revised to clarify the range of settings which would be impacted by the proposed project and acknowledge the range of potential impacts associated with the proposed project.	2-74 Con't
Page 4.2-2, Table 4.2-1 Estimated Number of NOx Control Devices Per Sector and Equipment/Source Category	As shown in this table, the Draft PEA states that Staff has assumed 74 SCRs would be installed on Refinery Process Heaters and Boilers under the proposed project. Staff does not explain the basis for this value, which conflicts with the Preliminary Draft Staff Report (PDSR). The PDSR suggests that the proposed project would result in 76 SCRs (25 upgraded, 51 new) for refinery heaters and boilers,[27] in which case the Draft PEA would be understating the potential project impacts. It should also be noted that AQMD's third-party refinery sector expert, Norton Engineering, found that only 48 refinery heaters and boilers could be cost effectively retrofit with new or upgraded SCRs.[28] Staff have done nothing to reconcile this discrepancy which is material. The Draft PEA must be revised to clarify the technical basis for the assumed emission controls outcome and associated potential impacts to the environment. The Draft PEA should also explain how emission controls which are not cost effective, according to AQMD's own third-party expert, will be implemented.	2-75
Page 4.2-4, Section 4.2.3.1, first paragraph	The Draft PEA states "Further, operators at each affected facility who construct NOx control equipment that utilize chemicals as part of the NOx control equipment operations, such as a new ammonia or caustic storage tank, may also need to build a containment berm large enough to hold 110 percent of the tank capacity in the event of an accidental release, pursuant to U.S. EPA's spill prevention control and countermeasure regulations." While other regulations and good engineering practices would require containment features for these tanks, the Spill Prevention Control and Countermeasure (SPCC) regulations actually don't apply to ammonia or caustic storage vessels. The Draft PEA should be clarified accordingly.	2-76
Page 4.2-7, last paragraph	The Draft PEA states "if a particular technology was identified as having a cost that exceeds $50,000 per ton, this CEQA analysis assumed that the facility operator would not install this type of air pollution control technology in response to the project." This statement is inconsistent with the project objectives which require compliance with the California Health & Safety Code. The $50,000 threshold fails in this regard. Under H&SC§39616(c)(1), the RECLAIM program is required to result in "an equivalent or greater reduction in emissions **at equivalent or less cost compared with current command and control regulations** and future air quality measures that would otherwise have been adopted as part of the District's plan for attainment." AQMD Staff has failed to demonstrate that the proposed amended RECLAIM program will be **at equivalent or less**	2-77

Re: Comment Letter on Draft Program Environmental Assessment for Proposed Amended Regulation XX; Cities of Burbank and Pasadena

Dear Ms. Radlein:

On behalf of the City of Burbank, Department of Water and Power ("BWP"), and the City of Pasadena, Water and Power Department ("PWP) (collectively "the Cities"), we are submitting the following comments on the Draft Environmental Assessment ("Draft PEA") for the proposed amendments to Regulation XX, Regional Clean Air Incentives Market ("RECLAIM") ("NOx shave proposal"), for which a Notice of Completion was published on 3-1 August 13, 2015. The Draft PEA purports to contain an analysis of the potential adverse environmental impacts that could be generated from the proposed project. Unfortunately, the Draft PEA does not contain any analysis of the potential adverse environmental impacts of the potential shortage of RECLAIM Trading Credits ("RTCs") for future power plant needs, which is of great concern to the Cities. 3-2

While the NOx shave proposal appears to include provisions that would mitigate some of its worst impacts on the Cities' well-controlled power plants, it still does not provide the needed certainty that adequate RTCs will be available at a reasonable price to cover these plants' anticipated emissions and other needs related to resource adequacy and utility-specific operating contingencies. We have suggested some improvements to the proposal that would provide the needed certainty and address other issues (see the Cities' comment letter on the proposed rule 3-3

dated August 21, 2015). In the absence of these improvements, the NOx shave proposal may have significant adverse air quality impacts that should be addressed in the Final PEA. 3-3 Con't

Both Cities operate their own power plants containing peaking units, and BWP also operates the Magnolia Power Plant ("MPP"), a baseload unit, on behalf of the Southern California Public Power Authority ("SCPPA"). Participants in MPP include Burbank, Pasadena, and four other municipalities. The Cities operate these power plants to serve their municipal customers. RTCs are required not only to cover anticipated annual emissions, but also to meet resource adequacy needs and prepare for utility-specific operating contingencies, such as grid reliability, increased cycling to support integration of renewables, and potential electrification of the transportation system. Unlike other industrial facilities operating under the RECLAIM program, the Cities' power plants are obligated to operate to serve load. If they are unable to serve load, there may be blackouts with serious adverse economic and other consequences. 3-4

The staff proposal would require a 47% reduction in the NOx RTC allocations for these power plants. The proposed reductions are so severe that insufficient RTCs would remain to cover Pasadena's and MPP's anticipated emissions, not to mention RTCs needed for resource adequacy and utility-specific operating contingencies. Pasadena and MPP may need to purchase additional RTCs to cover the shortfall. If these additional RTCs are prohibitively expensive or unavailable, then the Cities may be forced to curtail the output from these facilities in order to remain in compliance with the RECLAIM program. 3-5

One possible consequence of a curtailment of output from the Cities' facilities is that other facilities may generate replacement power. These facilities may be located either inside or outside of the South Coast Air Basin. Wherever they are located, these other facilities are unlikely to have emission rates as low as the emission rates from the Cities' own facilities. The increased emissions from these other facilities, and their potential adverse impacts, should be assessed in the Final PEA. 3-6

For example, replacement power may be generated by facilities that are located in the South Coast Air Basin that are not included in the RECLAIM program or that are included in the program but are not subject to the NOx shave proposal, such as certain co-generation facilities. The emissions would be generated in locations different from the locations of the Cities' facilities, and there are likely to be more emissions than would be generated by the Cities' own well-controlled units. These emissions and their potential adverse impacts, including their impacts on local receptors, should be assessed. These adverse impacts may trigger environmental justice concerns. 3-7

Replacement power may also be generated by facilities that are not located in the South Coast Air Basin. It is possible, for example, that replacement power may be generated by coal-fired units in other states. The potential adverse impacts of these emissions should be assessed. 3-8
